CHAPTER 1

Overview of the Controller	1
Overview of Cisco 9800 Series Wireless Controllers	1
Elements of the New Configuration Model	1
Configuration Workflow	2
Initial Setup	3
Interactive Help	4

PART I

System Configuration	7
-----------------------------	----------

CHAPTER 2

New Configuration Model	9
Information About New Configuration Model	9
Configuring a Wireless Profile Policy (GUI)	12
Configuring a Wireless Profile Policy (CLI)	12
Configuring a Flex Profile (GUI)	14
Configuring a Flex Profile	14
Configuring an AP Profile (GUI)	15
Configuring an AP Profile (CLI)	20
Configuring User for AP Management (CLI)	21
Setting a Private Configuration Key for Password Encryption	21

Configuring an RF Profile (GUI)	22
Configuring an RF Profile (CLI)	22
Configuring a Site Tag (GUI)	24
Configuring a Site Tag (CLI)	24
Enhanced Site Tag-Based Load Balancing	25
Feature History for Enhanced Site Tag-Based Load Balancing	25
Information About Enhanced Site Tag-Based Load Balancing	26
Prerequisites for Enhanced Site Tag-Based Load Balancing	26
Use Cases	27
Configuring Site Load (CLI)	27
Verifying Enhanced Site Tag-Based Load Balancing Configuration	27
Configuring Policy Tag (GUI)	28
Configuring a Policy Tag (CLI)	28
Configuring Wireless RF Tag (GUI)	29
Configuring Wireless RF Tag (CLI)	30
Attaching a Policy Tag and Site Tag to an AP (GUI)	31
Attaching Policy Tag and Site Tag to an AP (CLI)	31
Configuring a Radio Profile	32
Information About Wireless Radio Profile	32
Configuring a Wireless Radio Profile (GUI)	33
Configuring a Radio Profile and Beam Selection	34
Configuring the Antenna Count in a Wireless Radio Profile	34
Configuring a Slot Per Radio in the RF Tag Profile	35
Verifying a Radio Profile	35
AP Filter	36
Introduction to AP Filter	36
Set Tag Priority (GUI)	37
Set Tag Priority	37
Create an AP Filter (GUI)	38
Create an AP Filter (CLI)	38
Set Up and Update Filter Priority (GUI)	39
Set Up and Update Filter Priority	39
Verify AP Filter Configuration	40
Configuring Access Point for Location Configuration	41

Information About Location Configuration	41
Prerequisite for Location Configuration	41
Configuring a Location for an Access Point (GUI)	41
Configuring a Location for an Access Point (CLI)	42
Adding an Access Point to the Location (GUI)	42
Adding an Access Point to the Location (CLI)	43
Configuring SNMP in Location Configuration	44
SNMP MIB	44
Verifying Location Configuration	44
Verifying Location Statistics	45

CHAPTER 3**Wireless Management Interface 47**

Information About Wireless Management Interface	47
Recommendations for Wireless Management Interface	48
Configuring your Controller with Wireless Management Interface (CLI)	49
Verifying Wireless Management Interface Settings	51
Information About Network Address Translation (NAT)	52
Information About CAPWAP Discovery	52
Configuring Wireless Management Interface with a NAT Public IP (CLI)	53
Configuring CAPWAP Discovery to Respond Only with Public or Private IP (CLI)	54
Configuring the Controller to Respond only with a Public IP (CLI)	54
Configuring the Controller to Respond only with a Private IP (CLI)	54
Verifying NAT Settings	55

CHAPTER 4**BIOS Protection 57**

BIOS Protection on the Controller	57
BIOS or ROMMON Upgrade with BIOS Protection	57
Upgrading BIOS	58

CHAPTER 5**Smart Licensing Using Policy 59**

Introduction to Smart Licensing Using Policy	59
Information About Smart Licensing Using Policy	60
Overview	60
Supported Products	60

Architecture	61
Product Instance	61
CSLU	61
CSSM	62
Controller	62
SSM On-Prem	63
Concepts	64
License Enforcement Types	64
License Duration	65
Authorization Code	65
Policy	65
RUM Report and Report Acknowledgement	67
Trust Code	68
Supported Topologies	69
Connected to CSSM Through CSLU	69
Connected Directly to CSSM	71
CSLU Disconnected from CSSM	73
Connected to CSSM Through a Controller	74
No Connectivity to CSSM and No CSLU	75
SSM On-Prem Deployment	77
Interactions with Other Features	80
High Availability	80
Upgrades	81
Downgrades	83
How to Configure Smart Licensing Using Policy: Workflows by Topology	86
Workflow for Topology: Connected to CSSM Through CSLU	86
Workflow for Topology: Connected Directly to CSSM	89
Workflow for Topology: CSLU Disconnected from CSSM	90
Workflow for Topology: Connected to CSSM Through a Controller	93
Workflow for Topology: No Connectivity to CSSM and No CSLU	94
Workflow for Topology: SSM On-Prem Deployment	95
Tasks for Product Instance-Initiated Communication	95
Tasks for SSM On-Prem Instance-Initiated Communication	98
Migrating to Smart Licensing Using Policy	100

Example: Smart Licensing to Smart Licensing Using Policy	101
Example: SLR to Smart Licensing Using Policy	108
Example: Evaluation or Expired to Smart Licensing Using Policy	116
Migrating to a Version of SSM On-Prem That Supports Smart Licensing Using Policy	119
Task Library for Smart Licensing Using Policy	121
RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller	121
Logging into Cisco (CSLU Interface)	124
Configuring a Smart Account and a Virtual Account (CSLU Interface)	124
Adding a Product-Initiated Product Instance in CSLU (CSLU Interface)	124
Ensuring Network Reachability for Product Instance-Initiated Communication	125
Adding a CSLU-Initiated Product Instance in CSLU (CSLU Interface)	126
Collecting Usage Reports: CSLU Initiated (CSLU Interface)	127
Export to CSSM (CSLU Interface)	128
Import from CSSM (CSLU Interface)	128
Ensuring Network Reachability for CSLU-Initiated Communication	129
Assigning a Smart Account and Virtual Account (SSM On-Prem UI)	133
Validating Devices (SSM On-Prem UI)	133
Ensuring Network Reachability for Product Instance-Initiated Communication	134
Retrieving the Transport URL (SSM On-Prem UI)	137
Exporting and Importing Usage Data (SSM On-Prem UI)	137
Adding One or More Product Instances (SSM On-Prem UI)	138
Ensuring Network Reachability for SSM On-Prem-Initiated Communication	139
Setting Up a Connection to CSSM	144
Configuring Smart Transport Through an HTTPs Proxy	146
Configuring the Call Home Service for Direct Cloud Access	147
Configuring the Call Home Service for Direct Cloud Access through an HTTPs Proxy Server	150
Removing and Returning an Authorization Code	151
Removing the Product Instance from CSSM	153
Generating a New Token for a Trust Code from CSSM	154
Installing a Trust Code	155
Downloading a Policy File from CSSM	156
Uploading Data or Requests to CSSM and Downloading a File	157
Installing a File on the Product Instance	158

Setting the Transport Type, URL, and Reporting Interval 159

Configuring an AIR License 162

Sample Resource Utilization Measurement Report 164

Troubleshooting Smart Licensing Using Policy 164

System Message Overview 164

System Messages 166

Additional References for Smart Licensing Using Policy 176

Feature History for Smart Licensing Using Policy 176

CHAPTER 6

Management over Wireless 181

Information About Management over Wireless 181

Restrictions on Management over Wireless 181

Enabling Management over Wireless on Controller (GUI) 181

Enabling Management over Wireless on Controller (CLI) 182

CHAPTER 7

Boot Integrity Visibility 183

Overview of Boot Integrity Visibility 183

Verifying Software Image and Hardware 183

Verifying Platform Identity and Software Integrity 184

CHAPTER 8

SUDI99 Certificate Support 187

SUDI99 Certificate Support 187

Disabling SUDI99 Migration (GUI) 189

CHAPTER 9

Link Aggregation Group 191

Information About Link Aggregation Group 191

Link Aggregation Control Protocol 191

 Configuring LAG Using LACP 192

Port Aggregation Protocol 192

 Configuring LAG Using PAgP 192

Information About Port Channel Interface Number 192

Configuring LAG in ON Mode 193

Multichassis Link Aggregation Group 193

Prerequisites for Multi-LAG 193

Restrictions for Multi-LAG	194
Supported Topologies	194
Configuring a Port Channel Interface (GUI)	195
Create a Port-Channel Interface	196
Configuring LAG in ON Mode	196
Add an Interface to a Port Channel (LACP)	197
Add an Interface to a Port Channel (PAgP)	198
Add a VLAN to a Port Channel	198
Remove a Port Channel Group from a Physical Interface	199
Verify the LAG Configuration	199

CHAPTER 10	Reload Reason History	201
	Feature History for Reload Reason History	201
	Information About Reload Reason History	201
	Verifying Reload Reason History	201
	Requesting Reload Reason History using YANG	204

CHAPTER 11	Best Practices	207
	Introduction	207

PART II	System Upgrade	209
----------------	-----------------------	------------

CHAPTER 12	Upgrading the Cisco Catalyst 9800 Wireless Controller Software	211
	Overview of Upgrading the Controller Software	211
	Upgrading the Controller Software (GUI)	212
	Upgrade the Controller Software (CLI)	213
	Converting From Bundle-Mode to Install-Mode	214
	Copying a WebAuth Tar Bundle to the Standby Controller	217

CHAPTER 13	In-Service Software Upgrade	219
	Information About In-Service Software Upgrade	219
	Prerequisites for Performing In-Service Software Upgrade	220
	Guidelines and Restrictions for In-Service Software Upgrade	220
	Upgrading Software Using In-Service Software Upgrade	221

Upgrading Software Using ISSU (GUI)	222
Upgrading Software Using In-Service Software Upgrade with Delayed Commit	223
Monitoring In-Service Software Upgrade	224
Troubleshooting ISSU	226

CHAPTER 14**Software Maintenance Upgrade 229**

Introduction to Software Maintenance Upgrade	229
Installing a SMU (GUI)	231
Installing SMU	232
Roll Back an Image (GUI)	233
Rollback SMU	233
Deactivate SMU	233
Configuration Examples for SMU	234
Information About AP Device Package	234
Installing AP Device Package (GUI)	235
Installing AP Device Package (CLI)	236
Verifying APDP on the Controller	236
Information About Per Site or Per AP Model Service Pack (APSP)	237
Rolling AP Upgrade	238
Rolling AP Upgrade Process	238
Installing AP Service Package (GUI)	239
Installing AP Service Package (CLI)	240
Adding a Site to a Filter	241
Deactivating an Image	241
Roll Back APSP	242
Canceling the Upgrade	242
Verifying the Upgrade	242
Verifying of AP Upgrade on the Controller	245

CHAPTER 15**Efficient Image Upgrade 247**

Efficient Image Upgrade	247
Enable Pre-Download (GUI)	247
Enable Pre-Download (CLI)	248
Configuring a Site Tag (CLI)	248

Attaching Policy Tag and Site Tag to an AP (CLI)	249
Trigger Predownload to a Site Tag	251
Feature History for Out-of-Band AP Image Download	253
Information About Out-of-Band AP Image Download	253
Restrictions for Out-of-Band AP Image Download	253
Download AP Image from Controller Using HTTPS (CLI)	254
Download AP Image from Controller Using HTTPS (GUI)	255
Verifying Image Upgrade	256

CHAPTER 16**Predownloading an Image to an Access Point 259**

Information About Predownloading an Image to an Access Point	259
Restrictions for Predownloading an Image to an Access Point	259
Predownloading an Image to Access Points (CLI)	260
Predownloading an Image to Access Points (GUI)	262
Predownloading an Image to Access Points (YANG)	262
Monitoring the Access Point Predownload Process	263
Information About AP Image Download Time Enhancement (OEAP or Teleworker Only)	264
Configuring AP Image Download Time Enhancement (GUI)	265
Configuring AP Image Download Time Enhancement (CLI)	265
Verifying AP Image Download Time Enhancement Configuration	266

CHAPTER 17**N+1 Hitless Rolling AP Upgrade 267**

N+1 Hitless Rolling AP Upgrade	267
Configuring Hitless Upgrade	268
Verifying Hitless Upgrade	269
Feature History for Site-Based Rolling AP Upgrade in N+1 Networks	270
Information About Site-Based Rolling AP Upgrade in N+1 Network	270
Prerequisites for Site-Based Rolling AP Upgrade in N+1 Networks	270
Restrictions for Site-Based Rolling AP Upgrade in N+1 Networks	271
Use Cases	271
N+1 Upgrade and Move to Destination Controller	271
N+1 Move to Destination Controller	273
Hitless Software Upgrade (N+1 Upgrade)	274
Verifying Site-based Rolling AP Upgrade in a N+1 Network	276

Information About Client Steering Enhancement	281
Deauthenticate Clients	282

CHAPTER 18 **NBAR Dynamic Protocol Pack Upgrade** 283

NBAR Dynamic Protocol Pack Upgrade	283
Upgrading the NBAR2 Protocol Pack	284

CHAPTER 19 **Wireless Sub-Package for Switch** 285

Introduction to Wireless Sub-package	285
Booting in Install Mode	286
Installing Sub-Package in a Single Step (GUI)	287
Installing Sub-Package in a Single Step	287
Multi-step Installation of Sub-Package	288
Installing on a Stack	288
Upgrading to a Newer Version of Wireless Package	289
Deactivating the Wireless Package	289
Enabling or Disabling Auto-Upgrade	289

PART III **Lightweight Access Points** 291

CHAPTER 20 **Countries and Regulations** 293

Information About Country Codes	293
Prerequisites for Configuring Country Codes	293
Configuring Country Codes (GUI)	294
Configuring Country Codes (CLI)	294
Configuration Examples for Configuring Country Codes	296
Viewing Channel List for Country Codes	296
Information About Regulatory Compliance Domain	297
Global Country-Level Domains	298
Restrictions on Regulatory Compliance Domain	302
Countries Supporting 6-GHz Radio Band	302
Rest of World Domain	309
Configuring Country Code for Rest of the World (CLI)	317

CHAPTER 21**Access Points Modes 319**

- Information about Sniffer 320
- Information About XOR Radio Role Sniffer Support 321
- Feature History for Sniffer Mode 321
- Prerequisites for Sniffer 321
- Restrictions on Sniffer 321
- How to Configure Sniffer 322
 - Configuring an Access Point as Sniffer (GUI) 322
 - Configuring an Access Point as Sniffer (CLI) 323
 - Enabling or Disabling Sniffing on the Access Point (GUI) 323
 - Enabling or Disabling Sniffing on the Access Point (CLI) 324
 - Configuring XOR Radio Role Sniffer Support on the Access Point (CLI) 324
- Verifying Sniffer Configurations 325
- Verifying XOR Radio Role Sniffer Configuration 326
- Examples for Sniffer Configurations and Monitoring 327
- Introduction to Monitor Mode 327
- Enable Monitor Mode (GUI) 327
- Enable Monitor Mode (CLI) 328
- Feature History for Management Mode Migration in Cisco Catalyst Wireless 916X Access Points 328
- Information About Management Mode Migration in Cisco Catalyst Wireless 916X Series Access Points 329
- Regulatory Domain 329
- Configuring Management Mode Migration (GUI) 333
 - Exporting Meraki Management Mode-Migrated APs (GUI) 333
- Configuring the AP Management Mode (CLI) 334
- Verifying the Management Mode Migration Details 335
- Information About FlexConnect 335
 - FlexConnect Authentication 337
- Guidelines and Restrictions for FlexConnect 339
- Configuring a Site Tag 343
- Configuring a Policy Tag (CLI) 344
- Attaching a Policy Tag and a Site Tag to an Access Point (GUI) 345
- Attaching Policy Tag and Site Tag to an AP (CLI) 345

Linking an ACL Policy to the Defined ACL (GUI)	346
Applying ACLs on FlexConnect	347
Configuring FlexConnect	348
Configuring a Switch at a Remote Site	348
Configuring the Controller for FlexConnect	349
Configuring Local Switching in FlexConnect Mode (GUI)	349
Configuring Local Switching in FlexConnect Mode (CLI)	350
Configuring Central Switching in FlexConnect Mode (GUI)	350
Configuring Central Switching in FlexConnect Mode	351
Configuring an Access Point for FlexConnect	351
Configuring an Access Point for Local Authentication on a WLAN (GUI)	351
Configuring an Access Point for Local Authentication on a WLAN (CLI)	352
Connecting Client Devices to WLANs	352
Configuring FlexConnect Ethernet Fallback	353
Information About FlexConnect Ethernet Fallback	353
Configuring FlexConnect Ethernet Fallback	353
Flex AP Local Authentication (GUI)	354
Flex AP Local Authentication (CLI)	355
Flex AP Local Authentication with External Radius Server	357
Configuration Example: FlexConnect with Central and Local Authentication	360
NAT-PAT for FlexConnect	360
Configuring NAT-PAT for a WLAN or a Remote LAN	360
Creating a WLAN	360
Configuring a Wireless Profile Policy and NAT-PAT (GUI)	361
Configuring a Wireless Profile Policy and NAT-PAT	361
Mapping a WLAN to a Policy Profile	362
Configuring a Site Tag	363
Attaching a Policy Tag and a Site Tag to an Access Point (GUI)	363
Attaching a Policy Tag and a Site Tag to an Access Point	364
Split Tunneling for FlexConnect	364
Configuring Split Tunneling for a WLAN or Remote LAN	365
Defining an Access Control List for Split Tunneling (GUI)	365
Defining an Access Control List for Split Tunneling	365
Linking an ACL Policy to the Defined ACL	366

Creating a WLAN	367
Configuring a Wireless Profile Policy and a Split MAC ACL Name (GUI)	367
Configuring a Wireless Profile Policy and a Split MAC ACL Name	368
Mapping a WLAN to a Policy Profile (GUI)	369
Mapping WLAN to a Policy Profile	369
Configuring a Site Tag	370
Attaching a Policy Tag and Site Tag to an Access Point	370
VLAN-based Central Switching for FlexConnect	371
Configuring VLAN-based Central Switching (GUI)	371
Configuring VLAN-based Central Switching (CLI)	372
OfficeExtend Access Points for FlexConnect	373
Configuring OfficeExtend Access Points	374
Disabling OfficeExtend Access Point	374
Support for OEAP Personal SSID	375
Information About OEAP Personal SSID Support	375
Configuring OEAP Personal SSID (GUI)	375
Configuring OEAP Personal SSID (CLI)	376
Viewing OEAP Personal SSID Configuration	376
Clearing Personal SSID from an OfficeExtend Access Point	377
Example: Viewing OfficeExtend Configuration	377
Proxy ARP	378
Enabling Proxy ARP for FlexConnect APs (GUI)	378
Enabling Proxy ARP for FlexConnect APs	378
Overlapping Client IP Address in Flex Deployment	379
Overview of Overlapping Client IP Address in Flex Deployment	379
Enabling Overlapping Client IP Address in Flex Deployment (GUI)	379
Enabling Overlapping Client IP Address in Flex Deployment	380
Verifying Overlapping Client IP Address in Flex Deployment (GUI)	380
Verifying Overlapping Client IP Address in Flex Deployment	381
Information About FlexConnect High Scale Mode	382
Enabling PMK Propagation (CLI)	382
Flex Resilient with Flex and Bridge Mode Access Points	383
Information About Flex Resilient with Flex and Bridge Mode Access Points	383
Configuring a Flex Profile (GUI)	383

Configuring a Flex Profile (CLI)	384
Configuring a Site Tag (CLI)	385
Configuring a Mesh Profile (CLI)	385
Associating Wireless Mesh to an AP Profile (CLI)	386
Attaching Site Tag to an Access Point (CLI)	387
Configuring Switch Interface for APs (CLI)	387
Verifying Flex Resilient with Flex and Bridge Mode Access Points Configuration	388
Feature History for OEAP Link Test	388
Information About OEAP Link Test	389
Configuring OEAP Link Test (CLI)	389
Performing OEAP Link Test (GUI)	390
Verifying OEAP Link Test	390
Feature History for Cisco OEAP Split Tunneling	390
Information About Cisco OEAP Split Tunneling	391
Prerequisites for Cisco OEAP Split Tunneling	392
Restrictions for Cisco OEAP Split Tunneling	392
Use Cases for Cisco OEAP Split Tunneling	393
Workflow to Configure Cisco OEAP Split Tunneling	393
Create an IP Address ACL (CLI)	393
Create a URL ACL (CLI)	394
Add an ACL to a FlexConnect Profile	395
Enable Split Tunneling in a Policy Profile	396
Verifying the Cisco OEAP Split Tunnel Configuration	396
AP Survey Mode	397
Information About AP Deployment Mode	398
Use Case for AP Deployment Mode	398
Configuring AP Deployment Mode (GUI)	398
Configuring AP Deployment Mode (CLI)	399
Verifying AP Deployment Mode	399

CHAPTER 22
Security 401

Information About Data Datagram Transport Layer Security	401
Configuring Data DTLS (GUI)	402
Configuring Data DTLS (CLI)	402

Introduction to the 802.1X Authentication	403
EAP-FAST Protocol	404
EAP-TLS/EAP-PEAP Protocol	404
Limitations of the 802.1X Authentication	404
Topology - Overview	405
Configuring 802.1X Authentication Type and LSC AP Authentication Type (GUI)	406
Configuring 802.1X Authentication Type and LSC AP Authentication Type	406
Configuring the 802.1X Username and Password (GUI)	407
Configuring the 802.1X Username and Password (CLI)	408
Enabling 802.1X on the Switch Port	408
Verifying 802.1X on the Switch Port	410
Verifying the Authentication Type	411
Feature History for Access Point Client ACL Counter	411
Information About Access Point Client ACL Counter	411

CHAPTER 23**AP Joining 413**

Failover Priority for Access Points	413
Setting AP Priority (GUI)	414
Setting AP Priority	414
Overview of Access Point Plug-n-Play	414
Provisioning AP from PnP Server	415
Verifying AP Tag Configuration	415
Feature History for AP Fallback to Controllers Using AP Priming Profile	416
Information About AP Fallback to Controllers Using AP Priming Profile	416
Restrictions for AP Fallback to Controllers Using AP Priming Profile	416
Configure AP Priming Profile	417
Configure AP Priming Using Filters	418
Configure Per-AP Priming	419
Verify the Configuration	419

CHAPTER 24**AP Management 421**

AP Crash File Upload	422
Configuring AP Crash File Upload (CLI)	423
Information About LED States for Access Points	423

Configuring LED State in Access Points (GUI)	424
Configuring LED State for Access Points in the Global Configuration Mode (CLI)	424
Configuring LED State in the AP Profile	425
Verifying LED State for Access Points	425
Access Point Support Bundle	426
Exporting an AP Support Bundle (GUI)	426
Exporting an AP Support Bundle (CLI)	427
Monitoring the Status of Support Bundle Export	427
Information About Access Point Memory Information	427
Verifying Access Point Memory Information	428
Information About Access Point Tag Persistency	428
Configuring AP Tag Persistency (GUI)	428
Saving Tags on an Access Point (GUI)	429
Deleting Saved Tags on the Access Point	429
Configuring AP Tag Persistency (CLI)	429
Verifying AP Tag Persistency	430
Feature History for AP Power Save	431
Information About AP Power Save	431
Access Point Power Policy	432
Power-Save Mode	432
PoE Profiles	433
Wakeup Threshold for Access Point Power Save Mode	438
AP Power Save Scenarios	438
Configuring Power Policy Profile (GUI)	440
Configuring a Power Policy Profile (CLI)	440
Configuring a Calendar Profile (GUI)	443
Configuring a Calendar Profile (CLI)	444
Configuring a Power Policy in an AP Join Profile (GUI)	445
Mapping a Power Profile Under an AP Profile (CLI)	445
Configuring Client Wakeup Threshold (CLI)	446
Configuring PoE-Out Interface in Power Profile (GUI)	447
Configuring PoE-Out Interface in Power Profile (CLI)	447
Configuration Example of Power Profile	448
Verifying Access Point Power Policy (GUI)	448

449

Verifying the Access Point Power Profile	449
Verifying Radio Spatial Streams	450
Verifying Client Threshold	451
Verifying PoE-Out Details	451
Information About Access Point Real-Time Statistics	451
Feature History for Real Time Access Point Statistics	452
Restrictions for AP Radio Monitoring Statistics	452
Configuring Access Point Real Time Statistics (GUI)	452
Configuring Real-Time Access Point Statistics (CLI)	453
Configuring AP Radio Monitoring Statistics	455
Monitoring Access Point Real-Time Statistics (GUI)	456
Verifying Access Point Real-Time Statistics	457
Feature History for Access Point Auto Location Support	458
Information About Access Point Auto Location Support	458
Configuring Access Point Geolocation Derivation Using Ranging (GUI)	460
Configuring Access Point Geolocation Derivation Using Ranging (CLI)	460
Configuring Access Point Ranging Parameters (GUI)	460
Configuring Access Point Ranging Parameters (CLI)	461
Configuring Access Point Coordinates and Floor Information (CLI)	462
Configuring On-Demand Access Point Ranging (CLI)	462
Enabling Fine Time Measurement (802.11mc) Responder (GUI)	463
Configuring Fine Time Measurement (802.11mc) Responder (CLI)	463
Configuring Air Pressure Reporting (CLI)	464
Verifying Access Point Geolocation Information	464

CHAPTER 25**AP Configuration 467**

Feature History for Configuring the Access Point Console	468
Information About Configuring the Access Point Console	468
Configuring the AP Console (GUI)	469
Configuring the AP Console (CLI)	469
Verifying the AP Console Status	469
Information About AP Audit Configuration	470
Restrictions for AP Audit Configuration	470

Configure AP Audit Parameters (CLI)	471
Verifying AP Audit Report Summary	471
Verifying AP Audit Report Detail	471
2.4-GHz Radio Support	472
Configuring 2.4-GHz Radio Support for the Specified Slot Number	472
5-GHz Radio Support	474
Configuring 5-GHz Radio Support for the Specified Slot Number	474
6-GHz Radio Support	477
Configuring 6-GHz Radio Support for the Specified Slot Number	477
Information About Dual-Band Radio Support	479
Configuring Default XOR Radio Support	480
Configuring XOR Radio Support for the Specified Slot Number (GUI)	482
Configuring XOR Radio Support for the Specified Slot Number	483
Receiver Only Dual-Band Radio Support	485
Information About Receiver Only Dual-Band Radio Support	485
Configuring Receiver Only Dual-Band Parameters for Access Points	485
Enabling CleanAir with Receiver Only Dual-Band Radio on a Cisco Access Point (GUI)	485
Enabling CleanAir with Receiver Only Dual-Band Radio on a Cisco Access Point	485
Disabling Receiver Only Dual-Band Radio on a Cisco Access Point (GUI)	486
Disabling Receiver Only Dual-Band Radio on a Cisco Access Point	486
Configuring Client Steering (CLI)	486
Verifying Cisco Access Points with Dual-Band Radios	488
Information About OFDMA Support for 11ax Access Points	488
Supported Modes on 11ax Access Points	488
Configuring 11AX (GUI)	489
Configuring Channel Width	489
Configuring 802.11ax Radio Parameters (GUI)	490
Configuring 802.11ax Radio Parameters (CLI)	490
Setting up the 802.11ax Radio Parameters	491
Configuring OFDMA on a WLAN	492
Verifying Channel Width	493
Verifying Client Details	494
Verifying Radio Configuration	495
Information About Cisco Flexible Antenna Port	498

Configuring a Cisco Flexible Antenna Port (GUI)	498
Configuring a Cisco Flexible Antenna Port (CLI)	498
Verifying Flexible Antenna Port Configuration	499
Feature History for Environmental Sensors in Access Points	499
Information About Environmental Sensors in Access Points	500
Use Cases	500
Configuring Environmental Sensors in an AP Profile (CLI)	500
Configuring Environment Sensors in Privileged EXEC Mode (CLI)	501
Verifying the AP Sensor Status	502
Information About CAPWAP LAG Support	502
Restrictions for CAPWAP LAG Support	503
Enabling CAPWAP LAG Support on Controller (GUI)	503
Enabling CAPWAP LAG Support on Controller	504
Enabling CAPWAP LAG Globally on Controller	504
Disabling CAPWAP LAG Globally on Controller	504
Enabling CAPWAP LAG for an AP Profile (GUI)	505
Enabling CAPWAP LAG for an AP Profile	505
Disabling CAPWAP LAG for an AP Profile	506
Disabling CAPWAP LAG Support on Controller	506
Verifying CAPWAP LAG Support Configurations	507
Feature History for CAPWAP Message Aggregation	507
Information About CAPWAP Message Aggregation	507
Configuring CAPWAP Message Aggregation (CLI)	508
Verifying CAPWAP Message Aggregation	508
Configuring Bulk AP Provisioning	509

CHAPTER 26
Secure Data Wipe 511

Secure Data Wipe	511
------------------	-----

CHAPTER 27
Troubleshooting Lightweight Access Points 513

Overview	513
Support Articles	513
Feedback Request	514
Disclaimer and Caution	514

PART IV**Radio Resource Management 515**

CHAPTER 28**Radio Resource Management 517**

- Information About Radio Resource Management 517
 - Radio Resource Monitoring 518
 - Information About RF Groups 518
 - RF Group Leader 519
 - RF Group Name 521
 - Rogue Access Point Detection in RF Groups 522
 - Secure RF Groups 522
 - Transmit Power Control 522
 - Overriding the TPC Algorithm with Minimum and Maximum Transmit Power Settings 522
 - Dynamic Channel Assignment 523
 - Dynamic Bandwidth Selection 525
 - Coverage Hole Detection and Correction 525
 - Cisco AI Enhanced RRM 525
- Restrictions for Radio Resource Management 527
- How to Configure RRM 528
 - Configuring Neighbor Discovery Type (GUI) 528
 - Configuring Neighbor Discovery Type (CLI) 529
 - Configuring RF Groups 529
 - Configuring RF Group Selection Mode (GUI) 530
 - Configuring RF Group Selection Mode (CLI) 530
 - Configuring an RF Group Name (CLI) 531
 - Configuring a Secure RF Group (CLI) 531
 - Configuring Members in an 802.11 Static RF Group (GUI) 532
 - Configuring Members in an 802.11 Static RF Group (CLI) 532
 - Configuring Transmit Power Control 533
 - Configuring Transmit Power (GUI) 533
 - Configuring the Tx-Power Control Threshold (CLI) 533
 - Configuring the Tx-Power Level (CLI) 534
 - Configuring 802.11 RRM Parameters 535
 - Configuring Advanced 802.11 Channel Assignment Parameters (GUI) 535

Configuring Advanced 802.11 Channel Assignment Parameters (CLI)	537
Configuring 802.11 Coverage Hole Detection (GUI)	539
Configuring 802.11 Coverage Hole Detection (CLI)	539
Configuring 802.11 Event Logging (CLI)	541
Configuring 802.11 Statistics Monitoring (GUI)	542
Configuring 802.11 Statistics Monitoring (CLI)	542
Configuring the 802.11 Performance Profile (GUI)	544
Configuring the 802.11 Performance Profile (CLI)	544
Configuring Advanced 802.11 RRM	545
Enabling Channel Assignment (GUI)	545
Enabling Channel Assignment (CLI)	546
Restarting DCA Operation	546
Updating Power Assignment Parameters (GUI)	547
Updating Power Assignment Parameters (CLI)	547
Configuring Rogue Access Point Detection in RF Groups	547
Configuring Rogue Access Point Detection in RF Groups (CLI)	547
Monitoring RRM Parameters and RF Group Status	549
Monitoring RRM Parameters	549
Verifying RF Group Status (CLI)	549
Examples: RF Group Configuration	550
Information About ED-RRM	550
Configuring ED-RRM on the Cisco Wireless Controller (CLI)	551
Information About Rogue PMF Containment	552
Enabling Rogue PMF Containment	553
Verifying PMF Containment	553
Information About Rogue Channel Width	554
Configuring Rogue Channel Width (CLI)	554
Configuring Rogue Classification Rules (GUI)	556
Verifying Rogue Channel Width	558

CHAPTER 29
Coverage Hole Detection 561

Coverage Hole Detection and Correction	561
Configuring Coverage Hole Detection (GUI)	561
Configuring Coverage Hole Detection (CLI)	562

- Configuring CHD for RF Tag Profile (GUI) 564
- Configuring CHD for RF Profile (CLI) 564

CHAPTER 30**Optimized Roaming 567**

- Optimized Roaming 567
- Restrictions for Optimized Roaming 567
- Configuring Optimized Roaming (GUI) 568
- Configuring Optimized Roaming (CLI) 568

CHAPTER 31**Cisco Flexible Radio Assignment 571**

- Information About Flexible Radio Assignment 571
- Configuring an FRA Radio (GUI) 572
- Enabling FRA (CLI) 574
- Configuring Client FRA in RF Profile (CLI) 576
- Verifying FRA XOR 5-GHz and 6-GHz Details 576
- Flexible Radio Assignment (FRA) Action 577
 - Feature History for Flexible Radio Assignment Action 577
 - Information About Flexible Radio Assignment Action 578
 - Configuring FRA Action in Default RF Profile (CLI) 578
 - Configuring FRA Action in 2.4-GHz RF Profile (CLI) 578
 - Verifying FRA Action Configuration 579

CHAPTER 32**XOR Radio Support 581**

- Information About Dual-Band Radio Support 581
- Configuring Default XOR Radio Support 582
- Configuring XOR Radio Support for the Specified Slot Number (GUI) 584
- Configuring XOR Radio Support for the Specified Slot Number 585

CHAPTER 33**Cisco Receiver Start of Packet 587**

- Information About Receiver Start of Packet Detection Threshold 587
- Restrictions for Rx SOP 587
- Configuring Rx SOP (CLI) 588
- Customizing RF Profile (CLI) 588

CHAPTER 34	Client Limit	591
	Information About Client Limit	591
	Limitations for Client Limit	591
	Configuring Client Limit Per WLAN (GUI)	591
	Configuring Client Limit Per WLAN (CLI)	592
	Configuring Client Limit Per AP (GUI)	593
	Configuring Client Limit Per AP (CLI)	593
	Configuring Client Limit Per Radio (GUI)	594
	Configuring Client Limit Per Radio (CLI)	594
	Verifying Client Limit	595

CHAPTER 35	IP Theft	597
	Introduction to IP Theft	597
	Configuring IP Theft (GUI)	598
	Configuring IP Theft	598
	Configuring the IP Theft Exclusion Timer	598
	Adding Static Entries for Wired Hosts	599
	Verifying IP Theft Configuration	600

CHAPTER 36	Unscheduled Automatic Power Save Delivery	603
	Information About Unscheduled Automatic Power Save Delivery	603
	Viewing Unscheduled Automatic Power Save Delivery (CLI)	603

CHAPTER 37	Target Wake Time	605
	Target Wake Time	605
	Extended Power-Savings Using Target Wake Time	605
	Configuring Target Wake Time at the Radio Level (CLI)	606
	Configuring Target Wake Time on WLAN	607
	Enabling Target Wake Time on WLAN (CLI)	607
	Disabling Target Wakeup Time on WLAN (CLI)	608
	Configuring Target Wake Time (GUI)	609
	Verifying Target Wakeup Time	609

CHAPTER 38	Enabling USB Port on Access Points	611
	USB Port as Power Source for Access Points	611
	Configuring an AP Profile (CLI)	612
	Configuring USB Settings for an Access Point (CLI)	613
	Configuring USB Settings for an Access Point (GUI)	613
	Monitoring USB Configurations for Access Points (CLI)	614

CHAPTER 39	Dynamic Frequency Selection	615
	Feature History for Channel Availability Check (CAC)	615
	Information About Dynamic Frequency Selection	615
	Information About Channel Availability Check (CAC)	616
	Verifying DFS	616
	Information About Zero Wait Dynamic Frequency Selection	617
	Configuring Zero Wait Dynamic Frequency Selection Globally (CLI)	617
	Configuring Zero Wait Dynamic Frequency Selection Globally (GUI)	617
	Enabling Zero Wait Dynamic Frequency Selection on a RF Profile (CLI)	618
	Enabling Zero Wait Dynamic Frequency Selection on a RF Profile (GUI)	618
	Verifying Zero Wait Dynamic Frequency Selection Configuration	619

CHAPTER 40	Cisco Access Points with Tri-Radio	621
	Cisco Access Points with Tri-Radio	621
	Guidelines and Restrictions for Tri-Radio Access Points	623
	Configuring Tri-Radio	623
	Configuring Tri-Radio for AP (GUI)	623
	Configuring the Tri-Radio (CLI)	624
	Configuring 5-GHz Dual Radio Mode for AP (GUI)	624
	Configuring the Dual Radio Mode and Enabling Slots (CLI)	624
	Setting Radio Roles for Slots (CLI)	625
	Configuring the Tri-Radio Dual Radio Role (CLI)	625
	Verifying Tri-Radio Configuration on the Controller	626

CHAPTER 41	Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard	627
	Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard	627

Configuring Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard Parameters (CLI)	628
Verifying AP DFS Counters (CLI)	629
Verifying Wi-Fi 6 Access Point Parameters	630

CHAPTER 42**Antenna Disconnection Detection 631**

Feature History for Antenna Disconnection Detection	631
Information About Antenna Disconnection Detection	631
Recommendations and Limitations	632
Configuring Antenna Disconnection Detection (CLI)	632
Configuring Antenna Disconnection Detection (GUI)	633
Detecting Broken Antenna Using SNMP Trap (CLI)	634
Detecting Broken Antenna Using SNMP Trap (GUI)	634
Verifying Antenna Disconnection Detection	635
Verifying Antenna Disconnection Detection (GUI)	636

CHAPTER 43**Neighbor Discovery Protocol Mode on Access Points 637**

Information About Neighbor Discovery Protocol Mode	637
Configuring RRM Neighbor Discovery Mode (GUI)	638
Configuring the Neighbor Discovery Protocol Mode (CLI)	638
Configuring the Neighbor Discovery Protocol Type (CLI)	638
Configuring Neighbor Discovery Protocol Mode in the RF Profile (GUI)	639
Configuring Neighbor Discovery Protocol Mode in the RF Profile (CLI)	639
Monitoring Radio Statistics-NDP Capability and NDP Mode (GUI)	640
Verifying Neighbor Discovery Protocol Mode	641

CHAPTER 44**6-GHz Band Operations 643**

Configuring Preferred Scanning Channels in the RF Profile (GUI)	643
Configuring Preferred Scanning Channels in the RF Profile (CLI)	644
Configuring Broadcast Probe Response in RF Profile (GUI)	644
Configuring Broadcast Probe Response in RF Profile (CLI)	644
Configuring FILS Discovery Frames in the RF Profile (GUI)	645
Configuring FILS Discovery Frames in the RF Profile (CLI)	646
Configuring Multi BSSID Profile (GUI)	646
Configuring Multi BSSID Profile	647

Configuring Multi-BSSID in the RF Profile (GUI)	647
Configuring Multi-BSSID in the RF Profile (CLI)	648
Configuring Dynamic Channel Assignment Freeze (CLI)	648
Information About 6-GHz Client Steering	649
Configuring 6-GHz Client Steering in the Global Configuration Mode (GUI)	649
Configuring 6-GHz Client Steering in the Global Configuration Mode	649
Configuring 6-GHz Client Steering on the WLAN (GUI)	650
Configuring 6-GHz Client Steering on the WLAN	651
Verifying 6-GHz Client Steering	651

PART V
Network Management 653

CHAPTER 45
AP Packet Capture 655

Introduction to AP Client Packet Capture	655
Enabling Packet Capture (GUI)	655
Enabling Packet Capture (CLI)	656
Create AP Packet Capture Profile and Map to an AP Join Profile (GUI)	656
Create AP Packet Capture Profile and Map to an AP Join Profile	657
Start or Stop Packet Capture	657

CHAPTER 46
DHCP Option82 659

Information About DHCP Option 82	659
Configuring DHCP Option 82 Global Interface	661
Configuring DHCP Option 82 Globally Through Server Override (CLI)	661
Configuring DHCP Option 82 Through Server Override (CLI)	661
Configuring DHCP Option 82 Globally Through Different SVIs (GUI)	662
Configuring DHCP Option 82 Globally Through Different SVIs (CLI)	662
Configuring DHCP Option 82 Format	663
Configuring DHCP Option82 Through a VLAN Interface	664
Configuring DHCP Option 82 Through Option-Insert Command (CLI)	664
Configuring DHCP Option 82 Through the server-ID-override Command (CLI)	665
Configuring DHCP Option 82 Through a Subscriber-ID (CLI)	666
Configuring DHCP Option 82 Through server-ID-override and subscriber-ID Commands (CLI)	667
Configuring DHCP Option 82 Through Different SVIs (CLI)	668

Information About AP DHCP Option 82 Support on FlexConnect Local Switching Mode	669
Configuring AP DHCP Option82 Support	669
Verifying AP DHCP Option82 Support	670

CHAPTER 47**RADIUS Realm 671**

Information About RADIUS Realm	671
Enabling RADIUS Realm	672
Configuring Realm to Match the RADIUS Server for Authentication and Accounting	672
Configuring the AAA Policy for a WLAN	673
Verifying the RADIUS-Realm Configuration	675

CHAPTER 48**RADIUS Accounting 677**

Information About RADIUS Accounting of AP Events	677
Configuring Accounting Method-List for an AP Profile	677
Verifying the AP Accounting Information	678
AAA Accounting	678
Configuring AAA Accounting Using Default Method List (CLI)	678
Configuring HTTP Command Accounting Using Named Method List (CLI)	679
Feature History for Device Ecosystem Data	679
Information About Device Ecosystem Data	680
Enable Device Ecosystem Data	680
Verify Device Ecosystem Data	681

CHAPTER 49**RADIUS Call Station Identifier 683**

RADIUS Call Station Identifier	683
Configuring a RADIUS Call Station Identifier	684

CHAPTER 50**RADIUS VSA 685**

Information About RADIUS VSA	685
Create an Attribute List	686
Create a AAA Policy and Map it to Attribute List	687
Map a AAA Policy to the WLAN Policy Profile	688
Map the WLAN Policy Profile to a WLAN	689

CHAPTER 51	Cisco StadiumVision 691
	Cisco StadiumVision Overview 691
	Configure Parameters for Cisco StadiumVision (GUI) 692
	Configure Parameters for Cisco StadiumVision (CLI) 692
	Verify StadiumVision Configurations 693

CHAPTER 52	Persistent SSID Broadcast 695
	Persistent SSID Broadcast 695
	Configuring Persistent SSID Broadcast 695
	Verifying Persistent SSID Broadcast 696

CHAPTER 53	Network Monitoring 697
	Network Monitoring 697
	Status Information Received Synchronously - Configuration Examples 697
	Alarm and Event Information Received Asynchronously - Configuration Examples 699

CHAPTER 54	Creating a Lobby Ambassador Account 701
	Information About Lobby Ambassador Account 701
	Creating a Lobby Ambassador User Account (GUI) 701
	Creating a User Account 702
	Logging In Using the Lobby Account 703
	Creating a Lobby Ambassador Account (CLI) 703

CHAPTER 55	Lobby Ambassador Account 705
	Information About Lobby Ambassador Account 705
	Creating a Lobby Ambassador User Account (GUI) 706
	Creating a User Account 706
	Logging In Using the Lobby Account 707
	Creating a Lobby Ambassador Account (CLI) 707
	Configuring WLAN (GUI) 708
	Client Allowed List 709
	Restrictions for Client Allowed List 709

Creating a Client Allowed List (GUI)	709
Adding Single MAC Address to Allowed List	709
Adding Bulk MAC Address to Allowed List	710
Managing Guest Users	710
Viewing a Client Allowed List	711

CHAPTER 56**Guest User Accounts 713**

Information About Creating Guest User Accounts	713
Creating a Guest User Account (GUI)	713
Creating a Guest User Account (CLI)	714
Verifying Guest User Account	715
Assigning Username to Guest Users in a WLAN (CLI)	716

CHAPTER 57**Link Local Bridging 717**

Feature History for Link Local Bridging	717
Information About Link Local Bridging	717
Use Case for Link Local Bridging	718
Guidelines and Restrictions for Link Local Bridging	718
Enabling Link Local Bridging Per Policy Profile (GUI)	718
Enabling Link Local Bridging Per Policy Profile (CLI)	719
Verifying Link Local Bridging	719

CHAPTER 58**Web Admin Settings 721**

Information About Web Admin Settings	721
Configuring HTTP/HTTPS Access	721
Configuring HTTP Trust Point	722
Configuring Netconf Yang	723
Configuring Timeout Policy	723
Configuring VTY	724

CHAPTER 59**Web UI Configuration Command Accounting in TACACS Server 727**

Feature History for Web UI Configuration Command Accounting in TACACS+ Server	727
Information About Web UI Configuration Command Accounting in TACACS+ Server	727
Guidelines for Web UI Configuration Command Accounting in TACACS+ Server	728

Configuring AAA Accounting Using Default Method List (CLI)	728
Configuring HTTP Command Accounting Using Named Method List (CLI)	729

CHAPTER 60**Embedded Packet Capture 731**

Feature History for Embedded Packet Capture	731
Information About Embedded Packet Capture	731
Configuring Embedded Packet Capture (CLI)	732
Verifying Embedded Packet Capture	734

CHAPTER 61**Layer 3 Access 737**

Information About Layer 3 Access	737
Information About OSPF	738
Information About PIM Sparse Mode	738
Information About Network Address Translation	739
Restrictions for Layer 3 Access	740
Use Cases for Layer 3 Access	740
Configuring a Client Gateway (GUI)	741
Configuring a Client Gateway (CLI)	741
Configuring OSPF Interfaces (GUI)	742
Configuring OSPF Protocol (GUI)	742
Configuring OSPF (CLI)	743
Configuring Basic OSPF Parameters (CLI)	743
Configuring OSPF Interfaces (CLI)	744
Enabling Layer 3 Access on Policy Profile (GUI)	745
Enabling Layer 3 Access on Policy Profile (CLI)	745
Configuring Multicast Traffic	746
Enabling Multicast Traffic without VRF (GUI)	746
Enabling Multicast Traffic without VRF (CLI)	747
Enabling Multicast Traffic with PIM-SSM (CLI)	748
Selective NAT Support	750
Enabling Static NAT without VRF (CLI)	750
Enabling Static NAT with VRF (CLI)	751
Enabling Dynamic NAT without VRF (CLI)	752
Enabling Dynamic NAT with VRF (CLI)	754

Enabling Timeout for NAT (CLI)	756
Selective Internal DHCP with VRF Support	757
Enabling Internal DHCP with VRF (CLI)	757
Verifying Routing Protocol Details	758
Verifying Multicast Traffic Details	766
Verifying Static NAT Details	769
Verifying Dynamic NAT Details	770
Verifying NAT Details	771
Verifying NAT Timeout Details	772
Verifying Internal DHCP with VRF Details	773
Verifying Layer 3 Access Details	774

PART VI
System Management 775

CHAPTER 62
Network Mobility Services Protocol 777

Information About Network Mobility Services Protocol	777
Radioactive Tracing for NMSP	778
Enabling NMSP on Premises Services	778
Modifying the NMSP Notification Interval for Clients, RFID Tags, and Rogues	779
Modifying the NMSP Notification Threshold for Clients, RFID Tags, and Rogues	779
Configuring NMSP Strong Cipher	780
Verifying NMSP Settings	780
Examples: NMSP Settings Configuration	783
NMSP by AP Groups with Subscription List from CMX	783
Verifying NMSP by AP Groups with Subscription List from CMX	783
Probe RSSI Location	785
Configuring Probe RSSI	785
RFID Tag Support	787
Configuring RFID Tag Support	787
Verifying RFID Tag Support	788

CHAPTER 63
Application Visibility and Control 791

Information About Application Visibility and Control	791
Prerequisites for Application Visibility and Control	793

Restrictions for Application Visibility and Control	793
AVC Configuration Overview	793
Create a Flow Monitor	794
Configuring a Flow Monitor (GUI)	796
Create a Flow Record	796
Create a Flow Exporter	798
Configuring a Policy Tag	799
Attaching a Policy Profile to a WLAN Interface (GUI)	800
Attaching a Policy Profile to a WLAN Interface (CLI)	800
Attaching a Policy Profile to an AP	801
Verify the AVC Configuration	802
Default DSCP on AVC	803
Configuring Default DSCP for AVC Profile (GUI)	803
Configuring Default DSCP for AVC Profile	803
Creating Class Map	803
Creating Policy Map	804
AVC-Based Selective Reanchoring	805
Restrictions for AVC-Based Selective Reanchoring	806
Configuring the Flow Exporter	806
Configuring the Flow Monitor	806
Configuring the AVC Reanchoring Profile	807
Configuring the Wireless WLAN Profile Policy	808
Verifying AVC Reanchoring	809
CHAPTER 64	Software-Defined Application Visibility and Control 813
	Information About Software-Defined Application Visibility and Control 813
	Enabling Software-Defined Application Visibility and Control on a WLAN (CLI) 814
	Configuring Software-Defined Application Visibility and Control Global Parameters (CLI) 814
CHAPTER 65	Cisco Hyperlocation 817
	Information About Cisco Hyperlocation 817
	Restrictions on Cisco Hyperlocation 819
	Support for IPv6 in Cisco Hyperlocation or BLE Configuration 820
	Configuring Cisco Hyperlocation (GUI) 820

Configuring Cisco Hyperlocation (CLI)	821
Configuring Hyperlocation BLE Beacon Parameters for AP (GUI)	822
Configuring Hyperlocation BLE Beacon Parameters for AP (CLI)	822
Configuring Hyperlocation BLE Beacon Parameters (CLI)	823
Information About AP Group NTP Server	824
Configuring an AP Group NTP Server	824
Configuring AP Timezone	825
Information About BLE Concurrent Scanning and Beacons	825
Verifying BLE Concurrent Scanning and Beacons	826
Verifying Cisco Hyperlocation	827
Verifying Hyperlocation BLE Beacon Configuration	831
Verifying Hyperlocation BLE Beacon Configuration for AP	831

CHAPTER 66**FastLocate for Cisco Catalyst Series Access Points** 833

Information About FastLocate	833
Restrictions on FastLocate	833
Supported Access Points	834
FastLocate Network Components	834
Configuring FastLocate (GUI)	835
Verifying FastLocate on Cisco Catalyst APs	835

CHAPTER 67**IoT Services Management** 837

Information About IoT Services Management	837
Enabling the Dot15 Radio	838
Configuring the gRPC Token	838
Enabling gRPC in an AP Profile	839
Verifying BLE State and Mode	839
Verifying BLE Details	840
Verifying gRPC Summary, Status, and Statistics	841

CHAPTER 68**IoT Module Management in the Controller** 843

Information About IoT Module Management in the Controller	843
Enabling a USB on the Controller	843
Verifying the USB Modules	844

CHAPTER 69	Cisco Spaces	845
	Cisco Spaces	845
	Configuring Cisco Spaces	845
	Verifying Cisco Spaces Configuration	846

CHAPTER 70	EDCA Parameters	849
	Enhanced Distributed Channel Access Parameters	849
	Configuring EDCA Parameters (GUI)	849
	Configuring EDCA Parameters (CLI)	850

CHAPTER 71	Adaptive Client Load-Based EDCA	853
	Feature History for Adaptive Client Load-Based EDCA	853
	Information About Adaptive Client Load-Based EDCA	853
	Restrictions for Adaptive Client Load-Based EDCA	854
	Configuration Workflow	854
	Configuring Adaptive Client Load-Based EDCA (GUI)	854
	Configuring Adaptive Client Load-Based EDCA (CLI)	855
	Verifying Adaptive Client Load-Based EDCA Configuration	855

CHAPTER 72	802.11 parameters and Band Selection	857
	Information About Configuring Band Selection, 802.11 Bands, and Parameters	857
	Band Select	857
	802.11 Bands	858
	802.11n Parameters	858
	802.11h Parameters	858
	Restrictions for Band Selection, 802.11 Bands, and Parameters	859
	How to Configure 802.11 Bands and Parameters	859
	Configuring Band Selection (GUI)	859
	Configuring Band Selection (CLI)	860
	Configuring the 802.11 Bands (GUI)	861
	Configuring the 802.11 Bands (CLI)	862
	Configuring a Band-Select RF Profile (GUI)	864
	Configuring a Band-Select RF Profile (CLI)	865

Configuring 802.11n Parameters (GUI)	865
Configuring 802.11n Parameters (CLI)	866
Configuring 802.11h Parameters (CLI)	868
Monitoring Configuration Settings for Band Selection, 802.11 Bands, and Parameters	869
Verifying Configuration Settings Using Band Selection and 802.11 Bands Commands	869
Example: Viewing the Configuration Settings for the 6-GHz Band	869
Example: Viewing the Configuration Settings for the 5-GHz Band	871
Example: Viewing the Configuration Settings for the 2.4-GHz Band	872
Example: Viewing the status of 802.11h Parameters	874
Example: Verifying the Band-Selection Settings	874
Configuration Examples for Band Selection, 802.11 Bands, and Parameters	876
Examples: Band Selection Configuration	876
Examples: 802.11 Bands Configuration	877
Examples: 802.11n Configuration	877
Examples: 802.11h Configuration	878

CHAPTER 73**NBAR Protocol Discovery 879**

Introduction to NBAR Protocol Discovery	879
Configuring NBAR Protocol Discovery	879
Verifying Protocol Discovery Statistics	880

CHAPTER 74**Conditional Debug, Radioactive Tracing, and Packet Tracing 881**

Introduction to Conditional Debugging	881
Introduction to Radioactive Tracing	882
Conditional Debugging and Radioactive Tracing	882
Location of Tracefiles	883
Configuring Conditional Debugging (GUI)	883
Configuring Conditional Debugging	884
Radioactive Tracing for L2 Multicast	885
Recommended Workflow for Trace files	885
Copying Tracefiles Off the Box	886
Configuration Examples for Conditional Debugging	886
Verifying Conditional Debugging	887
Example: Verifying Radioactive Tracing Log for SISF	887

Information About Packet Tracing 888

Configuring Conditional Debugging Packet Tracing 889

Configuring Conditional Debugging Packet Tracing per AP 890

Configuring Conditional Debugging Packet Tracing per Client (GUI) 891

Configuring Conditional Debugging Packet Tracing per Client 891

Verifying Conditional Debugging Packet Tracing Configuration 891

Feature History for Wireless Client Debug Bundle 892

Information About Wireless Client Debug Bundle 892

 Types of Logs Collected 893

Collecting Wireless Client Debug Bundle (CLI) 893

CHAPTER 75

Aggressive Client Load Balancing 895

Information About Aggressive Client Load Balancing 895

Enabling Aggressive Client Load Balancing (GUI) 896

Configuring Aggressive Client Load Balancing (GUI) 896

Configuring Aggressive Client Load Balancing (CLI) 897

CHAPTER 76

RF based Automatic AP Load Balancing 899

Information about RF based Automatic AP Load Balancing 899

Configuring RF based Automatic AP Load Balancing 900

Disabling RF based Automatic AP Load Balancing 902

Verifying Automatic WNCd Load Balancing 903

CHAPTER 77

Accounting Identity List 905

Configuring Accounting Identity List (GUI) 905

Configuring Accounting Identity List (CLI) 905

Configuring Client Accounting (GUI) 906

Configuring Client Accounting (CLI) 906

CHAPTER 78

Support for Accounting Session ID 909

Information About Accounting Session ID 909

Configuring an Accounting Session ID (CLI) 909

Verifying an Account Session ID 910

CHAPTER 79**Interim Accounting 913**

- Information About Interim Accounting 913
- Disabling Interim Accounting (CLI) 914
- Verifying Interim Accounting 914

CHAPTER 80**Wireless Multicast 915**

- Information About Wireless Multicast 915
 - Multicast Optimization 916
 - IPv6 Global Policies 916
 - Information About IPv6 Snooping 916
 - IPv6 Neighbor Discovery Inspection 916
- Prerequisites for Configuring Wireless Multicast 918
- Restrictions on Configuring Wireless Multicast 919
 - Restrictions for IPv6 Snooping 919
- Configuring Wireless Multicast 919
 - Configuring Wireless Multicast-MCMC Mode (CLI) 919
 - Configuring Wireless Multicast-MCUC Mode 920
 - Configuring Multicast Listener Discovery Snooping (GUI) 920
 - Configuring IPv6 MLD Snooping 921
 - Verifying the Multicast VLAN Configuration 921
- IPv6 Multicast-over-Multicast 921
 - Configuring IPv6 Multicast-over-Multicast (GUI) 922
 - Configuring IPv6 Multicast-over-Multicast 923
 - Verifying IPv6 Multicast-over-Multicast 923
 - Verifying the Multicast Connection Between the Controller and the AP 923
- Directed Multicast Service 924
 - Configuring Directed Multicast Service(GUI) 924
 - Configuring Directed Multicast Service 924
 - Verifying the Directed Multicast Service Configuration 925
- Wireless Broadcast, Non-IP Multicast and Multicast VLAN 926
 - Configuring Non-IP Wireless Multicast (CLI) 927
 - Configuring Wireless Broadcast (GUI) 927
 - Configuring Wireless Broadcast (CLI) 928

Configuring Multicast-over-Multicast for AP Multicast Groups (CLI)	928
Verifying Wireless Multicast	929
Multicast Optimization	929
Configuring IP Multicast VLAN for WLAN (GUI)	930
Configuring IP Multicast VLAN for WLAN	930
Verifying the Multicast VLAN Configuration	931
Multicast Filtering	932
Information About Multicast Filtering	932
Configuring Multicast Filtering	933
Verifying Multicast Filtering	933

CHAPTER 81**Map-Server Per-Site Support 935**

Information About Map Server Per Site Support	935
Configuring the Default Map Server (GUI)	936
Configuring the Default Map Server (CLI)	936
Configuring a Map Server Per Site (GUI)	937
Configuring a Map Server Per Site (CLI)	937
Creating a Map Server for Each VNID (GUI)	938
Creating a Map Server for Each VNID	938
Creating a Fabric Profile and Associating a Tag and VNID (GUI)	939
Creating a Fabric Profile and Associating a Tag and VNID (CLI)	939
Verifying the Map Server Configuration	940

CHAPTER 82**Volume Metering 943**

Volume Metering	943
Configuring Volume Metering	943

CHAPTER 83**Enabling Syslog Messages in Access Points and Controller for Syslog Server 945**

Information About Enabling Syslog Messages in Access Points and Controller for Syslog Server	945
Configuring Syslog Server for an AP Profile	947
Configuring Syslog Server for the Controller (GUI)	948
Configuring Syslog Server for the Controller	949
Information About Syslog Support for Client State Change	950
Configuring Syslog Support for Client State Change (CLI)	951

Sample Syslogs	951
Verifying Syslog Server Configurations	952

CHAPTER 84 Login Banner 957

Information About Login Banner	957
Configuring a Login Banner (GUI)	957
Configuring a Login Banner	958

CHAPTER 85 Wi-Fi Alliance Agile Multiband 959

Introduction to Wi-Fi Alliance Agile Multiband	959
Limitations of MBO	961
Configuring MBO on a WLAN	961
Verifying MBO Configuration	962

CHAPTER 86 SNMP Traps 965

Information About Configuring SNMP Traps	965
Configuring SNMP Traps (GUI)	966
Enabling Access Points Traps (CLI)	966
Enabling Wireless Client Traps (CLI)	967
Enabling Mesh Traps (CLI)	967
Enabling RF Traps (CLI)	968
Enabling Rogue, Mobility, RRM, and General Traps (CLI)	968
Verifying SNMP Wireless Traps	969

CHAPTER 87 Disabling Clients with Random MAC Address 971

Information About Disabling Clients with Random MAC Addresses	971
Configuring Random MAC Address Deny (CLI)	971
Verifying Denial of Clients with a Random MAC Address	972

CHAPTER 88 Dataplane Packet Logging 975

Information About Dataplane Packet Logging	975
Enabling or Disabling Debug Level (CLI)	976
Enabling Packet Logging in Global and Filtered Buffer in Ingress Path (CLI)	976

Enabling Packet Logging in Global and Filtered Buffer in Punt-Inject Path (CLI)	977
Verifying Dataplane Packet Logging	978
Clearing Logs and Conditions in Global and Filtered Trace Buffers	979

CHAPTER 89**Streaming Telemetry 981**

Information About Streaming Telemetry	981
Gather Points	981
Subscription	982
Transport	983
Scale Considerations	983
Session	983
gNMI Dial-In-Mode	983
gRPC- Dial-Out-Mode	984
Configuring Telemetry on a Cisco Catalyst 9800 Series Wireless Controller	984
Enabling gNXI in Insecure Mode (CLI)	984
Enabling gNXI in Secure Mode (CLI)	985
Verifying the Status of a Telemetry Subscription on a Cisco Catalyst 9800 Series Wireless Controller	987
Managing Configured Subscriptions on a Cisco Catalyst 9800 Series Wireless Controller	987
Zero Trust Telemetry	988
Define a Protocol	989
Define a Named Receiver	989
Configure Telemetry Subscription	990
On-Change Telemetry Support	991
Supported XPathS for On-Change Subscription	991
Troubleshooting Telemetry Support	995
Cisco Catalyst Center Client Event and SSID Telemetry Filter	997
Feature History for Cisco Catalyst Center Client Event and SSID Telemetry Filter	997
Information About Cisco Catalyst Center Client Event and SSID Telemetry Filter	998
Restrictions for Cisco Catalyst Center Client Event and SSID Telemetry Filter	999
Supported Workflow for Cisco Catalyst Center Client Event and SSID Telemetry Filter	999
Enabling iCAP Filtering in APs (CLI)	999
Disabling Client Telemetry Data for a WLAN (YANG)	1000
Verifying Client Telemetry Data for a WLAN	1000

CHAPTER 90	Application Performance Monitoring	1001
	Feature History for Application Performance Monitoring	1001
	Information About Application Performance Monitoring	1001
	Restrictions for Application Performance Monitoring	1002
	Workflow	1002
	Create a Flow Monitor	1002
	Create a Wireless WLAN Profile Policy	1003
	Create a Policy Tag	1005
	Attach the Policy Profile to an AP	1005
	Verify Application Performance Monitoring	1006

CHAPTER 91	Wireless Clients Threshold Warning	1007
	Information About Wireless Clients Threshold Warning	1007
	Configuring a Warning Period	1007
	Configuring Client Threshold	1008

CHAPTER 92	Intelligent Capture Hardening	1009
	Feature History for Cisco Intelligent Capture Hardening	1009
	Information About Cisco Intelligent Capture Hardening	1009
	Anomaly Detection	1010
	RF Statistics	1010
	Configuring Anomaly Detection in AP Profile (CLI)	1010
	Configuring Anomaly Detection in an Access Point (CLI)	1011
	Verifying Anomaly Detection and RF Statistics	1012

CHAPTER 93	Amazon S3 Support	1015
	Information About Amazon S3 Support	1015
	Configuring Amazon S3 Support	1015
	Verifying Amazon S3 Support	1017

CHAPTER 94	Amazon Web Services CloudWatch	1019
	Information About Amazon Web Services CloudWatch Support	1019

Configuring Amazon Web Services CloudWatch Profile 1020
 Verifying AWS CloudWatch Configuration 1021

CHAPTER 95

Kernel Minidump and Trustzone Upgrade 1023

Information About Kernel Minidump and Trustzone Upgrade 1023
 Configuring Minidump from Access Point (CLI) 1024
 Configuring Minidump from Controller (CLI) 1024
 Verifying Minidump Configuration 1025

PART VII

Security 1027

CHAPTER 96

MAC Filtering 1029

MAC Filtering 1029
 MAC Filtering Configuration Guidelines 1029
 Configuring MAC Filtering for Local Authentication (CLI) 1031
 Configuring MAC Filtering (GUI) 1032
 Configuring MAB for External Authentication (CLI) 1032

CHAPTER 97

Web-Based Authentication 1035

Local Web Authentication Overview 1035
 Device Roles 1037
 Authentication Process 1038
 Local Web Authentication Banner 1039
 Customized Local Web Authentication 1041
 Guidelines 1042
 Redirection URL for Successful Login Guidelines 1043
 How to Configure Local Web Authentication 1043
 Configuring Default Local Web Authentication 1043
 Information About the AAA Wizard 1044
 Configuring AAA Authentication (GUI) 1048
 Configuring AAA Authentication (CLI) 1048
 Configuring the HTTP/HTTPS Server (GUI) 1050
 Configuring the HTTP Server (CLI) 1050
 Allowing Special Characters for Serial Port 1051

Allowing Special Characters for VTY Port	1052
Configuring HTTP and HTTPS Requests for Web Authentication	1053
Information About Configuring HTTP and HTTPS Requests for Web Authentication	1053
Guidelines and Limitations	1055
Configuring HTTP and HTTPS Requests for Web Authentication (CLI)	1055
Creating a Parameter Map (GUI)	1056
Creating Parameter Maps	1056
Configuring Local Web Authentication (GUI)	1056
Configuring the Internal Local Web Authentication (CLI)	1057
Configuring the Customized Local Web Authentication (CLI)	1058
Configuring the External Local Web Authentication (CLI)	1059
Configuring the Web Authentication WLANs	1061
Configuring Pre-Auth Web Authentication ACL (GUI)	1062
Configuring Pre-Auth Web Authentication ACL (CLI)	1062
Configuring the Maximum Web Authentication Request Retries	1064
Configuring a Local Banner in Web Authentication Page (GUI)	1064
Configuring a Local Banner in Web Authentication Page (CLI)	1065
Configuring Type WebAuth, Consent, or Both	1065
Configuring Preauthentication ACL	1066
Configuring TrustPoint for Local Web Authentication	1067
Configuration Examples for Local Web Authentication	1067
Example: Obtaining Web Authentication Certificate	1067
Example: Displaying a Web Authentication Certificate	1069
Example: Choosing the Default Web Authentication Login Page	1069
Example: Choosing a Customized Web Authentication Login Page from an IPv4 External Web Server	1070
Example: Choosing a Customized Web Authentication Login Page from an IPv6 External Web Server	1070
Example: Assigning Login, Login Failure, and Logout Pages per WLAN	1071
Example: Configuring Preauthentication ACL	1071
Example: Configuring Webpassthrough	1071
Verifying Web Authentication Type	1072
External Web Authentication (EWA)	1073
Configuring EWA with Single WebAuth Server Address and Default Ports (80/443) (CLI)	1073

Configuring EWA with Multiple Web Servers and/or Ports Different than Default (80/443)	1075
Configuring Wired Guest EWA with Multiple Web Servers and/or Ports Different than Default (80/443)	1077
Authentication for Sleeping Clients	1078
Information About Authenticating Sleeping Clients	1078
Restrictions on Authenticating Sleeping Clients	1078
Configuring Authentication for Sleeping Clients (GUI)	1079
Configuring Authentication for Sleeping Clients (CLI)	1079
Sleeping Clients with Multiple Authentications	1080
Mobility Support for Sleeping Clients	1080
Supported Combinations of Multiple Authentications	1080
Configuring Sleeping Clients with Multiple Authentications	1081
Configuring WLAN for Dot1x and Local Web Authentication	1081
Configuring a WLAN for MAC Authentication Bypass and Local Web Authentication	1082
Configuring a WLAN for Local Web Authentication and MAC Filtering	1083
Configuring a PSK + LWA in a WLAN	1084
Configuring a Sleeping Client	1085
Verifying a Sleeping Client Configuration	1086
Multi Authentication Combination with 802.1X Authentication and Local Web Authentication	1086
Feature History for Multiauthentication Combination of 802.1X and Local Web Authentication	1086
Information About Multiauthentication Combination with 802.1X Authentication and Local Web Authentication	1086
Limitations for Multi Authentication Combination of 802.1X and Local Web Authentication	1087
Enabling the Multiauthentication Combination of 802.1X Authentication and Local Web Authentication (CLI)	1087
Verifying Multiauthentication Combination with 802.1X Authentication and Local Web Authentication	1088
CHAPTER 98	Central Web Authentication 1089
Information About Central Web Authentication	1089
Prerequisites for Central Web Authentication	1090
How to Configure ISE	1090
Creating an Authorization Profile	1090
Creating an Authentication Rule	1091
Creating an Authorization Rule	1091

How to Configure Central Web Authentication on the Controller	1092
Configuring WLAN (GUI)	1092
Configuring WLAN (CLI)	1093
Configuring Policy Profile (CLI)	1095
Configuring a Policy Profile (GUI)	1096
Creating Redirect ACL	1097
Configuring AAA for Central Web Authentication	1098
Configuring Redirect ACL in Flex Profile (GUI)	1098
Configuring Redirect ACL in Flex Profile (CLI)	1099
Troubleshooting Central Web Authentication	1100
Authentication for Sleeping Clients	1100
Information About Authenticating Sleeping Clients	1100
Restrictions on Authenticating Sleeping Clients	1101
Configuring Authentication for Sleeping Clients (GUI)	1101
Configuring Authentication for Sleeping Clients (CLI)	1102
Sleeping Clients with Multiple Authentications	1102
Mobility Support for Sleeping Clients	1102
Supported Combinations of Multiple Authentications	1102
Configuring Sleeping Clients with Multiple Authentications	1103
Configuring WLAN for Dot1x and Local Web Authentication	1103
Configuring a WLAN for MAC Authentication Bypass and Local Web Authentication	1104
Configuring a WLAN for Local Web Authentication and MAC Filtering	1105
Configuring a PSK + LWA in a WLAN	1106
Configuring a Sleeping Client	1107
Verifying a Sleeping Client Configuration	1108

CHAPTER 99
Private Shared Key 1109

Information About Private Preshared Key	1109
Configuring a PSK in a WLAN (CLI)	1110
Configuring a PSK in a WLAN (GUI)	1111
Applying a Policy Profile to a WLAN (GUI)	1112
Applying a Policy Profile to a WLAN (CLI)	1112
Verifying a Private PSK	1113

CHAPTER 100**Multi-Preshared Key 1117**

- Information About Multi-Preshared Key 1117
- Restrictions on Multi-PSK 1118
- Configuring Multi-Preshared Key (GUI) 1118
- Configuring Multi-Preshared Key (CLI) 1121
- Verifying Multi-PSK Configurations 1122

CHAPTER 101**Multiple Authentications for a Client 1125**

- Information About Multiple Authentications for a Client 1125
 - Information About Supported Combination of Authentications for a Client 1125
 - Jumbo Frame Support for RADIUS Packets 1126
 - Combination of Authentications on MAC Failure Not Supported on a Client 1127
- Configuring Multiple Authentications for a Client 1127
 - Configuring WLAN for 802.1X and Local Web Authentication (GUI) 1127
 - Configuring WLAN for 802.1X and Local Web Authentication (CLI) 1127
 - Configuring WLAN for Preshared Key (PSK) and Local Web Authentication (GUI) 1129
 - Configuring WLAN for Preshared Key (PSK) and Local Web Authentication 1129
 - Configuring WLAN for PSK or Identity Preshared Key (iPSK) and Central Web Authentication (GUI) 1131
 - Configuring WLAN for PSK or Identity Preshared Key (iPSK) and Central Web Authentication 1131
 - Configuring WLAN 1131
 - Applying Policy Profile to a WLAN 1132
- Configure WLAN for Web Authentication on MAC Authentication Bypass Failure with Pre-Shared Key (CLI) 1133
- Configure WLAN for Web Authentication on MAC Authentication Bypass Failure with OWE (CLI) 1135
- Configure WLAN for Web Authentication on MAC Authentication Bypass Failure with Secure Agile Exchange (CLI) 1137
- Configuring 802.1x and Central Web Authentication on Controller (CLIs) 1138
 - Creating AAA Authentication 1138
 - Configuring AAA Server for External Authentication 1139
 - Configuring AAA for Authentication 1140
 - Configuring Accounting Identity List 1141
 - Configuring AAA for Central Web Authentication 1141

Defining an Access Control List for Radius Server	1142
Configuration Example to Define an Access Control List for Radius Server	1142
Configuring WLAN	1143
Configuring Policy Profile	1143
Mapping WLAN and Policy Profile to Policy Tag	1144
Configuring ISE for Central Web Authentication with Dot1x (GUI)	1145
Defining Guest Portal	1145
Defining Authorization Profile for a Client	1145
Defining Authentication Rule	1145
Defining Authorization Rule	1146
Creating Rules to Match Guest Flow Condition	1146
Verifying Multiple Authentication Configurations	1147

CHAPTER 102**Wi-Fi Protected Access 3 1151**

Simultaneous Authentication of Equals	1151
Opportunistic Wireless Encryption	1152
Hash-to-Element (H2E)	1152
YANG (RPC model)	1153
Transition Disable	1155
WPA3 SAE iPSK	1155
Configuring SAE (WPA3+WPA2 Mixed Mode)	1155
Configuring WPA3 Enterprise (GUI)	1157
Configuring WPA3 Enterprise	1157
Configuring the WPA3 OWE	1159
Configuring WPA3 OWE Transition Mode (GUI)	1160
Configuring WPA3 OWE Transition Mode	1160
Configuring WPA3 SAE (GUI)	1162
Configuring WPA3 SAE	1162
Configuring WPA3 SAE iPSK (CLI)	1164
Configuring a WPA3 SAE iPSK WLAN Profile (CLI)	1164
Configuring a Policy Profile (CLI)	1166
Configuring a Passphrase in a Client Authorization Policy in the RADIUS Server(GUI)	1166
Configuring WPA3 SAE H2E (GUI)	1167
Configuring WPA3 SAE H2E	1167

Configuring WPA3 WLAN for Transition Disable 1169
 Configuring Anti-Clogging and SAE Retransmission (GUI) 1170
 Configuring Anti-Clogging and SAE Retransmission 1170
 Verifying WPA3 SAE and OWE 1171
 Verifying WPA3 SAE H2E Support in WLAN 1175
 Verifying WPA3 Transition Disable in WLAN 1180

CHAPTER 103 IP Source Guard 1185

Information About IP Source Guard 1185
 Configuring IP Source Guard (GUI) 1185
 Configuring IP Source Guard 1186

CHAPTER 104 802.11w 1187

Information About 802.11w 1187
 Prerequisites for 802.11w 1190
 Restrictions for 802.11w 1190
 How to Configure 802.11w 1191
 Configuring 802.11w (GUI) 1191
 Configuring 802.11w (CLI) 1191
 Disabling 802.11w 1192
 Monitoring 802.11w 1193

CHAPTER 105 Management Frame Protection 1195

Information About Management Frame Protection 1195
 Restrictions for Management Frame Protection 1196
 Configuring Management Frame Protection (CLI) 1197
 Verifying Management Frame Protection Settings 1197

CHAPTER 106 IPv4 ACLs 1199

Information about Network Security with ACLs 1199
 ACL Overview 1199
 Access Control Entries 1199
 ACL Supported Types 1200
 Supported ACLs 1200

ACL Precedence	1200
Port ACLs	1200
Router ACLs	1201
ACEs and Fragmented and Unfragmented Traffic	1202
ACEs and Fragmented and Unfragmented Traffic Examples	1202
Standard and Extended IPv4 ACLs	1203
IPv4 ACL Switch Unsupported Features	1203
Access List Numbers	1203
Numbered Standard IPv4 ACLs	1204
Numbered Extended IPv4 ACLs	1205
Named IPv4 ACLs	1205
ACL Logging	1206
Hardware and Software Treatment of IP ACLs	1206
IPv4 ACL Interface Considerations	1207
Restrictions for Configuring IPv4 Access Control Lists	1207
How to Configure ACLs	1208
Configuring IPv4 ACLs (GUI)	1208
Configuring IPv4 ACLs	1208
Creating a Numbered Standard ACL (GUI)	1209
Creating a Numbered Standard ACL (CLI)	1209
Creating a Numbered Extended ACL (GUI)	1211
Creating a Numbered Extended ACL (CLI)	1211
Creating Named Standard ACLs (GUI)	1215
Creating Named Standard ACLs	1215
Creating Extended Named ACLs (GUI)	1217
Creating Extended Named ACLs	1217
Applying an IPv4 ACL to an Interface (GUI)	1219
Applying an IPv4 ACL to an Interface (CLI)	1219
Applying ACL to Policy Profile (GUI)	1220
Applying ACL to Policy Profile	1220
Configuration Examples for ACLs	1221
Examples: Including Comments in ACLs	1221
Examples: Applying an IPv4 ACL to a Policy Profile in a Wireless Environment	1221
IPv4 ACL Configuration Examples	1222

ACLs in a Small Networked Office	1222
Examples: ACLs in a Small Networked Office	1223
Example: Numbered ACLs	1223
Examples: Extended ACLs	1224
Examples: Named ACLs	1224
Monitoring IPv4 ACLs	1225

CHAPTER 107**Downloadable ACL 1227**

Feature History for Downloadable ACL	1227
Information About Downloadable ACL	1228
Scale Considerations for Downloadable ACL	1228
Guidelines and Restrictions for Downloadable ACL	1228
Configuring dACL Name and Definition in Cisco ISE	1229
Configuring dACL in a Controller (CLI)	1229
Configuring Explicit Authorization Server List (CLI)	1230
Verifying dACL Configuration	1231

CHAPTER 108**DNS-Based Access Control Lists 1233**

Information About DNS-Based Access Control Lists	1233
Defining ACLs	1234
Applying ACLs	1235
Types of URL Filters	1235
Restrictions on DNS-Based Access Control Lists	1236
Flex Mode	1237
Defining URL Filter List	1237
Applying URL Filter List to Flex Profile	1238
Configuring ISE for Central Web Authentication (GUI)	1238
Local Mode	1239
Defining URL Filter List	1239
Applying URL Filter List to Policy Profile (GUI)	1240
Applying URL Filter List to Policy Profile	1241
Configuring ISE for Central Web Authentication	1241
Creating Authorization Profiles	1241
Mapping Authorization Profiles to Authentication Rule	1242

Mapping Authorization Profiles to Authorization Rule	1242
Viewing DNS-Based Access Control Lists	1243
Configuration Examples for DNS-Based Access Control Lists	1243
Verifying DNS Snoop Agent (DSA)	1244
Information About Flex Client IPv6 Support with WebAuth Pre and Post ACL	1245
Enabling Pre-Authentication ACL for LWA and EWA (GUI)	1246
Enabling Pre-Authentication ACL for LWA and EWA	1247
Enabling Post-Authentication ACL for LWA and EWA (GUI)	1248
Enabling Post-Authentication ACL for LWA and EWA	1249
Enabling DNS ACL for LWA and EWA (GUI)	1249
Enabling DNS ACL for LWA and EWA	1249
Verifying Flex Client IPv6 Support with WebAuth Pre and Post ACL	1250

CHAPTER 109	Allowed List of Specific URLs	1251
	Allowed List of Specific URLs	1251
	Adding URL to Allowed List	1251
	Verifying URLs on the Allowed List	1253

CHAPTER 110	Cisco Umbrella WLAN	1255
	Information About Cisco Umbrella WLAN	1255
	Registering Controller to Cisco Umbrella Account	1256
	Configuring Cisco Umbrella WLAN	1257
	Importing CA Certificate to the Trust Pool	1257
	Creating a Local Domain RegEx Parameter Map	1259
	Configuring Parameter Map Name in WLAN (GUI)	1259
	Configuring the Umbrella Parameter Map	1260
	Enabling or Disabling DNSCrypt (GUI)	1260
	Enabling or Disabling DNSCrypt	1261
	Configuring Timeout for UDP Sessions	1261
	Configuring Parameter Map Name in WLAN (GUI)	1262
	Configuring Parameter Map Name in WLAN	1262
	Configuring the Umbrella Flex Profile	1263
	Configuring the Umbrella Flex Profile (GUI)	1263
	Configuring Umbrella Flex Parameters	1264

- Configuring the Umbrella Flex Policy Profile (GUI) 1264
- Verifying the Cisco Umbrella Configuration 1265

CHAPTER 111**RADIUS Server Load Balancing 1267**

- Information About RADIUS Server Load Balancing 1267
- Prerequisites for RADIUS Server Load Balancing 1269
- Restrictions for RADIUS Server Load Balancing 1269
- Enabling Load Balancing for a Named RADIUS Server Group (CLI) 1269

CHAPTER 112**AAA Dead-Server Detection 1271**

- Information About AAA Dead-Server Detection 1271
- Prerequisites for AAA Dead-Server Detection 1272
- Restrictions for AAA Dead-Server Detection 1272
- Configuring AAA Dead-Server Detection (CLI) 1272
- Verifying AAA Dead-Server Detection 1273

CHAPTER 113**ISE Simplification and Enhancements 1275**

- Utilities for Configuring Security 1275
 - Configuring Multiple Radius Servers 1276
 - Verifying AAA and Radius Server Configurations 1277
- Configuring Captive Portal Bypassing for Local and Central Web Authentication 1277
 - Information About Captive Bypassing 1277
 - Configuring Captive Bypassing for WLAN in LWA and CWA (GUI) 1278
 - Configuring Captive Bypassing for WLAN in LWA and CWA (CLI) 1279
- Sending DHCP Options 55 and 77 to ISE 1280
 - Information about DHCP Option 55 and 77 1280
 - Configuration to Send DHCP Options 55 and 77 to ISE (GUI) 1280
 - Configuration to Send DHCP Options 55 and 77 to ISE (CLI) 1280
 - Configuring EAP Request Timeout (GUI) 1281
 - Configuring EAP Request Timeout 1282
 - Configuring EAP Request Timeout in Wireless Security (CLI) 1282
- Captive Portal 1283
 - Captive Portal Configuration 1283
 - Configuring Captive Portal (GUI) 1283

Configuring Captive Portal	1284
Captive Portal Configuration - Example	1286

CHAPTER 114**RADIUS DTLS 1289**

Information About RADIUS DTLS	1289
Prerequisites	1291
Configuring RADIUS DTLS Server	1291
Configuring RADIUS DTLS Connection Timeout	1292
Configuring RADIUS DTLS Idle Timeout	1292
Configuring Source Interface for RADIUS DTLS Server	1293
Configuring RADIUS DTLS Port Number	1294
Configuring RADIUS DTLS Connection Retries	1294
Configuring RADIUS DTLS Trustpoint	1295
Configuring DTLS Dynamic Author	1296
Enabling DTLS for Client	1296
Configuring Client Trustpoint for DTLS	1297
Configuring DTLS Idle Timeout	1298
Configuring Server Trustpoint for DTLS	1298
Verifying the RADIUS DTLS Server Configuration	1299
Clearing RADIUS DTLS Specific Statistics	1299

CHAPTER 115**Policy Enforcement and Usage Monitoring 1301**

Policy Enforcement and Usage Monitoring	1301
Configuring Policy Enforcement and Enabling Change-of-Authorization (CLI)	1301
Example: Configuring Policy Enforcement and Usage Monitoring	1302
Verifying Policy Usage and Enforcement	1303

CHAPTER 116**Local Extensible Authentication Protocol 1305**

Information About Local EAP	1305
Restrictions for Local EAP	1306
Configuring Local EAP Profile (CLI)	1306
Configuring Local EAP profile (GUI)	1307
Configuring AAA Authentication (GUI)	1307
Configuring AAA Authorization Method (GUI)	1307

Configuring AAA Authorization Method (CLI)	1308
Configuring Local Advanced Methods (GUI)	1309
Configuring WLAN (GUI)	1309
Configuring WLAN (CLI)	1310
Creating a User Account (CLI)	1310
Attaching a Policy Profile to a WLAN Interface (GUI)	1311
Deploy Policy Tag to Access Points (GUI)	1312

CHAPTER 117 Local EAP Ciphersuite 1313

Information About Local EAP Ciphersuite	1313
Restrictions for Local EAP Ciphersuite	1314
Configuring Local EAP Ciphersuite (CLI)	1315

CHAPTER 118 Authentication and Authorization Between Multiple RADIUS Servers 1317

Information About Authentication and Authorization Between Multiple RADIUS Servers	1317
Configuring 802.1X Security for WLAN with Split Authentication and Authorization Servers	1318
Configuring Explicit Authentication and Authorization Server List (GUI)	1318
Configuring Explicit Authentication Server List (GUI)	1319
Configuring Explicit Authentication Server List (CLI)	1319
Configuring Explicit Authorization Server List (GUI)	1320
Configuring Explicit Authorization Server List (CLI)	1321
Configuring Authentication and Authorization List for 802.1X Security (GUI)	1322
Configuring Authentication and Authorization List for 802.1X Security	1322
Configuring Web Authentication for WLAN with Split Authentication and Authorization Servers	1323
Configuring Authentication and Authorization List for Web Authentication (GUI)	1323
Configuring Authentication and Authorization List for Web Authentication	1324
Verifying Split Authentication and Authorization Configuration	1325
Configuration Examples	1326

CHAPTER 119 CUI Information in RADIUS Accounting 1327

CUI Information in RADIUS Accounting Request	1327
Adding CUI Information in a RADIUS Accounting Request	1328
Verifying CUI Information in a RADIUS Accounting Request	1328

CHAPTER 120	Secure LDAP	1329
	Information About SLDAP	1329
	Prerequisite for Configuring SLDAP	1331
	Restrictions for Configuring SLDAP	1331
	Configuring SLDAP	1331
	Configuring an AAA Server Group (GUI)	1332
	Configuring a AAA Server Group	1333
	Configuring Search and Bind Operations for an Authentication Request	1334
	Configuring a Dynamic Attribute Map on an SLDAP Server	1335
	Verifying the SLDAP Configuration	1335

CHAPTER 121	Network Access Server Identifier	1337
	Information About Network Access Server Identifier	1337
	Creating a NAS ID Policy(GUI)	1338
	Creating a NAS ID Policy	1338
	Attaching a Policy to a Tag (GUI)	1339
	Attaching a Policy to a Tag (CLI)	1339
	Verifying the NAS ID Configuration	1340

CHAPTER 122	Locally Significant Certificates	1343
	Information About Locally Significant Certificates	1343
	Certificate Provisioning in Controllers	1344
	Device Certificate Enrollment Operation	1344
	Certificate Provisioning on Lightweight Access Point	1344
	Restrictions for Locally Significant Certificates	1345
	Provisioning Locally Significant Certificates	1346
	Configuring RSA Key for PKI Trustpoint	1346
	Configuring PKI Trustpoint Parameters	1346
	Authenticating and Enrolling a PKI Trustpoint (GUI)	1347
	Authenticating and Enrolling the PKI Trustpoint with CA Server (CLI)	1348
	Configuring AP Join Attempts with LSC Certificate (GUI)	1349
	Configuring AP Join Attempts with LSC Certificate (CLI)	1350
	Configuring Subject-Name Parameters in LSC Certificate	1350

Configuring Key Size for LSC Certificate	1351
Configuring Trustpoint for LSC Provisioning on an Access Point	1351
Configuring an AP LSC Provision List (GUI)	1351
Configuring an AP LSC Provision List (CLI)	1352
Configuring LSC Provisioning for all the APs (GUI)	1353
Configuring LSC Provisioning for All APs (CLI)	1354
Configuring LSC Provisioning for the APs in the Provision List	1354
Importing a CA Certificate to the Trustpool (GUI)	1354
Importing a CA Certificate to the Trustpool (CLI)	1355
Cleaning the CA Certificates Imported in Trustpool (GUI)	1356
Cleaning CA Certificates Imported in Trustpool (CLI)	1356
Creating a New Trustpoint Dedicated to a Single CA Certificate	1356
Verifying LSC Configuration	1357
Configuring Management Trustpoint to LSC (GUI)	1358
Configuring Management Trustpoint to LSC (CLI)	1358
Information About MIC and LSC Access Points Joining the Controller	1359
Overview of Support for MIC and LSC Access Points Joining the Controller	1359
Recommendations and Limitations	1359
Configuration Workflow	1359
Configuring LSC on the Controller (CLI)	1359
Enabling the AP Certificate Policy on the APs (CLI)	1360
Configuring the AP Policy Certificate (GUI)	1361
Configuring the Allowed List of APs to Join the Controller (CLI)	1362
Verifying the Configuration Status	1362
LSC Fallback Access Points	1363
Information About LSC Fallback APs	1363
Troubleshooting LSC Fallback State	1363
Recovery Steps	1364
Configuring Controller Self-Signed Certificate for Wireless AP Join	1364
Use Cases	1364
Prerequisites	1365
Configuring Clock Calendar (CLI)	1365
Enabling HTTP Server (CLI)	1366
Configuring CA Server (CLI)	1366

Configuring Trustpoint (CLI)	1368
Authenticating and Enrolling the PKI TrustPoint with CA Server (CLI)	1369
Tagging Wireless Management TrustPoint Name (CLI)	1370
Verifying Controller Certificates for Wireless AP Join	1370

CHAPTER 123**Certificate Management 1373**

About Public Key Infrastructure Management (GUI)	1373
Authenticating and Enrolling a PKI Trustpoint (GUI)	1373
Generating an AP Self-Signed Certificate (GUI)	1374
Adding the Certificate Authority Server (GUI)	1374
Adding an RSA or EC Key for PKI Trustpoint (GUI)	1375
Adding and Managing Certificates	1375
	1376

CHAPTER 124**Controller Self-Signed Certificate for Wireless AP Join 1377**

Use Cases	1377
Prerequisites	1378
Configuring Clock Calendar (CLI)	1378
Enabling HTTP Server (CLI)	1379
Configuring CA Server (CLI)	1379
Configuring Trustpoint (CLI)	1381
Authenticating and Enrolling the PKI TrustPoint with CA Server (CLI)	1382
Tagging Wireless Management TrustPoint Name (CLI)	1383
Verifying Controller Certificates for Wireless AP Join	1383

CHAPTER 125**Managing Rogue Devices 1385**

Rogue Detection	1385
Rogue Devices	1385
Information About Rogue Containment (Protected Management Frames (PMF) Enabled)	1387
AP Impersonation Detection	1388
Configuring Rogue Detection (GUI)	1388
Configuring Rogue Detection (CLI)	1389
Configuring RSSI Deviation Notification Threshold for Rogue APs (CLI)	1390
Configuring Management Frame Protection (GUI)	1390

Configuring Management Frame Protection (CLI)	1391
Enabling Access Point Authentication	1391
Verifying Management Frame Protection	1392
Verifying Rogue Events	1392
Verifying Rogue Detection	1393
Examples: Rogue Detection Configuration	1394
Configuring Rogue Policies (GUI)	1395
Configuring Rogue Policies (CLI)	1395
Rogue Detection Security Level	1397
Setting Rogue Detection Security-level	1398
Wireless Service Assurance Rogue Events	1399
Monitoring Wireless Service Assurance Rogue Events	1400
Rogue Full Scale Quotas and Priorities	1400
Feature History for Rogue Full Scale Quotas and Priorities	1400
Rogue AP Scale Modes Per Class	1401
Configuring Rogue AP Scale (CLI)	1402
Verifying Rogue Scale Details	1403

CHAPTER 126
Classifying Rogue Access Points 1405

Information About Classifying Rogue Access Points	1405
Guidelines and Restrictions for Classifying Rogue Access Points	1407
How to Classify Rogue Access Points	1407
Classifying Rogue Access Points and Clients Manually (GUI)	1407
Classifying Rogue Access Points and Clients Manually (CLI)	1408
Configuring Rogue Classification Rules (GUI)	1409
Configuring Rogue Classification Rules (CLI)	1410
Monitoring Rogue Classification Rules	1413
Examples: Classifying Rogue Access Points	1413

CHAPTER 127
Advanced WIPS 1415

Feature History for Advanced WIPS	1415
Information About Advanced WIPS	1416
Guidelines and Restrictions	1418
Enabling Advanced WIPS	1419

Syslog Support for Advanced WIPS	1419
Advanced WIPS Solution Components	1420
Supported Modes and Platforms	1420
Enabling Advanced WIPS(GUI)	1421
Enabling Advanced WIPS (CLI)	1421
Configuring Syslog Threshold for Advanced WIPS (CLI)	1422
Viewing Advanced WIPS Alarms (GUI)	1422
Verifying Advanced WIPS	1423
Verifying Syslog Configuration for Advanced WIPS	1424

CHAPTER 128**Cisco TrustSec 1425**

Information about Cisco TrustSec	1425
Cisco TrustSec Features	1426
Security Group Access Control List	1427
Inline Tagging	1429
Policy Enforcement	1429
SGACL Support for Wireless Guest Access	1430
Enabling SGACL on the AP (GUI)	1430
Enabling SGACL on the AP	1431
Enabling SGACL Policy Enforcement Globally (CLI)	1432
Enabling SGACL Policy Enforcement Per Interface (CLI)	1433
Manually Configure a Device SGT (CLI)	1433
Configuring SGACL, Inline Tagging, and SGT in Local Mode (GUI)	1434
Configuring SGACL, Inline Tagging, and SGT in Local Mode	1434
Configuring ISE for TrustSec	1435
Verifying Cisco TrustSec Configuration	1437

CHAPTER 129**SGT Inline Tagging and SXPv4 1439**

Introduction to SGT Inline Tagging on AP and SXPv4	1439
Creating an SXP Profile	1439
Configuring SGT Inline Tagging on Access Points	1440
Configuring an SXP Connection (GUI)	1440
Configuring an SXP Connection	1441
Verifying SGT Push to Access Points	1442

CHAPTER 130	Multiple Cipher Support	1445
	Default Ciphersuites Supported for CAPWAP-DTLS	1445
	Configuring Multiple Ciphersuites	1446
	Setting Server Preference	1447
	Verifying Operational Ciphersuites and Priority	1447

CHAPTER 131	Configuring Secure Shell	1449
	Information About Configuring Secure Shell	1449
	SSH and Device Access	1449
	SSH Servers, Integrated Clients, and Supported Versions	1449
	SSH Configuration Guidelines	1450
	Secure Copy Protocol Overview	1450
	Secure Copy Protocol	1451
	SFTP Support	1451
	Prerequisites for Configuring Secure Shell	1451
	Restrictions for Configuring Secure Shell	1452
	How to Configure SSH	1453
	Setting Up the Device to Run SSH	1453
	Configuring the SSH Server	1454
	Monitoring the SSH Configuration and Status	1455

CHAPTER 132	Encrypted Traffic Analytics	1457
	Information About Encrypted Traffic Analytics	1457
	Exporting Records to IPv4 Flow Export Destination	1458
	Exporting Records to IPv6 Flow Export Destination	1459
	Exporting Records to IPv4 and IPv6 Destination over IPFIX	1459
	Allowed List of Traffic	1460
	Configuring Source Interface for Record Export	1461
	Configuring Source Interface for Record Export Without IPFIX	1462
	Configuring ETA Flow Export Destination (GUI)	1463
	Enabling In-Active Timer	1463
	Enabling ETA on WLAN Policy Profile	1464
	Attaching Policy Profile to VLAN (GUI)	1465

Attaching Policy Profile to VLAN 1465

Verifying ETA Configuration 1466

CHAPTER 133 FIPS 1471

FIPS 1471

Guidelines and Restrictions for FIPS 1472

FIPS Self-Tests 1472

Configuring FIPS 1473

Configuring FIPS in HA Setup 1474

Verifying FIPS Configuration 1475

CHAPTER 134 Internet Protocol Security 1477

Information about Internet Protocol Security 1477

Internet Key Exchange Version 1 Transform Sets 1478

Configure IPsec Using Internet Key Exchange Version 1 1479

Internet Key Exchange Version 2 Transform Sets 1481

Configure IPsec Using Internet Key Exchange Version 2 1482

IPsec Transforms and Lifetimes 1484

Use of X.509 With Internet Key Exchange Version 1485

 For IKEv2 Commands 1486

IPsec Session Interruption and Recovery 1486

Example: Configure IPsec Using ISAKMP 1487

Verifying IPsec Traffic 1487

Example: Configure IPsec Using Internet Key Exchange Version 2 1488

Verifying IPsec With Internet Key Exchange Version 2 Traffic 1489

CHAPTER 135 Transport Layer Security Tunnel Support 1493

Information About Transport Layer Security Tunnel Support 1493

Configuring a Transport Layer Security Tunnel 1494

Verifying a Transport Layer Security Tunnel 1495

CHAPTER 136 Configuring RFC 5580 Location Attributes 1499

Feature History for RFC 5580 Location Attributes 1499

Information About RFC 5580 Location Attributes 1500

- Information About Location-Capable Attribute 1502
- Restriction for Configuring RFC 5580 Location Attributes 1502
- Configuring Location Delivery Based on Out-of-Band Agreement (CLI) 1502
- Configuring Location-Capable Attribute (CLI) 1503
- Creating Location Attributes 1503
 - Configuring a Civic Profile (CLI) 1503
 - Configuring a Geo Profile (CLI) 1505
 - Configuring an Operator Name (CLI) 1506
- Associating Location Attributes with User Location (CLI) 1507
- Associating Location Attributes with the NAS Location (CLI) 1508
- Verifying RFC 5580 Location Attribute Configuration 1509

CHAPTER 137 IP MAC Binding 1511

- Information About IP MAC Binding 1511
- Use Cases for No IP MAC Binding 1511
- Disabling IP MAC Binding (CLI) 1512
- Verifying IP MAC Binding 1512

CHAPTER 138 Disabling IP Learning in FlexConnect Mode 1513

- Information About Disabling IP Learning in FlexConnect Mode 1513
- Restrictions for Disabling IP Learning in FlexConnect Mode 1513
- Disabling IP Learning in FlexConnect Mode (CLI) 1514
- Verifying MAC Entries from Database 1514

CHAPTER 139 Disabling Device Tracking to Support NAC Devices 1515

- Feature History for Disabling Device Tracking to Support NAC Devices 1515
- Information About Disabling Device Tracking to Support NAC Devices 1515
- Restrictions for Disabling Device Tracking to Support NAC Devices 1516
- Disabling Device Tracking for Wireless Clients (CLI) 1516
- Verifying ARP Broadcast 1517

CHAPTER 140 Disabling IP Learning in Local Mode 1519

- Information About Disabling IP Learning in Local Mode 1519
- Restrictions for Disabling IP Learning in Local Mode 1519

Disabling IP Learning in Local Mode (CLI)	1520
Verifying MAC Entries from Database	1521
Verifying ARP Broadcast	1521

PART VIII **Mobility** **1523**

CHAPTER 141 **Mobility** **1525**

Introduction to Mobility	1525
SDA Roaming	1528
Definitions of Mobility-related Terms	1529
Mobility Groups	1529
Guidelines and Restrictions	1530
Configuring Mobility (GUI)	1532
Configuring Mobility (CLI)	1533
Configuring Inter-Release Controller Mobility (GUI)	1535
Configuring Inter-Release Controller Mobility	1535
Verifying Mobility	1539

CHAPTER 142 **NAT Support on Mobility Groups** **1545**

Information About NAT Support on Mobility Groups	1545
Restrictions for NAT Support on Mobility Groups	1546
Functionalities Supported on Mobility NAT	1546
Configuring a Mobility Peer	1547
Verifying NAT Support on Mobility Groups	1547

CHAPTER 143 **Static IP Client Mobility** **1549**

Information About Static IP Client Mobility	1549
Restrictions	1549
Configuring Static IP Client Mobility (GUI)	1550
Configuring Static IP Client Mobility (CLI)	1550
Verifying Static IP Client Mobility	1551

CHAPTER 144 **Mobility Domain ID - Dot11i Roaming** **1553**

Information about Mobility Domain ID - 802.11i Roaming	1553
--	------

Verifying Mobility Domain ID - 802.11i Roaming 1554

CHAPTER 145

802.11r Support for Flex Local Authentication 1555

Information About 802.11r Support for FlexConnect Local Authentication 1555

Support Guidelines 1555

Verifying 802.11r Support for Flex Local Authentication 1556

CHAPTER 146

Opportunistic Key Caching 1557

Information about Opportunistic Key Caching 1557

Enabling Opportunistic Key Caching 1558

Enabling Opportunistic Key Caching (GUI) 1558

Verifying Opportunistic Key Caching 1558

PART IX

High Availability 1561

CHAPTER 147

High Availability 1563

Feature History for High Availability 1564

Information About High Availability 1565

Prerequisites for High Availability 1566

Restrictions on High Availability 1567

Configuring High Availability (CLI) 1568

Disabling High Availability 1569

Copying a WebAuth Tar Bundle to the Standby Controller 1570

System and Network Fault Handling 1572

Handling Recovery Mechanism 1577

Verifying High Availability Configurations 1578

Verifying AP or Client SSO Statistics 1578

Verifying High Availability 1580

High Availability Deployment for Application Centric Infrastructure (ACI) Network 1583

Information About Deploying ACI Network in Controller 1583

Prerequisite for Deploying the ACI Network in the Controller 1585

Disabling the Fast Switchover Notification Mechanism (CLI) 1585

Configuring Gratuitous ARP (GARP) Retransmit (CLI) 1586

Disabling Initial GARP (CLI) 1586

Information About Redundancy Management Interface	1587
Configuring Redundancy Management Interface (GUI)	1591
Configuring Redundancy Management Interface (CLI)	1592
Configuring Gateway Monitoring (CLI)	1594
Configuring Gateway Monitoring Interval (CLI)	1595
Gateway Reachability Detection	1595
Information About Gateway Reachability Detection	1595
Configuration Workflow	1596
Migrating to RMI IPv6	1596
Monitoring the Health of the Standby Controller	1596
Monitoring the Health of Standby Parameters Using SNMP	1598
Standby Monitoring Using Standby RMI IP	1598
Standby Monitoring Using the Active Controller	1598
Standby IOS Linux Syslogs	1599
Standby Interface Status Using Active SNMP	1599
Monitoring the Health of Standby Controller Using Programmatic Interfaces	1600
Monitoring the Health of Standby Controller Using CLI	1601
Verifying the Gateway-Monitoring Configuration	1604
Verifying the RMI IPv4 Configuration	1605
Verifying the RMI IPv6 Configuration	1606
Verifying Redundancy Port Interface Configuration	1606
Information About Auto-Upgrade	1609
Use Cases	1609
Configuration Workflow	1610
Configuring Auto-Upgrade (CLI)	1610
Use Case for Link Layer Discovery Protocol (LLDP)	1610
Enabling LLDP (CLI)	1611
Enabling LLDP Timers (CLI)	1611
Enabling LLDP TLV-Select (CLI)	1612
Verifying LLDP	1612
Feature History for Reload Reason History	1614
Information About Reload Reason History	1614
Verifying Reload Reason History	1614
Requesting Reload Reason History using YANG	1617

PART X**Quality of Service 1619****CHAPTER 148****Quality of Service 1621**

- Wireless QoS Overview 1621
- Wireless QoS Targets 1622
 - SSID Policies 1622
 - Client Policies 1622
 - Supported QoS Features on Wireless Targets 1622
- Wireless QoS Mobility 1623
- Precious Metal Policies for Wireless QoS 1623
- Prerequisites for Wireless QoS 1624
- Restrictions for QoS on Wireless Targets 1624
- Metal Policy Format 1625
 - Metal Policy Map 1625
 - Class Maps 1627
 - DSCP to UP Mapping for Downstream Traffic 1628
 - Auto QoS Policy Format 1629
 - Architecture for Voice, Video and Integrated Data (AVVID) 1631
- How to apply Bi-Directional Rate Limiting 1632
 - Information about Bi-Directional Rate Limiting 1632
 - Prerequisites for Bi-Directional Rate Limiting 1633
 - Configure Metal Policy on SSID 1634
 - Configure Metal Policy on Client 1634
 - Configure Bi-Directional Rate Limiting for All Traffic 1635
 - Configure Bi-Directional Rate Limiting Based on Traffic Classification 1635
 - Apply Bi-Directional Rate Limiting Policy Map to Policy Profile 1637
 - Apply Metal Policy with Bi-Directional Rate Limiting 1638
- How to apply Per Client Bi-Directional Rate Limiting 1639
 - Information About Per Client Bi-Directional Rate Limiting 1639
 - Prerequisites for Per Client Bi-Directional Rate Limiting 1640
 - Restrictions on Per Client Bi-Directional Rate Limiting 1640
 - Configuring Per Client Bi-Directional Rate Limiting (GUI) 1641
 - Verifying Per Client Bi-Directional Rate Limiting 1641

Configuring BDRL Using AAA Override	1641
Verifying Bi-Directional Rate-Limit	1642
How to Configure Wireless QoS	1644
Configuring a Policy Map with Class Map (GUI)	1644
Configuring a Class Map (CLI)	1645
Configuring Policy Profile to Apply QoS Policy (GUI)	1645
Configuring Policy Profile to Apply QoS Policy (CLI)	1646
Applying Policy Profile to Policy Tag (GUI)	1647
Applying Policy Profile to Policy Tag (CLI)	1647
Attaching Policy Tag to an AP	1648
Configuring Custom QoS Mapping	1648
Configuring DSCP-to-User Priority Mapping Exception	1649
Configuring Trust Upstream DSCP Value	1651

CHAPTER 149
Wireless Auto-QoS 1653

Information About Auto QoS	1653
How to Configure Wireless AutoQoS	1654
Configuring Wireless AutoQoS on Profile Policy	1654
Disabling Wireless AutoQoS	1655
Rollback AutoQoS Configuration (GUI)	1655
Rollback AutoQoS Configuration	1655
Clearing Wireless AutoQoS Policy Profile (GUI)	1656
Clearing Wireless AutoQoS Policy Profile	1656
Viewing AutoQoS on policy profile	1657

CHAPTER 150
Native Profiling 1659

Information About Native Profiling	1659
Creating a Class Map (GUI)	1660
Creating a Class Map (CLI)	1661
Creating a Service Template (GUI)	1663
Creating a Service Template (CLI)	1664
Creating a Parameter Map	1665
Creating a Policy Map (GUI)	1665
Creating a Policy Map (CLI)	1666

Configuring Native Profiling in Local Mode	1668
Verifying Native Profile Configuration	1668

CHAPTER 151**Air Time Fairness 1671**

Information About Air Time Fairness	1671
Restrictions on Cisco Air Time Fairness	1673
Cisco Air Time Fairness (ATF) Use Cases	1674
Configuring Cisco Air Time Fairness (ATF)	1674
Configuring Cisco Air Time Fairness	1674
Creating a Cisco ATF Profile (GUI)	1674
Creating Cisco ATF Profile (CLI)	1675
Attaching Cisco ATF Profile to a Policy Profile (GUI)	1676
Attaching Cisco ATF Profile to a Policy Profile (CLI)	1676
Enabling ATF in the RF Profile (GUI)	1677
Enabling ATF in the RF Profile (CLI)	1677
Verifying Cisco ATF Configurations	1678
Verifying Cisco ATF Statistics	1678

CHAPTER 152**IPv6 Non-AVC QoS Support 1681**

Information About IPv6 Non-AVC QoS Support	1681
Configuring IPv6 Non-AVC QoS	1681
Marking DSCP Values for an IPv6 Packet	1682
Dropping an IPv6 Packet with DSCP Values	1682
Policing IPv6 Traffic	1683
Verifying IPv6 Non-AVC QoS	1684

CHAPTER 153**QoS Basic Service Set Load 1685**

Information About QoS Basic Set Service Load	1685
Configuring QBSS Load	1686
Configuring Wi-Fi Multimedia	1686
Enabling QoS Basic Set Service Load	1687
Verifying QoS Basic Set Service Load	1687

PART XI**IPv6 1689**

CHAPTER 154	IPv6 Client IP Address Learning	1691
	Information About IPv6 Client Address Learning	1691
	Address Assignment Using SLAAC	1691
	Stateful DHCPv6 Address Assignment	1692
	Router Solicitation	1693
	Router Advertisement	1693
	Neighbor Discovery	1693
	Neighbor Discovery Suppression	1694
	Router Advertisement Guard	1694
	Router Advertisement Throttling	1695
	Prerequisites for IPv6 Client Address Learning	1695
	IPv6 Address Tracking for Wireless Clients	1695
	Configuring Unknown Address Multicast Neighbor Solicitation Forwarding	1696
	Configuring RA Throttle Policy (CLI)	1696
	Applying RA Throttle Policy on VLAN (GUI)	1697
	Applying RA Throttle Policy on a VLAN (CLI)	1698
	Configuring IPv6 Interface on a Switch (GUI)	1698
	Configuring IPv6 on Interface (CLI)	1699
	Configuring DHCP Pool on Switch (GUI)	1700
	Configuring DHCP Pool on Switch (CLI)	1700
	Configuring Stateless Auto Address Configuration Without DHCP on Switch (CLI)	1701
	Configuring Stateless Auto Address Configuration With DHCP on Switch	1703
	Configuring Stateless Address Auto Configuration Without DHCP on Switch (CLI)	1704
	Native IPv6	1705
	Information About IPv6	1705
	Configuring IPv6 Addressing	1706
	Creating an AP Join Profile (GUI)	1707
	Creating an AP Join Profile (CLI)	1708
	Configuring the Primary and Backup Controller (GUI)	1708
	Configuring Primary and Backup Controller (CLI)	1708
	Verifying IPv6 Configuration	1709
CHAPTER 155	IPv6 ACL	1711

Information About IPv6 ACL	1711
Understanding IPv6 ACLs	1711
Types of ACL	1711
Per User IPv6 ACL	1711
Filter ID IPv6 ACL	1712
Prerequisites for Configuring IPv6 ACL	1712
Restrictions for Configuring IPv6 ACL	1712
Configuring IPv6 ACLs	1712
Default IPv6 ACL Configuration	1713
Interaction with Other Features and Switches	1713
How To Configure an IPv6 ACL	1713
Creating an IPv6 ACL (GUI)	1713
Creating an IPv6 ACL	1714
Creating WLAN IPv6 ACL (GUI)	1718
Creating WLAN IPv6 ACL	1718
Verifying IPv6 ACL	1718
Displaying IPv6 ACLs	1718
Configuration Examples for IPv6 ACL	1719
Example: Creating an IPv6 ACL	1719
Example: Applying an IPv6 ACL to a Policy Profile in a Wireless Environment	1719
Displaying IPv6 ACLs	1720
Example: Displaying IPv6 ACLs	1720
Example: Configuring RA Throttling	1721

CHAPTER 156**IPv6 Client Mobility 1723**

Information About IPv6 Client Mobility	1723
Using Router Advertisement	1724
Router Advertisement Throttling	1724
IPv6 Address Learning	1725
Handling Multiple IP Addresses	1725
IPv6 Configuration	1725
Prerequisites for IPv6 Client Mobility	1725
Monitoring IPv6 Client Mobility	1726

CHAPTER 157	IPv6 Support on Flex and Mesh	1727
	IPv6 Support on Flex + Mesh Deployment	1727
	Configuring IPv6 Support for Flex + Mesh	1727
	Configuring Preferred IP Address as IPv6 (GUI)	1728
	Configuring Preferred IP Address as IPv6	1729
	Verifying IPv6 on Flex+Mesh	1729

CHAPTER 158	IPv6 CAPWAP UDP Lite Support	1731
	Information About UDP Lite	1731
	Enabling UDP Lite Support	1731
	Verifying UDP Lite Support Configuration	1732

CHAPTER 159	Neighbor Discovery Proxy	1733
	Information About Neighbor Discovery	1733
	Configure Neighbor Discovery Proxy (CLI)	1733
	Configure Duplicate Address Detection Proxy (CLI)	1734

CHAPTER 160	Address Resolution Protocol Proxy	1737
	Information About Address Resolution Protocol	1737
	Configure Address Resolution Protocol Proxy (CLI)	1737

CHAPTER 161	IPv6 Ready Certification	1739
	Feature History for IPv6-Ready Certification	1739
	IPv6 Ready Certification	1739
	Configuring IPv6 Route Information	1740
	Verifying IPv6 Route Information	1740

PART XII	CleanAir	1741
-----------------	-----------------	-------------

CHAPTER 162	Cisco CleanAir	1743
	Feature History for CleanAir	1743
	Information About Cisco CleanAir	1743

Cisco CleanAir-Related Terms	1744
Cisco CleanAir Components	1744
Interference Types that Cisco CleanAir can Detect	1746
EDRRM and AQR Update Mode	1747
Prerequisites for CleanAir	1747
Restrictions for CleanAir	1747
How to Configure CleanAir	1748
Enabling CleanAir for the 2.4-GHz Band (GUI)	1748
Enabling CleanAir for the 2.4-GHz Band (CLI)	1748
Configuring Interference Reporting for a 2.4-GHz Device (GUI)	1748
Configuring Interference Reporting for a 2.4-GHz Device (CLI)	1749
Enabling CleanAir for the 5-GHz Band (GUI)	1751
Enabling CleanAir for the 5-GHz Band (CLI)	1751
Configuring Interference Reporting for a 5-GHz Device (GUI)	1752
Configuring Interference Reporting for a 5-GHz Device (CLI)	1752
Configuring Event Driven RRM for a CleanAir Event (GUI)	1754
Configuring EDRRM for a CleanAir Event (CLI)	1754
CleanAir Pro Scanning	1755
Feature History for CleanAir Pro Scanning	1755
Information About CleanAir Pro Scanning	1756
Enabling CleanAir Pro Scanning (CLI)	1757
Monitoring CleanAir Pro Statistics (GUI)	1758
Verifying CleanAir Pro Scanning Details	1758
Verifying CleanAir Parameters	1759
Monitoring Interference Devices	1760
Configuration Examples for CleanAir	1760
CleanAir FAQs	1761

CHAPTER 163**Bluetooth Low Energy 1763**

Information About Bluetooth Low Energy	1763
Enabling Bluetooth Low Energy Beacon (GUI)	1764
Enabling Bluetooth Low Energy Beacon	1764

CHAPTER 164**Persistent Device Avoidance 1767**

Information about Cisco Persistent Device Avoidance 1767

Configuring Persistent Device Avoidance (GUI) 1768

Configuring Persistent Device Avoidance (CLI) 1768

Verifying Persistent Device Avoidance 1768

CHAPTER 165

Spectrum Intelligence 1771

Spectrum Intelligence 1771

Configuring Spectrum Intelligence 1772

Verifying Spectrum Intelligence Information 1772

Debugging Spectrum Intelligence on Supported APs (CLI) 1773

CHAPTER 166

Spectrum Analysis 1775

Information About Spectrum Analysis 1775

Live Spectrum Analysis 1776

Performing AP Spectrum Analysis (GUI) 1776

Configuring Spectrum Analysis 1777

Verifying Spectrum Analysis 1777

PART XIII

Mesh Access Points 1779

CHAPTER 167

Mesh Access Points 1781

Introduction to the Mesh Network 1783

Restrictions for Mesh Access Points 1784

MAC Authorization 1786

Preshared Key Provisioning 1786

EAP Authentication 1786

Bridge Group Names 1787

Background Scanning 1788

Information About Background Scanning and MAP Fast Ancestor Find Mode 1788

Mesh Backhaul at 2.4 GHz and 5 GHz 1789

Information About Mesh Backhaul 1789

Information About Mesh Serial Backhaul 1790

Information About Mesh Backhaul RRM 1791

Dynamic Frequency Selection 1792

Country Codes	1792
Intrusion Detection System	1793
Mesh Interoperability Between Controllers	1793
Information About DHCP and NAT Functionality on Root AP (RAP)	1793
Mesh Convergence	1794
Noise-Tolerant Fast	1794
Ethernet Bridging	1794
Multicast Over Mesh Ethernet Bridging Network	1795
Radio Resource Management on Mesh	1796
Air Time Fairness on Mesh	1796
Spectrum Intelligence for Mesh	1797
Indoor Mesh Interoperability with Outdoor Mesh	1797
Workgroup Bridge	1797
Link Test	1798
Mesh Daisy Chaining	1798
Mesh Leaf Node	1799
Flex+Bridge Mode	1799
Backhaul Client Access	1799
Mesh CAC	1799
Prerequisites for Mesh Ethernet Daisy Chaining	1800
Restrictions for Mesh Ethernet Daisy Chaining	1800
Speeding up Mesh Network Recovery Through Fast Detection of Uplink Gateway Reachability Failure	1801
Fast Teardown for a Mesh Deployment	1801
Configuring MAC Authorization (GUI)	1801
Configuring MAC Authorization (CLI)	1802
Configuring MAP Authorization - EAP (GUI)	1803
Configuring MAP Authorization (CLI)	1804
Configuring PSK Provisioning (CLI)	1805
Configuring a Bridge Group Name (GUI)	1806
Configuring a Bridge Group Name (CLI)	1806
Configuring Background Scanning (GUI)	1807
Configuring Background Scanning	1807
Configuring AP Fast Ancestor Find Mode (GUI)	1808

Configuring Background Scanning and MAP Fast Ancestor Find Mode (CLI)	1808
Configuring Backhaul Client Access (GUI)	1809
Configuring Backhaul Client Access (CLI)	1809
Configuring Dot11ax Rates on Mesh Backhaul Per Access Point (GUI)	1810
Configuring Dot11ax Rates on Mesh Backhaul in Mesh Profile (GUI)	1810
Configuring Wireless Backhaul Data Rate (CLI)	1811
Configuring Data Rate Per AP (CLI)	1812
Configuring Data Rate Using Mesh Profile (CLI)	1812
Configuring Mesh Backhaul (CLI)	1813
Configuring Dynamic Frequency Selection (CLI)	1813
Configuring the Intrusion Detection System (CLI)	1814
Configuring Ethernet Bridging (GUI)	1814
Configuring Ethernet Bridging (CLI)	1815
Configuring Multicast Modes over Mesh	1816
Configuring RRM on Mesh Backhaul (CLI)	1817
Configuring RRM Channel Assignment for Root Access Points Globally	1818
	1818
Configuring RRM Channel Assignment for an Access Point	1819
Selecting a Preferred Parent (GUI)	1819
Selecting a Preferred Parent (CLI)	1819
Changing the Role of an AP (GUI)	1821
Changing the Role of an AP (CLI)	1821
Configuring the Mesh Leaf Node (CLI)	1821
Configuring the Mesh Leaf Node (GUI)	1822
Configuring Subset Channel Synchronization	1822
Provisioning LSC for Bridge-Mode and Mesh APs (GUI)	1823
Provisioning LSC for Bridge-Mode and Mesh APs	1823
Specifying the Backhaul Slot for the Root AP (GUI)	1824
Specifying the Backhaul Slot for the Root AP (CLI)	1824
Using a Link Test on Mesh Backhaul (GUI)	1825
Using a Link Test on Mesh Backhaul	1825
Configuring Battery State for Mesh AP (GUI)	1826
Configuring Battery State for Mesh AP	1826
Configuring Mesh Convergence (CLI)	1827

Configuring DHCP Server on Root Access Point (RAP)	1827
Configuring Mesh Ethernet Daisy Chaining (CLI)	1828
Enabling Mesh Ethernet Daisy Chaining	1828
Configuring Mesh CAC (CLI)	1829
Configuring ATF on Mesh (GUI)	1829
Configuring ATF on Mesh	1830
Create an ATF Policy for a MAP	1830
Creating an ATF Policy (GUI)	1831
Adding an ATF to a Policy Profile (GUI)	1831
Enabling ATF Mode in an RF Profile (GUI)	1831
Enabling Wireless Mesh Profile	1832
Enabling Serial Backhaul in Radio Profile (GUI)	1832
Enabling Mesh Configurations in Radio Profile (CLI)	1833
Enabling Serial Backhaul (CLI)	1834
Configuration Example for Mesh Serial Backhaul	1835
Associating Wireless Mesh to an AP Profile (CLI)	1835
Configuring Fast Teardown for a Mesh AP Profile (GUI)	1835
Configuring Fast Teardown for a Mesh AP Profile (CLI)	1836
Flex Resilient with Flex and Bridge Mode Access Points	1837
Information About Flex Resilient with Flex and Bridge Mode Access Points	1837
Configuring a Flex Profile (GUI)	1837
Configuring a Flex Profile (CLI)	1838
Configuring a Site Tag (CLI)	1839
Configuring a Mesh Profile (CLI)	1840
Associating Wireless Mesh to an AP Profile (CLI)	1840
Attaching Site Tag to an Access Point (CLI)	1841
Configuring Switch Interface for APs (CLI)	1842
Verifying Flex Resilient with Flex and Bridge Mode Access Points Configuration	1842
Verifying ATF Configuration on Mesh	1843
Verifying Mesh Ethernet Daisy Chaining	1844
Verifying Mesh Convergence	1844
Verifying DHCP Server for Root AP Configuration	1845
Verifying Mesh Backhaul	1845
Verifying Mesh Configuration	1846

Verifying Dot11ax Rates on Mesh Backhaul	1854
Verifying Mesh Serial Backhaul	1854
Verifying the RRM DCA Status	1855
Verifying Fast Teardown with Default Mesh Profile	1855
Verifying Background Scanning and MAP Fast Ancestor Find	1856

CHAPTER 168
Redundant Root Access Point (RAP) Ethernet Daisy Chaining 1857

Overview of Redundant RAP Ethernet Daisy Chaining	1857
Prerequisites for Redundant RAP Ethernet Daisy Chaining Support	1858
Configuring Redundant RAP Ethernet Daisy Chaining Support (CLI)	1858
Verifying Daisy Chain Redundancy (CLI)	1858

PART XIV
VideoStream 1861

CHAPTER 169
VideoStream 1863

Information about Media Stream	1863
Prerequisites for Media Stream	1864
How to Configure Media Stream	1864
Configuring Multicast-Direct Globally for Media Stream (CLI)	1864
Configuring Media Stream for 802.11 Bands (CLI)	1865
Configuring a WLAN to Stream Video(GUI)	1867
Configuring a WLAN to Stream Video (CLI)	1867
Deleting a Media Stream (GUI)	1868
Deleting a Media Stream (CLI)	1868
Monitoring Media Streams	1869
Configuring the General Parameters for a Media Stream (GUI)	1870
Adding Media Stream (CLI)	1870
Enabling a Media Stream per WLAN (GUI)	1871
Enabling a Media Stream per WLAN (CLI)	1871
Configuring the General Parameters for a Media Stream (GUI)	1872
Configuring the General Parameters for a Media Stream (CLI)	1872
Configuring Multicast Direct Admission Control (GUI)	1873
Configuring Multicast Direct Admission Control (CLI)	1874
Create and Attach Policy-based QoS Profile	1875

- Create a QoS Profile (GUI) 1876
- Create a QoS Profile (CLI) 1876
- Create a Service Template (GUI) 1877
- Create a Service Template (CLI) 1877
- Map the Service Template to the Policy Map (GUI) 1878
- Map the Service Template to the Policy Map (CLI) 1879
- Map the Policy Map (GUI) 1880
- Map the Policy Map (CLI) 1880
- Viewing Media Stream Information 1881

PART XV

Software-Defined Access Wireless 1885

CHAPTER 170

Software-Defined Access Wireless 1887

- Information to Software-Defined Access Wireless 1887
- Information About SD-Access Wireless Mesh Inter Fabric Edge Switch Roaming Protection 1890
- Configuring SD-Access Wireless 1892
 - Configuring Default Map Server (GUI) 1893
 - Configuring Default Map Server (CLI) 1893
 - Configuring SD-Access Wireless Profile (GUI) 1893
 - Configuring SD-Access Wireless Profile (CLI) 1894
 - Configuring Map Server in Site Tag (GUI) 1894
 - Configuring Map Server in Site Tag (CLI) 1895
 - Configuring Map Server per L2-VNID (GUI) 1895
 - Configuring Map Server per L2-VNID (CLI) 1896
- Verifying SD-Access Wireless 1896

CHAPTER 171

Passive Client 1899

- Information About Passive Clients 1899
- Enabling Passive Client on WLAN Policy Profile (GUI) 1900
- Enabling Passive Client on WLAN Policy Profile (CLI) 1900
- Enabling ARP Broadcast on VLAN (GUI) 1901
- Enabling ARP Broadcast on VLAN (CLI) 1901
- Configuring Passive Client in Fabric Deployment 1902
 - Enabling Broadcast Underlay on VLAN 1902

Enabling ARP Flooding	1904
Verifying Passive Client Configuration	1905

CHAPTER 172 **Fabric in a Box with External Fabric Edge** **1907**

Introduction to Fabric in a Box with External Fabric Edge	1907
Configuring a Fabric Profile (CLI)	1907
Configuring a Policy Profile (CLI)	1908
Configuring a Site Tag (CLI)	1909
Configuring a WLAN (CLI)	1910
Configuring a Policy Tag (CLI)	1910
Configuring an AP Profile	1911
Configuring Map Server and AP Subnet (CLI)	1911
Configuring Fabric on FiaB Node	1912
Configuring a Fabric Edge Node	1918
Verifying Fabric Configuration	1925

PART XVI **VLAN** **1931**

CHAPTER 173 **VLANs** **1933**

Information About VLANs	1933
Logical Networks	1933
Supported VLANs	1933
VLAN Port Membership Modes	1933
VLAN Configuration Files	1934
Normal-Range VLAN Configuration Guidelines	1935
Extended-Range VLAN Configuration Guidelines	1935
Prerequisites for VLANs	1936
Restrictions for VLANs	1936
How to Configure VLANs	1937
How to Configure Normal-Range VLANs	1937
Creating or Modifying an Ethernet VLAN	1937
Assigning Static-Access Ports to a VLAN (GUI)	1938
Assigning Static-Access Ports to a VLAN	1938
How to Configure Extended-Range VLANs	1939

[Creating an Extended-Range VLAN \(GUI\)](#) 1940
[Creating an Extended-Range VLAN](#) 1940
[Monitoring VLANs](#) 1941

CHAPTER 174

VLAN Groups 1943

[Information About VLAN Groups](#) 1943
[Prerequisites for VLAN Groups](#) 1944
[Restrictions for VLAN Groups](#) 1944
[Creating a VLAN Group \(GUI\)](#) 1944
[Creating a VLAN Group \(CLI\)](#) 1945
[Adding a VLAN Group to Policy Profile \(GUI\)](#) 1945
[Adding a VLAN Group to a Policy Profile](#) 1946
[Viewing the VLANs in a VLAN Group](#) 1946
[VLAN Group Support for DHCP and Static IP Clients](#) 1947
[Supported Features](#) 1947

PART XVII

WLAN 1949

CHAPTER 175

WLANs 1951

[Information About WLANs](#) 1951
[Band Selection](#) 1952
[Off-Channel Scanning Deferral](#) 1952
[DTIM Period](#) 1952
[WLAN Radio Policy](#) 1953
[Restrictions for WLAN Radio Policy](#) 1953
[Prerequisites for Configuring Cisco Client Extensions](#) 1953
[Peer-to-Peer Blocking](#) 1954
[Diagnostic Channel](#) 1954
[Prerequisites for WLANs](#) 1954
[Restrictions for WLANs](#) 1954
[How to Configure WLANs](#) 1956
[WLAN Wizard](#) 1956
[Local Mode](#) 1956
[FlexConnect Mode](#) 1960

Guest CWA Mode	1964
Creating WLANs (GUI)	1967
Creating WLANs (CLI)	1967
Deleting WLANs (GUI)	1968
Deleting WLANs	1968
Searching WLANs (CLI)	1969
Enabling WLANs (GUI)	1969
Enabling WLANs (CLI)	1970
Disabling WLANs (GUI)	1970
Disabling WLANs (CLI)	1970
Configuring General WLAN Properties (CLI)	1971
Configuring Advanced WLAN Properties (CLI)	1972
Configuring Advanced WLAN Properties (GUI)	1974
Configuring WLAN Radio Policy (GUI)	1976
Configuring a WLAN Radio Policy (CLI)	1977
Verifying WLAN Properties (CLI)	1978
Verifying WLAN-VLAN Information for an AP	1978
Verifying a WLAN Radio Policy	1979
CHAPTER 176	
WLAN Security	1981
Information About WPA1 and WPA2	1981
Information About AAA Override	1982
Configuring AAA Override	1982
Information About VLAN Override	1983
Configuring Override VLAN for Central Switching	1983
Configuring Override VLAN for Local Switching	1984
VLAN Override on Layer 3 Web Authentication	1985
Verifying VLAN Override on Layer 3 Web Authentication	1985
Prerequisites for Layer 2 Security	1985
Restrictions for WPA2 and WP3	1986
Feature History for Fallback for AAA-Overridden VLAN	1986
Information About Fallback for AAA- Overridden VLAN	1987
Central Switching and FlexConnect Mode Scenarios	1987
Configuring Fallback for AAA-Overridden VLAN (CLI)	1988

Verifying Fallback for AAA-Overridden VLAN	1988
How to Configure WLAN Security	1989
Configuring Static WEP Layer 2 Security Parameters (GUI)	1989
Configuring Static WEP Layer 2 Security Parameters (CLI)	1989
Configuring WPA + WPA2 Layer 2 Security Parameters (GUI)	1991
Configuring WPA + WPA2 Layer 2 Security Parameters (CLI)	1991

CHAPTER 177**Remote LANs 1995**

Information About Remote LANs	1995
Configuring Remote LANs (RLANs)	1997
Enabling or Disabling all RLANs	1997
Creating RLAN Profile (GUI)	1998
Creating RLAN Profile (CLI)	1998
Configuring RLAN Profile Parameters (GUI)	1999
Configuring RLAN Profile Parameters (CLI)	1999
Creating RLAN Policy Profile (GUI)	2001
Creating RLAN Policy Profile (CLI)	2001
Configuring RLAN Policy Profile Parameters (GUI)	2001
Configuring RLAN Policy Profile Parameters (CLI)	2003
Configuring Policy Tag and Mapping an RLAN Policy Profile to an RLAN Profile (CLI)	2005
Configuring LAN Port (CLI)	2006
Attaching Policy Tag to an Access Point (GUI)	2006
Attaching Policy Tag to an Access Point (CLI)	2006
Verifying RLAN Configuration	2007
Information About RLAN Authentication Fallback	2010
Configuring RLAN Authentication Fallback (CLI)	2010
Modifying 802.1X EAP Timers for RLAN Clients	2011
Verifying RLAN Authentication Fallback	2012

CHAPTER 178**RLAN External Module 2013**

Information About External Module	2013
Prerequisites for Configuring External Module	2013
Configuring External Module (GUI)	2013
Configuring External Module (CLI)	2014

Verifying External Module 2014

CHAPTER 179

802.11ax Per WLAN 2015

Information About 802.11ax Mode Per WLAN 2015

Configuring 802.11ax Mode Per WLAN (GUI) 2015

Configuring 802.11ax Mode Per WLAN (CLI) 2016

Verifying 802.11ax Mode Per WLAN 2016

CHAPTER 180

BSS Coloring 2019

Information About BSS Coloring 2019

BSS Coloring 2020

OBSS-PD and Spatial Reuse 2020

Configuring BSS Color on AP (GUI) 2020

Configuring BSS Color in the Privileged EXEC Mode 2021

Configuring BSS Color Globally (GUI) 2021

Configuring BSS Color in the Configuration Mode 2022

Configuring Overlapping BSS Packet Detect (GUI) 2022

Configuring OBSS-PD Spatial Reuse Globally (CLI) 2023

Configuring OBSS PD in an RF Profile (GUI) 2023

Configuring OBSS-PD Spatial Reuse in the RF Profile Mode (CLI) 2024

Verifying BSS Color and OBSS-PD 2024

CHAPTER 181

DHCP for WLANs 2027

Information About Dynamic Host Configuration Protocol 2027

Internal DHCP Servers 2027

External DHCP Servers 2028

DHCP Assignments 2028

DHCP Option 82 2029

Restrictions for Configuring DHCP for WLANs 2030

Guidelines for DHCP Relay Configuration 2030

How to Configure DHCP for WLANs 2031

Configuring DHCP Scopes (GUI) 2031

Configuring DHCP Scopes (CLI) 2032

Configuring the Internal DHCP Server 2033

- Configuring the Internal DHCP Server Under Client VLAN SVI (GUI) 2033
- Configuring the Internal DHCP Server Under Client VLAN SVI (CLI) 2033
- Configuring the Internal DHCP Server Under a Wireless Policy Profile (GUI) 2036
- Configuring the Internal DHCP Server Under a Wireless Policy Profile 2036
- Configuring the Internal DHCP Server Globally (GUI) 2039
- Configuring the Internal DHCP Server Globally (CLI) 2039
- Verifying Internal DHCP Configuration 2041
- Configuring DHCP-Required for FlexConnect 2043
 - Information About FlexConnect DHCP-Required 2043
 - Restrictions and Limitations for FlexConnect DHCP-Required 2043
 - Configuring FlexConnect DHCP-Required (GUI) 2043
 - Configuring FlexConnect DHCP-Required (CLI) 2044
 - Verifying FlexConnect DHCP-Required 2044

CHAPTER 182

Aironet Extensions IE (CCX IE) 2047

- Information About Aironet Extensions Information Element 2047
- Configuring Aironet Extensions IE (GUI) 2047
- Configuring Aironet Extensions IE (CLI) 2047
- Verifying the Addition of AP Name 2048

CHAPTER 183

Device Analytics 2051

- Device Analytics 2051
 - Information About Device Analytics 2051
 - Restrictions for Device Analytics 2051
 - Configuring Device Analytics (GUI) 2052
 - Configuring Device Analytics (CLI) 2052
 - Verifying Device Analytics 2053
 - Verifying Device Analytics Configuration 2054
- Adaptive 802.11r 2055
 - Information About Adaptive 802.11r 2055
 - Configuring Adaptive 802.11r (GUI) 2056
 - Verifying Adaptive 802.11r 2056

CHAPTER 184

Device Classifier Dynamic XML Support 2057

Feature History for Device Classifier Dynamic XML Support	2057
Information About Device Classifier Dynamic XML Support	2058
Enabling Device Classifier (CLI)	2061
Updating Dynamic XML File	2061
Verifying TLV Values	2062
Clearing Old Classification Cache	2062

CHAPTER 185**BSSID Counters 2065**

BSSID Counters	2065
Enabling BSSID Statistics and BSSID Neighbor Statistics	2065
Verifying BSSID Statistics on the Controller	2066

CHAPTER 186**Fastlane+ 2069**

Information About Fastlane+	2069
Configuring an Fastlane+ on a WLAN (CLI)	2069
Configuring an Fastlane+ on a WLAN (GUI)	2070
Monitoring Fastlane+	2070
Verifying Fastlane+	2071

CHAPTER 187**Workgroup Bridges 2073**

Cisco Workgroup Bridges	2073
Configuring Workgroup Bridge on a WLAN	2076
Verifying the Status of a Workgroup Bridge on the Controller	2078
Configuring Access Points as Workgroup Bridge	2078
Turning Cisco Aironet 2700/3700/1572 Series AP into Autonomous Mode	2078
Configuring Cisco Wave 2 APs or 11AX APs in Workgroup Bridge or CAPWAP AP Mode (CLI)	2079
Configure an SSID Profile for Cisco Wave 2 and 11AX APs (CLI)	2079
Configuring the Authentication Server (CLI)	2081
Configuring a Dot1X Credential (CLI)	2081
Configuring an EAP Profile (CLI)	2082
Configuring Manual-Enrollment of a Trustpoint for Workgroup Bridge (CLI)	2083
Configuring Auto-Enrollment of a Trustpoint for Workgroup Bridge (CLI)	2084
Configuring Manual Certificate Enrolment Using TFTP Server (CLI)	2086
Importing the PKCS12 Format Certificates from the TFTP Server (CLI)	2087

Configuring Radio Interface for Workgroup Bridges (CLI)	2088
Configuring Workgroup Bridge Timeouts (CLI)	2091
Configuring Bridge Forwarding for Workgroup Bridge (CLI)	2092
Information About Simplifying WGB Configuration	2093
Configuring Multiple WGBs (CLI)	2094
Verifying WGB Configuration	2094

CHAPTER 188**Peer-to-Peer Client Support 2097**

Information About Peer-to-Peer Client Support	2097
Configure Peer-to-Peer Client Support	2097

CHAPTER 189**Deny Wireless Client Session Establishment Using Calendar Profiles 2099**

Information About Denial of Wireless Client Session Establishment	2099
Configuring Daily Calendar Profile	2100
Configuring Weekly Calendar Profile	2101
Configuring Monthly Calendar Profile	2102
Mapping a Daily Calendar Profile to a Policy Profile	2103
Mapping a Weekly Calendar Profile to a Policy Profile	2104
Mapping a Monthly Calendar Profile to a Policy Profile	2105
Verifying Calendar Profile Configuration	2106
Verifying Policy Profile Configuration	2106

CHAPTER 190**Ethernet over GRE 2109**

Introduction to EoGRE	2109
EoGRE Configuration Overview	2110
Create a Tunnel Gateway	2111
Configuring the Tunnel Gateway (GUI)	2112
Configuring a Tunnel Domain	2112
Configuring Tunnel Domain (GUI)	2113
Configuring EoGRE Global Parameters	2114
Configuring EoGRE Global Parameters (GUI)	2114
Configuring a Tunnel Profile	2115
Configuring the Tunnel Profile (GUI)	2116
Associating WLAN to a Wireless Policy Profile	2117

Attaching a Policy Tag and a Site Tag to an AP	2118
Verifying the EoGRE Tunnel Configuration	2118

CHAPTER 191**Wireless Guest Access 2127**

Wireless Guest Access	2127
Foreign Map Overview	2130
Wireless Guest Access: Use Cases	2130
Load Balancing Among Multiple Guest Controllers	2131
Guidelines and Limitations for Wireless Guest Access	2131
Troubleshooting IPv6	2131
Configure Mobility Tunnel for Guest Access (GUI)	2132
Configure Mobility Tunnel for Guest Access (CLI)	2132
Configuring Guest Access Policy (GUI)	2132
Configuring Guest Access Policy (CLI)	2133
Viewing Guest Access Debug Information (CLI)	2135
Configure Guest Access Using Different Security Methods	2135
Open Authentication	2135
Configure a WLAN Profile for Guest Access with Open Authentication (GUI)	2135
Configure a WLAN Profile For Guest Access with Open Authentication (CLI)	2136
Configuring a Policy Profile	2137

Preface

This preface describes the conventions of this document and information on how to obtain other documentation. It also provides information on what's new in Cisco product documentation.

- [Document Conventions](#) , on page ci
- [Related Documentation](#), on page ciiv
- [Communications, Services, and Additional Information](#), on page ciiv

Document Conventions

This document uses the following conventions:

Convention	Description
^ or Ctrl	Both the ^ symbol and Ctrl represent the Control (Ctrl) key on a keyboard. For example, the key combination ^D or Ctrl-D means that you hold down the Control key while you press the D key. (Keys are indicated in capital letters but are not case sensitive.)
bold font	Commands and keywords and user-entered text appear in bold font .
<i>Italic font</i>	Document titles, new or emphasized terms, and arguments for which you supply values are in <i>italic font</i> .
Courier font	Terminal sessions and information the system displays appear in <code>courier font</code> .
Bold Courier font	Bold Courier font indicates text that the user must enter.
[x]	Elements in square brackets are optional.
...	An ellipsis (three consecutive nonbolded periods without spaces) after a syntax element indicates that the element can be repeated.
	A vertical line, called a pipe, indicates a choice within a set of keywords or arguments.
[x y]	Optional alternative keywords are grouped in brackets and separated by vertical bars.

Convention	Description
{x y}	Required alternative keywords are grouped in braces and separated by vertical bars.
[x {y z}]	Nested set of square brackets or braces indicate optional or required choices within optional or required elements. Braces and a vertical bar within square brackets indicate a required choice within an optional element.
string	A nonquoted set of characters. Do not use quotation marks around the string or the string will include the quotation marks.
<>	Nonprinting characters such as passwords are in angle brackets.
[]	Default responses to system prompts are in square brackets.
!, #	An exclamation point (!) or a pound sign (#) at the beginning of a line of code indicates a comment line.

Reader Alert Conventions

This document may use the following conventions for reader alerts:

Note Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the manual.

Tip Means *the following information will help you solve a problem*.

Caution Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

Timesaver Means *the described action saves time*. You can save time by performing the action described in the paragraph.

Warning IMPORTANT SAFETY INSTRUCTIONS

Before you work on any equipment, be aware of the hazards involved with electrical circuitry and be familiar with standard practices for preventing accidents. Read the installation instructions before using, installing, or connecting the system to the power source. Use the statement number provided at the end of each warning statement to locate its translation in the translated safety warnings for this device. Statement 1071

SAVE THESE INSTRUCTIONS

- [Initial Setup](#), on page 3
- [Interactive Help](#), on page 4

Overview of Cisco 9800 Series Wireless Controllers

Cisco Catalyst 9800 Series Wireless Controllers are the next generation of wireless controllers built for the Intent-based networking. The Cisco Catalyst 9800 Series Controllers are IOS XE based and integrates the RF Excellence from Aironet with Intent-based Networking capabilities of IOS XE to create the best-in-class wireless experience for your evolving and growing organization.

The controllers are deployable in physical and virtual (private and public cloud) form factors and can be managed using Cisco Catalyst Center, Netconf/YANG, Cisco Prime Infrastructure, web-based GUI, or CLI.

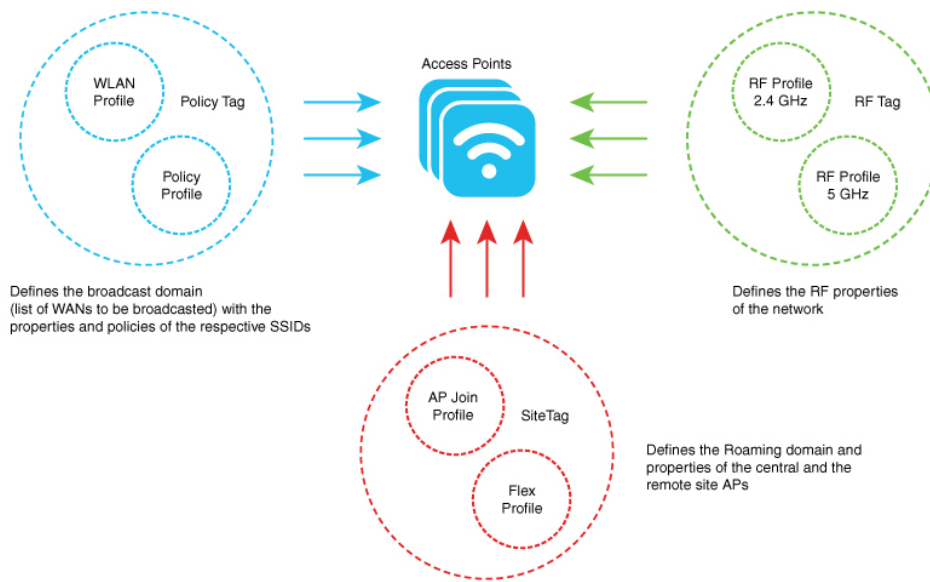

The Cisco Catalyst 9800 Series Wireless Controllers are available in multiple form factors to cater to your deployment options:

- Cisco Catalyst 9800 Series Wireless Controller Appliance
- Cisco Catalyst 9800 Series Wireless Controller for Cloud
- Cisco Catalyst 9800 Embedded Wireless for Switch

The configuration data model is based on design principles of reusability, simplified provisioning, enhanced flexibility and modularization to help manage networks as they scale up and simplify the management of dynamically changing business and IT requirements.

Elements of the New Configuration Model

The following diagram depicts the elements of the new configuration model.

Tags

The property of a tag is defined by the property of the policies associated to it, which in turn is inherited by an associated client or an AP. There are various type of tags, each of which is associated to different profiles. Every tag has a default that is created when the system boots up.

Profiles

Profiles represent a set of attributes that are applied to the clients associated to the APs or the APs themselves. Profiles are reusable entities that can be used across tags.

Configuration Workflow

The following set of steps defines the logical order of configuration. Apart from the WLAN profile, all the profiles and tags have a default object associated with it.

1. Create the following profiles:

- WLAN
- Policy
- AP Join
- Flex
- RF

2. Create the following tags:

- Policy
- Site

- RF

3. Associate tags to an AP.

Figure 1: Configuration Workflow

Initial Setup

Setting up the Controller

The initial configuration wizard in Cisco Catalyst 9800 Series Wireless Controller is a simplified, out-of-the-box installation and configuration interface for controller. This section provides instructions to set up a controller

to operate in a small, medium, or large network wireless environment, where access points can join and together as a simple solution provide various services, such as corporate employee or guest wireless access on the network.

Setting Up the Controller Using GUI

To set up the controller using GUI, see the *Configuring Wireless Controller* section in [Cisco Catalyst 9800 Wireless Controller Series Web UI Deployment Guide](#).

Note If you make configuration changes in the Command Line Interface (CLI) and in the GUI simultaneously, you must click the **Refresh** button in the GUI to synch both the changes. You should always click the **Refresh** button in the GUI, to update the changes done through CLI.

Note The banner text is fetched from the controller when you land on the login page. You will be able to see this request on the RADIUS server.

Setting Up the Controller Using CLI

To set up the controller using CLI, see the *Performing the Initial Configuration on the Controller* section of your respective controller installation guides.

- [Cisco Catalyst 9800-80 Wireless Controller Hardware Installation Guide](#)
- [Cisco Catalyst 9800-40 Wireless Controller Hardware Installation Guide](#)
- [Cisco Catalyst 9800-L Wireless Controller Hardware Installation Guide](#)
- [Cisco Catalyst 9800-CL Cloud Wireless Controller Installation Guide](#)

- [Cisco Catalyst CW9800H1 and CW9800H2 Wireless Controllers Hardware Installation Guide](#)

Interactive Help

The Cisco Catalyst 9800 Series Wireless Controller GUI features an interactive help that walks you through the GUI and guides you through complex configurations.

You can start the interactive help in the following ways:

- By hovering your cursor over the blue flap at the right-hand corner of a window in the GUI and clicking **Interactive Help**.
- By clicking **Walk-me Thru** in the left pane of a window in the GUI.
- By clicking **Show me How** displayed in the GUI. Clicking **Show me How** triggers a specific interactive help that is relevant to the context you are in.

For instance, **Show me How** in **Configure > AAA** walks you through the various steps for configuring a RADIUS server. Choose **Configuration > Wireless Setup > Advanced** and click **Show me How** to trigger the interactive help that walks you through the steps relating to various kinds of authentication.

The following features have an associated interactive help:

- Configuring AAA
- Configuring FlexConnect Authentication
- Configuring 802.1x Authentication
- Configuring Local Web Authentication
- Configuring OpenRoaming
- Configuring Mesh APs

Note If the WalkMe launcher is unavailable on Safari, modify the settings as follows:

1. Choose **Preferences > Privacy**.
 2. In the **Website tracking** section, uncheck the **Prevent cross-site tracking** check box to disable this action.
 3. In the **Cookies and website data** section, uncheck the **Block all cookies** check box to disable this action.

Information About New Configuration Model

The configuration of Cisco Catalyst 9800 Series Wireless Controllers is simplified using different tags, namely rf-tag, policy-tag, and site-tag. The access points would derive their configuration from the profiles that are contained within the tags.

Profiles are a collection of feature-specific attributes and parameters applied to tags. The rf-tag contains the radio profiles, the site-tag contains flex-profile and ap-join-profile, and the policy-tag contains the WLAN profile and policy profile.

The FlexConnect configuration helps the central controller to manage sites that are geo-distributed, for example, retail, campus, and so on.

Policy Tag

The policy tag constitutes mapping of the WLAN profile to the policy profile. The WLAN profile defines the wireless characteristics of the WLAN. The policy profile defines the network policies and the switching policies for the client (Quality of Service [QoS] is an exception which constitutes AP policies as well).

The policy tag contains the map of WLAN policy profile. There are 16 such entries per policy tag. Changes to the map entries are effected based on the status of the WLAN profile and policy profile. For example, if a map (WLAN1 and Policy1) is added to the policy tag, and both the WLAN profile and the policy profile are enabled, the definitions are pushed to the APs using the policy tag. However, if one of them is in disabled state, the definition is not pushed to the AP. Similarly, if a WLAN profile is already being broadcast by an AP, it can be deleted using the no form of the command in the policy tag.

Site Tag

The site tag defines the properties of a site and contains the flex profile and the AP join profile. The attributes that are specific to the corresponding flex or remote site are part of the flex profile. Apart from the flex profile, the site tag also comprises attributes that are specific to the physical site (and hence cannot be a part of the profile that is a reusable entity). For example, the list of primary APs for efficient upgrade is a part of a site tag rather than that of a flex profile.

If a flex profile name or an AP profile name is changed in the site tag, the AP is forced to rejoin the controller by disconnecting the Datagram Transport Layer Security (DTLS) session. When a site tag is created, the AP and flex profiles are set to default values (default-ap-profile and default-flex-profile).

RF Tag

The RF tag contains the 2.4 GHz, 5 GHz, and 6 GHz RF profiles. The default RF tag contains the global configuration for 2.4 and 5 GHz bands and default RF profile for 6 GHz band. All these profiles contain the same default values for global or RF profile parameters for the respective radios.

Profiles

Profiles are a collection of feature-specific attributes and parameters applied to tags. Profiles are reusable entities that can be used across tags. Profiles (used by tags) define the properties of the APs or its associated clients.

WLAN Profile

WLAN profiles are configured with same or different service set identifiers (SSIDs). An SSID identifies the specific wireless network for the controller to access. Creating WLANs with the same SSID allows to assign different Layer 2 security policies within the same wireless LAN.

To distinguish WLANs having the same SSID, create a unique profile name for each WLAN. WLANs with the same SSID must have unique Layer 2 security policies so that clients can select a WLAN based on the information advertised in the beacon and probe responses. The switching and network policies are not part of the WLAN definition.

Policy Profile

Policy profile broadly consists of network and switching policies. Policy profile is a reusable entity across tags. Anything that is a policy for a client that is applied on an AP or controller is moved to the policy profile, for example, VLAN, ACL, QoS, session timeout, idle timeout, AVC profile, Bonjour profile, local profiling, device classification, BSSID QoS, and so on. However, all the wireless-related security attributes and features on the WLAN are grouped under the WLAN profile.

Flex Profile

Flex profile contains policy attributes and remote site-specific parameters. For example, the EAP profiles that can be used when the AP acts as an authentication server for local RADIUS server information, VLAN-ACL mapping, VLAN name-to-ID mapping, and so on.

AP Join Profile

The default AP join profile values will have the global AP parameters and the AP group parameters. The AP join profile contains attributes that are specific to AP, such as CAPWAP, IPv4 and IPv6, UDP Lite, High Availability, Retransmit config parameters, Global AP failover, Hyperlocation config parameters, Telnet and SSH, 11u parameters, and so on.

Note Telnet is not supported for the following Cisco AP models: 1542D, 1542I, 1562D, 1562E, 1562I, 1562PS, 1800S, 1800T, 1810T, 1810W, 1815M, 1815STAR, 1815TSN, 1815T, 1815W, 1832I, 1840I, 1852E, 1852I, 2802E, 2802I, 2802H, 3700C, 3800, 3802E, 3802I, 3802P, 4800, IW6300, ESW6300, 9105AXI, 9105AXW, 9115AXI, 9115AXE, 9117I, APVIRTUAL, 9120AXI, 9120AXE, 9124AXI, 9124AXD, 9130AXI, 9130AXE, 9136AXI, 9162I, 9164I, and 9166I.

RF Profile

RF profile contains the common radio configuration for the APs. RF profiles are applied to all the APs that belong to an AP group, where all the APs in that group have the same profile settings.

Some of the 6-GHz band specific 802.11ax features like Unsolicited Broadcast Probe Response, FILS Discovery, Multi-BSSID reduce the overhead of management traffic in 6-GHz band channels. Preferred Scanning Channels is another feature in 6-GHz band which helps RRM to choose PSC channels to 6-GHz radios.

Association of APs

APs can be associated using different ways. The default option is by using Ethernet MAC address, where the MAC is associated with policy-tag, site tag, and RF tag.

In filter-based association, APs are mapped using regular expressions. A regular expression (regex) is a pattern to match against an input string. Any number of APs matching that regex will have policy-tag, site tag, and RF tag mapped to them, which is created as part of the AP filter.

In AP-based association, tag names are configured at the PnP server and the AP stores them and sends the tag name as part of discovery process.

In location-based association, tags are mapped as per location and are pushed to any AP Ethernet MAC address mapped to that location.

Modifying AP Tags

Modifying an AP tag results in DTLS connection reset, forcing the AP to rejoin the controller. If only one tag is specified in the configuration, default tags are used for other types, for example, if only policy tag is specified, the default-site-tag and default-rf-tag will be used for site tag and RF tag.

Configuring a Wireless Profile Policy (GUI)

Procedure

-
- Step 1** Choose **Configuration** > **Tags & Profiles** > **Policy**.
- Step 2** On the **Policy Profile** page, click **Add**.
- Step 3** In the **Add Policy Profile** window, in **General** tab, enter a name and description for the policy profile. The name can be ASCII characters from 32 to 126, without leading and trailing spaces. Do not use spaces as it causes system instability.
- Step 4** To enable the policy profile, set **Status** as **Enabled**.
- Step 5** Use the slider to enable or disable **Passive Client** and **Encrypted Traffic Analytics**.
- Step 6** In the **CTS Policy** section, choose the appropriate status for the following:
- Inline Tagging—a transport mechanism using which a controller or access point understands the source SGT.
 - SGACL Enforcement
- Step 7** Specify a default **SGT**. The valid range is from 2 to 65519.
- Step 8** In the **WLAN Switching Policy** section, choose the following, as required:
- Central Switching: Tunnels both the wireless user traffic and all control traffic via CAPWAP to the centralized controller where the user traffic is mapped to a dynamic interface/VLAN on the controller. This is the normal CAPWAP mode of operation.
 - Central Authentication: Tunnels client data to the controller, as the controller handles client authentication.
 - Central DHCP: The DHCP packets received from AP are centrally switched to the controller and then forwarded to the corresponding VLAN based on the AP and the SSID.
 - Central Association Enable: When central association is enabled, all switching is done on the controller.
 - Flex NAT/PAT: Enables Network Address Translation(NAT) and Port Address Translation (PAT) mode.
- Step 9** Click **Save & Apply to Device**.
-

Configuring a Wireless Profile Policy (CLI)

Follow the procedure given below to configure a wireless profile policy:

Note When a client moves from an old controller to a new controller (managed by Cisco Prime Infrastructure), the old IP address of the client is retained, if the IP address is learned by ARP or data gleaning. To avoid this scenario, ensure that you enable **ipv4 dhcp required** command in the policy profile. Otherwise, the IP address gets refreshed only after a period of 24 hours.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy rr-xyz-policy-1	Configures WLAN policy profile and enters wireless policy configuration mode.
Step 3	idle-timeout <i>timeout</i> Example: Device(config-wireless-policy)# idle-timeout 1000	(Optional) Configures the duration of idle timeout, in seconds.
Step 4	vlan <i>vlan-id</i> Example: Device(config-wireless-policy)# vlan 24	Configures VLAN name or VLAN ID.
Step 5	accounting-list <i>list-name</i> Example: Device(config-wireless-policy)# accounting-list user1-list	Sets the accounting list for IEEE 802.1x.
Step 6	no shutdown Example: Device(config-wireless-policy)# no shutdown	Saves the configuration and exits configuration mode and returns to privileged EXEC mode.
Step 7	show wireless profile policy summary Example: Device# show wireless profile policy summary	Displays the configured policy profiles. Note (Optional) To view detailed information about a policy profile, use the show wireless profile policy detailed <i>policy-profile-name</i> command.

Configuring a Flex Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Flex**.
 - Step 2** Click **Add**.
 - Step 3** Enter the **Name** of the Flex Profile. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
 - Step 4** In the **Description** field, enter a description for the Flex Profile.
 - Step 5** Click **Apply to Device**.
-

Configuring a Flex Profile

Follow the procedure given below to set a flex profile:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex <i>flex-profile</i> Example: Device(config)# wireless profile flex rr-xyz-flex-profile	Configures a Flex profile and enters Flex profile configuration mode.
Step 3	description Example: Device(config-wireless-flex-profile)# description xyz-default-flex-profile	(Optional) Enables default parameters for the flex profile.
Step 4	arp-caching Example: Device(config-wireless-flex-profile)# arp-caching	(Optional) Enables ARP caching.
Step 5	end Example: Device(config-wireless-flex-profile)# end	Saves the configuration and exits configuration mode and returns to privileged EXEC mode.

	Command or Action	Purpose
Step 6	show wireless profile flex summary Example: Device# show wireless profile flex summary	(Optional) Displays the flex-profile parameters. Note To view detailed parameters about the flex profile, use the show wireless profile flex detailed flex-profile-name command.

Configuring an AP Profile (GUI)

Before you begin

The default AP join profile values will have the global AP parameters and the AP group parameters. The AP join profile contains attributes that are specific to AP, such as CAPWAP, IPv4/IPv6, UDP Lite, High Availability, retransmit configuration parameters, global AP failover, Hyperlocation configuration parameters, Telnet/SSH, 11u parameters, and so on.

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
- Step 2** On the **AP Join Profile** page, click **Add**.
- The **Add AP Join Profile** page is displayed.
- Note** DHCP fallback is enabled by default. So, if an AP is assigned a static IP address and unable to reach the controller, the AP falls back to the DHCP. To stop an AP from moving the static IP to DHCP, you must disable the DHCP fallback configuration in an AP join profile.
- Step 3** In the **General** tab, enter a name and description for the AP join profile. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
- Step 4** Check the **LED State** check box to set the LED state of all APs connected to the device to blink so that the APs are easily located. The LED state is enabled by default.
- Step 5** In the **Client** tab and **Statistics Timer** section, enter the time in seconds that the AP sends its 802.11 statistics to the controller.
- Step 6** In the **TCP MSS Configuration** section, check the **Adjust MSS Enable** check box to enter value for Adjust MSS. You can enter or update the maximum segment size (MSS) for transient packets that traverse a router. TCP MSS adjustment enables the configuration of the maximum segment size (MSS) for transient packets that traverse a router, specifically TCP segments with the SYN bit set.
- In a CAPWAP environment, a lightweight access point discovers a device by using CAPWAP discovery mechanisms, and then sends a CAPWAP join request to the device. The device sends a CAPWAP join response to the access point that allows the access point to join the device.
- When the access point joins the device, the device manages its configuration, firmware, control transactions, and data transactions.
- Step 7** In the **CAPWAP** tab, you can configure the following:

- High Availability

You can configure primary and secondary backup controllers for all access points (which are used if primary, secondary, or tertiary controllers are not responsive) in this order: primary, secondary, tertiary, primary backup, and secondary backup. In addition, you can configure various timers, including heartbeat timers and discovery request timers. To reduce the controller failure detection time, you can configure the fast heartbeat interval (between the controller and the access point) with a smaller timeout value. When the fast heartbeat timer expires (at every heartbeat interval), the access point determines if any data packets have been received from the controller within the last interval. If no packets have been received, the access point sends a fast echo request to the controller.

- In the **High Availability** tab, enter the time (in seconds) in the **Fast Heartbeat Timeout** field to configure the heartbeat timer for all access points. Specifying a small heartbeat interval reduces the amount of time it takes to detect device failure.

Note Configure **Fast Heartbeat Timeout** to assist AP in sending primary discovery request periodically to the configured backup controllers along with the primary, secondary, and tertiary-base controllers.

- In the **Heartbeat Timeout** field, enter the time (in seconds) to configure the heartbeat timer for all access points. Specifying a small heartbeat interval reduces the amount of time it takes to detect device failure.
- In the **Discovery Timeout** field, enter a value between 1 and 10 seconds (inclusive) to configure the AP discovery request timer.
- In the **Primary Discovery Timeout** field, enter a value between 30 and 3000 seconds (inclusive) to configure the access point primary discovery request timer.
- In the **Primed Join Timeout** field, enter a value between 120 and 43200 seconds (inclusive) to configure the access point primed join timeout.
- In the **Retransmit Timers Count** field, enter the number of times that you want the AP to retransmit the request to the device and vice-versa. Valid range is between 3 and 8.
- In the **Retransmit Timers Interval** field, enter the time duration between retransmission of requests. Valid range is between 2 and 5.
- Check the **Enable Fallback** check box to enable fallback.
- Enter the **Primary Controller** name and IP address.
- Enter the **Secondary Controller** name and IP address.
- Click **Save & Apply to Device**.

Note The primary and secondary settings in the AP join profile are not used for AP fallback. This means that the AP will not actively probe for those controllers (which are a part of the AP join profile), when it has joined one of them.

This setting is used only when the AP loses its connection with the controller, and then prioritizes which other controller it should join. These controllers have a priority of 4 and 5, following APs in the **High Availability** tab of the AP page.

The APs that are added as the primary, secondary, and tertiary APs in the **High Availability** tab of the AP configuration page, are actively probed and are used for the AP fallback option.

- Advanced

- In the **Advanced** tab, check the **Enable VLAN Tagging** check box to enable VLAN tagging.
- Check the **Enable Data Encryption** check box to enable Datagram Transport Layer Security (DTLS) data encryption.

- c) Check the **Enable Jumbo MTU** to enable big maximum transmission unit (MTU). MTU is the largest physical packet size, measured in bytes, that a network can transmit. Any messages larger than the MTU are divided into smaller packets before transmission. Jumbo frames are frames that are bigger than the standard Ethernet frame size, which is 1518 bytes (including Layer 2 (L2) header and FCS). The definition of frame size is vendor-dependent, as these are not part of the IEEE standard.
- d) Use the **Link Latency** drop-down list to select the link latency. Link latency monitors the round-trip time of the CAPWAP heartbeat packets (echo request and response) from the AP to the controller and back.
- e) From the **Preferred Mode** drop-down list, choose the mode.
- f) Click **Save & Apply to Device**.

Step 8

In the **AP** tab, you can configure the following:

- General

- a) In the **General** tab, check the **Switch Flag** check box to enable switches.
- b) Check the **Power Injector State** check box if power injector is being used. Power Injector increases wireless LAN deployment flexibility of APs by providing an alternative powering option to local power, inline power-capable multiport switches, and multiport power patch panels.

Power Injector Selection parameter enables you to protect your switch port from an accidental overload if the power injector is inadvertently bypassed.

- c) From the **Power Injector Type** drop-down list, choose power injector type from the following options:
 - Installed—This option examines and remembers the MAC address of the currently connected switch port and assumes that a power injector is connected. Choose this option if your network contains older Cisco 6-Watt switches and you want to avoid possible overloads by forcing a double-check of any relocated access points.

If you want to configure the switch MAC address, enter the MAC address in the Injector Switch MAC Address text box. If you want the access point to find the switch MAC address, leave the Injector Switch MAC Address text box blank.

Note Each time an access point is relocated, the MAC address of the new switch port fails to match the remembered MAC address, and the access point remains in low-power mode. You must then physically verify the existence of a power injector and reselect this option to cause the new MAC address to be remembered.

- Override—This option allows the access point to operate in high-power mode without first verifying a matching MAC address. You can use this option if your network does not contain any older Cisco 6-W switches that could be overloaded if connected directly to a 12-W access point. The advantage of this option is that if you relocate the access point, it continues to operate in high-power mode without any further configuration. The disadvantage of this option is that if the access point is connected directly to a 6-W switch, an overload occurs.
- d) In the **Injector Switch MAC** field, enter the MAC address of the switch either in xx:xx:xx:xx:xx:xx, xx-xx-xx-xx-xx-xx, or xxxx.xxxx.xxxx format.
 - e) From the **EAP Type** drop-down list, choose the EAP type as *EAP-FAST*, *EAP-TLS*, or *EAP-PEAP*.
 - f) From the **AP Authorization Type** drop-down list, choose the type as either *CAPWAP DTLS +* or *CAPWAP DTLS*.
 - g) In the **Client Statistics Reporting Interval** section, enter the interval for 5 GHz and 2.4 GHz radios in seconds.
 - h) Check the **Enable** check box to enable extended module.

- i) From the **Profile Name** drop-down list, choose a profile name for mesh.
- j) Click **Save & Apply to Device**.
 - **Hyperlocation**: Cisco Hyperlocation is a location solution that allows to track the location of wireless clients with the accuracy of one meter. Selecting this option disables all other fields in the screen, except NTP Server.
- a) In the **Hyperlocation** tab, check the **Enable Hyperlocation** check box.
- b) Enter the **Detection Threshold** value to filter out packets with low RSSI. The valid range is –100 dBm to –50 dBm.
- c) Enter the **Trigger Threshold** value to set the number of scan cycles before sending a BAR to clients. The valid range is 0 to 99.
- d) Enter the **Reset Threshold** value to reset value in scan cycles after trigger. The valid range is 0 to 99.
- e) Enter the **NTP Server** IP address.
- f) Click **Save & Apply to Device**.
 - **BLE**: If your APs are Bluetooth Low Energy (BLE) enabled, they can transmit beacon messages that are packets of data or attributes transmitted over a low energy link. These BLE beacons are frequently used for health monitoring, proximity detection, asset tracking, and in-store navigation. For each AP, you can customize BLE Beacon settings configured globally for all APs.
- a) In the **BLE** tab, enter a value in the **Beacon Interval** field to indicate how often you want your APs to send out beacon advertisements to nearby devices. The range is from 1 to 10, with a default of 1.
- b) In the **Advertised Attenuation Level** field, enter the attenuation level. The range is from 40 to 100, with a default of 59.
- c) Click **Save & Apply to Device**.
 - **Packet Capture**: Packet Capture feature allows to capture the packets on the AP for the wireless client troubleshooting. The packet capture operation is performed on the AP by the radio drivers on the current channel on which it is operational, based on the specified packet capture filter.
- a) In the **Packet Capture** tab, choose an **AP Packet Capture Profile** from the drop-down list.
- b) You can also create a new profile by clicking the + sign.
- c) Enter a name and description for the AP packet capture profile.
- d) Enter the **Buffer Size**.
- e) Enter the **Duration**.
- f) Enter the **Truncate Length** information.
- g) In the **Server IP** field, enter the IP address of the TFTP server.
- h) In the **File Path** field, enter the directory path.
- i) Enter the username and password details.
- j) From the **Password Type** drop-down list, choose the type.
- k) In the **Packet Classifiers** section, use the option to select or enter the packets to be captured.
- l) Click **Save**.
- m) Click **Save & Apply to Device**.

Step 9

In the **Management** tab, you can configure the following:

- **Device**
 - a) In the **Device** tab, enter the **IPv4/IPv6 Address** of the TFTP server, **TFTP Downgrade** section.
 - b) In the **Image File Name** field, enter the name of the software image file.

- c) From the **Facility Value** drop-down list, choose the appropriate facility.
- d) Enter the IPv4 or IPv6 address of the host.
- e) Choose the appropriate **Log Trap Value**.
- f) Enable Telnet and/or SSH configuration, if required.
- g) Enable core dump, if required.
- h) Click **Save & Apply to Device**.

- User

- a) In the **User** tab, enter username and password details.
- b) Choose the appropriate password type.
- c) In the **Secret** field, enter a custom secret code.
- d) Choose the appropriate secret type.
- e) Choose the appropriate encryption type.
- f) Click **Save & Apply to Device**.

- Credentials

- a) In the **Credentials** tab, enter local username and password details.
- b) Choose the appropriate local password type.
- c) Enter 802.1x username and password details.
- d) Choose the appropriate 802.1x password type.
- e) Enter the time in seconds after which the session should expire.
- f) Enable local credentials and/or 802.1x credentials as required.
- g) Click **Save & Apply to Device**.

- CDP Interface

- a) In the **CDP Interface** tab, enable the CDP state, if required.
- b) Click **Save & Apply to Device**.

Step 10 In the **Rogue AP** tab, check the **Rogue Detection** check box to enable rogue detection.

Step 11 In the **Rogue Detection Minimum RSSI** field, enter the RSSI value.

This field specifies the minimum RSSI value for which a Rogue AP should be reported. All Rogue APs with RSSI lower than what is configured will not be reported to controller.

Step 12 In the **Rogue Detection Transient Interval** field, enter the transient interval value.

This field indicates how long the Rogue AP should be seen before reporting the controller.

Step 13 In the **Rogue Detection Report Interval** field, enter the report interval value.

This field indicates the frequency (in seconds) of Rogue reports sent from AP to controller.

Step 14 Check the **Rogue Containment Automatic Rate Selection** check box to enable rogue containment automatic rate selection.

Here, the AP selects the best rate for the target Rogue, based on its RSSI.

Step 15 Check the **Auto Containment on FlexConnect Standalone** check box to enable the feature.

Here, the AP will continue containment in case it moves to FlexConnect standalone mode.

Step 16 Click **Save & Apply to Device**.

Configuring an AP Profile (CLI)

Follow the procedure given below to configure and AP profile:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# ap profile xyz-ap-profile	Configures an AP profile and enters AP profile configuration mode. Note In an AP profile, the EAP-FAST is the default EAP type. Note When you delete a named profile, the APs associated with that profile will not revert to the default profile.
Step 3	description <i>ap-profile-name</i> Example: Device(config-ap-profile)# description "xyz ap profile"	Adds a description for the ap profile.
Step 4	ip dhcp fallback Example: Device(config-ap-profile)# ip dhcp fallback	Configures DHCP fallback. Note DHCP fallback is enabled by default. So, if an AP is assigned a static IP address and unable to reach the controller, the AP falls back to the DHCP. To stop an AP from moving the static IP to DHCP, you must disable the DHCP fallback configuration in an AP join profile.
Step 5	cdp Example: Device(config-ap-profile)# cdp	Enables CDP for all Cisco APs.
Step 6	end Example:	Saves the configuration and exits configuration mode and returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config-ap-profile)# end	
Step 7	show ap profile name <i>profile-name</i> detailed Example: Device# show ap profile name xyz-ap-profile detailed	(Optional) Displays detailed information about an AP join profile.

Configuring User for AP Management (CLI)

Follow the procedure given below to configure a user for the AP management:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# ap profile default-ap-profile	Configures an AP profile and enters AP profile configuration mode.
Step 3	mgmtuser username <username> password {0 8} <password> Example: Device(config-ap-profile)# mgmtuser username myusername password 0 12345678	Specifies the AP management username and password for managing all of the access points configured to the controller. <ul style="list-style-type: none"> • 0: Specifies an UNENCRYPTED password. • 8: Specifies an AES encrypted password. <p>Note While configuring an username, ensure that special characters are not used as it results in error with bad configuration.</p>
Step 4	end Example: Device(configure-ap-profile)# end	Returns to privileged EXEC mode.

Setting a Private Configuration Key for Password Encryption

Follow the procedure given below to set a private configuration key for password encryption:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	key config-key password encrypt key <config-key> Example: Device(config)# key config-key password-encrypt 12345678	Sets the password encryption keyword. Here, <i>config-key</i> refers to any key value with minimum 8 characters. Note The <i>config-key</i> value must not begin with the following special characters: !, #, and ;
Step 3	password encryption aes Example: Device(config)# password encryption aes	Enables the encrypted preshared key.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring an RF Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration** > **Tags & Profiles** > **RF**.
 - Step 2** On the **RF Profile** page, click **Add**.
 - Step 3** In the **General** tab, enter a name for the RF profile. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
 - Step 4** Choose the appropriate **Radio Band**.
 - Step 5** To enable the profile, set the status as **Enable**.
 - Step 6** Enter a **Description** for the RF profile.
 - Step 7** Click **Save & Apply to Device**.
-

Configuring an RF Profile (CLI)

Follow the procedure given below to configure an RF profile:

Before you begin

Ensure that you use the same RF profile name that you create here, when configuring the wireless RF tag too. If there is a mismatch in the RF profile name (for example, if the RF tag contains an RF profile that does not exist), the corresponding radios will not come up.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 24ghz rf-profile <i>rf-profile</i> Example: Device(config)# ap dot11 24ghz rf-profile rfprof24_1	Configures an RF profile and enters RF profile configuration mode. Note Use the 24ghz command to configure the 802.11b parameters. Use the 5ghz command to configure the 802.11a parameters. Use the 6ghz command to configure the 802.11 6-GHz parameters.
Step 3	default Example: Device(config-rf-profile)# default	(Optional) Enables default parameters for the RF profile.
Step 4	no shutdown Example: Device(config-rf-profile)# no shutdown	Enables the RF profile on the device.
Step 5	end Example: Device(config-rf-profile)# end	Exits configuration mode and returns to privileged EXEC mode.
Step 6	show ap rf-profile summary Example: Device# show ap rf-profile summary	(Optional) Displays the summary of the available RF profiles.
Step 7	show ap rf-profile name <i>rf-profile</i> detail Example: Device# show ap rf-profile name rfprof24_1 detail	(Optional) Displays detailed information about a particular RF profile.

Configuring a Site Tag (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Tags**.
- Step 2** On the **Manage Tags** page, click the **Site** tab.
- Step 3** Click **Add** to view the **Add Site Tag** window.
- Step 4** Enter a name and description for the site tag. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
- Step 5** Choose the required **AP Join Profile** to be attached to the site tag.
- Step 6** Choose the required **Control Plane Name**.
- Step 7** If required, enable the **Local Site**.
- Disabling Local Site means that the site is remote and the deployment is FlexConnect mode.
- Step 8** Click **Save & Apply to Device**.
-

Configuring a Site Tag (CLI)

Follow the procedure given below to configure a site tag:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag site <i>site-name</i> Example: Device(config)# wireless tag site rr-xyz-site	Configures a site tag and enters site tag configuration mode.
Step 3	flex-profile <i>flex-profile-name</i> Example: Device(config-site-tag)# flex-profile rr-xyz-flex-profile	Configures a flex profile. Note You cannot remove the flex profile configuration from a site tag if local site is configured on the site tag.

	Command or Action	Purpose
		<p>Note The no local-site command needs to be used to configure the Site Tag as Flexconnect, otherwise the Flex profile config does not take effect.</p>
Step 4	<p>description <i>site-tag-name</i></p> <p>Example:</p> <pre>Device(config-site-tag)# description "default site tag"</pre>	Adds a description for the site tag.
Step 5	<p>end</p> <p>Example:</p> <pre>Device(config-site-tag)# end</pre>	Saves the configuration and exits configuration mode and returns to privileged EXEC mode.
Step 6	<p>show wireless tag site summary</p> <p>Example:</p> <pre>Device# show wireless tag site summary</pre>	<p>(Optional) Displays the number of site tags.</p> <p>Note To view detailed information about a site, use the show wireless tag site detailed <i>site-tag-name</i> command.</p> <p>Note The output of the show wireless loadbalance tag affinity wncd <i>wncd-instance-number</i> command displays default tag (site-tag) type, if both site tag and policy tag are not configured.</p>

Enhanced Site Tag-Based Load Balancing

Feature History for Enhanced Site Tag-Based Load Balancing

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 1: Feature History for Enhanced Site Tag-Based Load Balancing

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.10.1	Enhanced Site Tag-Based Load Balancing	<p>The Site Tag-based load balancing is available from Cisco IOS-XE Gibraltar 16.10.1 release.</p> <p>When the first AP from a site joins the controller, it takes the decision to load balance the entire site. However, this is done without knowing the site load.</p> <p>The enhancement to load balancing feature introduced in Cisco IOS-XE 17.10.1 specifies a site load to help with better load balancing.</p>

Information About Enhanced Site Tag-Based Load Balancing

Load balancing of APs is done among session handling processes called Wireless Network Control Daemon (WNCD). The load balancer assigns APs to WNCDs based on site tags. The decision to load balance a site tag to a WNCD is taken when the first AP from that site tag joins the controller.

Prior to this enhancement, the controller had no indication about the size of the site. Therefore, the site size is not taken into consideration for this load balancing decision. The system works well only if the sites are of approximately equal size. However, in case where you have sites of disparate sizes, it is possible for some WNCDs to be more loaded than the others. This enhancement allows you to configure a site load, thus allowing the system to take better load balancing decisions.

The behavior of the load balancing feature in the controller reboot case is as follows:

- After you have configured the feature in one or more site tags and rebooted the controller, after the reboot, even before any APs join, the load balancing feature retains the site tags that are used actively in persistent memory and load balances them during bootup. The load balancing during bootup occurs in descending order of the configured site load.
- After you have configured the load balancing feature in a site tag with APs already joined, the load balancing remains unchanged unless all APs, including those not in the site tag, disconnects or the controller reboots.

Prerequisites for Enhanced Site Tag-Based Load Balancing

- You must have configured the site load.
- We recommended that you configure all the named sites with a load value.

Note The configured load is only an estimate. It will only be used for site load balancing. Specifically, it does not prevent APs, or clients from joining or associating.

Use Cases

To cater to a variety of use cases, the site load configuration is designed to be a load factor rather than an absolute number. Specifically, it need not be the number of APs in a site, although, for most practical purposes, the number of APs can be used as a good approximation of the load. The following are the two use cases:

- Sites with normal client density and roaming load. You can use AP count as a good approximate site load in these cases. Examples of such sites are cubicle areas in offices and hospitals.
- Sites with high client density and roaming load. For these, you can use a higher load configuration than the number of APs. For example, if the number of APs in such a site is 200, you can use a load factor of 300 or 400 to compensate for higher client load. Examples of such sites include stadiums, cafeterias, and conference floors.

Configuring Site Load (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag site <i>site-tag</i> Example: Device(config)# wireless tag site areal	Configures site tag and enters site tag configuration mode.
Step 3	load <i>load</i> Example: Device(config-site-tag)# load 200	Configures the site load. The <i>load</i> is the estimate of the relative load reserved for the site. Values range between 0 to 1000. The default value 0 means no load recommendation for the site.
Step 4	end Example: Device(config-site-tag)# end	Returns to privileged EXEC mode.

Verifying Enhanced Site Tag-Based Load Balancing Configuration

To view detailed information about a site, use the following command:

```
Device# show wireless tag site detailed areal
Site Tag Name      : areal
Description       :
-----
AP Profile        : default-ap-profile
Local-site        : Yes
Image Download Profile: default
Fabric AP DHCP Broadcast : Disabled
```

```
Fabric Multicast Group IPv4 Address : 232.255.255.1
Site Load : 200
```

To view the default site tag type for WNCN instances, use the following command:

```
Device# show wireless loadbalance tag affinity
Tag          Tag type      No of AP's Joined  Wncd Instance
-----
area1        SITE TAG      50                 0
area2        SITE TAG      50                 0
area3        SITE TAG      100                1
area4        SITE TAG      150                2
```

Configuring Policy Tag (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Tags > Policy**.
 - Step 2** Click **Add** to view the **Add Policy Tag** window.
 - Step 3** Enter a name and description for the policy tag. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
 - Step 4** Click **Add** to map WLAN and policy.
 - Step 5** Choose the WLAN profile to map with the appropriate policy profile, and click the tick icon.
 - Step 6** Click **Save & Apply to Device**.
-

Configuring a Policy Tag (CLI)

Follow the procedure given below to configure a policy tag:

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	wireless tag policy <i>policy-tag-name</i> Example:	Configures policy tag and enters policy tag configuration mode.

	Command or Action	Purpose
	<code>Device(config-policy-tag)# wireless tag policy default-policy-tag</code>	Note When performing LWA, the clients connected to a controller gets disconnected intermittently before session timeout.
Step 4	description <i>description</i> Example: <code>Device(config-policy-tag)# description "default-policy-tag"</code>	Adds a description to a policy tag.
Step 5	remote-lan <i>name</i> policy <i>profile-policy-name</i> { <i>ext-module</i> port-id } Example: <code>Device(config-policy-tag)# remote-lan rr-xyz-rlan-aa policy rr-xyz-rlan-policy1 port-id 2</code>	Maps a remote-LAN profile to a policy profile.
Step 6	wlan <i>wlan-name</i> policy <i>profile-policy-name</i> Example: <code>Device(config-policy-tag)# wlan rr-xyz-wlan-aa policy rr-xyz-policy-1</code>	Maps a policy profile to a WLAN profile. Note Ensure that the WLAN profile is not used by any other profiles. If the AP uses the default profile, ensure that the no central switching command is configured on other profiles.
Step 7	end Example: <code>Device(config-policy-tag)# end</code>	Exits policy tag configuration mode, and returns to privileged EXEC mode.
Step 8	show wireless tag policy summary Example: <code>Device# show wireless tag policy summary</code>	(Optional) Displays the configured policy tags. Note To view detailed information about a policy tag, use the show wireless tag policy detailed <i>policy-tag-name</i> command.

Configuring Wireless RF Tag (GUI)

Procedure

-
- Step 1** a) Choose **Configuration > Tags & Profiles > Tags > RF**.
- Step 2** Click **Add** to view the **Add RF Tag** window.

- Step 3** Enter a name and description for the RF tag. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
- Step 4** Choose the required **5 GHz Band RF Profile**, **5 GHz Band RF Profile**, and **2.4 GHz Band RF Profile** to be associated with the RF tag.
- Step 5** Click **Update & Apply to Device**.

Configuring Wireless RF Tag (CLI)

Follow the procedure given below to configure a wireless RF tag:

Before you begin

- You can use only two profiles (2.4-GHz and 5-GHz band RF profiles) in an RF tag.
- You can use only three profiles (2.4-GHz, 5-GHz and 6GHz band RF profiles) in an RF tag.
- Ensure that you use the same AP tag name that you created when configuring the AP tag task too.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag rf rf-tag Example: Device(config)# wireless tag rf rftag1	Creates an RF tag and enters wireless RF tag configuration mode.
Step 3	24ghz-rf-policy rf-policy Example: Device(config-wireless-rf-tag)# 24ghz-rf-policy rfprof24_1	Attaches an IEEE 802.11b RF policy to the RF tag. To configure a dot11a policy, use the 5ghz-rf-policy command. To configure a 6GHz radio dot11 policy, use the 6ghz-rf-policy command.
Step 4	description policy-description Example: Device(config-wireless-rf-tag)# description Test	Adds a description for the RF tag.
Step 5	end Example: Device(config-wireless-rf-tag)# end	Exits configuration mode and returns to privileged EXEC mode.

	Command or Action	Purpose
Step 6	show wireless tag rf summary Example: Device# show wireless tag rf summary	Displays the available RF tags.
Step 7	show wireless tag rf detailed <i>rf-tag</i> Example: Device# show wireless tag rf detailed rftag1	Displays detailed information of a particular RF tag.

Attaching a Policy Tag and Site Tag to an AP (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
- The **All Access Points** section displays details of all the APs on your network.
- Step 2** To edit the configuration details of an AP, select the row for that AP.
- The **Edit AP** window is displayed.
- Step 3** In the **General** tab and **Tags** section, specify the appropriate policy, site, RF tags, and radio profile that you created on the **Configuration > Tags & Profiles > Tags** page.
- Step 4** Click **Update & Apply to Device**.
-

Attaching Policy Tag and Site Tag to an AP (CLI)

Follow the procedure given below to attach a policy tag and a site tag to an AP:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap <i>mac-address</i> Example: Device(config)# ap F866.F267.7DFB	Configures a Cisco AP and enters AP profile configuration mode. Note The <i>mac-address</i> should be a wired mac address.

	Command or Action	Purpose
Step 3	policy-tag <i>policy-tag-name</i> Example: Device(config-ap-tag)# policy-tag rr-xyz-policy-tag	Maps a policy tag to the AP.
Step 4	site-tag <i>site-tag-name</i> Example: Device(config-ap-tag)# site-tag rr-xyz-site	Maps a site tag to the AP.
Step 5	rf-tag <i>rf-tag-name</i> Example: Device(config-ap-tag)# rf-tag rf-tag1	Associates the RF tag.
Step 6	end Example: Device(config-ap-tag)# end	Saves the configuration, exits configuration mode, and returns to privileged EXEC mode.
Step 7	show ap tag summary Example: Device# show ap tag summary	(Optional) Displays AP details and the tags associated to it.
Step 8	show ap name <ap-name> tag info Example: Device# show ap name ap-name tag info	(Optional) Displays the AP name with tag information.
Step 9	show ap name <ap-name> tag detail Example: Device# show ap name ap-name tag detail	(Optional) Displays the AP name with tag details.

Configuring a Radio Profile

Information About Wireless Radio Profile

From Cisco IOS XE Bengaluru 17.6.1 onwards, you can configure radio profiles for the slots in access points (APs). In this release, you can configure radio profiles for beam-selection APs with the C-ANT9104 antenna and configure antenna count for Cisco Catalyst 9124AXI/D outdoor Access Points. You can configure the antenna beam-selection for the 5-GHz slots—slot 1 and slot 2. Because there is no default value for the beam-selection configuration, you must explicitly configure the beam selection mode for APs with the C-ANT9104 antenna.

The C-ANT9104 antenna-enabled Cisco Catalyst 9130AX Series APs have precise control over the antennae pattern. Therefore, a configuration knob in the controller is introduced to select the beam-steering direction

for the antennae. The C-ANT9104 antenna-enabled Cisco Catalyst 9130AX Series APs can operate on the following beam-steering modes:

- Wide beam
- Narrow beam
- Narrow beam with 10 degrees tilt
- Narrow beam with 20 degrees tilt

After creating the radio profile, you must link or attach the radio profile under the radio frequency (RF) tag configuration, so that the radio profile is applied to the APs.

Note When you add Cisco ANT9104 antennas to the wireless controller, RRM configuration is not supported for these antennas.

RRM features such as Dynamic Channel Assignment (DCA), Radio Transmit Power Control (TPC), Flexible Radio Assignment (FRA), and so on, are disabled on C-ANT9104 antenna-enabled Cisco Catalyst 9130 Series Access Points.

The sections in this topic describe the steps to configure radio profile, beam selection, antenna count, and how to link the radio profile to the slots.

Note Cisco Catalyst 9130 Series Access Points enabled with Cisco ANT9104 antenna are able to function with unsupported versions, for example, Cisco IOS XE Bengaluru 17.5.1.

If the AP that is enabled with Cisco ANT9104 antenna, has a software version that is earlier than Cisco IOS XE 17.6.1, the AP joins the controller but the AP will not be functional as the operation status of the radios will be down.

Configuring a Wireless Radio Profile (GUI)

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > RF/Radio**.
- Step 2** On the **Radio Profile** page, click **Add**.
- Step 3** Enter a name for the Radio profile. Enter a description for the Radio profile.
- Step 4** Choose the appropriate **Antenna Beam** selection.
- Note** The antenna beam selection is set to **Not Configured** if no settings are detected. This option is to be configured for APs connected with the C-ANT9104 antenna.
- Step 5** Enter the number in the **Number of antenna to be enabled** field.
- Note** The option is available for the Cisco Catalyst 9124AXE Outdoor Access Points.

Step 6 Click **Save & Apply to Device**.

Configuring a Radio Profile and Beam Selection

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile radio <i>wireless-radio-profile</i> Example: Device(config)# wireless profile radio <i>wireless-radio-profile</i>	Configures the radio profile. Enters the wireless radio profile configuration mode.
Step 3	antenna beam-selection { narrow tilt { 10 20 } wide } Example: Device(config-wireless-radio-profile)# antenna beam-selection narrow tilt 10	Configures the beam selection of the antenna under the new radio profile.

Configuring the Antenna Count in a Wireless Radio Profile

To configure the number of antennae for each slot, complete the following steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile radio <i>wireless-radio-profile</i> Example: Device(config)# wireless profile radio <i>wireless-radio-profile</i>	Configures the radio profile. Enters the wireless radio profile configuration mode.
Step 3	antenna count <0 - 8> Example: Device(config-wireless-radio-profile)# antenna count 4	Configures the number of antennas to be enabled under the new radio profile.

Configuring a Slot Per Radio in the RF Tag Profile

It is mandatory to link radio profiles under an RF tag for the radio profile configurations to get applied. To configure a radio profile for each slot in an RF tag profile, complete the following steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag rf <i>wireless-rf-tagname</i> Example: Device(config)# wireless tag rf <i>wireless-rf-tagname</i>	Configures the RF tag. Enters the wireless RF tag configuration mode.
Step 3	dot11 { 24ghz slot0 5ghz { slot1 slot2 } radio-profile <i>radio-profile-name</i> } Example: Device(config-wireless-rf-tag)# dot11 5ghz slot1 radio-profile <i>wireless-radio-profile</i>	Configures the 802.11a/802.11b radio profile.

Verifying a Radio Profile

To view the summary of all the configured radio profiles, use the following command:

```
Device# show wireless profile radio summary
```

```
Number of radio-profiles: 3
```

```
Antenna Profile Name          Description
-----
radio-profile-1              Custom profile for Slot1
antenna-ewlc                 Add description
default_radio_profile        Preconfigured default radio profile
```

To view detailed information about the parameters configured for a radio profile, use the following command:

```
Device# show wireless profile radio detailed radio-profile-name
Radio Profile name           : radio-profile-1
Description                   : Custom profile for slot1
Beam-Selection                : Wide beam
```

To view radio profile and RF tag information, use the following command:

```
Device # show ap name Cisco-AP tag info
AP Name                       : Cisco-AP
AP Mac                         : 04xx.40xx.XXXX
```

```
Applied Tags :
```

```
-----
Tag Type          Tag Name
-----
```

```

RF Tag          test-rf
Site Tag        default-site-tag
Policy Tag      default-policy-tag

```

```

Tag/Profile Type Misconfigured
-----

```

```

RF Tag No
Policy Tag No
Site Tag No
Flex profile No
AP join profile No
2.4GHz Rf Profile No
5 GHz Rf Profile No
5 GHz Slot1 Radio Profile NO
5 GHz Slot2 Radio Profile Yes

```

```

Resolved Tags :
-----

```

```

Tag Source      : Static

```

```

Tag Type      Tag Name
-----
RF Tag        test-rf
Site Tag      default-site-tag
Policy Tag    default-policy-tag

```

To display beam selection and the number of antennas, run the following commands:

```

Device# show wireless profile radio detailed radio-profile-1
Radio Profile name : radio-profile-1
Description        : Custom profile for slot1
Beam-Selection     : Wide beam

```

```

Device# show ap name cisco-ap config slot 1 | section 11n
802.11n Antennas
      Number of Antennas selected           : 2
      Supported Antenna modes              : 1x1 2x2 4x4
      Antenna port mapping                 : AB
      SIA Status                           : Not Present

```

```

Device# show ap name cisco-ap config slot 1 | include beam
Beam Selection : Narrow from centre 20

```

AP Filter

Introduction to AP Filter

The introduction of tags in the new configuration model in the Cisco Catalyst 9800 Series Wireless Controller has created multiple sources for tags to be associated with access points (APs). Tag sources can be static configuration, AP filter engine, per-AP PNP, or default tag sources. In addition to this, the precedence of the tags also plays an important role. The AP filter feature addresses these challenges in a seamless and intuitive manner.

AP filters are similar to the access control lists (ACLs) used in the controller and are applied at the global level. You can add AP names as filters, and other attributes can be added as required. Add the filter criteria as part of the discovery requests.

The AP Filter feature organizes tag sources with the right priority, based on the configuration.

You cannot disable the AP filter feature. However, the relative priority of a tag source can be configured using **ap filter-priority** *priority filter-name* command.

Note You can configure tag names at the PnP server (similar to the Flex group and AP group) and the AP stores and send the tag name as part of discovery and join requests.

Set Tag Priority (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Tags > AP > Tag Source**.
- Step 2** Drag and Drop the Tag Sources to change priorities.
-

Set Tag Priority

Multiple tag sources might result in ambiguity for network administrators. To address this, you can define priority for tags. When an AP joins the controller, the tags are picked based on priority. If precedence is not set, the defaults are used.

Use the following procedure to set tag priority:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	ap tag-source-priority <i>source-priority source</i> {filter pnp} Example: Device(config)# ap tag-source-priority 2 source pnp	Configures AP tag source priority. Note It is not mandatory to configure AP filter. It comes with default priorities for Static, Filter, and PnP.
Step 3	end Example: Device(config)# end	Exits configuration mode and returns to privileged EXEC mode.
Step 4	ap tag-sources revalidate Example:	Revalidates AP tag sources. The priorities become active only after this command is run.

	Command or Action	Purpose
	Device# ap tag-sources revalidate	Note If you change the priorities for Filter and PnP, and want to evaluate them, run the revalidate command.

Create an AP Filter (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Tags > AP > Filter**.
- Step 2** Click **Add**.
- Step 3** In the **Associate Tags to AP** dialog box which is displayed, enter the **Rule Name**, the **AP name regex** and the **Priority**. Optionally, you can also choose the policy tag from the **Policy Tag Name** drop-down list, the site tag from the **Site Tag Name** drop-down list and the RF tag from the **RF Tag Name** drop-down list.
- Step 4** Click **Apply to Device**.
-

Create an AP Filter (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	ap filter name <i>filter_name</i> Example: Device(config)# ap filter filter-1	Configures an AP filter.
Step 3	ap name-regex <i>regular-expression</i> Example: Device(config-ap-filter)# ap name-regex testany	Configures the AP filter based on regular expression. For example, if you have named an AP as ap-1ab-12 , then you can configure the filter with a regular expression, such as ap-1ab-\d+ , to match the AP name.
Step 4	tag policy <i>policy-tag</i> Example: Device(config-ap-filter)# tag policy pol-tag1	Configures a policy tag for this filter.

	Command or Action	Purpose
Step 5	tag rf <i>rf-tag</i> Example: Device(config-ap-filter)# tag rf rf-tag1	Configures an RF tag for this filter.
Step 6	tag site <i>site-tag</i> Example: Device(config-ap-filter)# tag site site1	Configures a site tag for this filter.
Step 7	end Example: Device(config-ap-filter)# end	Exits configuration mode and returns to privileged EXEC mode.

Set Up and Update Filter Priority (GUI)

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > Tags > AP > Filter**.
- Step 2**
- If you want to setup a new AP filter, then click **Add**. In the **Associate Tags to AP** dialog box which is displayed, enter the **Rule Name**, the **AP name regex** and the **Priority**. Optionally, you can also select the **Policy Tag Name**, the **Site Tag Name** and the **RF Tag Name**. Click **Apply to Device**.
 - If you want to update the priority of an existing AP filter, click on the Filter and in the **Edit Tags** dialog box and change the **Priority**. In case the Filter is Inactive, no priority can be set to it. Click **Update and Apply to Device**.

Set Up and Update Filter Priority

Follow the procedure given below to set and update filter priority:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap filter priority <i>priority filter-name</i> <i>filter-name</i> Example: Device(config)# ap filter priority 10 filter-name test1	Configure AP filter priority. Valid values range from 0 to 1023; 0 is the highest priority. Note A filter without a priority is not active. Similarly, you cannot set a filter priority without a filter.

	Command or Action	Purpose
Step 3	end Example: Device(config-ap)# end	Exits configuration mode and returns to privileged EXEC mode.

Verify AP Filter Configuration

The following **show** commands are used to display tag sources and filters, and their priorities.

To view the tag source priorities, use the following command:

```
Device# show ap tag sources
```

```
Priority Tag source
-----
0 Static
1 Filter
2 AP
3 Default
```

To view the available filters, use the following command:

```
Device# show ap filter all
```

```
Filter Name          regex          Policy Tag          RF Tag          Site
Tag
-----
first                abcd           pol-tag1            rf-tag1
site-tag1
test1                testany                          site1
filter1              testany
```

To view the list of active filters, use the following command:

```
Device# show ap filters active
```

```
Priority  Filter Name    regex          Policy Tag          RF Tag
Site Tag
-----
10       test1          testany
site1
```

To view the source of an AP tag, use the following command:

```
Device# show ap tag summary
```

```
Number of APs: 4
```

```
AP Name          AP Mac          Site Tag Name    Policy Tag Name    RF Tag Name
Misconfigured Tag Source
-----
AP002A.1034.CA78 002a.1034.ca78  named-site-tag  named-policy-tag  named-rf-tag  No Filter
AP00A2.891C.2480 00a2.891c.2480  named-site-tag  named-policy-tag  named-rf-tag  No Filter
AP58AC.78DE.9946 58ac.78de.9946  default-site-tag default-policy-tag default-rf-tag  No AP
AP0081.C4F4.1F34 0081.c4f4.1f34  default-site-tag default-policy-tag default-rf-tag  No Default
```

Configuring Access Point for Location Configuration

Information About Location Configuration

During location configuration, you can perform the following:

- Configure a site or location for an AP.
- Configure a set of tags for this location.
- Add APs to this location.

Any location comprises of the following components:

- A set of unique tags, one for each kind, namely: Policy, RF and Site.
- A set of ethernet MAC addresses that applies to the tags.

This feature works in conjunction with the existing tag resolution scheme. The location is considered as a new tag source to the existing system. Similar, to the static tag source.

Prerequisite for Location Configuration

If you configure an access point in one location, you cannot configure the same access point in another location.

Configuring a Location for an Access Point (GUI)

Before you begin

Note When you create local and remote sites in the Basic Setup workflow, corresponding policies and tags are created in the backend. These tags and policies that are created in the Basic Setup cannot be modified using the Advanced workflow, and vice versa.

Procedure

-
- Step 1** Choose **Configuration > Wireless Setup > Basic**.
 - Step 2** On the **Basic Wireless Setup** page, click **Add**.
 - Step 3** In the **General** tab, enter a name and description for the location.
 - Step 4** Set the **Location Type** as either *Local* or *Flex*.
 - Step 5** Use the slider to set **Client Density** as *Low*, *Typical* or *High*.
 - Step 6** Click **Apply**.
-

Configuring a Location for an Access Point (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap location name <i>location_name</i> Example: Device(config)# <code>ap location name location1</code>	Configures a location for an access point. Run the no form of this command to remove location for an access point.
Step 3	tag { policy <i>policy_name</i> rf <i>rf_name</i> site <i>site_name</i> } Example: Device(config-ap-location)# <code>tag policy policy_tag</code> Device(config-ap-location)# <code>tag rf rf_tag</code> Device(config-ap-location)# <code>tag site site_tag</code>	Configures tags for the location.
Step 4	location <i>description</i> Example: Device(config-ap-location)# <code>location description</code>	Adds description to the location.
Step 5	end Example: Device(config-ap-location)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Adding an Access Point to the Location (GUI)

Note When the tag source is not set to location, the AP count and AP location tagging will not be correctly reflected on the web UI. To change static tag source on the AP, run the **no ap ap-mac** command on the controller to change AP tag source to default (which is location).

Procedure

- Step 1** Choose **Configuration > Wireless Setup > Basic**.
- Step 2** On the **Basic Wireless Setup** page, click **Add** to configure the following:

- General
- Wireless Networks
- AP Provisioning

Step 3 In the **AP Provisioning** tab and **Add/Select APs** section, enter the AP MAC address and click the right arrow to add the AP to the associated list. The MAC address can be either in *xx:xx:xx:xx:xx:xx*, *xx-xx-xx-xx-xx-xx*, or *xxxx.xxxx.xxxx* format.

You can also add a CSV file from your system. Ensure that the CSV has the MAC Address column.

Step 4 Use the search option in the **Available AP List** to select the APs from the Selected AP list and click the right arrow to add the AP to the associated list.

Step 5 Click **Apply**.

Adding an Access Point to the Location (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap location name <i>location_name</i> Example: Device(config)# <code>ap location name location1</code>	Configures a location for an access point.
Step 3	ap-eth-mac <i>ap_ethernet_mac</i> Example: Device(config-ap-location)# <code>ap-eth-mac 188b.9dbe.6eac</code>	Adds an access point to the location.
Step 4	end Example: Device(config-ap-location)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode. Note After adding an AP to a location, the AP may reset automatically to get the new configuration

Configuring SNMP in Location Configuration

SNMP MIB

The SNMP MIB provides information on a set of managed objects that represent logical and physical entities, and relationships between them.

Table 2: MIB Objects and Notes

MIB Objects	Notes
cLApLocationName	Provides the name of the AP location.
cLApLocationPolicyTag	Provides the policy tag configured on the location.
cLApLocationSitetag	Provides the site tag configured on the location.
cLApLocationRfTag	Provides the RF tag configured on the location.
cLAssociatedApsApMac	Provides the configured APs on the location.

Verifying Location Configuration

To view the summary of AP location configuration, use the following command:

```
Device# show ap location summary
```

Location Name	Description	Policy Tag	RF Tag	Site Tag
first	first floor	default-policy-tag	default-rf-tag	default-site-tag
second	second floor	default-policy-tag	default-rf-tag	default-site-tag

To view the AP location configuration details for a specific location, use the following command:

```
Device# show ap location details first
```

```
Location Name.....: first
Location description.....: first floor
Policy tag.....: default-policy-tag
Site tag.....: default-site-tag
RF tag.....: default-rf-tag
```

```
Configured list of APs
005b.3400.0af0
005b.3400.0bf0
```

To view the AP tag summary, use the following command:

```
Device# show ap tag summary
```

Number of APs: 4		AP Name	AP Mac	Site Tag Name	Policy Tag Name	RF Tag Name	
Misconfigured	Tag Source						
		Asim_5-1	005b.3400.02f0	default-site-tag	default-policy-tag	default-rf-tag	Yes
	Filter						
		Asim_5-2	005b.3400.03f0	default-site-tag	default-policy-tag	default-rf-tag	No
	Default						
		Asim_5-9	005b.3400.0af0	default-site-tag	default-policy-tag	default-rf-tag	No

```
Asim_5-10      Location
               005b.3400.0bf0  default-site-tag  default-policy-tag  default-rf-tag  No
               Location
```

Verifying Location Statistics

To view the AP location statistics, use the following command:

```
Device# show ap location stats
```

Location name	APs joined	Clients joined	Clients on 11a	Clients on 11b
first	2	0	3	4
second	0	0	0	0

CHAPTER 3

Wireless Management Interface

- [Information About Wireless Management Interface, on page 47](#)
- [Recommendations for Wireless Management Interface, on page 48](#)
- [Configuring your Controller with Wireless Management Interface \(CLI\), on page 49](#)
- [Verifying Wireless Management Interface Settings, on page 51](#)
- [Information About Network Address Translation \(NAT\), on page 52](#)
- [Information About CAPWAP Discovery, on page 52](#)
- [Configuring Wireless Management Interface with a NAT Public IP \(CLI\), on page 53](#)
- [Configuring CAPWAP Discovery to Respond Only with Public or Private IP \(CLI\), on page 54](#)
- [Verifying NAT Settings, on page 55](#)

Information About Wireless Management Interface

The Wireless Management Interface (WMI) is the mandatory Layer 3 interface on the Cisco Catalyst 9800 Wireless Controller. It is used for all communications between the controller and access points. Also, it is used for all CAPWAP or inter-controller mobility messaging and tunneling traffic.

WMI is also the default interface for in-band management and connectivity to enterprise services, such as, AAA, syslog, SNMP, and so on. You can use the WMI IP address to remotely connect to the device using SSH or Telnet (or) access the Graphical User Interface (GUI) using HTTP or HTTPS by entering the wireless management interface IP address of the controller in the address field of your browser.

The Cisco Catalyst 9800 Series Wireless Controller should be able to use Ethernet Service Port (SP) (Management Interface VRF/GigabitEthernet 0) for the below management/control plane protocols from release 17.6.1 onwards:

- SNMP
- RADIUS (both for user authentication to the box and wireless client authorization)
- TACACS
- Syslog
- NTP
- SSH/NETCONF/HTTPS
- NetFlow

Recommendations for Wireless Management Interface

The Wireless Management Interface is a Layer 3 interface, which can be configured only with a single IP address (IPv4 or IPv6) or using a dual-stack configuration.

It is always recommended to use a wireless management VLAN and configure WMI as a Switched VLAN Interface (SVI). If the uplink port or port-channel to the next-hop switch is configured as a dot1q trunk, the wireless management VLAN would be one of the allowed tagged VLAN on the trunk.

The recommendation is true, independent of the deployment mode of APs (local, FlexConnect, or SDA) with the following exceptions:

- The WMI is configured as an L3 port for Cisco Catalyst 9800 Wireless Controller deployed in a Public Cloud environment.
- The WMI is configured as a loopback interface for embedded wireless controller in Cisco Catalyst 9000 switches.

It is always recommended to statically assign IPv6 address in WMI and not configure using the **ipv6 auto-config** command.

Note The **ipv6 auto-config** command is not supported.

Note You can use only one AP manager interface on Cisco Catalyst 9800 Wireless Controller called the WMI to terminate CAPWAP traffic.

Note There is only one Wireless Management Interface (WMI) on the controller.

Note Layer 3 interface is not supported in Cisco Catalyst 9800-CL Cloud Wireless Controller Guest anchor scenarios. Instead, it is recommended to use the Layer 2 interfaces and SVI for WMI.

It is recommended to use Layer 3 interface for Public cloud deployments only and not for on-premise as it poses some limitations.

The following are the sample Layer 3 and Layer 2 interface configurations:

Layer 3 interface configuration:

```
interface GigabitEthernet2
no switchport
ip address <ip_address> <mask>
negotiation auto
no mop enabled
no mop sysid
end
```

Layer 2 interface configuration:

```
interface GigabitEthernet2
switchport trunk allowed vlan 25,169,504
switchport mode trunk
negotiation auto
no mop enabled
no mop sysid
end
```

Note To change the WMI interface when RMI is configured, perform the following:

1. Unconfigure the RMI, save the changes using the **write memory** command, and reload the controller.
 2. Change the WMI interface.
 3. Reconfigure the RMI in the same interface as WMI, save the changes using the **write memory** command, and reload the controller.
-

Configuring your Controller with Wireless Management Interface (CLI)

You can configure the Wireless Management interface using CLI by directly accessing the physical console (for the Cisco Catalyst 9800 appliances) (or) using the virtual console in case of the Cisco Catalyst 9800-CL Cloud Wireless Controller.

Note The example assumes that:

- You have a Cisco Catalyst 9800-CL Cloud Wireless Controller and the GigabitEthernet 2 is connected to a trunk interface on the uplink switch.
- You want to configure multiple VLANs and dedicate one for Wireless Management interface.

Procedure

Step 1 Access the CLI using VGA or monitor console from the hypervisor of your choice.

Step 2 Terminate the configuration wizard.

```
Would you like to enter the initial configuration dialog? [yes/no]:
no
Would you like to terminate autoinstall? [yes]:
yes
```

Step 3 Enter the configuration mode and add the login credentials using the following command:

```
Device# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# username <name> privilege 15 password <yourpwd>
```

Step 4 (Optional) Set a hostname.

```
Device(config)# hostname C9800
```

Step 5 Configure the VLAN for wireless management interface:

```
Device(config)# vlan 201
Device(config-vlan)# name wireless_management
```

Step 6 Configure the L3 SVI for wireless management interface:

```
Device(config)# int vlan 201
Device(config-if)# description wireless-management-interface
Device(config-if)# ip address 172.16.201.21 255.255.255.192
Device(config-if)# no shutdown
```

Step 7 Configure the interface GigabitEthernet 2 as trunk and allow the wireless management VLAN:

```
Device(config-if)# interface GigabitEthernet2
Device(config-if)# switchport mode trunk
Device(config-if)# switchport trunk allowed vlan 201,210,211
Device(config-if)# shut
Device(config-if)# no shut
```

Note VLANs 210 and 211 are added to the trunk to carry client traffic.

Step 8 Configure a default route (or a more specific route) to reach the device:

```
Device(config-if)# ip route 0.0.0.0 0.0.0.0 172.16.201.1
```

At this point you can use SSH or Telnet, or GUI to access the device, or use the Cisco Catalyst Center or Cisco Prime to continue with the DAY 0 configuration.

Verifying Wireless Management Interface Settings

To verify if the Layer 3 interface is configured correctly, use the following command:

```
Device# show run int vlan 201

Building configuration...

Current configuration : 128 bytes
!
interface Vlan201
  description wireless-management-interface
  ip address 172.16.201.21 255.255.255.0
  no mop enabled
  no mop sysid
end
```

To verify if the wireless management VLAN is active on the uplink to the network, use the following command. In this case the uplink is a trunk interface, so the VLAN needs to be active and forwarding state.

```
Device# show interfaces trunk

Port      Mode          Encapsulation  Status        Native vlan
Gi2       on            802.1q         trunking      1
.....
Port      Vlans allowed on trunk
Gi2       201,210-211
.....
Port      Vlans allowed and active in management domain
Gi2       201,210-211
....
Port      Vlans in spanning tree forwarding state and not pruned
Gi2       201,210-211
.....
```

To verify if the wireless management interface is up, use the following command:

```
Device# show ip int brief | i Vlan201
Vlan201  172.16.201.21 YES NVRAM up up
```

To verify if the selected interface has been configured as wireless management, use the following command:

```
Device# show wireless interface summary

Wireless Interface Summary

Interface Name Interface Type VLAN ID IP Address      IP Netmask  NAT-IP Address MAC Address
-----
Vlan201       Management      201  172.16.201.21  255.255.255.0  0.0.0.0      001e.e51c.a7ff
```

Information About Network Address Translation (NAT)

NAT enables private IP networks that use non-registered IP addresses to connect to the Internet. NAT operates on a device, usually connecting two networks. Before packets are forwarded onto another network, NAT translates the private (not globally unique) addresses from the internal network into public addresses. NAT can be configured to advertise to the outside world only few addresses for the entire internal network. This ability provides more security by effectively hiding the private network details.

If you want to deploy your Cisco Catalyst 9800 Wireless Controller on a private network and make it reachable from internet, you need to have the controller behind a router, firewall, or other gateway device that uses one-to-one mapping Network Address Translation (NAT).

To do so, perform the following:

- Configure the NAT device with 1:1 static mapping of the Wireless Management interface IP address (private IP) to a unique external (public) IP address configured on the NAT device.
- Enable the NAT feature on the Wireless Controller and specify its external public IP address. This public IP is used in the discovery responses to APs, so that the APs can then send CAPWAP packets to the right destination.
- Make sure that the external APs discover the public IP of the controller using DHCP, DNS, or PnP.

Note You need not enable NAT if the Cisco Catalyst 9800 Wireless Controller is deployed with a public address. Instead you will need to configure the public IP directly on the Wireless Management Interface (WMI).

Information About CAPWAP Discovery

In a CAPWAP environment, a lightweight access point discovers a wireless controller by using CAPWAP discovery mechanisms, and then sends a CAPWAP join request to the controller. The controller sends a CAPWAP join response to the access point that allows the access point to join the controller.

If the wireless controller is behind a NAT device, the controller responds to the discovery response in the following ways:

- Using the public IP.
- Using the private IP.
- Using public and private IP.

The Public IP needs to be mapped to the controller's Private IP using static 1:1 NAT configuration on the router or firewall performing the NAT translation.

If your wireless controller manages only Access Points reachable through the public internet (external APs), you need to configure the controller so it responds with only the Public IP in the discovery response.

If your wireless controller manages both internal and external APs, you need to configure the controller so it responds with both Public and Private IPs in the discovery response.

Note In NAT deployments, the APs running internally and externally must use different AP join profiles with CAPWAP Discovery Private and Public enabled separately. This applies to APs upgraded to Cisco IOS XE 17.12.x and later.

Configuring Wireless Management Interface with a NAT Public IP (CLI)

The first step is to configure the controller to use the public NAT IP (this is the public IP that has been configured on the NAT device to statically map 1:1 the WMI's private IP address).

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless management interface <i>interface-type</i> <i>interface-number</i> Example: Device(config)# wireless management interface vlan 20	Defines the management interface. Here, <ul style="list-style-type: none"> • <i>interface-type</i>—Refers to the VLAN, Gigabit, or loopback types. • <i>interface-number</i>—Is the interface number.
Step 3	public-ip <i>external-public-ip</i> Example: Device(config-mgmt-interface)# public-ip 2.2.2.2	Defines the external NAT or Public IP.
Step 4	end Example: Device(config-mgmt-interface)# end	Returns to privileged EXEC mode.

Configuring CAPWAP Discovery to Respond Only with Public or Private IP (CLI)

Note By default, if the wireless management interface is configured with a public IP, the controller responds with both Public and Private IP in the CAPWAP discovery response.

The setting to determine the IP (private or public) to include in the discovery response is available in the AP Join profile.

Configuring the Controller to Respond only with a Public IP (CLI)

Configure the Controller to respond only with a Public IP using commands.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>profile-name</i> Example: Device(config)# ap profile xyz-ap-profile	Configures an AP profile and enters AP profile configuration mode.
Step 3	no capwap-discovery private Example: Device(config-ap-profile)# no capwap-discovery private	Instructs the controller to not respond with the internal IP. Enables AP to join the controller over Public IP only.
Step 4	end Example: Device(config-ap-profile)# end	Returns to privileged EXEC mode.

Configuring the Controller to Respond only with a Private IP (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Device# configure terminal	
Step 2	ap profile <i>profile-name</i> Example: Device(config)# ap profile xyz-ap-profile	Configures an AP profile and enters AP profile configuration mode.
Step 3	no capwap-discovery public Example: Device(config-ap-profile)# no capwap-discovery public	Instructs the controller to not respond with the public IP. Enables AP to join the controller over private IP only.
Step 4	end Example: Device(config-ap-profile)# end	Returns to privileged EXEC mode.

Verifying NAT Settings

Verify NAT Settings using commands.

```
Device# show wireless interface summary
```

```
Wireless Interface Summary
```

```
Interface Name Interface Type VLAN ID IP Address      IP Netmask      NAT-IP Address  MAC
Address
-----
Vlan20          Management    20      10.58.20.25    255.255.255.0  2.2.2.2        001e.4963.1cff
```

To verify the settings in the AP join profile, use the following command

```
Device# show run | b ap profile
```

```
ap profile default-ap-profile
 no capwap-discovery private
 description "default ap profile"
...
```

CHAPTER 4

BIOS Protection

- [BIOS Protection on the Controller, on page 57](#)
- [BIOS or ROMMON Upgrade with BIOS Protection, on page 57](#)
- [Upgrading BIOS, on page 58](#)

BIOS Protection on the Controller

BIOS Protection enables you to protect and securely update BIOS flash for Intel-based platforms. If BIOS Protection is not used, the flash utility that stores the BIOS for an Intel platform is not write-protected. As a result, when BIOS updates are applied, malicious code also makes its way through.

By default, BIOS Protection works by bundling the flash containing the BIOS image, and by accepting updates only through the BIOS capsules that enable writing on the BIOS Flash.

BIOS or ROMMON Upgrade with BIOS Protection

To upgrade BIOS or ROMMON use the BIOS Protection feature as follows:

1. The new BIOS image capsule bundled together with the ROMMON binary is inserted into the media of the Cisco device by the ROMMON upgrade scripts.
2. The Cisco device is then reset for the new BIOS/ROMMON upgrade to take place.
3. On reset, the original BIOS detects the updated capsule and determines if the updated BIOS is available.
4. The original BIOS then verifies the digital signature of the BIOS capsule. If the signature is valid, the original BIOS will remove write-protection from the flash utility and update the SPI flash with the new BIOS image. If the BIOS capsule is invalid, the SPI flash is not updated.
5. After the new BIOS/ROMMON image is written to the SPI flash, the required regions of the SPI flash are once again write-protected.
6. After the card is reset, the updated BIOS is rebooted.
7. The capsule is deleted by BIOS.

Upgrading BIOS

Procedure

Use the **upgrade rom-monitor filename** command to update the BIOS capsule.

Example:

```
upgrade rom-monitor filename bootflash:capsule.pkg <slot>
```

Example

The following example shows you how to verify a BIOS Protection upgrade:

```
Device# upgrade rom-monitor filename bootflash:qwlc-rommon-capsule-p106.pkg all
Verifying the code signature of the ROMMON package...
Chassis model AIR-CT5540-K9 has a single rom-monitor.
```

```
Upgrade rom-monitor
```

```
Target copying rom-monitor image file
```

```
Secure update of the ROMMON image will occur after a reload.
```

```

131072+0 records out
131072 bytes (131 kB, 128 KiB) copied, 2.43394 s, 53.9 kB/s
ROMMON upgrade complete.
To make the new ROMMON permanent, you must restart the RP.
Device#reload
```

CHAPTER 5

Smart Licensing Using Policy

- [Introduction to Smart Licensing Using Policy, on page 59](#)
- [Information About Smart Licensing Using Policy, on page 60](#)
- [How to Configure Smart Licensing Using Policy: Workflows by Topology , on page 86](#)
- [Migrating to Smart Licensing Using Policy, on page 100](#)
- [Task Library for Smart Licensing Using Policy, on page 121](#)
- [Troubleshooting Smart Licensing Using Policy, on page 164](#)
- [Additional References for Smart Licensing Using Policy, on page 176](#)
- [Feature History for Smart Licensing Using Policy, on page 176](#)

Introduction to Smart Licensing Using Policy

Smart Licensing Using Policy is an enhanced version of Smart Licensing, with the overarching objective of providing a licensing solution that does not interrupt the operations of your network, rather, one that enables a compliance relationship to account for the hardware and software licenses you purchase and use.

Smart Licensing Using Policy is supported starting with Cisco IOS XE Amsterdam 17.3.2a.

The primary benefits of this enhanced licensing model are:

- Seamless day-0 operations

After a license is ordered, no preliminary steps, such as registration or generation of keys etc., are required unless you use an export-controlled or enforced license. There are no export-controlled or enforced licenses on Cisco Catalyst Wireless Controllers and product features can be configured on the device right-away.

- Consistency in Cisco IOS XE

Campus and industrial ethernet switching, routing, and wireless devices that run Cisco IOS XE software, have a uniform licensing experience.

- Visibility and manageability

Tools, telemetry and product tagging, to know what is in-use.

- Flexible, time series reporting to remain compliant

Easy reporting options are available, whether you are directly or indirectly connected to Cisco Smart Software Manager (CSSM), or in an air-gapped network.

This document provides conceptual, configuration, and troubleshooting information for Smart Licensing Using Policy on Cisco Catalyst Wireless Controllers.

For a more detailed overview on Cisco Licensing, go to cisco.com/go/licensingguide.

Information About Smart Licensing Using Policy

This section provides conceptual information about Smart Licensing Using Policy, supported products, an overview of each supported topology, and explains how Smart Licensing Using Policy interacts, with other features.

Overview

Smart Licensing Using Policy is a software license management solution that provides a seamless experience with the various aspects of licensing.

- Purchase licenses: Purchase licenses through the existing channels and use the Cisco Smart Software Manager (CSSM) portal to view product instances and licenses.

Note For new hardware or software orders, Cisco simplifies the implementation of Smart Licensing Using Policy, by factory-installing the following (terms are explained in the [#unique_88](#) section further below):

- A custom policy, if available.
 - A trust code, which ensures authenticity of data sent to CSSM. This is installed starting with Cisco IOS XE Cupertino 17.7.1. This trust code cannot be used to *communicate* with CSSM.
-
- Use: All licenses on Cisco Catalyst Wireless Controllers are unenforced. This means that you do not have to complete any licensing-specific operations, such as registering or generating keys before you start using the software and the licenses that are tied to it. License usage is recorded on your device with timestamps and the required workflows can be completed at a later date.
 - Report license usage to CSSM: Multiple options are available for license usage reporting. You can use Cisco Smart Licensing Utility (CSLU), or report usage information directly to CSSM. For air-gapped networks, a provision for offline reporting where you download usage information and upload it to CSSM, is also available. The usage report is in plain text XML format. See: [#unique_89](#).
 - Reconcile: For situations where delta billing applies (purchased versus consumed).

Supported Products

This section provides information about the Cisco IOS-XE product instances that support Smart Licensing Using Policy. All models (Product IDs or PIDs) in a product series are supported – unless indicated otherwise.

Table 3: Supported Product Instances: Cisco Catalyst Wireless Controllers

Cisco Catalyst Wireless Controllers	When Support for Smart Licensing Using Policy was Introduced
Cisco Catalyst 9800-40 Wireless Controller	Cisco IOS XE Amsterdam 17.3.2a
Cisco Catalyst 9800-L Wireless Controller	Cisco IOS XE Amsterdam 17.3.2a
Cisco Catalyst 9800-CL Wireless Controller	Cisco IOS XE Amsterdam 17.3.2a
Cisco Catalyst 9800 embedded Wireless Controller	Cisco IOS XE Amsterdam 17.3.2a
Cisco Embedded Wireless Controller on Cisco Catalyst 9100 Access Points (EWC-AP)	Cisco IOS XE Amsterdam 17.3.2a

Architecture

This section explains the various components that can be part of your implementation of Smart Licensing Using Policy. One or more components make up a topology.

Product Instance

A product instance is a single instance of a Cisco product, identified by a Unique Device Identifier (UDI).

A product instance records and reports license usage (RUM reports), and provides alerts and system messages about overdue reports, communication failures, etc. RUM reports and usage data are securely stored in the product instance.

Throughout this document, the term *product instance* refers to all supported physical and virtual product instances - unless noted otherwise. For information about the product instances that are within the scope of this document, see [#unique_93](#).

CSLU

Cisco Smart License Utility (CSLU) is a Windows-based reporting utility that provides aggregate licensing workflows. This utility performs the following key functions:

- Provides options relating to how workflows are triggered. The workflows can be triggered by CSLU or by a product instance.
- Collects usage reports from one or more product instances and uploads these usage reports to the corresponding Smart Account or Virtual Account – online, or offline, using files. Similarly, the RUM report ACK is collected online, or offline, and sent back to the product instance.
- Sends authorization code requests to CSSM and receives authorization codes from CSSM, if applicable.

CSLU can be part of your implementation in the following ways:

- Install the windows application, to use CSLU as a standalone tool that is connected to CSSM.
- Install the windows application, to use CSLU as a standalone tool that is disconnected from CSSM. With this option, the required usage information is downloaded to a file and then uploaded to CSSM. This is suited to air-gapped networks.

- Embedded (by Cisco) in a controller such as Cisco Catalyst Center.
- Deploy CSLU on a machine (laptop or desktop) running Linux.

CSLU supports Windows 10 and Linux operating systems. For release notes and to download the latest version, click *Smart Licensing Utility* on the [Software Download](#) page

CSSM

Cisco Smart Software Manager (CSSM) is a portal that enables you to manage all your Cisco software licenses from a centralized location. CSSM helps you manage current requirements and review usage trends to plan for future license requirements.

You can access the CSSM Web UI at <https://software.cisco.com>. Under the **License** tab, click the **Smart Software Licensing** link.

See the [#unique_96](#) section to know about the different ways in which you can connect to CSSM

In CSSM you can:

- Create, manage, or view virtual accounts.
- Create and manage Product Instance Registration Tokens.
- Transfer licenses between virtual accounts or view licenses.
- Transfer, remove, or view product instances.
- Run reports against your virtual accounts.
- Modify your email notification settings.
- View overall account information.

Controller

A management application or service that manages multiple product instances.

Note Throughout this chapter, and in the context of Smart Licensing Using Policy, the term "controller" or "Controller" always means a management application or service that manages a product instance. The term is not used to refer to Cisco Catalyst Wireless Controllers, which are *product instances*.

On Cisco Catalyst Wireless Controllers, Cisco Catalyst Center is the supported controller. Information about the controller, product instances that support the controller, and minimum required software versions on the controller and on the product instance is provided below:

Table 4: Support Information for Controller: Cisco Catalyst Center

Minimum Required Cisco Catalyst Center Version for Smart Licensing Using Policy ¹	Minimum Required Cisco IOS XE Version ²	Supported Product Instances
Cisco Catalyst Center Release 2.2.2	Cisco IOS XE Amsterdam 17.3.2a	<ul style="list-style-type: none"> • Cisco Catalyst 9800-40 Wireless Controller • Cisco Catalyst 9800-80 Wireless Controller • Cisco Catalyst 9800-L Wireless Controller • Cisco Catalyst 9800-CL Wireless Controller • Cisco Catalyst 9800 embedded Wireless Controller • Cisco Embedded Wireless Controller on Cisco Catalyst 9100 Access Points (EWC-AP)

¹ The minimum required software version on the controller. This means support continues on all subsequent releases - unless noted otherwise

² The minimum required software version on the product instance. This means support continues on all subsequent releases - unless noted otherwise.

For more information about Cisco Catalyst Center, see the support page at:

<https://www.cisco.com/c/en/us/support/cloud-systems-management/dna-center/series.html>.

SSM On-Prem

Smart Software Manager On-Prem (SSM On-Prem) is an asset manager, which works in conjunction with CSSM. It enables you to administer products and licenses on your premises instead of having to directly connect to CSSM.

Information about the required software versions to implement Smart Licensing Using Policy with SSM On-Prem, is provided below:

Minimum Required SSM On-Prem Version for Smart Licensing Using Policy ³	Minimum Required Cisco IOS XE Version ⁴	Supported Product Instances
Version 8, Release 202102	Cisco IOS XE Amsterdam 17.3.3	<ul style="list-style-type: none"> • Cisco Catalyst 9800-40 Wireless Controller • Cisco Catalyst 9800-80 Wireless Controller • Cisco Catalyst 9800-L Wireless Controller • Cisco Catalyst 9800-CL Wireless Controller • Cisco Catalyst 9800 embedded Wireless Controller • Cisco Embedded Wireless Controller on Cisco Catalyst 9100 Access Points (EWC-AP)

³ The minimum required SSM On-Prem version. This means support continues on all subsequent releases - unless noted otherwise

⁴ The minimum required software version on the product instance. This means support continues on all subsequent releases - unless noted otherwise.

For more information about SSM On-Prem, see [Smart Software Manager On-Prem](#) on the Software Download page. Hover over the .iso image to display the documentation links.

Concepts

This section explains the key concepts of Smart Licensing Using Policy.

License Enforcement Types

A given license belongs to one of three enforcement types. The enforcement type indicates if the license requires authorization before use, or not.

- Unenforced or Not Enforced

Unenforced licenses *do not* require authorization before use in air-gapped networks, or registration, in connected networks. The terms of use for such licenses are as per the [General Terms and Conditions](#).

All licenses available on Cisco Catalyst Wireless Controllers are unenforced licenses.

- Enforced

Licenses that belong to this enforcement type require authorization before use. The required authorization is in the form of an authorization code, which must be installed in the corresponding product instance.

An example of an enforced license is the Media Redundancy Protocol (MRP) Client license, which is available on Cisco's Industrial Ethernet Switches.

- Export-Controlled

Licenses that belong to this enforcement type are export-restricted by U.S. trade-control laws and these licenses require authorization before use. The required authorization code must be installed in the corresponding product instance for these licenses as well. Cisco may pre-install export-controlled licenses when ordered with hardware purchase.

An example of an export-controlled license is the High Speed Encryption (HSECK9) license, which is available on certain Cisco Routers.

License Duration

This refers to the duration or term for which a purchased license is valid. A given license may belong to any one of the enforcement types mentioned above and be valid for the following durations:

- Perpetual: There is no expiration date for such a license.

AIR Network Essentials and AIR Network Advantage licenses are examples of unenforced, perpetual licenses that are available on Cisco Catalyst Wireless Controllers.

- Subscription: The license is valid only until a certain date.

AIR Digital Network Architecture (DNA) Essentials and AIR DNA Advantage licenses are examples of unenforced subscription licenses that are available on Cisco Catalyst Wireless Controllers.

Authorization Code

The Smart Licensing Authorization Code (SLAC) allows activation and continued use of a license that is export-controlled or enforced.

A SLAC is not required for any of the licenses available on Cisco Catalyst Wireless Controllers, but if you are upgrading from an earlier licensing model to Smart Licensing Using Policy, you may have a Specific License Reservation (SLR) with its own authorization code. The SLR authorization code is supported after upgrade to Smart Licensing Using Policy.

Note While existing SLRs are carried over after upgrade, you cannot request a new SLR in the Smart Licensing Using Policy environment, because the notion of “reservation” does not apply. For an air-gapped network, the [No Connectivity to CSSM and No CSLU](#) topology applies instead

For more information about how the SLR authorization code is handled, see [#unique_104](#). If you want to return an SLR authorization code, see [#unique_105](#).

Policy

A policy provides the product instance with these reporting instructions:

- License usage report acknowledgement requirement (Reporting ACK required): The license usage report is known as a RUM Report and the acknowledgement is referred to as an ACK (See [RUM Report and Report Acknowledgement](#)). This is a yes or no value which specifies if the report for this product instance requires CSSM acknowledgement or not. The default policy is always set to “yes”.
- First report requirement (days): The first report must be sent within the duration specified here.

If the value here is zero, no first report is required.

- Reporting frequency (days): The subsequent report must be sent within the duration specified here.
If the value here is zero, it means no further reporting is required *unless* there is a usage change.
- Report on change (days): In case of a change in license usage, a report must be sent within the duration specified here.

If the value here is zero, no report is required on usage change.

If the value here is not zero, reporting *is* required after the change is made. All the scenarios listed below count as changes in license usage on the product instance:

- Changing licenses consumed (includes changing to a different license, and, adding or removing a license).
- Going from consuming zero licenses to consuming one or more licenses.
- Going from consuming one or more licenses to consuming zero licenses.

Note If a product instance has *never* consumed a license, reporting is not required even if the policy has a non-zero value for any of the reporting requirements (First report requirement, Reporting frequency, Report on change).

Understanding Policy Selection

CSSM determines the policy that is applied to a product instance. Only one policy is in use at a given point in time. The policy and its values are based on a number of factors, including the licenses being used.

`Cisco default` is the default policy that is always available in the product instance. If no other policy is applied, the product instance applies this default policy. The table below ([#unique_108 unique_108_Connect_42_table_kz1_snm_wmb](#)) shows the `Cisco default` policy values.

While you cannot configure a policy, you can request for a customized one, by contacting the Cisco Global Licensing Operations team. Go to [Support Case Manager](#). Click **OPEN NEW CASE** > Select **Software Licensing**. The licensing team will contact you to start the process or for any additional information. Customized policies are also made available through your Smart account in CSSM.

Note To know which policy is applied (the policy in-use) and its reporting requirements, enter the **show license all** command in privileged EXEC mode.

Table 5: Policy: Cisco default

Policy: <code>Cisco default</code>	Default Policy Values
Export (Perpetual/Subscription)	Reporting ACK required: Yes
Note Applied only to licenses with enforcement type "Export-Controlled".	First report requirement (days): 0
	Reporting frequency (days): 0
	Report on change (days): 0

Policy: Cisco default	Default Policy Values
Enforced (Perpetual/Subscription) Note Applied only to licenses with enforcement type "Enforced".	Reporting ACK required: Yes First report requirement (days): 0 Reporting frequency (days): 0 Report on change (days): 0
Unenforced/Non-Export Perpetual ⁵	Reporting ACK required: Yes First report requirement (days): 365 Reporting frequency (days): 0 Report on change (days): 90
Unenforced/Non-Export Subscription	Reporting ACK required: Yes First report requirement (days): 90 Reporting frequency (days): 90 Report on change (days): 90

⁵ For Unenforced/Non-Export Perpetual: the default policy's first report requirement (within 365 days) applies only if you have purchased hardware or software from a distributor or partner.

RUM Report and Report Acknowledgement

A Resource Utilization Measurement report (RUM report) is a license usage report, which fulfills reporting requirements as specified by the policy. RUM reports are generated by the product instance and consumed by CSSM. The product instance records license usage information and all license usage changes in an open RUM report. At system-determined intervals, open RUM reports are closed and new RUM reports are opened to continue recording license usage. A closed RUM report is ready to be sent to CSSM.

A RUM acknowledgement (RUM ACK or ACK) is a response from CSSM and provides information about the status of a RUM report. Once the ACK for a report is available on the product instance, it indicates that the corresponding RUM report is no longer required and can be deleted.

The reporting method, that is, how a RUM report is sent to CSSM, depends on the topology you implement.

CSSM displays license usage information as per the last received RUM report.

A RUM report may be accompanied by other requests, such as a trust code request, or a SLAC request. So in addition to the RUM report IDs that have been received, an ACK from CSSM may include authorization codes, trust codes, and policy files.

The policy that is applied to a product instance determines the following aspects of the reporting requirement:

- Whether a RUM report is sent to CSSM and the maximum number of days provided to meet this requirement.
- Whether the RUM report requires an acknowledgement (ACK) from CSSM.
- The maximum number of days provided to report a change in license consumption.

If the product instance you are using is a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the conditions for a mandatory ACK starting with Cisco IOS XE Cupertino 17.7.1. For more

information, see [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller, on page 121](#).

RUM report generation, storage, and management

Starting with Cisco IOS XE Cupertino 17.7.1, RUM report generation and related processes have been optimized and enhanced as follows:

- You can display the list of all available RUM reports on a product instance (how many there are, the processing state each one is in, if there are errors in any of them, and so on). This information is available in the **show license rum**, **show license all**, and **show license tech** privileged EXEC commands. For detailed information about the fields displayed in the output, see the command reference of the corresponding release.
- RUM reports are stored in a new format that reduces processing time, and reduces memory usage. In order to ensure that there are no usage reporting inconsistencies resulting from the difference in the old and new formats, we recommend that you send a RUM report in the method that will apply to your topology, in these situations:

When you upgrade from an earlier release supporting Smart Licensing Using Policy, to Cisco IOS XE Cupertino 17.7.1 or a later release.

When you downgrade from Cisco IOS XE Cupertino 17.7.1 or a later release to an earlier release supporting Smart Licensing Using Policy.

- To ensure continued disk space and memory availability, the product instance detects and triggers deletion of RUM reports that are deemed eligible.

Trust Code

A *UDI-tied public key*, which the product instance uses to

- Sign a RUM report. This prevents tampering and ensures data authenticity.
- Enable secure communication with CSSM.

There are multiple ways to obtain a trust code.

- From Cisco IOS XE Cupertino 17.7.1, a trust code is factory-installed for all new orders.

Note A factory-installed trust code cannot be used for *communication* with CSSM.

- A trust code can be obtained from CSSM, using an ID token.

Here you generate an *ID token* in the CSSM Web UI to obtain a trust code and install it on the product instance. You must overwrite the factory-installed trust code if there is one. If a product instance is directly connected to CSSM, use this method to enable the product instance to communicate with CSSM in a secure manner. This method of obtaining a trust code is applicable to all the options of directly connecting to CSSM. For more information, see [Connected Directly to CSSM, on page 71](#).

- From Cisco IOS XE Cupertino 17.7.1, a trust code is automatically obtained in topologies where the product instance initiates the sending of data to CSLU and in topologies where the product instance is in an air-gapped network.

From Cisco IOS XE Cupertino 17.9.1, a trust code is automatically obtained in topologies where CSLU initiates the retrieval of data from the product instance.

If there is a factory-installed trust code, it is automatically overwritten. A trust code obtained this way can be used for secure communication with CSSM.

Refer to the topology description and corresponding workflow to know how the trust code is requested and installed in each scenario: [Supported Topologies, on page 69](#).

If a trust code is installed on the product instance, the output of the **show license status** command displays a timestamp in the `Trust Code Installed:` field.

Supported Topologies

This section describes the various ways in which you can implement Smart Licensing Using Policy. For each topology, refer to the accompanying overview to know how the set-up is designed to work, and refer to the considerations and recommendations, if any.

After Topology Selection

After you have selected a topology, see [#unique_114](#). These workflows are only for new deployments. They provide the simplest and fastest way to implement a topology.

If you are migrating from an existing licensing model, see [#unique_115](#).

After initial implementation, for any additional configuration tasks you have to perform, for instance, changing the AIR license, or synchronizing RUM reports, see the *Task Library for Smart Licensing Using Policy*.

Note Always check the “Supported topologies” where provided, before you proceed.

Connected to CSSM Through CSLU

Overview:

Here, product instances in the network are connected to CSLU, and CSLU becomes the single point of interface with CSSM. A product instance can be configured to *push* the required information to CSLU. Alternatively, CSLU can be set-up to *pull* the required information from a product instance at a configurable frequency.

Product instance-initiated communication (push): A product instance initiates communication with CSLU, by connecting to a REST endpoint in CSLU. Data that is sent includes RUM reports and requests for authorization codes, UDI-tied trust codes, and policies. You can configure the product instance to automatically send RUM reports to CSLU at required intervals. This is the default method for a product instance.

CSLU-initiated communication (pull): To initiate the retrieval of information from a product instance, CSLU uses NETCONF, or RESTCONF, or gRPC with YANG models, or native REST APIs, to connect to the product instance. Supported workflows include retrieving RUM reports from the product instance and sending the same to CSSM, authorization code installation, UDI-tied trust code installation, and application of policies.

Figure 2: Topology: Connected to CSSM Through CSLU

**Considerations or Recommendations:**

Choose the method of communication depending on your network's security policy.

Release-Wise Changes and Enhancements:

This section outlines important release-wise software changes and enhancements that affect this topology.

From Cisco IOS XE Cupertino 17.7.1:

- Trust code request and installation

If a trust code is not available on the product instance, the product instance detects and automatically includes a request for one, as part of a RUM report. A corresponding ACK from CSSM includes the trust code. If there is an existing factory-installed trust code, it is automatically overwritten. A trust code obtained this way can be used for communication with CSSM.

This is supported in a standalone, as well as a High Availability set-up. In a High Availability set-up, the active product instance requests the trust code for all connected product instances where a trust code is not available.

In this release, this enhancement applies only to the product instance-initiated mode.

From Cisco IOS XE Cupertino 17.9.1:

- Trust code request and installation

From this release, trust code request and installation is supported in the CSLU-initiated mode as well.

- RUM report throttling

In the product instance-initiated mode, the minimum reporting frequency is throttled to one day. This means the product instance does not send more than one RUM report a day. This resolves the problem of too many RUM reports being generated and sent for certain licenses. It also resolves the memory-related issues and system slow-down caused by an excessive generation of RUM reports.

You can override the throttling restriction by entering the **license smart sync** command in privileged EXEC mode.

RUM report throttling applies to the Cisco IOS XE Amsterdam 17.3.6 and later releases of the 17.3.x train and Cisco IOS XE Bengaluru 17.6.4 and later releases of the 17.6.x train. From Cisco IOS XE Cupertino 17.9.1, RUM report throttling is applicable to *all* subsequent releases.

Where to Go Next:

To implement this topology, see [#unique_117](#).

Connected Directly to CSSM

Overview:

This topology is available in the earlier version of Smart Licensing and continues to be supported with Smart Licensing Using Policy.

Here, you establish a *direct* and *trusted* connection from a product instance to CSSM. The direct connection, requires network reachability to CSSM. For the product instance to then exchange messages and communicate with CSSM, configure one of the transport options available with this topology (described below). Lastly, the establishment of trust requires the generation of a token from the corresponding Smart Account and Virtual Account in CSSM, and installation on the product instance.

Note A factory-installed trust code cannot be used for communication with CSSM. This means that for this topology, even if a factory-installed trust code exists, you must obtain a trust code by generating an ID token in CSSM, and you must overwrite the existing factory-installed trust code. Also see: [Trust Code, on page 68](#).

You can configure a product instance to communicate with CSSM in the following ways:

- Use Smart transport to communicate with CSSM

Smart transport is a transport method where a Smart Licensing (JSON) message is contained within an HTTPs message, and exchanged between a product instance and CSSM, to communicate. The following Smart transport configuration options are available:

- Smart transport: In this method, a product instance uses a specific Smart transport licensing server URL. This must be configured exactly as shown in the workflow section.
- Smart transport through an HTTPs proxy: In this method, a product instance uses a proxy server to communicate with the licensing server, and eventually, CSSM.

- Use Call Home to communicate with CSSM.

Call Home provides e-mail-based and web-based notification of critical system events. This method of connecting to CSSM is available in the earlier Smart Licensing environment, and continues to be available with Smart Licensing Using Policy. The following Call Home configuration options are available:

- Direct cloud access: In this method, a product instance sends usage information directly over the internet to CSSM; no additional components are needed for the connection.

- Direct cloud access through an HTTPs proxy: In this method, a product instance sends usage information over the internet through a proxy server - either a Call Home Transport Gateway or an off-the-shelf proxy (such as Apache) to CSSM.

Figure 3: Topology: Connected Directly to CSSM

Considerations or Recommendations:

Smart transport is the recommended transport method when directly connecting to CSSM. This recommendation applies to:

- New deployments.
- Earlier licensing models. Change configuration after migration to Smart Licensing Using Policy.
- Registered licenses that currently use the Call Home transport method. Change configuration after migration to Smart Licensing Using Policy.
- Evaluation or expired licenses in an earlier licensing model. Change configuration after migration to Smart Licensing Using Policy.

To change configuration after migration, see [#unique_118](#) > Product Instance Configuration > Configure a connection method and transport type > Option 1.

Release-Wise Changes and Enhancements:

This section outlines important release-wise software changes and enhancements that affect this topology.

From Cisco IOS XE Cupertino 17.9.1:

- RUM report throttling

The minimum reporting frequency for this topology, is throttled to one day. This means the product instance does not send more than one RUM report a day. This resolves the problem of too many RUM reports being generated and sent for certain licenses. It also resolves the memory-related issues and system slow-down caused by an excessive generation of RUM reports.

You can override the throttling restriction by entering the **license smart sync** command in privileged EXEC mode.

RUM report throttling applies to the Cisco IOS XE Amsterdam 17.3.6 and later releases of the 17.3.x train and Cisco IOS XE Bengaluru 17.6.4 and later releases of the 17.6.x train. From Cisco IOS XE Cupertino 17.9.1, RUM report throttling is applicable to *all* subsequent releases.

Where to Go Next:

To implement this topology, see [#unique_118](#).

CSLU Disconnected from CSSM

Overview:

Here, a product instance communicates with CSLU, and you have the option of implementing product instance-initiated communication or CSLU-initiated communication (as in the *Connected to CSSM Through CSLU* topology). The other side of the communication, between CSLU and CSSM, is offline. CSLU provides you with the option of working in a mode that is disconnected from CSSM.

Communication between CSLU and CSSM is sent and received in the form of signed files that are saved offline and then uploaded to or downloaded from CSLU or CSSM, as the case may be.

Figure 4: Topology: CSLU Disconnected from CSSM

Considerations or Recommendations:

Choose the method of communication depending on your network's security policy.

Release-Wise Changes and Enhancements:

This section outlines important release-wise software changes and enhancements that affect this topology.

From Cisco IOS XE Cupertino 17.7.1:

- Trust code request and installation

If a trust code is not available on the product instance, the product instance detects and automatically includes a request for one, as part of a RUM report that is sent to CSLU, which you upload to CSSM. The ACK that you download from CSSM includes the trust code. If there is an existing factory-installed

trust code, it is automatically overwritten. A trust code obtained this way can be used for communication with CSSM.

This is supported in a standalone, as well as a High Availability set-up. In a High Availability set-up, the active product instance requests the trust code for members or standbys where a trust code is not available.

In this release, this enhancement applies only to the product instance-initiated mode.

From Cisco IOS XE Cupertino 17.9.1:

- Trust code request and installation

From this release, trust code request and installation is supported in the CSLU-initiated mode as well.

- RUM report throttling

In the product instance-initiated mode, the minimum reporting frequency is throttled to one day. This means the product instance does not send more than one RUM report a day. This resolves the problem of too many RUM reports being generated and sent for certain licenses. It also resolves the memory-related issues and system slow-down caused by an excessive generation of RUM reports.

You can override the throttling restriction by entering the **license smart sync** command in privileged EXEC mode.

RUM report throttling applies to the Cisco IOS XE Amsterdam 17.3.6 and later releases of the 17.3.x train and Cisco IOS XE Bengaluru 17.6.4 and later releases of the 17.6.x train. From Cisco IOS XE Cupertino 17.9.1, RUM report throttling is applicable to *all* subsequent releases.

Where to Go Next:

To implement this topology, see [#unique_120](#).

Connected to CSSM Through a Controller

When you use a controller to manage a product instance, the controller connects to CSSM, and is the interface for all communication to and from CSSM. The supported controller for Cisco Catalyst Wireless Controllers is Cisco Catalyst Center

Overview:

If a product instance is managed by Cisco Catalyst Center as the controller, the product instance records license usage and saves the same, but it is the Cisco Catalyst Center that initiates communication with the product instance to retrieve RUM reports, report to CSSM, and return the ACK for installation on the product instance.

All product instances that must be managed by Cisco Catalyst Center must be part of its inventory and must be assigned to a site. Cisco Catalyst Center uses the NETCONF protocol to provision configuration and retrieve the required information from the product instance - the product instance must therefore have NETCONF enabled, to facilitate this.

In order to meet reporting requirements, Cisco Catalyst Center retrieves the applicable policy from CSSM and provides the following reporting options:

- Ad hoc reporting: You can trigger an ad hoc report when required.

- Scheduled reporting: Corresponds with the reporting frequency specified in the policy and is automatically handled by Cisco Catalyst Center.

Note Ad hoc reporting must be performed at least once before a product instance is eligible for scheduled reporting.

The first ad hoc report enables Cisco Catalyst Center to determine the Smart Account and Virtual Account to which subsequent RUM reports must be uploaded. You will receive notifications if ad hoc reporting for a product instance has not been performed even once.

Cisco Catalyst Center also enables you to install and remove SLAC for export-controlled licenses. Since all available licenses on Cisco Catalyst Wireless Controllers are unenforced licenses, SLAC installation and removal do not apply.

A trust code is *not* required.

Figure 5: Topology: Connected to CSSM Through a Controller

Considerations or Recommendations:

This is the recommended topology if you are using Cisco Catalyst Center.

Where to Go Next:

To implement this topology, see [Workflow for Topology: Connected to CSSM Through a Controller, on page 93](#).

No Connectivity to CSSM and No CSLU

Overview:

Here you have a product instance and CSSM disconnected from each other, and without any other intermediary utilities or components. All communication is in the form of uploaded and downloaded files. These files can be RUM reports and requests for UDI-tied trust codes.

Figure 6: Topology: No Connectivity to CSSM and No CSLU

**Considerations or Recommendations:**

This topology is suited to a high-security deployment where a product instance cannot communicate online, with anything outside its network.

Release-Wise Changes and Enhancements

This section outlines the release-wise software changes and enhancements that affect this topology.

From Cisco IOS XE Cupertino 17.7.1:

- Trust code request and installation

If a trust code is not available on the product instance, the product instance automatically includes a trust code request in the RUM report that you save, to upload to CSSM. The ACK that you then download from CSSM includes the trust code.

If there is a factory-installed trust code, it is automatically overwritten when you install the ACK. A trust code obtained this way can be used for secure communication with CSSM.

This is supported in a standalone, as well as a High Availability set-up. In a High Availability set-up, the active product instance requests the trust code for all connected product instances where a trust code is not available.

- Simpler authorization code return

A simpler way to upload an authorization code return file is available in the CSSM Web UI. You do not have to locate the product instance in the correct Virtual Account in the CSSM Web UI any longer. You can upload the return file, as you would a RUM report.

Where to Go Next:

To implement this topology, see [#unique_124](#).

SSM On-Prem Deployment

Overview:

SSM On-Prem is designed to work as an extension of CSSM that is deployed on your premises.

Here, a product instance is connected to SSM On-Prem, and SSM On-Prem becomes the single point of interface with CSSM. Each instance of SSM On-Prem must be made known to CSSM through a mandatory registration and synchronization of the local account in SSM On-Prem, with a Virtual Account in CSSM.

When you deploy SSM On-Prem to manage a product instance, the product instance can be configured to *push* the required information to SSM On-Prem. Alternatively, SSM On-Prem can be set-up to *pull* the required information from a product instance at a configurable frequency.

- Product instance-initiated communication (push): The product instance initiates communication with SSM On-Prem, by connecting to a REST endpoint in SSM On-Prem. Data that is sent includes RUM reports and requests for authorization codes, trust codes, and policies.

Options for communication between the product instance and SSM On-Prem in this mode:

- Use a CLI command to push information to SSM On-Prem as and when required.
- Use a CLI command and configure a reporting interval, to automatically send RUM reports to SSM On-Prem at a scheduled frequency.

- SSM On-Prem-initiated communication (pull): To initiate the retrieval of information from a product instance, SSM On-Prem NETCONF, RESTCONF, and native REST API options, to connect to the product instance. Supported workflows include receiving RUM reports from the product instance and sending the same to CSSM, authorization code installation, trust code installation, and application of policies.

Options for communication between the product instance and SSM On-Prem in this mode:

- Collect usage information from one or more product instances as and when required (on-demand).
- Collect usage information from one or more product instances at a scheduled frequency.

In SSM On-Prem, the reporting interval is set to the default policy on the product instance. You can change this, but only to report more frequently (a narrower interval), or you can install a custom policy if available.

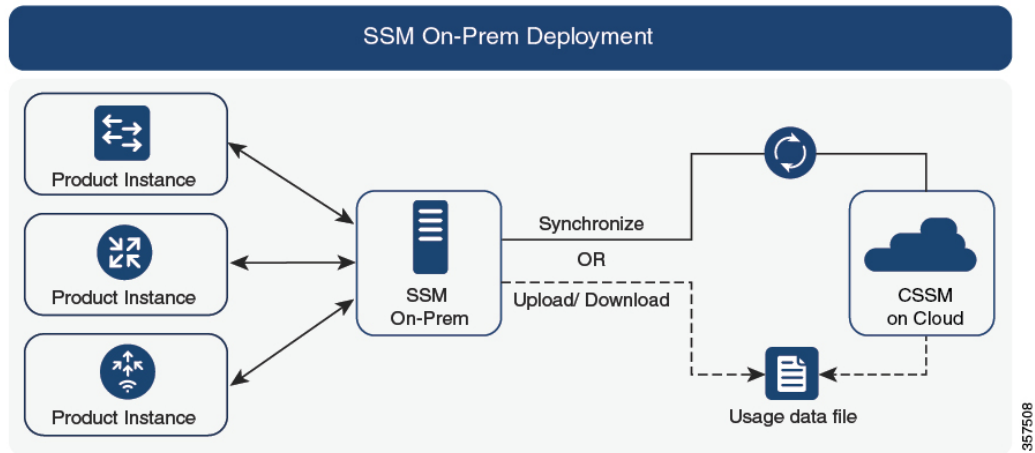

After usage information is available in SSM On-Prem, you must synchronize the same with CSSM, to ensure that the product instance count, license count and license usage information is the same on both, CSSM and SSM On-Prem. Options for usage synchronization between SSM On-Prem and CSSM – for the push *and* pull mode:

- Perform ad-hoc synchronization with CSSM (Synchronize now with Cisco).
- Schedule synchronization with CSSM for specified times.
- Communicate with CSSM through signed files that are saved offline and then upload to or download from SSM On-Prem or CSSM, as the case may be.

Note This topology involves two different kinds of synchronization between SSM On-Prem and CSSM. The first is where the *local account* is synchronized with CSSM - this is for the SSM On-Prem instance to be known to CSSM and is performed by using the **Synchronization** widget in SSM On-Prem. The second is where *license usage* is synchronized with CSSM, either by being connected to CSSM or by downloading and uploading files. You must synchronize the local account before you can synchronize license usage.

Figure 7: Topology: SSM On-Prem Deployment

Considerations or Recommendations:

This topology is suited to the following situations:

- If you want to manage your product instances on your premises, as opposed communicating directly with CSSM for this purpose.
- If your company's policies prevent your product instances from reporting license usage directly to Cisco (CSSM).
- If your product instances are in an air-gapped network and cannot communicate online, with anything outside their network.

Apart from support for Smart Licensing Using Policy, some of the key benefits of SSM On-Prem *Version 8* include:

- **Multi-tenancy:** One tenant constitutes one Smart Account-Virtual Account pair. SSM On-Prem enables you to manage multiple pairs. Here you create local accounts that reside in SSM On-Prem. Multiple local accounts roll-up to a Smart Account-Virtual Account pair in CSSM. For more information, see the [Cisco Smart Software Manager On-Prem User Guide > About Accounts and Local Virtual Accounts](#).

Note The relationship between CSSM and SSM On-Prem instances is still one-to-one.

- **Scale:** Supports up to a total of 300,000 product instances

- **High-Availability:** Enables you to run two SSM On-Prem servers in the form of an active-standby cluster. For more information, see the [Cisco Smart Software On-Prem Installation Guide > Appendix 4. Managing a High Availability \(HA\) Cluster in Your System](#).

High-Availability deployment is supported on the SSM On-Prem console and the required command details are available in the [Cisco Smart Software On-Prem Console Guide](#).

- Options for online and offline connectivity to CSSM.

SSM On-Prem Limitations:

- Proxy support for communication with CSSM, for the purpose of *license usage* synchronization is available only from Version 8 202108 onwards. The use of a proxy for *local account* synchronization, which is performed by using the **Synchronization** widget, is available from the introductory SSM On-Prem release where Smart Licensing Using Policy is supported.
- SSM On-Prem-initiated communication is not supported on a product instance that is in a Network Address Translation (NAT) set-up. You must use product instance-initiated communication, and further, you must *enable* SSM On-Prem to support a product instance that is in a NAT setup. Details are provided in the workflow for this topology.

Release-Wise Changes and Enhancements:

This section outlines important release-wise software changes and enhancements that affect this topology.

From Cisco IOS XE Cupertino 17.9.1:

- RUM report throttling

In the product instance-initiated mode, the minimum reporting frequency is throttled to one day. This means the product instance does not send more than one RUM report a day. This resolves the problem of too many RUM reports being generated and sent for certain licenses. It also resolves the memory-related issues and system slow-down caused by an excessive generation of RUM reports.

You can override the throttling restriction by entering the **license smart sync** command in privileged EXEC mode.

RUM report throttling applies to the Cisco IOS XE Amsterdam 17.3.6 and later releases of the 17.3.x train and Cisco IOS XE Bengaluru 17.6.4 and later releases of the 17.6.x train. From Cisco IOS XE Cupertino 17.9.1, RUM report throttling is applicable to *all* subsequent releases.

Where to Go Next:

To implement this topology, see [Workflow for Topology: SSM On-Prem Deployment, on page 95](#)

If you are migrating from an existing version of SSM On-Prem, the sequence in which you perform the various upgrade-related activities is crucial. See [Migrating to a Version of SSM On-Prem That Supports Smart Licensing Using Policy, on page 119](#)

Interactions with Other Features

High Availability

This section explains considerations that apply to a High Availability configuration, when running a software version that supports Smart Licensing Using Policy. The following High Availability set-ups are within the scope of this document:

A dual-chassis set-up (could be fixed or modular), with the active in one chassis and a standby in the other chassis.

A wireless N+1 topology, where “n” number of wireless controllers act as primary and a “+1” wireless controller acts as the secondary or fallback wireless controller for Access Points (APs). Each Access Point is configured with a primary and a secondary wireless controller. In case of a failure on the primary, all access points that were connected to the primary now fallback to the secondary wireless controller.

Trust Code Requirements in a High Availability Set-Up

The number of trust codes required depends on the number of UDIs. The active product instance can submit requests for all devices in the High Availability set-up and install all the trust codes that are returned in an ACK.

Policy Requirements in a High Availability Set-Up

There are no policy requirements that apply exclusively to a High Availability set-up. As in the case of a standalone product instance, only one policy exists in a High Availability set-up as well, and this is on the active. The policy on the active applies to any standbys in the set-up.

Product Instance *Functions* in a High Availability Set-Up

This section explains general product instance functions in a High Availability set-up, as well as what the product instance does when a new standby or secondary is added to an existing High Available set-up.

For authorization and trust codes: The active product instance can request (if required) and install authorization codes and trust codes for standbys.

For policies: The active product instance synchronizes with the standby.

For reporting: Only the active product instance reports usage. The active reports usage information for all devices in the High Availability set-up. In addition to scheduled reporting, the following events trigger reporting:

- The addition or removal of a standby. The RUM report includes information about the standby that was added or removed.
- A switchover.
- A reload.

When one of the above events occur, the “Next report push” date of the **show license status** privileged EXEC command is updated. But it is the implemented topology and associated reporting method that determine if the report is sent by the product instance or not. For example, if you have implemented a topology where the product instance is disconnected (Transport Type is Off), then the product instance does not send RUM reports even if the “Next report push” date is updated.

For addition or removal of a new standby:

- A product instance that is connected to CSLU, does not take any further action.
- A product instance that is directly connected to CSSM, performs trust synchronization. Trust synchronization involves the following:

Installation of trust code on the standby if not installed already.

If a trust code is already installed, the trust synchronization process ensures that the new standby is in the same Smart Account and Virtual Account as the active. If it is not, the new standby is *moved* to the same Smart Account and Virtual Account as the active.

Installation of an authorization code, policy, and purchase information, if applicable

Sending of a RUM report with current usage information.

For addition or removal of a secondary:

There are no product instance functions that apply exclusively to the addition or removal of a secondary product instance. Further, all the secondary product instances are in the same Smart Account and Virtual Account as the primary product instance.

Upgrades

This section explains the following aspects:

Migrating from earlier licensing models to Smart Licensing Using Policy. When migrating from earlier licensing models, also see the [#unique_115](#) section for examples of migration scenarios that apply to Cisco Catalyst Wireless Controllers.

Upgrading in the Smart Licensing Using Policy environment - where the software version you are upgrading from and the software version you are upgrading to, both support Smart Licensing Using Policy.

Identifying the Current Licensing Model Before Upgrade

Before you upgrade to Smart Licensing Using Policy, if you want to know the current licensing model that is effective on the product instance, enter the **show license all** command in privileged EXEC mode.

How Upgrade Affects Enforcement Types for Existing Licenses

When you upgrade to a software version which supports Smart Licensing Using Policy, the way existing licenses are handled, depends primarily on the license enforcement type.

- An unenforced license that was being used before upgrade, continues to be available after the upgrade. All licenses on Cisco Catalyst Wireless Controllers are unenforced licenses. This includes licenses from all earlier licensing models:
 - Smart Licensing
 - Specific License Reservation (SLR), which has an accompanying authorization code. The authorization code continues to be valid after upgrade to Smart Licensing Using Policy and authorizes existing license consumption.
 - Evaluation or expired licenses from any of the above mentioned licensing models.
- An enforced or export-controlled license that was being used before upgrade, continues to be available after upgrade if the required authorization exists.

There are no export-controlled or enforced licenses on any of the supported Cisco Catalyst Wireless Controllers, therefore, these enforcement types and the requisite SLAC do not apply.

How Upgrade Affects Reporting for Existing Licenses

Existing License	Reporting Requirements After Migration to Smart Licensing Using Policy
Specific License Reservation (SLR)	Required only if there is a change in license consumption. An existing SLR authorization code authorizes existing license consumption after upgrade to Smart Licensing Using Policy.
Smart Licensing (Registered and Authorized license)	Depends on the policy.
Evaluation or expired licenses	Based on the reporting requirements of the Cisco default policy.

How Upgrade Affects Transport Type for Existing Licenses

The transport type, if configured in your existing set-up, is retained after upgrade to Smart Licensing Using Policy.

When compared to the earlier version of Smart Licensing, additional transport types are available with Smart Licensing Using Policy. There is also a change in the default transport mode. The following table clarifies how this may affect upgrades:

Transport type Before Upgrade	License or License State Before Upgrade	Transport Type After Upgrade
Default (callhome)	evaluation	cslu (default in Smart Licensing Using Policy)
	SLR	off
	registered	callhome
smart	evaluation	off
	SLR	off
	registered	smart

How Upgrade Affects the Token Registration Process

In the earlier version of Smart Licensing, a token was used to register and connect to CSSM. ID token registration is not required in Smart Licensing Using Policy. The token generation feature is still available in CSSM, and is used to *establish trust* when a product instance is directly connected to CSSM. See [Connected Directly to CSSM](#).

Upgrades Within the Smart Licensing Using Policy Environment

This section covers any release-specific considerations or actions that apply when you upgrade the product instance from one release where Smart Licensing Using Policy is supported to another release where Smart Licensing Using Policy is supported.

Starting with Cisco IOS XE Cupertino 17.7.1, RUM reports are stored in a format that reduces processing time. In order to ensure that there are no usage reporting inconsistencies resulting from the differences in the old and new formats, we recommend completing one round of usage reporting as a standard practice when upgrading from an earlier release that supports Smart Licensing Using Policy, to Cisco IOS XE Cupertino 17.7.1 or a later release.

Downgrades

This section provides information about downgrades to an earlier licensing model, for new deployments and existing deployments. It also covers information relevant to downgrades within in the Smart Licensing Using Policy environment.

New Deployment Downgrade

This section describes considerations and actions that apply if a newly purchased product instance with a software version where Smart Licensing Using Policy is enabled by default, is downgraded to a software version where Smart Licensing Using Policy is not supported.

The outcome of the downgrade depends on whether a trust code was installed while still operating in the Smart Licensing Using Policy environment, and further action may be required depending on the release you downgrade to.

If the topology you implemented while in the Smart Licensing Using Policy environment was "Connected Directly to CSSM", then a trust code installation can be expected or assumed, because it is required as part of topology implementation. For any of the other topologies, trust establishment is not mandatory. Downgrading product instances with one of these other topologies will therefore mean that you have to restore licenses to a registered and authorized state by following the procedures that are applicable in the Smart Licensing environment. See the table (*Outcome and Action for New Deployment Downgrade to Smart Licensing*) below.

Table 6: Outcome and Action for New Deployment Downgrade to Smart Licensing

In the Smart Licensing Using Policy Environment	Downgrade to..	Outcome and Further Action
Standalone product instance, connected directly to CSSM, and trust established.	Cisco IOS XE Amsterdam 17.3.1 OR Cisco IOS XE Gibraltar 16.12.4 and later releases in Cisco IOS XE Gibraltar 16.12.x	No further action is required. The product instance attempts to renew trust with CSSM after downgrade. After a successful renewal, licenses are in a registered state and the earlier version of Smart Licensing is effective on the product instance.
	Any other release (other than the ones mentioned in the row above) that supports Smart Licensing	Action is required: You must reregister the product instance. Generate an ID token in the CSSM Web UI and on the product instance, configure the license smart register idtoken idtoken command in global configuration mode.
High Availability set-up, connected directly to CSSM, and trust established.	Any release that supports Smart Licensing	Action is required: You must reregister the product instance. Generate an ID token in the CSSM Web UI and on the product instance, configure the license smart register idtoken idtoken all command in global configuration mode.
Any other topology. (Connected to CSSM Through CSLU, CSLU Disconnected from CSSM, No Connectivity to CSSM and No CSLU)	Any release that supports Smart Licensing	Action is required. Restore licenses to a registered and authorized state by following the procedures that are applicable in the Smart Licensing environment.

Upgrade and Then Downgrade

This section describes considerations and actions that apply if a product instance is upgraded to a software version that supports Smart Licensing Using Policy and then downgraded to an earlier licensing model.

When you downgrade such a product instance, *license consumption does not change* and any product features you have configured on the product instance are preserved – only the features and functions that are available with Smart Licensing Using Policy are not available anymore. Refer to the corresponding section below to know more about reverting to an earlier licensing model.

Upgrade to Smart Licensing Using Policy and then Downgrade to Smart Licensing

The outcome of the downgrade depends on whether a trust code was installed while you were still operating in the Smart Licensing Using Policy environment, and further action may be required depending on the release you downgrade to. See the table below.

Table 7: Outcome and Action for Upgrade to Smart Licensing Using Policy and then Downgrade to Smart Licensing

In the Smart Licensing Using Policy Environment	Downgrade to..	Outcome and Further Action
Standalone product instance, connected directly to CSSM, and trust established.	Cisco IOS XE Amsterdam 17.3.1 OR Cisco IOS XE Gibraltar 16.12.4 and later releases in Cisco IOS XE Gibraltar 16.12.x	No further action is required. The system recognizes the trust code and converts it back to a registered ID token, and this reverts the license to an AUTHORIZED and REGISTERED state.
	Any other release (other than the ones mentioned in the row above) that supports Smart Licensing	Action is required: You must reregister the product instance. Generate an ID token in the CSSM Web UI and on the product instance, configure the license smart register idtoken idtoken command in global configuration mode.
High Availability set-up, connected directly to CSSM, and trust established.	Any release that supports Smart Licensing	Action is required: You must reregister the product instance. Generate an ID token in the CSSM Web UI and on the product instance, configure the license smart register idtoken idtoken all command in global configuration mode.
Any other topology (Connected to CSSM Through CSLU, CSLU Disconnected from CSSM, No Connectivity to CSSM and No CSLU)	Any release that supports Smart Licensing.	Action is required. Restore licenses to a registered and authorized state by following the procedures that are applicable in the Smart Licensing environment.

Note Licenses that were in an evaluation or expired state in the Smart Licensing environment, revert to that same state after downgrade.

Upgrade to Smart Licensing Using Policy and then Downgrade to SLR

To revert to SLR, all that is required is for the image to be downgraded. The license remains reserved and authorized – no further action is required.

However, if you have returned an SLR while in the Smart Licensing Using Policy environment, then you must repeat the process of procuring an SLR as required, in the supported release.

Downgrades Within the Smart Licensing Using Policy Environment

This section covers any release-specific considerations or actions that apply when you downgrade the product instance from one release where Smart Licensing Using Policy is supported to another release where Smart Licensing Using Policy is supported.

Starting with Cisco IOS XE Cupertino 17.7.1, RUM reports are stored in a format that reduces processing time. In order to ensure that there are no usage reporting inconsistencies resulting from the differences in the old and new formats, we recommend completing one round of usage reporting as a standard practice when downgrading from Cisco IOS XE Cupertino 17.7.1 or a later release to an earlier release supporting Smart Licensing Using Policy.

How to Configure Smart Licensing Using Policy: Workflows by Topology

This section provides the simplest and fastest way to implement a topology.

Note These workflows are meant for new deployments only. If you are migrating from an existing licensing model, see [#unique_115](#).

Workflow for Topology: Connected to CSSM Through CSLU

Depending on whether you want to implement a product instance-initiated or CSLU-initiated method of communication, complete the corresponding sequence of tasks:

- [Tasks for Product Instance-Initiated Communication](#)
- [Tasks for CSLU-Initiated Communication](#)

Tasks for Product Instance-Initiated Communication

CSLU Installation → **CSLU Preference Settings** → **Product Instance Configuration**

1. *CSLU Installation*

Where task is performed: A laptop, desktop, or a Virtual Machine (VM) running Windows 10 or Linux.

Download the file from [Smart Software Manager](#) > **Smart Licensing Utility**.

Refer to [Cisco Smart License Utility Quick Start Setup Guide](#) and [Cisco Smart Licensing Utility User Guide](#) for help with installation and set-up.

2. *CSLU Preference Settings*

Where tasks are performed: CSLU

- a. [#unique_144](#)

- b. #unique_145
- c. #unique_146

3. Product Instance Configuration

Where tasks are performed: Product Instance

- a. #unique_147

- b. Ensure that transport type is set to **cslu**.

CSLU is the default transport type. If you have configured a different option, enter the **license smart transport cslu** command in global configuration mode. Save any changes to the configuration file.

```
Device(config)# license smart transport cslu
Device(config)# exit
Device# copy running-config startup-config
```

- c. Specify how you want CSLU to be discovered (*choose one*):

- Option 1:

No action required. Name server configured for Zero-touch DNS discovery of `cslu-local`

Here, if you have configured DNS (the name server IP address is configured on the product instance), and the DNS server has an entry where hostname `cslu-local` is mapped to the CSLU IP address, then no further action is required. The product instance automatically discovers hostname `cslu-local`.

- Option 2:

No action required. Name server and domain configured for Zero-touch DNS discovery of `cslu-local.<domain>`

Here if you have configured DNS (the name server IP address and domain is configured on the product instance), and the DNS server has an entry where `cslu-local.<domain>` is mapped to the CSLU IP address, then no further action is required. The product instance automatically discovers hostname `cslu-local`.

- Option 3:

Configure a specific URL for CSLU.

Enter the **license smart url cslu** `http://<cslu_ip_or_host>:8182/cslu/v1/pi` command in global configuration mode. For `<cslu_ip_or_host>`, enter the hostname or the IP address of the windows host where you have installed CSLU. 8182 is the port number and it is the only port number that CSLU uses.

```
Device(config)# license smart url cslu http://192.168.0.1:8182/cslu/v1/pi
Device(config)# exit
Device# copy running-config startup-config
```

Result:

Since the product instance initiates communication, it automatically sends out the first RUM report at the scheduled time, as per the policy. Along with this first report, if applicable, it sends a request for a UDI-tied trust code. CSLU forwards the RUM report to CSSM and retrieves the ACK, which also contains the trust code. The ACK is applied to the product instance the next time the product instance contacts CSLU.

In the Cisco IOS XE Amsterdam 17.3.6 and later releases of the 17.3.x train, Cisco IOS XE Bengaluru 17.6.4 and later releases of the 17.6.x train, and all subsequent releases from Cisco IOS XE Cupertino 17.9.1 onwards: The product instance does not send more than one RUM report a day. You can override this for an on-demand synchronization between the product instance and CSSM, by entering the **license smart sync** command in privileged EXEC mode.

To know when the product instance will be sending the next RUM report, enter the **show license all** command in privileged EXEC mode and in the output, check the date in the `Next report push` field.

To verify trust code installation, enter the **show license status** command in privileged EXEC mode. Check for the updated timestamp in the `Trust Code Installed` field.

In case of a change in license usage, see [#unique_148](#) to know how it affects reporting.

If you are using a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the mandatory ACK requirement starting with Cisco IOS XE Cupertino 17.7.1. See [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller](#), on page 121.

Tasks for CSLU-Initiated Communication

CSLU Installation → **CSLU Preference Settings** → **Product Instance Configuration** → **Usage Synchronization**

1. *CSLU Installation*

Where task is performed: A laptop, desktop, or a Virtual Machine (VM) running Windows 10 or Linux.

Download the file from [Smart Software Manager](#) > **Smart Licensing Utility**.

Refer to [Cisco Smart License Utility Quick Start Setup Guide](#) and [Cisco Smart Licensing Utility User Guide](#) for help with installation and set-up.

2. *CSLU Preference Settings*

Where task is performed: CSLU

- a. [#unique_144](#)
- b. [#unique_145](#)
- c. [#unique_149](#)

3. *Product Instance Configuration*

Where task is performed: Product Instance

[#unique_150](#)

4. *Usage Synchronization*

Where task is performed: Product Instance

[#unique_151](#)

Result:

Since CSLU is logged into CSSM, the reports are automatically sent to the associated Smart Account and Virtual Account in CSSM and CSSM will send an ACK to CSLU as well as to the product instance. It gets the ACK from CSSM and sends this back to the product instance for installation. The ACK from CSSM contains the trust code and SLAC if this was requested.

In case of a change in license usage, see [#unique_148](#) to know how it affects reporting.

If you are using a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the mandatory ACK requirement starting with Cisco IOS XE Cupertino 17.7.1. See [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller](#), on page 121.

Trust code request and installation is supported starting with Cisco IOS XE Cupertino 17.9.1.

Workflow for Topology: Connected Directly to CSSM

Smart Account Set-Up → Product Instance Configuration → Trust Establishment with CSSM

1. Smart Account Set-Up

Where task is performed: CSSM Web UI, <https://software.cisco.com/>

Ensure that you have a user role with proper access rights to a Smart Account and the required Virtual Accounts.

2. Product Instance Configuration

Where tasks are performed: Product Instance

- a. Set-Up product instance connection to CSSM: [#unique_153](#)
- b. Configure a connection method and transport type (choose one)

- Option 1:

Smart transport: Set transport type to **smart** and configure the corresponding URL.

If the transport mode is set to **license smart transport smart**, and you configure **license smart url default**, the Smart URL (<https://smartreceiver.cisco.com/licservice/license>) is automatically configured. Save any changes to the configuration file.

```
Device(config)# license smart transport smart
Device(config)# license smart url default
Device(config)# exit
Device# copy running-config startup-config
```

- Option 2:

Configure Smart transport through an HTTPs proxy. See [#unique_154](#)

- Option 3:

Configure Call Home service for direct cloud access. See [#unique_155](#).

- Option 4:

Configure Call Home service for direct cloud access through an HTTPs proxy. See [#unique_156](#).

3. Trust Establishment with CSSM

Where task is performed: CSSM Web UI and then the product instance

- a. Generate one token for each *Virtual Account* you have. You can use same token for all the product instances that are part of one Virtual Account: [#unique_157](#)
- b. Having downloaded the token, you can now install the trust code on the product instance: [#unique_158](#)

Result:

After establishing trust, CSSM returns a policy. The policy is automatically installed on all product instances of that Virtual Account. The policy specifies if and how often the product instance reports usage.

In the Cisco IOS XE Amsterdam 17.3.6 and later releases of the 17.3.x train, Cisco IOS XE Bengaluru 17.6.4 and later releases of the 17.6.x train, and all subsequent releases from Cisco IOS XE Cupertino 17.9.1 onwards: The product instance does not send more than one RUM report a day. You can override this for an on-demand synchronization between the product instance and CSSM, by entering the **license smart sync** command in privileged EXEC mode.

To change the reporting interval, configure the **license smart usage interval** command in global configuration mode. For syntax details see the *license smart (privileged EXEC)* command in the Command Reference for the corresponding release.

In case of a change in license usage, see [#unique_148](#) to know how it affects reporting.

If you are using a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the mandatory ACK requirement starting with Cisco IOS XE Cupertino 17.7.1. See [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller, on page 121](#).

Workflow for Topology: CSLU Disconnected from CSSM

Depending on whether you want to implement a product instance-initiated or CSLU-initiated method of communication. Complete the corresponding table of tasks below.

- [Tasks for Product Instance-Initiated Communication](#)
- [Tasks for CSLU-Initiated Communication](#)

Tasks for Product Instance-Initiated Communication

CSLU Installation → **CSLU Preference Settings** → **Product Instance Configuration** → **Usage Synchronization**

1. *CSLU Installation*

Where task is performed: A laptop, desktop, or a Virtual Machine (VM) running Windows 10 or Linux.

Download the file from [Smart Software Manager](#) > **Smart Licensing Utility**.

Refer to [Cisco Smart License Utility Quick Start Setup Guide](#) and [Cisco Smart Licensing Utility User Guide](#) for help with installation and set-up.

2. *CSLU Preference Settings*

Where tasks are performed: CSLU

- a. In the CSLU Preferences tab, click the **Cisco Connectivity** toggle switch to **off**. The field switches to “Cisco Is Not Available”.
- b. [#unique_145](#)
- c. [#unique_146](#)

3. *Product Instance Configuration*

Where tasks are performed: Product Instance

a. [#unique_147](#)b. Ensure that transport type is set to **cslu**.

CSLU is the default transport type. If you have configured a different option, enter the **license smart transport cslu** command in global configuration mode. Save any changes to the configuration file.

```
Device(config)# license smart transport cslu
Device(config)# exit
Device# copy running-config startup-config
```

c. Specify how you want CSLU to be discovered (*choose one*)

• Option 1:

No action required. Name server configured for Zero-touch DNS discovery of `cslu-local`

Here, if you have configured DNS (the name server IP address is configured on the product instance), and the DNS server has an entry where hostname `cslu-local` is mapped to the CSLU IP address, then no further action is required. The product instance automatically discovers hostname `cslu-local`.

• Option 2:

No action required. Name server and domain configured for Zero-touch DNS discovery of `cslu-local.<domain>`

Here if you have configured DNS (the name server IP address and domain is configured on the product instance), and the DNS server has an entry where `cslu-local.<domain>` is mapped to the CSLU IP address, then no further action is required. The product instance automatically discovers hostname `cslu-local`.

• Option 3:

Configure a specific URL for CSLU.

Enter the **license smart url cslu** `http://<cslu_ip_or_host>:8182/cslu/v1/pi` command in global configuration mode. For `<cslu_ip_or_host>`, enter the hostname or the IP address of the windows host where you have installed CSLU. 8182 is the port number and it is the only port number that CSLU uses.

```
Device(config)# license smart url cslu http://192.168.0.1:8182/cslu/v1/pi
Device(config)# exit
Device# copy running-config startup-config
```

4. *Usage Synchronization*

Where tasks are performed: CSLU and CSSM

Since the product instance initiates communication, it automatically sends out the first RUM report at the scheduled time, as per the policy. You can also enter the **license smart sync** privileged EXEC command to trigger this. Along with this first report, if applicable, it sends a request for a UDI-tied trust code. Since CSLU is disconnected from CSSM, perform the following tasks to send the RUM Reports to CSSM.

a. [#unique_160](#)b. [#unique_161](#)c. [#unique_162](#)

Result:

The ACK you have imported from CSSM contains the trust code if this was requested. The ACK is applied to the product instance the next time the product instance contacts CSLU.

In the Cisco IOS XE Amsterdam 17.3.6 and later releases of the 17.3.x train, Cisco IOS XE Bengaluru 17.6.4 and later releases of the 17.6.x train, and all subsequent releases from Cisco IOS XE Cupertino 17.9.1 onwards: The product instance does not send more than one RUM report a day. You can override this for an on-demand synchronization between the product instance and CSSM, by entering the **license smart sync** command in privileged EXEC mode.

To know when the product instance will be sending the next RUM report, enter the **show license all** command in privileged EXEC mode and in the output, check the date for the `Next report push` field.

To verify trust code installation, enter the `show license status` command in privileged EXEC mode. Check for the updated timestamp in the `Trust Code Installed` field.

In case of a change in license usage, see [#unique_148](#) to know how it affects reporting.

If you are using a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the mandatory ACK requirement starting with Cisco IOS XE Cupertino 17.7.1. See [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller, on page 121](#).

Tasks for CSLU-Initiated Communication**CSLU Installation → CSLU Preference Settings → Product Instance Configuration → Usage Synchronization****1. CSLU Installation**

Where task is performed: A laptop, desktop, or a Virtual Machine (VM) running Windows 10 or Linux.

Download the file from [Smart Software Manager](#) > **Smart Licensing Utility**.

Refer to [Cisco Smart License Utility Quick Start Setup Guide](#) and [Cisco Smart Licensing Utility User Guide](#) for help with installation and set-up.

2. CSLU Preference Settings

Where tasks is performed: CSLU

- a. In the CSLU Preferences tab, click the **Cisco Connectivity** toggle switch to **off**. The field switches to “Cisco Is Not Available”.
- b. [#unique_145](#)
- c. [#unique_149](#)
- d. [#unique_151](#)

3. Product Instance Configuration

Where task is performed: Product Instance

[#unique_150](#)

4. Usage Synchronization

Where tasks are performed: CSLU and CSSM

Collect usage data from the product instance. Since CSLU is disconnected from CSSM, you then save usage data which CSLU has collected from the product instance to a file. Along with this first report, if applicable, an authorization code and a UDI-tied trust code request is included in the RUM report. Then, from a workstation that is connected to Cisco, upload it to CSSM. After this, download the ACK from CSSM. In the workstation where CSLU is installed and connected to the product instance, upload the file to CSLU.

- a. [#unique_160](#)
- b. [#unique_161](#)
- c. [#unique_162](#)

Result:

The ACK you have imported from CSSM contains the trust code and SLAC if this was requested. The uploaded ACK is applied to the product instance the next time CSLU runs an update.

In case of a change in license usage, see [#unique_148](#) to know how it affects reporting.

If you are using a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the mandatory ACK requirement starting with Cisco IOS XE Cupertino 17.7.1. See [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller](#), on page 121.

Trust code request and installation is supported starting with Cisco IOS XE Cupertino 17.9.1.

Workflow for Topology: Connected to CSSM Through a Controller

To deploy Cisco Catalyst Center as the controller, complete the following workflow:

Product Instance Configuration → Cisco Catalyst Center **Configuration**

1. *Product Instance Configuration*

Where task is performed: Product Instance

Enable NETCONF. Cisco Catalyst Center uses the NETCONF protocol to provision configuration and retrieve the required information from the product instance - the product instance must therefore have NETCONF enabled, to facilitate this.

For more information, see the [Programmability Configuration Guide, Cisco IOS XE Amsterdam 17.3.x](#). In the guide, go to *Model-Driven Programmability > NETCONF Protocol*.

2. *Cisco Catalyst Center Configuration*

Where tasks is performed: Cisco Catalyst Center GUI

An outline of the tasks you must complete and the accompanying documentation reference is provided below. The document provides detailed steps you have to complete in the Cisco Catalyst Center GUI:

- a. Set-up the Smart Account and Virtual Account.

Enter the same log in credentials that you use to log in to the CSSM Web UI. This enables Cisco Catalyst Center to establish a connection with CSSM.

See the [Cisco Catalyst Center Administrator Guide](#) of the required release (Release 2.2.2 onwards) > *Manage Licenses > Set Up License Manager*.

- b. Add the required product instances to Cisco Catalyst Center inventory and assign them to a site.

This enables Cisco Catalyst Center to push any necessary configuration, including the required certificates, for Smart Licensing Using Policy to work as expected.

See the [Cisco Catalyst Center User Guide](#) of the required release (Release 2.2.2 onwards) > *Display Your Network Topology > Assign Devices to a Site*.

Result:

After you implement the topology, *you* must trigger the very first ad hoc report in Cisco Catalyst Center, to establish a mapping between the Smart Account and Virtual Account, and product instance. See the [Cisco Catalyst Center Administrator Guide](#) of the required release (Release 2.2.2 onwards) > *Manage Licenses > Upload Resource Utilization Details to CSSM*. Once this is done, Cisco Catalyst Center handles subsequent reporting based on the reporting policy.

If multiple policies are available, Cisco Catalyst Center maintains the narrowest reporting interval. You can change this, but only to report more frequently (a narrower interval). See the [Cisco Catalyst Center Administrator Guide](#) of the required release (Release 2.2.2 onwards) > *Manage Licenses > Modify License Policy*.

If you want to change the license level after this, see the [Cisco Catalyst Center Administrator Guide](#) of the required release (Release 2.2.2 onwards) > *Manage Licenses > Change License Level*.

If you are using a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the mandatory ACK requirement starting with Cisco IOS XE Cupertino 17.7.1. See [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller, on page 121](#).

Workflow for Topology: No Connectivity to CSSM and No CSLU

Since you do not have to configure connectivity to any other component, the list of tasks required to set-up the topology is a small one. See, the **Results** section at the end of the workflow to know how you can complete requisite usage reporting after you have implemented this topology.

Product Instance Configuration

Where task is performed: Product Instance

Set transport type to **off**.

Enter the **license smart transport off** command in global configuration mode. Save any changes to the configuration file.

```
Device(config)# license smart transport off
Device(config)# exit
Device# copy running-config startup-config
```

Result:

All communication to and from the product instance is disabled. To report license usage you must save RUM reports to a file on the product instance. From a workstation that has connectivity to the Internet and Cisco, upload the file to CSSM:

1. Generate and save RUM reports

Enter the **license smart save usage** command in privileged EXEC mode. In the example below, all RUM reports are saved to the flash memory of the product instance, in file `all_rum.txt`.

Starting with Cisco IOS XE Cupertino 17.7.1, if a trust code does not already exist on the product instance, configuring this command automatically includes a trust code request in the RUM report. This is supported in a standalone, as well as a High Availability set-up.

In the example below, the file is first saved to bootflash and then copied to a TFTP location:

```
Device# license smart save usage all file bootflash:all_rum.txt
Device# copy bootflash:all_rum.txt tftp://10.8.0.6/all_rum.txt
```

2. Upload usage data to CSSM: [#unique_161](#).
3. Install the ACK on the product instance: [#unique_164](#)

If you want to change license usage, see [#unique_148](#).

If you want to return an SLR authorization code, see [Removing and Returning an Authorization Code, on page 151](#).

If you are using a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the mandatory ACK requirement starting with Cisco IOS XE Cupertino 17.7.1. See [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller, on page 121](#).

Workflow for Topology: SSM On-Prem Deployment

Depending on whether you want to implement a product instance-initiated (push) or SSM On-Prem-initiated (pull) method of communication, complete the corresponding sequence of tasks.

Tasks for Product Instance-Initiated Communication

SSM On-Prem Installation → **Addition and Validation of Product Instances (Only if Applicable)** → **Product Instance Configuration** → **Initial Usage Synchronization**

1. *SSM On-Prem Installation*

Where task is performed: A physical server such as a Cisco UCS C220 M3 Rack Server, or a hardware-based server that meets the necessary requirements.

Download the file from [Smart Software Manager](#) > **Smart Software Manager On-Prem**.

Refer to the [Cisco Smart Software On-Prem Installation Guide](#) and the [Cisco Smart Software On-Prem User Guide](#) for help with installation.

Installation is complete when you have deployed SSM On-Prem, configured a common name on SSM On-Prem (**Security Widget** > **Certificates**), synchronized the NTP server (**Settings** widget > **Time Settings**), and created, registered, and synchronized (**Synchronization** widget) the SSM On-Prem local account with your Smart Account and Virtual Account in CSSM.

Note Licensing functions in the **On-Prem Licensing Workspace** are greyed-out until you complete the creation, registration, and synchronization of the local account with your Smart Account in CSSM. The *local accounts* synchronization with CSSM is for the SSM On-Prem instance to be known to CSSM, and is different from usage synchronization which is performed in **4. Initial Usage Synchronization** below.

2. *Addition and Validation of Product Instances*

Where tasks are performed: SSM On-Prem UI

This step ensures that the product instances are validated and mapped to the applicable Smart Account and Virtual account in CSSM. This step is required only in the following cases:

- If you want your product instances to be added and validated in SSM On-Prem before they are reported in CSSM (for added security).
 - If you have created local virtual accounts (in addition to the default local virtual account) in SSM On-Prem. In this case you must provide SSM On-Prem with the Smart Account and Virtual Account information for the product instances in these local virtual accounts, so that SSM On-Prem can report usage to the correct license pool in CSSM.
- a. [Assigning a Smart Account and Virtual Account \(SSM On-Prem UI\), on page 133](#)
 - b. [Validating Devices \(SSM On-Prem UI\), on page 133](#)

Note If your product instance is in a NAT set-up, also enable support for a NAT Setup when you enable device validation – both toggle switches are in the same window.

3. *Product Instance Configuration*

Where tasks are performed: Product Instance and the SSM On-Prem UI

Remember to save any configuration changes on the product instance, by entering the **copy running-config startup-config** command in privileged EXEC mode.

- a. [Ensuring Network Reachability for Product Instance-Initiated Communication, on page 134](#)
- b. [Retrieving the Transport URL \(SSM On-Prem UI\), on page 137](#)
- c. [Setting the Transport Type, URL, and Reporting Interval, on page 159](#)

The transport type configuration for CSLU and SSM On-Prem are the same (**license smart transport cslu** command in global configuration mode), but the URLs are different.

4. *Initial Usage Synchronization*

Where tasks are performed: Product instance, SSM On-Prem, CSSM

- a. Synchronize the product instance with SSM On-Prem.

On the product instance, enter the **license smart sync {all | local}** command, in privileged EXEC mode. This synchronizes the product instance with SSM On-Prem, to send and receive any pending data. For example:

```
Device# license smart sync local
```

You can verify this in the SSM On-Prem UI. Log in and select the **Smart Licensing** workspace. Navigate to the **Inventory > SL Using Policy** tab. In the **Alerts** column of the corresponding product instance, the following message is displayed: Usage report from product instance.

Note If you have not performed Step 2 above (Addition and Validation of Product Instances), completing this sub-step will add the product instance to the SSM On-Prem database.

b. Synchronize usage information with CSSM (*choose one*):

- Option 1:

SSM On-Prem is connected to CSSM: In the SSM On-Prem UI, Smart Licensing workspace, navigate to **Reports > Usage Schedules > Synchronize now with Cisco**.

- Option 2:

SSM On-Prem is not connected to CSSM: See [Exporting and Importing Usage Data \(SSM On-Prem UI\)](#), on page 137.

Result:

You have completed initial usage synchronization. Product instance and license usage information is now displayed in SSM On-Prem.

For subsequent reporting, you have the following options:

- To synchronize data between the product instance and SSM On-Prem:

Schedule periodic synchronization between the product instance and the SSM On-Prem, by configuring the reporting interval. Enter the **license smart usage interval** *interval_in_days* command in global configuration mode.

In the Cisco IOS XE Amsterdam 17.3.6 and later releases of the 17.3.x train, Cisco IOS XE Bengaluru 17.6.4 and later releases of the 17.6.x train, and all subsequent releases from Cisco IOS XE Cupertino 17.9.1 onwards: The product instance does not send more than one RUM report a day. You can override this for an on-demand synchronization between the product instance and CSSM, by entering the **license smart sync** command in privileged EXEC mode.

To know when the product instance will be sending the next RUM report, enter the **show license all** command in privileged EXEC mode and in the output, check the `Next report push`: field.

- To synchronize usage information with CSSM schedule periodic synchronization, or , upload and download the required files:

- Schedule periodic synchronization with CSSM. In the SSM On-Prem UI, navigate to **Reports > Usage Schedules > Synchronization schedule with Cisco**. Enter the following frequency information and save:

- **Days:** Refers to how *often* synchronization occurs. For example, if you enter 2, synchronization occurs once every two days.

- **Time of Day:** Refers to the time at which synchronization occurs, in the 24-hour notation system. For example, if you enter 14 hours and 0 minutes, synchronization occurs at 2 p.m. (1400) in your local time zone.

- Upload and download the required files for reporting: [Exporting and Importing Usage Data \(SSM On-Prem UI\)](#), on page 137).

If you are using a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the mandatory ACK requirement starting with Cisco IOS XE Cupertino 17.7.1. See [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller](#), on page 121.

Tasks for SSM On-Prem Instance-Initiated Communication

SSM On-Prem Installation → **Product Instance Addition** → **Product Instance Configuration** → **Initial Usage Synchronization**

1. *SSM On-Prem Installation*

Where task is performed: A physical server such as a Cisco UCS C220 M3 Rack Server, or a hardware-based server that meets the necessary requirements.

Download the file from [Smart Software Manager](#) > **Smart Software Manager On-Prem**.

Refer to the [Cisco Smart Software On-Prem Installation Guide](#) and the [Cisco Smart Software On-Prem User Guide](#) for help with installation.

Installation is complete when you have deployed SSM On-Prem, configured a common name on SSM On-Prem (**Security Widget** > **Certificates**), synchronized the NTP server (**Settings** widget > **Time Settings**), and created, registered, and synchronized (**Synchronization** widget) the SSM On-Prem local account with your Smart Account and Virtual Account in CSSM.

Note Licensing functions in the **On-Prem Licensing Workspace** are greyed-out until you complete the creation, registration, and synchronization of the local account with your Smart Account in CSSM. The *local account* synchronization with CSSM is for the SSM On-Prem instance to be known to CSSM, and is different from usage synchronization which is performed in **4. Initial Usage Synchronization** below.

2. *Product Instance Addition*

Where task is performed: SSM On-Prem UI

Depending on whether you want to add a single product instance or multiple product instances, follow the corresponding sub-steps: [Adding One or More Product Instances \(SSM On-Prem UI\)](#), on page 138.

3. *Product Instance Configuration*

Where tasks are performed: Product Instance and the SSM On-Prem UI

Remember to save any configuration changes on the product instance, by entering the **copy running-config startup-config** command in privileged EXEC mode: [Ensuring Network Reachability for SSM On-Prem-Initiated Communication](#), on page 139.

4. *Initial Usage Synchronization*

Where tasks are performed: SSM On-Prem UI, and CSSM

- a. Retrieve usage information from the product instance.

In the SSM On-Prem UI, navigate to **Reports** > **Synchronization pull schedule with the devices** > **Synchronize now with the device**.

In the **Alerts** column, the following message is displayed: Usage report from product instance.

Tip It takes 60 seconds before synchronization is triggered. To view progress, navigate to the **On-Prem Admin Workspace**, and click the **Support Centre** widget. The system logs here display progress.

- b. Synchronize usage information with CSSM (*choose one*)

- Option 1:
SSM On-Prem is connected to CSSM: In the SSM On-Prem UI, Smart Licensing workspace, navigate to **Reports > Usage Schedules > Synchronize now with Cisco**.
- Option 2:
SSM On-Prem is not connected to CSSM. See: [Exporting and Importing Usage Data \(SSM On-Prem UI\)](#), on page 137.

Result:

You have completed initial usage synchronization. Product instance and license usage information is now displayed in SSM On-Prem. SSM On-Prem automatically sends the ACK back to the product instance. To verify that the product instance has received the ACK, enter the **show license status** command in privileged EXEC mode, and in the output, check the date for the `Last ACK received` field.

For subsequent reporting, you have the following options:

- To retrieve usage information from the product instance, you can:
 - In the SSM On-Prem UI, Smart Licensing workspace, navigate to **Reports > Usage Schedules > Synchronize now with Cisco**.
 - Schedule periodic retrieval of information from the product instance by configuring a frequency. In the SSM On-Prem UI, Smart Licensing workspace, navigate to **Reports > Usage Schedules > Synchronization pull schedule with the devices**. Enter values in the following fields:
 - **Days:** Refers to how *often* synchronization occurs. For example, if you enter 2, synchronization occurs once every two days.
 - **Time of Day:** Refers to the time at which synchronization occurs, in the 24-hour notation system. For example, if you enter 14 hours and 0 minutes, synchronization occurs at 2 p.m. (1400).
 - Collect usage data from the product instance without being connected to CSSM. In the SSM On-Prem UI, Smart Licensing workspace, navigate to **Inventory > SL Using Policy** tab. Select one or more product instances by enabling the corresponding check box. Click **Actions for Selected... > Collect Usage**. On-Prem connects to the selected Product Instance(s) and collects the usage reports. These usage reports are then stored in On-Prem's local library. These reports can then be transferred to Cisco if On-Prem is connected to Cisco, or (if you are not connected to Cisco) you can manually trigger usage collection by selecting **Export/Import All.. > Export Usage to Cisco**.
- To synchronize usage information with CSSM, you can:
 - Schedule periodic synchronization with CSSM. In the SSM On-Prem UI, navigate to **Reports > Usage Schedules > Synchronization schedule with Cisco**. Enter the following frequency information and save:
 - **Days:** Refers to how *often* synchronization occurs. For example, if you enter 2, synchronization occurs once every two days.
 - **Time of Day:** Refers to the time at which synchronization occurs, in the 24-hour notation system. For example, if you enter 14 hours and 0 minutes, synchronization occurs at 2 p.m. (1400).

- Upload and download the required files for reporting: [Exporting and Importing Usage Data \(SSM On-Prem UI\)](#), on page 137).

If you are using a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the mandatory ACK requirement starting with Cisco IOS XE Cupertino 17.7.1. See [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller](#), on page 121.

Migrating to Smart Licensing Using Policy

To upgrade to Smart Licensing Using Policy, you must upgrade the software version (image) on the product instance to a supported version.

Before you Begin

Ensure that you have read the [#unique_104](#) section, to understand how Smart Licensing Using Policy handles all earlier licensing models.

Smart Licensing Using Policy is introduced in Cisco IOS XE Amsterdam 17.3.2a. This is therefore the minimum required version for Smart Licensing Using Policy.

Note that all the licenses that you are using prior to migration will be available after upgrade. This means that not only registered and authorized licenses (including reserved licenses), but also evaluation licenses will be migrated. The advantage with migrating registered and authorized licenses is that you will have fewer configuration steps to complete after migration, because your configuration is retained after upgrade (transport type configuration and configuration for connection to CSSM, all authorization codes). This ensures a smoother transition to the Smart Licensing Using Policy environment.

Device-led conversion is not supported for migration to Smart Licensing Using Policy.

Upgrading the Wireless Controller Software

For information about the upgrade procedure:

- For Cisco Embedded Wireless Controller on Cisco Catalyst 9100 Access Points, see the *Software Upgrade* section in the [Cisco Embedded Wireless Controller on Catalyst Access Points Online Help](#)
- For all other supported wireless controllers, see the *System Upgrade > Upgrading the Cisco Catalyst 9800 Wireless Controller Software* section of the [Cisco Catalyst 9800 Series Wireless Controller Software Configuration Guide](#) for the required release.

If you are upgrading a Cisco Catalyst 9800-CL Wireless Controller, ensure that you are familiar with the conditions for a mandatory ACK starting with Cisco IOS XE Cupertino 17.7.1. See [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller](#), on page 121.

You can use the procedure to upgrade in install mode or ISSU (ISSU only on supported platforms and supported releases)

After Upgrading the Software Version

- Complete topology implementation.

If a transport mode is available in your pre-upgrade set-up, this is retained after you upgrade. Only in some cases, like with evaluation licenses or with licensing models where the notion of a transport type

does not exist, the default (**cslu**) is applied - in these cases you may have a few more steps to complete before you are set to operate in the Smart Licensing Using Policy environment.

No matter which licensing model you upgrade from, you can change the topology after upgrade.

- Synchronize license usage with CSSM

No matter which licensing model you are upgrading from and no matter which topology you implement, synchronize your usage information with CSSM. For this you have to follow the reporting method that applies to the topology you implement. This initial synchronization ensures that up-to-date usage information is reflected in CSSM and a custom policy (if available), is applied. The policy that is applicable after this synchronization also indicates subsequent reporting requirements. These rules are also tabled here: [How Upgrade Affects Reporting for Existing Licenses, on page 82](#)

Note After initial usage synchronization is completed, reporting is required only if the policy, or, system messages indicate that it is.

Sample Migration Scenarios

Sample migration scenarios have been provided considering the various existing licensing models and licenses. All scenarios provide sample outputs before and after migration, any CSSM Web UI changes to look out for (as an indicator of a successful migration or further action), and how to identify and complete any necessary post-migration steps.

Note For SSM On-Prem, the sequence in which you perform the various upgrade-related activities is crucial. So only for this scenario, the migration sequence has been provided - and not an example.

Example: Smart Licensing to Smart Licensing Using Policy

The following is an example of a Cisco Catalyst 9800-CL Wireless Controller migrating from Smart Licensing to Smart Licensing Using Policy.

- [#unique_178 unique_178_Connect_42_table_11p_yvl_knb](#)
- [#unique_178 unique_178_Connect_42_section_wgh_yvl_knb](#)
- [#unique_178 unique_178_Connect_42_section_crc_yvl_knb](#)

The **show** command outputs below call-out key fields to check, before and after migration.

Table 8: Smart Licensing to Smart Licensing Using Policy: show Commands

Before Upgrade (Smart Licensing)	After Upgrade (Smart Licensing Using Policy)

Before Upgrade (Smart Licensing)	After Upgrade (Smart Licensing Using Policy)
show license udi	show license udi This is a High Availability set-up and the command displays all UDIs in the set-up. There is no change in the sample output before and after migration.
Device# show license udi UDI: PID:C9800-CL-K9,SN:93BBAH93MGS HA UDI List: Active:PID:C9800-CL-K9,SN:93BBAH93MGS Standby:PID:C9800-CL-K9,SN:9XECPSUU4XN	Device# show license udi UDI: PID:C9800-CL-K9,SN:93BBAH93MGS HA UDI List: Active:PID:C9800-CL-K9,SN:93BBAH93MGS Standby:PID:C9800-CL-K9,SN:9XECPSUU4XN

The CSSM Web UI After Migration

Log in to the CSSM Web UI at <https://software.cisco.com> and click **Smart Software Licensing**. Under **Inventory > Product Instances**.

The product instance previously displayed with the host name (Catalyst 9800CL Cloud Wireless Controller in this example) is now displayed with the UDI instead. All migrated UDIs are displayed, that is, PID:C9800-CL-K9,SN:93BBAH93MGS, and PID:C9800-CL-K9,SN:9XECPSUU4XN.

Only the active product instance reports usage, therefore, PID:C9800-CL-K9,SN:93BBAH93MGS displays license consumption information under **License Usage**. The standby does not report usage and the **License Usage** for the standby displays No Records Found.

Figure 8: Smart Licensing to Smart Licensing Using Policy: Hostname of Product Instance on the CSSM Web UI Before Migration

No license usage information under standby product instance

License Usage

License	Billing	Expires	Required
No Records Found			

Actions ▾

It is always the active that reports usage, so if the active in this High Availability set-up changes, the new active product instance will display license consumption information and report usage.

Reporting After Migration

The product instance sends the next RUM report to CSSM, based on the policy.

If you want to change your reporting interval to report more frequently: on the product instance, configure the **license smart usage interval** command in global configuration mode. For syntax details see the *license smart (global config)* command in the Command Reference for the corresponding release.

Example: SLR to Smart Licensing Using Policy

The following is an example of a Cisco Catalyst 9800-CL Wireless Controller migrating from Specific License Reservation (SLR) to Smart Licensing Using Policy. This is a High Availability set-up with an active and standby.

License conversion is automatic and authorization codes are migrated. No further action is required to complete migration. After migration the [#unique_103](#) topology is effective. For information about the SLR authorization code in the Smart Licensing Using Policy environment, see [#unique_180](#).

The CSSM Web UI After Migration

Log in to the CSSM Web UI at <https://software.cisco.com> and click **Smart Software Licensing**. Under **Inventory > Product Instances**.

There are no changes in the **Product Instances** tab. The Last Contact column displays "Reserved Licenses" since there has been no usage reporting yet. After the requisite RUM report is uploaded and acknowledged "Reserved Licenses" is no longer displayed and license usage is displayed only in the active product instance.

Figure 11: SLR to Smart Licensing Using Policy: Active Product Instance Before Upgrade

The screenshot displays the configuration page for a Catalyst 9800CL Cloud Wireless Controller. The page is divided into several sections:

- Overview** and **Event Log** tabs are visible at the top.
- Description**: Catalyst 9800CL Cloud Wireless Controller
- General** section contains the following details:
 - Name: UDI_PID:C9800-CL-K9; UDI_SN:93BBAH93MGS;
 - Product: Catalyst 9800CL Cloud Wireless Controller
 - Host Identifier: -
 - MAC Address: -
 - PID: C9800-CL-K9
 - Serial Number: 93BBAH93MGS
 - UUID: -
 - Virtual Account: Dept-02
 - Registration Date: 2020-Nov-02 05:36:20
 - Last Contact: 2020-Nov-02 05:36:20 (Reserved Licenses) - [Download Reservation Authorization Code](#)
- License Usage** section shows a table of reserved licenses. A note above the table states: "These licenses are reserved on this product instance [Update reservation](#)".

License	Billing	Expires	Required
Aironet DNA Advantage Term Licenses	Prepaid	multiple terms	10
AP Perpetual Networkstack Advantage	Prepaid	multiple terms	10

Annotations in the image include a red box around the UDI information at the top, a grey box labeled "Active product instance" with an arrow pointing to it, and another red box around the Last Contact information at the bottom, with a grey box labeled "SLR before upgrade" and an arrow pointing to it.

Figure 12: SLR to Smart Licensing Using Policy: Active Product Instance After Upgrade

The screenshot displays the configuration page for a Catalyst 9800CL Cloud Wireless Controller. The 'General' tab is selected, showing the following details:

- Name:** UDI_PID:C9800-CL-K9; UDI_SN:93BBAH93MGS; (highlighted as 'Active product instance')
- Product:** Catalyst 9800CL Cloud Wireless Controller
- Host Identifier:** -
- MAC Address:** -
- PID:** C9800-CL-K9
- Serial Number:** 93BBAH93MGS
- UUID:** -
- Virtual Account:** Dept-02
- Registration Date:** 2020-Nov-02 06:08:58
- Last Contact:** 2020-Nov-02 06:09:01 (highlighted as 'SLR after upgrade and usage reporting')

The 'License Usage' section contains the following table:

License	Billing	Expires	Required
Aironet DNA Advantage Term Licenses	Prepaid	-	1
AP Perpetual Networkstack Advantage	Prepaid	-	1

Reporting After Migration

SLR licenses require reporting only when there is a change in license consumption (For example, when using a subscription license which is for specified term).

In an air-gapped network, use the `Next report push: date` in the **show license status** output to know when the next usage report must be sent. This ensures that the product instance and CSSM are synchronized.

Since all communication to and from the product instance is disabled, to report license usage you must save RUM reports to a file and upload it to CSSM (from a workstation that has connectivity to the internet, and Cisco):

1. Generate and save RUM reports

Enter the **license smart save usage** command in privileged EXEC mode. In the example below, all RUM reports are saved to the flash memory of the product instance, in file `all_rum.txt`. For syntax details see the *license smart (privileged EXEC)* command in the Command Reference. In the example, the file is first saved to bootflash and then copied to a TFTP location:

```
Device# license smart save usage all bootflash:all_rum.txt
Device# copy bootflash:all_rum.txt tftp://10.8.0.6/all_rum.txt
```

2. Upload usage data to CSSM: `#unique_161`

3. Install the ACK on the product instance: `#unique_164`

Example: Evaluation or Expired to Smart Licensing Using Policy

The following is an example of a Cisco Catalyst 9800-CL Wireless Controller with evaluation expired licenses (Smart Licensing) that are migrated to Smart Licensing Using Policy.

The notion of evaluation licenses does not apply to Smart Licensing Using Policy. When the software version is upgraded to one that supports Smart Licensing Using Policy, all licenses are displayed as IN USE and the Cisco default policy is applied to the product instance. Since all licenses on Cisco Catalyst Wireless Controllers are unenforced (enforcement type), no functionality is lost.

- [#unique_183 unique_183_Connect_42_table_hdp_4tl_knb](#)
- [#unique_183 unique_183_Connect_42_section_qfh_3wl_knb](#)
- [#unique_183 unique_183_Connect_42_section_y12_ptl_knb](#)

The table below calls out key changes or new fields to check for in the **show** command outputs, after upgrade to Smart Licensing Using Policy

Table 10: Evaluation or Expired to Smart Licensing Using Policy: show Commands

The CSSM Web UI After Migration

Log in to the CSSM Web UI at <https://software.cisco.com> and click **Smart Software Licensing**. Under **Inventory > Product Instances**, the Last Contact field for the migrated product instances display an updated timestamp after migration.

Reporting After Migration

Implement any one of the supported topologies, and fulfil reporting requirements. See [#unique_96](#) and [#unique_114](#). The reporting method you can use depends on the topology you implement.

Migrating to a Version of SSM On-Prem That Supports Smart Licensing Using Policy

If you are using a version of SSM On-Prem that is earlier than the minimum required version (See [SSM On-Prem, on page 63](#)), you can use this section as an outline of the process and sequence you have to follow to migrate the SSM On-Prem version and the product instance.

1. Upgrade SSM On-Prem.

Upgrade to the minimum required Version 8, Release 202102 or a later version.

Refer to the [Cisco Smart Software Manager On-Prem Migration Guide](#).

2. Upgrade the product instance.

For information about the minimum required software version, see [SSM On-Prem, on page 63](#).

For information about the upgrade procedure, see [#unique_115 unique_115_Connect_42_section_ixm_qty_jqb](#).

3. Re-Register a local account with CSSM

Online and Offline options are available. Refer to the [Cisco Smart Software Manager On-Prem Migration Guide > Re-Registering a local Account \(Online Mode\)](#) or [Manually Re-Registering a Local Account \(Offline Mode\)](#).

Once re-registration is complete, the following events occur automatically:

- SSM On-Prem responds with new transport URL that points to the tenant in SSM On-Prem.
- The transport type configuration on the product instance changes from **call-home** or **smart**, to **cslu**. The transport URL is also updated automatically.

4. Save configuration changes on the product instance, by entering the **copy running-config startup-config** command in privileged EXEC mode.

5. Clear older On-Prem Smart Licensing certificates on the product instance and reload the product instance. Do not save configuration changes after this.

Note This step is required only if the software version running on the product instance is Cisco IOS XE Amsterdam 17.3.x or Cisco IOS XE Bengaluru 17.4.x.

Enter the **license smart factory reset** and then the **reload** commands in privileged EXEC mode.

```
Device# license smart factory reset
Device# reload
```

6. Perform usage synchronization

- a. On the product instance, enter the **license smart sync {all|local}** command, in privileged EXEC mode. This synchronizes the product instance with SSM On-Prem, to send and receive any pending data.

```
Device(config)# license smart sync local
```

You can verify this in the SSM On-Prem UI. Go to **Inventory > SL Using Policy**. In the **Alerts** column, the following message is displayed: Usage report from product instance.

- b. Synchronize usage information with CSSM (*choose one*)

- Option 1:

SSM On-Prem is connected to CSSM: In the SSM On-Prem UI, Smart Licensing workspace, navigate to **Reports > Usage Schedules > Synchronize now with Cisco**.

- Option 2:

SSM On-Prem is not connected to CSSM. See [Exporting and Importing Usage Data \(SSM On-Prem UI\), on page 137](#).

Result:

You have completed migration and initial usage synchronization. Product instance and license usage information is now displayed in SSM On-Prem.

For subsequent reporting, you have the following options:

- To synchronize data between the product instance and SSM On-Prem:
 - Schedule periodic synchronization between the product instance and SSM On-Prem, by configuring the reporting interval. Enter the **license smart usage interval *interval_in_days*** command in global configuration mode.

To know when the product instance will be sending the next RUM report, enter the **show license all** command in privileged EXEC mode and in the output, check the `Next report push:` field.
 - Enter the **license smart sync** privileged EXEC command, for ad hoc or on-demand synchronization between the product instance and SSM On-Prem.
- To synchronize usage information with CSSM:
 - Schedule periodic synchronization with CSSM. In the SSM On-Prem UI, navigate to **Reports > Usage Schedules > Synchronization schedule with Cisco**. Enter the following frequency information and save:
 - **Days:** Refers to how *often* synchronization occurs. For example, if you enter 2, synchronization occurs once every two days.
 - **Time of Day:** Refers to the time at which synchronization occurs, in the 24-hour notation system. For example, if you enter 14 hours and 0 minutes, synchronization occurs at 2 p.m. (1400) in your local time zone.

- Upload and download the required files for reporting. See [Exporting and Importing Usage Data \(SSM On-Prem UI\)](#), on page 137.

Task Library for Smart Licensing Using Policy

This section is a grouping of tasks that apply to Smart Licensing Using Policy. It includes tasks performed on a product instance, on the CSLU interface, and on the CSSM Web UI.

To implement a particular topology, refer to the corresponding workflow to know the sequential order of tasks that apply. See [#unique_114](#).

To perform any additional configuration tasks, for instance, to configure a different license, or use an add-on license, or to configure a narrower reporting interval, refer to the corresponding task here. Check the "Supported Topologies" where provided, before you proceed.

RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller

About This Requirement

Beginning with Cisco IOS XE Cupertino 17.7.1, if you are using a *Cisco Catalyst 9800-CL Wireless Controller*, you must complete RUM (Resource Utilization Measurement) reporting and ensure that the Acknowledgment (ACK) is made available on the product instance - at least once. This is to ensure that correct and up-to-date usage information is reflected in CSSM.

Prior to Cisco IOS XE Cupertino 17.7.1, RUM reporting and ACK installation was not mandatory for a Cisco Catalyst 9800-CL Wireless Controller (unlike other Cisco Catalyst Wireless Controllers).

This requirement is applicable to:

- A new Cisco Catalyst 9800-CL Wireless Controller purchased through the [Cisco Commerce](#) portal or downloaded from the [Software Download](#) page, and where the software version running on the product instance is Cisco IOS XE Cupertino 17.7.1 or a later release.
- An existing Cisco Catalyst 9800-CL Wireless Controller that is upgraded to Cisco IOS XE Cupertino 17.7.1 or later release.

Required Action to Meet This Requirement

The following procedure provides information about what you have to do to ensure compliance with this requirement and avoid any throttling restrictions on new and upgraded product instances. This procedure is followed by a flow chart which depicts the same information.

1. Check when the ACK is expected. Note system behavior if you don't meet the ACK deadline.

Enter the **show license air entities summary** command in privileged EXEC mode and check field `License Ack expected within.....: [n] days`.

System behavior if you do not meet the ACK deadline:

Note If the number of AP joins is greater than 10, the system displays this system message once-a-day until an ACK is installed: `%IOSXE_RP_EWLC_NOT-2-MSGDEVICENOTREG`.

- *If an ACK is not installed by the ACK deadline, and the count of currently active APs is lesser than or equal to 50, the system throttles the AP join count to 50.*
- *If an ACK is not installed by the ACK deadline and the count of currently active APs is greater than 50, these currently active APs are not disconnected, but no new AP joins are allowed.*
- *If there is a reload after the throttled state has come into effect, the system throttles the number of currently active APs to 50 when the system comes up after reload.*
- *If there is a stateful switchover (SSO) after the throttled state has come into effect, all connected APs remain joined.*
- *The following system message is displayed when the throttling restriction is effective and a new AP tries to join: `%CAPWAPAC_TRACE_MSG-3-MAX_LICENSE_AP_LIMIT_REACHED`.*

The AP join restriction and the display of the system messages continues until the first ACK is made available on the product instance.

2. Implement a supported topology.

If you have not already done so, implement one of the supported topologies and complete usage reporting. The method you use to send the RUM report to CSSM and ACK installation depends on the topology you implement.

For more information, see: [Supported Topologies, on page 69](#) and [How to Configure Smart Licensing Using Policy: Workflows by Topology , on page 86](#).

3. Ensure that the ACK is available on the product instance.

In the output of the `show license status` command in privileged EXEC mode check for an updated timestamp in the `Last ACK received:`.

```
Device# show license status
<output truncated>
Usage Reporting:
  Last ACK received: <none>
  Next ACK deadline: <none>
  Reporting push interval: 0 (no reporting)
  Next ACK push check: <none>
  Next report push: <none>
  Last report push: <none>
  Last report file write: <none>
```

In the output of the `show license air entities summary` command in privileged EXEC mode, the `License Ack expected within.....: [n] days` field is no longer displayed.

```
Device# show license air entities summary
Upcoming license report time.....: 21:05:16.092 UTC Mon Oct 25 2021
No. of APs active at last report.....: 57
No. of APs newly added with last report.....: 57
No. of APs deleted with last report.....: 0
```

Once the first ACK is installed, the system messages (`%IOSXE_RP_EWLC_NOT-2-MSGDEVICENOTREG` and

%CAPWAPAC_TRACE_MSG-3-MAX_LICENSE_AP_LIMIT_REACHED) are not displayed any longer and AP join throttling restrictions are lifted.

Figure 13: Flow Chart of System Events, User Actions, and System Actions on a Cisco Catalyst 9800-CL Wireless Controller

Logging into Cisco (CSLU Interface)

Depending on your needs, when working in CSLU, you can either be in connected or disconnected mode. To work in the connected mode, complete these steps to connect with Cisco.

Procedure

- Step 1** From the CSLU Main screen, click **Login to Cisco** (located at the top right corner of the screen).
 - Step 2** Enter: **CCO User Name** and **CCO Password**.
 - Step 3** In the CSLU Preferences tab, check that the Cisco connectivity toggle displays “Cisco Is Available”.
-

Configuring a Smart Account and a Virtual Account (CSLU Interface)

Both the Smart Account and Virtual Account are configured through the Preferences tab. Complete the following steps to configure both Smart and Virtual Accounts for connecting to Cisco.

Procedure

- Step 1** Select the **Preferences Tab** from the CSLU home screen.
- Step 2** Perform these steps for adding both a Smart Account and Virtual Account:
 - a) In the Preferences screen navigate to the **Smart Account** field and add the **Smart Account Name**.
 - b) Next, navigate to the **Virtual Account** field and add the **Virtual Account Name**.

If you are connected to CSSM (In the Preferences tab, **Cisco is Available**), you can select from the list of available SA/VAs.

If you are not connected to CSSM (In the Preferences tab, **Cisco Is Not Available**), enter the SA/VAs manually.

Note SA/VA names are case sensitive.

- Step 3** Click **Save**. The SA/VA accounts are saved to the system
- Only one SA/VA pair can reside on CSLU at a time. You cannot add multiple accounts. To change to another SA/VA pair, repeat Steps 2a and 2b then Save. A new SA/VA account pair replaces the previous saved pair
-

Adding a Product-Initiated Product Instance in CSLU (CSLU Interface)

Complete these steps to add a device-created Product Instance using the Preferences tab.

Procedure

- Step 1** Select the **Preferences** tab.

- Step 2** In the Preferences screen, de-select the **Validate Device** check box.
- Step 3** Set the **Default Connect Method** to **Product Instance Initiated** and then click **Save**.

Ensuring Network Reachability for Product Instance-Initiated Communication

This task provides *possible* configurations that may be required to ensure network reachability for product instance-initiated communication. Steps marked as "(Required)" are required for all product instances, all other steps may be required or optional, depending the kind of product instance and network requirements. Configure the applicable commands:

Before you begin

Supported topologies: Connected to CSSM Through CSLU (product instance-initiated communication).

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface interface-type-number Example: Device (config)# interface gigabitethernet0/0	Enters interface configuration mode and specifies the Ethernet interface, subinterface, or VLAN to be associated with the VRF.
Step 4	vrf forwarding vrf-name Example: Device (config-if)# vrf forwarding Mgmt-vrf	Associates the VRF with the Layer 3 interface. This command activates multiprotocol VRF on an interface
Step 5	ip address ip-address mask Example: Device (config-if)# ip address 192.168.0.1 255.255.0.0	Defines the IP address for the VRF.
Step 6	negotiation auto Example: Device (config-if)# negotiation auto	Enables auto-negotiation operation for the speed and duplex parameters of an interface. Note Cisco Catalyst 9800-L-F Wireless Controller 10G Ports do not support in an auto-negotiation operation.

	Command or Action	Purpose
Step 7	end Example: Device(config-if)# end	Exits the interface configuration mode and enters global configuration mode.
Step 8	ip http client source-interface <i>interface-type-number</i> Example: Device(config)# ip http client source-interface gigabitethernet0/0	Configures a source interface for the HTTP client.
Step 9	ip route <i>ip-address ip-mask subnet mask</i> Example: Device(config)# ip route vrf mgmt-vrf 192.168.0.1 255.255.0.0 192.168.255.1	(Required) Configures a route and gateway on the product instance. You can configure either a static route or a dynamic route.
Step 10	{ip ipv6} name-server <i>server-address 1</i> <i>...server-address 6]</i> Example: Device(config)# Device(config)# ip name-server vrf mgmt-vrf 173.37.137.85	Configures Domain Name System (DNS) on the VRF interface.
Step 11	ip domain lookup source-interface <i>interface-type-number</i> Example: Device(config)# ip domain lookup source-interface gigabitethernet0/0	Configures the source interface for the DNS domain lookup. Note If you configure this command on a Layer 3 physical interface, it is automatically removed from running configuration in case the port mode is changed or if the device reloads. The only available workaround is to reconfigure the command. Starting with Cisco IOS XE Dublin 17.12.1, this issue is resolved.
Step 12	ip domain name <i>domain-name</i> Example: Device(config)# ip domain name example.com	Configure DNS discovery of your domain. In accompanying example, the name-server creates entry <code>cslu-local.example.com</code> .

Adding a CSLU-Initiated Product Instance in CSLU (CSLU Interface)

Using the CSLU interface, you can configure the connect method to be CSLU Initiated. This connect method (mode) enables CSLU to retrieve Product Instance information from the Product Instance.

Note The default Connect Method is set in the **Preferences** tab.

Complete these steps to add a Product Instance from the Inventory tab

Procedure

- Step 1** Go to the **Inventory** tab and from the Product Instances table, select **Add Single Product**.
- Step 2** Enter the **Host** (IP address of the Host).
- Step 3** Select the **Connect Method** and select one of the CSLU Initiated connect methods.
- Step 4** In the right panel, click **Product Instance Login Credentials**. The left panel of the screen changes to show the User Name and Password fields.
- Step 5** Enter the product instance **User Name** and **Password**.
- Step 6** Click **Save**.

The information is saved to the system and the device is listed in the Product Instances table with the Last Contact listed as never.

Collecting Usage Reports: CSLU Initiated (CSLU Interface)

CSLU also allows you to manually trigger the gathering of usage reports from devices.

After configuring and selecting a product instance (selecting **Add Single Product**, filling in the **Host** name and selecting a CSLU-initiated connect method), click **Actions for Selected > Collect Usage**. CSLU connects to the selected product instances and collects the usage reports. These usage reports are stored in CSLU's local library. These reports can then be transferred to Cisco if CSLU is connected to Cisco, or (if you are not connected to Cisco) you can manually trigger usage collection by selecting **Data > Export to CSSM**.

If you are working in CSLU-initiated mode, complete these steps to configure CSLU to collect RUM reports from Product Instances.

Procedure

- Step 1** Click the **Preference** tab and enter a valid **Smart Account** and **Virtual Account**, and then select an appropriate CSLU-initiated collect method. (If there have been any changes in Preferences, make sure you click **Save**).
- Step 2** Click the **Inventory** tab and select one or more product instances.
- Step 3** Click **Actions for Selected > Collect Usage**.

RUM reports are retrieved from each selected device and stored in the CSLU local library. The Last Contacted column is updated to show the time the report was received, and the Alerts column shows the status.

If CSLU is currently logged into Cisco the reports will be automatically sent to the associated Smart Account and Virtual Account in Cisco and Cisco will send an acknowledgement to CSLU as well as to the product instance. The acknowledgement will be listed in the alerts column of the Product Instance table. To manually transfer usage reports Cisco, from the CSLU main screen select **Data > Export to CSSM**.

- Step 4** From the **Export to CSSM** modal, select the local directory where the reports are to be stored. (<CSLU_WORKING_Directory>/data/default/rum/unsent)

At this point, the usage reports are saved in your local directory (library). To upload these usage reports to Cisco, follow the steps described in [#unique_161](#).

Note The Windows operating system can change the behavior of a usage report file properties by dropping the extension when that file is renamed. The behavior change happens when you rename the downloaded file and the renamed file drops the extension. For example, the downloaded default file named UD_xxx.tar is renamed to UD_yyy. The file loses its TAR extension and cannot function. To enable the usage file to function normally, after re-naming a usage report file, you must also add the TAR extension back to the file name, for example UD_yyy.tar.

Export to CSSM (CSLU Interface)

The Download All for Cisco menu option is a manual process used for offline purposes. Complete these steps to use the Download For Cisco menu option

Procedure

- Step 1** Go to the **Preferences** tab, and turn off the **Cisco Connectivity** toggle switch. The field switches to “Cisco Is Not Available”.
- Step 2** From the main menu in the CSLU home screen navigate to **Data > Export to CSSM**.
- Step 3** Select the file from the modal that opens and click **Save**. You now have the file saved.
- Note** At this point you have a DLC file, RUM file, or both.
- Step 4** Go to a station that has connectivity to Cisco, and complete the following: [#unique_161](#)
Once the file is downloaded, you can import it into CSLU, see [#unique_162](#).

Import from CSSM (CSLU Interface)

Once you have received the ACK or other file (such as an authorization code) from Cisco, you are ready to Upload that file to your system. This procedure can be used for workstations that are offline. Complete these steps to select and upload files from Cisco.

Procedure

- Step 1** Ensure that you have downloaded the file to a location that is accessible to CSLU.
- Step 2** From the main menu in the CSLU home screen, navigate to **Data > Import from CSSM**.
- Step 3** An Import from CSSM modal open for you to either:

- Drag and Drop a file that resides on your local drive, or
- Browse for the appropriate *.xml file, select the file and click **Open**.

If the upload is successful, you will get message indicating that the file was successfully sent to the server. If the upload is not successful, you will get an import error.

Step 4 When you have finished uploading, click the **x** at the top right corner of the modal to close it.

Ensuring Network Reachability for CSLU-Initiated Communication

This task provides *possible* configurations that may be required to ensure network reachability for CSLU-initiated communication. Steps marked as "(Required)" are required for all product instances, all other steps may be required or optional, depending the kind of product instance and network requirements. Configure the applicable commands:

Before you begin

Supported topologies: Connected to CSSM Through CSLU (CSLU-initiated communication).

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	aaa new model Example: Device(config)# aaa new model	(Required) Enable the authentication, authorization, and accounting (AAA) access control model.
Step 4	aaa authentication login default local Example: Device(config)# aaa authentication login default local	(Required) Sets AAA authentication to use the local username database for authentication.
Step 5	aaa authorization exec default local Example: Device(config)# aaa authorization exec default local	Sets the parameters that restrict user access to a network. The user is allowed to run an EXEC shell.
Step 6	ip routing Example:	Enables IP routing.

	Command or Action	Purpose
	Device (config)# ip routing	
Step 7	<p>{ip ipv6} name-server server-address 1 ...server-address 6]</p> <p>Example:</p> <pre>Device (config)# ip name-server vrf Mgmt-vrf 192.168.1.100 192.168.1.200 192.168.1.300</pre>	<p>(Optional) Specifies the address of one or more name servers to use for name and address resolution.</p> <p>You can specify up to six name servers. Separate each server address with a space. The first server specified is the primary server. The device sends DNS queries to the primary server first. If that query fails, the backup servers are queried.</p>
Step 8	<p>ip domain lookup source-interface interface-type-number</p> <p>Example:</p> <pre>Device (config)# ip domain lookup source-interface gigabitethernet0/0</pre>	<p>Enables DNS-based hostname-to-address translation on your device. This feature is enabled by default.</p> <p>If your network devices require connectivity with devices in networks for which you do not control name assignment, you can dynamically assign device names that uniquely identify your devices by using the global Internet naming scheme (DNS).</p> <p>Note If you configure this command on a Layer 3 physical interface, it is automatically removed from running configuration in case the port mode is changed or if the device reloads. The only available workaround is to reconfigure the command. Starting with Cisco IOS XE Dublin 17.12.1, this issue is resolved.</p>
Step 9	<p>ip domain name name</p> <p>Example:</p> <pre>Device (config)# ip domain name vrf Mgmt-vrf cisco.com</pre>	<p>Defines a default domain name that the software uses to complete unqualified hostnames (names without a dotted-decimal domain name).</p>
Step 10	<p>no username name</p> <p>Example:</p> <pre>Device (config)# no username admin</pre>	<p>(Required) Clears the specified username, if it exists. For <i>name</i>, enter the same username you will create in the next step. This ensures that a duplicate of the username you are going to create in the next step does not exist.</p> <p>If you plan to use REST APIs for CSLU-initiated retrieval of RUM reports, you have to log in to CSLU. Duplicate usernames may cause the feature to work incorrectly if there are duplicate usernames in the system.</p>

	Command or Action	Purpose
Step 11	<p>username <i>name</i> privilege level password <i>password</i></p> <p>Example:</p> <pre>Device(config)# username admin privilege 15 password 0 lab</pre>	<p>(Required) Establishes a username-based authentication system.</p> <p>The privilege keyword sets the privilege level for the user. A number between 0 and 15 that specifies the privilege level for the user.</p> <p>The password allows access to the name argument. A password must be from 1 to 25 characters, can contain embedded spaces, and must be the last option specified in the username command.</p> <p>This enables CSLU to use the product instance native REST.</p> <p>Note Enter this username and password in CSLU (#unique_151 → <i>Step 4. f.</i> CSLU can then collect RUM reports from the product instance.</p>
Step 12	<p>interface <i>interface-type-number</i></p> <p>Example:</p> <pre>Device (config)# interface gigabitethernet0/0</pre>	Enters interface configuration mode and specifies the Ethernet interface, subinterface, or VLAN to be associated with the VRF.
Step 13	<p>vrf forwarding <i>vrf-name</i></p> <p>Example:</p> <pre>Device(config-if)# vrf forwarding Mgmt-vrf</pre>	Associates the VRF with the Layer 3 interface. This command activates multiprotocol VRF on an interface
Step 14	<p>ip address <i>ip-address mask</i></p> <p>Example:</p> <pre>Device(config-if)# ip address 192.168.0.1 255.255.0.0</pre>	Defines the IP address for the VRF.
Step 15	<p>negotiation auto</p> <p>Example:</p> <pre>Device(config-if)# negotiation auto</pre>	Enables auto-negotiation operation for the speed and duplex parameters of an interface.
Step 16	<p>no shutdown</p> <p>Example:</p> <pre>Device(config-if)# no shutdown</pre>	Restarts a disabled interface.
Step 17	<p>end</p> <p>Example:</p> <pre>Device(config-if)# end</pre>	Exits the interface configuration mode and enters global configuration mode.

	Command or Action	Purpose
Step 18	ip http server Example: Device (config) # ip http server	(Required) Enables the HTTP server on your IP or IPv6 system, including a Cisco web browser user interface. The HTTP server uses the standard port 80, by default.
Step 19	ip http authentication local Example: ip http authentication local Device (config) #	(Required) Specifies a particular authentication method for HTTP server users. The local keyword means that the login user name, password and privilege level access combination specified in the local system configuration (by the username global configuration command) should be used for authentication and authorization.
Step 20	ip http secure-server Example: Device (config) # ip http server	(Required) Enables a secure HTTP (HTTPS) server. The HTTPS server uses the Secure Sockets Layer (SSL) version 3.0 protocol.
Step 21	ip http max-connections Example: Device (config) # ip http max-connections 16	(Required) Configures the maximum number of concurrent connections allowed for the HTTP server. Enter an integer in the range from 1 to 16. The default is 5.
Step 22	ip tftp source-interface interface-type-number Example: Device (config) # ip tftp source-interface GigabitEthernet0/0	Specifies the IP address of an interface as the source address for TFTP connections.
Step 23	ip route ip-address ip-mask subnet mask Example: Device (config) # ip route vrf mgmt-vrf 192.168.0.1 255.255.0.0 192.168.255.1	Configures a route and gateway on the product instance. You can configure either a static route or a dynamic route.
Step 24	logging host Example: Device (config) # logging host 172.25.33.20 vrf Mgmt-vrf	Logs system messages and debug output to a remote host.
Step 25	end Example: Device (config) # end	Exits the global configuration mode and enters privileged EXEC mode.
Step 26	show ip http server session-module Example:	(Required) Verifies HTTP connectivity. In the output, check that <code>SL_HTTP</code> is active. Additionally, you can also perform the following checks :

	Command or Action	Purpose
	Device# <code>show ip http server session-module</code>	<ul style="list-style-type: none"> • From device where CSLU is installed, verify that you can ping the product instance. A successful ping confirms that the product instance is reachable. • From a Web browser on the device where CSLU is installed verify <code>https://<product-instance-ip>/</code>. This ensures that the REST API from CSLU to the product instance works as expected.

Assigning a Smart Account and Virtual Account (SSM On-Prem UI)

You can use this procedure to import one or more product instances along with corresponding Smart Account and Virtual Account information, into the SSM On-Prem database. This enables SSM On-Prem to map product instances that are part of local virtual accounts (other than the default local virtual account), to the correct license pool in CSSM:

Before you begin

Supported topologies: SSM On-Prem Deployment (product instance-initiated communication).

Procedure

-
- Step 1** Log into the SSM On-Prem and select the **Smart Licensing** workspace.
- Step 2** Navigate to **Inventory > SL Using Policy > Export/Import All > Import Product Instances List**. The **Upload Product Instances** window is displayed.
- Step 3** Click **Download** to download the .csv template file and enter the required information for all the product instances in the template.
- Step 4** Once you have filled-out the template, click **Inventory > SL Using Policy > Export/Import All > Import Product Instances List**. The **Upload Product Instances** window is displayed.
- Step 5** Now, click **Browse** and upload the filled-out .csv template. Smart Account and Virtual Account information for all uploaded product instances is now available in SSM On-Prem.
-

Validating Devices (SSM On-Prem UI)

When device validation is enabled, RUM reports from an unknown product instance (not in the SSM On-Prem database) are rejected.

By default, devices are not validated. Complete the following steps to enable it:

Before you begin

Supported topologies: SSM On-Prem Deployment (product instance-initiated communication).

Procedure

-
- Step 1** In the **On-Prem License Workspace** window, click **Admin Workspace** and log in, if prompted. The **On-Prem Admin Workspace** window is displayed.
- Step 2** Click the **Settings** widget. The **Settings** window is displayed.
- Step 3** Navigate to the **CSLU** tab and turn-on the **Validate Device** toggle switch. RUM reports from an unknown product instance will now be rejected. If you haven't already, you must now add the required product instances to the SSM On-Prem database before sending RUM reports. See [Assigning a Smart Account and Virtual Account \(SSM On-Prem UI\)](#), on page 133
-

Ensuring Network Reachability for Product Instance-Initiated Communication

This task provides *possible* configurations that may be required to ensure network reachability for product instance-initiated communication. Steps marked as "(Required)" are required for all product instances, all other steps may be required or optional, depending the kind of product instance and network requirements. Configure the applicable commands:

Note Ensure that you configure steps 13, 14, and 15 exactly as shown below. These commands must be configured to ensure that the correct trustpoint is used and that the necessary certificates are accepted for network reachability.

Before you begin

Supported topologies: SSM On-Prem Deployment(product instance-initiated communication).

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	interface <i>interface-type-number</i> Example: Device (config)# interface gigabitethernet0/0	Enters interface configuration mode and specifies the Ethernet interface, subinterface, or VLAN to be associated with the VRF.
Step 4	vrf forwarding <i>vrf-name</i> Example: Device (config-if)# vrf forwarding Mgmt-vrf	Associates the VRF with the Layer 3 interface. This command activates multiprotocol VRF on an interface
Step 5	ip address <i>ip-address mask</i> Example: Device (config-if)# ip address 192.168.0.1 255.255.0.0	Defines the IP address for the VRF.
Step 6	negotiation auto Example: Device (config-if)# negotiation auto	Enables auto-negotiation operation for the speed and duplex parameters of an interface.
Step 7	end Example: Device (config-if)# end	Exits the interface configuration mode and enters global configuration mode.
Step 8	ip http client source-interface <i>interface-type-number</i> Example: Device (config)# ip http client source-interface gigabitethernet0/0	Configures a source interface for the HTTP client.
Step 9	ip route <i>ip-address ip-mask subnet mask</i> Example: Device (config)# ip route vrf mgmt-vrf 192.168.0.1 255.255.0.0 192.168.255.1	(Required) Configures a route and gateway on the product instance. You can configure either a static route or a dynamic route.
Step 10	{ ip ipv6 } name-server <i>server-address 1</i> <i>...server-address 6]</i> Example: Device (config)# Device (config)# ip name-server vrf mgmt-vrf 198.51.100.1	Configures Domain Name System (DNS) on the VRF interface.
Step 11	ip domain lookup source-interface <i>interface-type-number</i> Example:	Configures the source interface for the DNS domain lookup.

	Command or Action	Purpose
	Device (config) # <code>ip domain lookup source-interface gigabitethernet0/0</code>	Note If you configure this command on a Layer 3 physical interface, it is automatically removed from running configuration in case the port mode is changed or if the device reloads. The only available workaround is to reconfigure the command. Starting with Cisco IOS XE Dublin 17.12.1, this issue is resolved.
Step 12	ip domain name <i>domain-name</i> Example: Device (config) # <code>ip domain name example.com</code>	Configure DNS discovery of your domain. In the accompanying example, the name-server creates entry <code>cslu-local.example.com</code> .
Step 13	crypto pki trustpoint SLA-TrustPoint Example: Device (config) # <code>crypto pki trustpoint SLA-TrustPoint</code> Device (ca-trustpoint) #	(Required) Declares that the product instance should use trustpoint “SLA-TrustPoint” and enters the ca-trustpoint configuration mode. The product instance does not recognize any trustpoints until you declare a trustpoint using this command.
Step 14	enrollment terminal Example: Device (ca-trustpoint) # <code>enrollment terminal</code>	(Required) Specifies the certificate enrollment method.
Step 15	revocation-check none Example: Device (ca-trustpoint) # <code>revocation-check none</code>	(Required) Specifies a method that is to be used to ensure that the certificate of a peer is not revoked. For the SSM On-Prem Deployment topology, enter the none keyword. This means that a revocation check will not be performed and the certificate will always be accepted.
Step 16	exit Example: Device (ca-trustpoint) # <code>exit</code> Device (config) # <code>exit</code>	Exits the ca-trustpoint configuration mode and then the global configuration mode and returns to privileged EXEC mode.
Step 17	copy running-config startup-config Example: Device # <code>copy running-config startup-config</code>	Saves your entries in the configuration file.

Retrieving the Transport URL (SSM On-Prem UI)

You must configure the transport URL on the product instance when you deploy the product instance-initiated communication with SSM On-Prem deployment. This task show you how to easily copy the complete URL including the tenant ID from SSM On-Prem.

Before you begin

Supported topologies: SSM On-Prem Deployment (product instance-initiated communication).

Procedure

- Step 1** Log into SSM On-Prem and select the **Smart Licensing** workspace.
- Step 2** Navigate to the **Inventory** tab and from the dropdown list of local virtual accounts (top right corner), select the *default local virtual account*. When you do, the area under the **Inventory** tab displays **Local Virtual Account: Default**.
- Step 3** Navigate to the **General** tab.
The **Product Instance Registration Tokens** area is displayed.
- Step 4** In the **Product Instance Registration Tokens** area click **CSLU Transport URL**.
The **Product Registration URL** pop-window is displayed.
- Step 5** Copy the entire URL and save it in an accessible place.
You will require the URL when you configure the transport type and URL on the product instance.
- Step 6** Configure the transport type and URL. See: [Setting the Transport Type, URL, and Reporting Interval, on page 159](#).
-

Exporting and Importing Usage Data (SSM On-Prem UI)

You can use this procedure to complete usage synchronization between SSM On-Prem and CSSM when SSM On-Prem is disconnected from CSSM.

Before you begin

Supported topologies:

- SSM On-Prem Deployment (SSM On-Prem-initiated communication)
- SSM On-Prem Deployment (product instance-initiated communication).

Reporting data must be available in SSM On-Prem. You must have either pushed the necessary reporting data from the product instance to SSM On-Prem (product instance-initiated communication) or retrieved the necessary reporting data from the product instance (SSM On-Prem-initiated communication).

Procedure

- Step 1** Log into SSM On-Prem and select **Smart Licensing**.
- Step 2** Navigate to **Inventory > SL Using Policy** tab.
- Step 3** In the **SL Using Policy** tab area, click **Export/Import All... > Export Usage to Cisco**.
This generates one .tar file with *all* the usage reports available in the SSM On-Prem server.
- Step 4** Complete this task in CSSM: [#unique_161](#).
At the end of this task you will have an ACK file to import into SSM On-Prem.
- Step 5** Again navigate to the **Inventory > SL Using Policy** tab.
- Step 6** In the **SL Using Policy** tab area, click **Export/Import All... > Import From Cisco** . Upload the .tar ACK file.
To verify ACK import, in the **SL Using Policy** tab area check the **Alerts** column of the corresponding product instance. The following message is displayed: Acknowledgement received from CSSM.
-

Adding One or More Product Instances (SSM On-Prem UI)

You can use this procedure to add one product instance or to import and add multiple product instances. It enables SSM On-Prem to retrieve information from the product instance.

Before you begin

Supported topologies: SSM On-Prem Deployment (SSM On-Prem-initiated communication).

Procedure

- Step 1** Log into the SSM On-Prem UI and click **Smart Licensing**.
- Step 2** Navigate to **Inventory** tab. Select a local virtual account from the drop-down list in the top right corner.
- Step 3** Navigate to the **SL Using Policy** tab.
- Step 4** Add a single product or import multiple product instances (*choose one*).
- **To add a single product instance:**
 - a. In the **SL Using Policy** tab area, click **Add Single Product**.
 - b. In the **Host** field, enter the IP address of the host (product instance).
 - c. From the **Connect Method** dropdown list, select an appropriate SSM On-Prem-initiated connect method.

The available connect methods for SSM On-Prem-initiated communication are: NETCONF, RESTCONF, and REST API.
 - d. In the right panel, click **Product Instance Login Credentials**.

The **Product Instance Login Credentials** window is displayed

Note You need the login credentials only if a product instance requires a SLAC.

- e. Enter the **User ID** and **Password**, and click **Save**.

This is the same user ID and password that you configured as part of commands required to establish network reachability ([Ensuring Network Reachability for SSM On-Prem-Initiated Communication, on page 139](#)).

Once validated, the product instance is displayed in the listing in the **SL Using Policy** tab area.

• **To import multiple product instances:**

- a. In **SL Using Policy** tab, click **Export/Import All... > Import Product Instances List**.

The **Upload Product Instances** window is displayed.

- b. Click **Download** to download the predefined .csv template.

- c. Enter the required information for all the product instances in the .csv template.

In the template, ensure that you provide **Host**, **Connect Method** and **Login Credentials** for all product instances.

The available connect methods for SSM On-Prem-initiated communication are: NETCONF, RESTCONF, and REST API.

Login credentials refer to the user ID and password that you configured as part of commands required to establish network reachability ([Ensuring Network Reachability for SSM On-Prem-Initiated Communication, on page 139](#)).

- d. Again navigate to **Inventory > SL Using Policy** tab. Click **Export/Import All... > Import Product Instances List**.

The **Upload Product Instances** window is displayed.

- e. Now upload the filled-out .csv template.

Once validated, the product instances are displayed in the listing in the **SL Using Policy** tab.

Ensuring Network Reachability for SSM On-Prem-Initiated Communication

This task provides *possible* configurations that may be required to ensure network reachability for SSM On-Prem-initiated communication. Steps marked as "(Required)" are required for all product instances, all other steps may be required or optional, depending the kind of product instance and network requirements. Configure the applicable commands:

Note Ensure that you configure steps 25, 26, and 27 exactly as shown below. These commands must be configured to ensure that the correct trustpoint is used and that the necessary certificates are accepted for network reachability.

Before you begin

Supported topologies: SSM On-Prem Deployment (SSM On-Prem-initiated communication).

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	aaa new model Example: Device(config)# aaa new model	(Required) Enable the authentication, authorization, and accounting (AAA) access control model.
Step 4	aaa authentication login default local Example: Device(config)# aaa authentication login default local	(Required) Sets AAA authentication to use the local username database for authentication.
Step 5	aaa authorization exec default local Example: Device(config)# aaa authorization exec default local	Sets the parameters that restrict user access to a network. The user is allowed to run an EXEC shell.
Step 6	ip routing Example: Device(config)# ip routing	Enables IP routing.
Step 7	{ip ipv6} name-server server-address 1 ...server-address 6] Example: Device(config)# ip name-server vrf Mgmt-vrf 192.168.1.100 192.168.1.200 192.168.1.300	(Optional) Specifies the address of one or more name servers to use for name and address resolution. You can specify up to six name servers. Separate each server address with a space. The first server specified is the primary server. The device sends DNS queries to the primary server first. If that query fails, the backup servers are queried.
Step 8	ip domain lookup source-interface interface-type-number Example: Device(config)# ip domain lookup source-interface gigabitethernet0/0	Enables DNS-based hostname-to-address translation on your device. This feature is enabled by default. If your network devices require connectivity with devices in networks for which you do not

	Command or Action	Purpose
		<p>control name assignment, you can dynamically assign device names that uniquely identify your devices by using the global Internet naming scheme (DNS).</p> <p>Note If you configure this command on a Layer 3 physical interface, it is automatically removed from running configuration in case the port mode is changed or if the device reloads. The only available workaround is to reconfigure the command. Starting with Cisco IOS XE Dublin 17.12.1, this issue is resolved.</p>
Step 9	<p>ip domain name <i>name</i></p> <p>Example:</p> <pre>Device(config)# ip domain name vrf Mgmt-vrf cisco.com</pre>	<p>Defines a default domain name that the software uses to complete unqualified hostnames (names without a dotted-decimal domain name).</p>
Step 10	<p>no username <i>name</i></p> <p>Example:</p> <pre>Device(config)# no username admin</pre>	<p>(Required) Clears the specified username, if it exists. For <i>name</i>, enter the same username you will create in the next step. This ensures that a duplicate of the username you are going to create in the next step does not exist.</p> <p>If you plan to use REST APIs for SSM On-Prem-initiated retrieval of RUM reports, you have to log in to SSM On-Prem. Duplicate usernames may cause the feature to work incorrectly if there are present in the system.</p>
Step 11	<p>username <i>name</i> privilege <i>level</i> password <i>password</i></p> <p>Example:</p> <pre>Device(config)# username admin privilege 15 password 0 lab</pre>	<p>(Required) Establishes a username-based authentication system.</p> <p>The privilege keyword sets the privilege level for the user. A number between 0 and 15 that specifies the privilege level for the user.</p> <p>The password allows access to the name argument. A password must be from 1 to 25 characters, can contain embedded spaces, and must be the last option specified in the username command.</p> <p>This enables SSM On-Prem to use the product instance native REST.</p>

	Command or Action	Purpose
		<p>Note Enter this username and password in SSM On-Prem (Adding One or More Product Instances (SSM On-Prem UI), on page 138). This enables SSM On-Prem to collect RUM reports from the product instance.</p>
Step 12	<p>interface <i>interface-type-number</i></p> <p>Example:</p> <pre>Device (config)# interface gigabitethernet0/0</pre>	Enters interface configuration mode and specifies the Ethernet interface, subinterface, or VLAN to be associated with the VRF.
Step 13	<p>vrf forwarding <i>vrf-name</i></p> <p>Example:</p> <pre>Device (config-if)# vrf forwarding Mgmt-vrf</pre>	Associates the VRF with the Layer 3 interface. This command activates multiprotocol VRF on an interface
Step 14	<p>ip address <i>ip-address mask</i></p> <p>Example:</p> <pre>Device (config-if)# ip address 192.168.0.1 255.255.0.0</pre>	Defines the IP address for the VRF.
Step 15	<p>negotiation auto</p> <p>Example:</p> <pre>Device (config-if)# negotiation auto</pre>	Enables auto-negotiation operation for the speed and duplex parameters of an interface.
Step 16	<p>no shutdown</p> <p>Example:</p> <pre>Device (config-if)# no shutdown</pre>	Restarts a disabled interface.
Step 17	<p>end</p> <p>Example:</p> <pre>Device (config-if)# end</pre>	Exits the interface configuration mode and enters global configuration mode.
Step 18	<p>ip http server</p> <p>Example:</p> <pre>Device (config)# ip http server</pre>	(Required) Enables the HTTP server on your IP or IPv6 system, including a Cisco web browser user interface. The HTTP server uses the standard port 80, by default.
Step 19	<p>ip http authentication local</p> <p>Example:</p> <pre>ip http authentication local Device (config)#</pre>	<p>(Required) Specifies a particular authentication method for HTTP server users.</p> <p>The local keyword means that the login user name, password and privilege level access combination specified in the local system configuration (by the username global</p>

	Command or Action	Purpose
		configuration command) should be used for authentication and authorization.
Step 20	ip http secure-server Example: Device(config)# ip http server	(Required) Enables a secure HTTP (HTTPS) server. The HTTPS server uses the Secure Sockets Layer (SSL) version 3.0 protocol.
Step 21	ip http max-connections Example: Device(config)# ip http max-connections 16	(Required) Configures the maximum number of concurrent connections allowed for the HTTP server. Enter an integer in the range from 1 to 16. The default is 5.
Step 22	ip tftp source-interface interface-type-number Example: Device(config)# ip tftp source-interface GigabitEthernet0/0	Specifies the IP address of an interface as the source address for TFTP connections.
Step 23	ip route ip-address ip-mask subnet mask Example: Device(config)# ip route vrf mgmt-vrf 192.168.0.1 255.255.0.0 192.168.255.1	Configures a route and gateway on the product instance. You can configure either a static route or a dynamic route.
Step 24	logging host Example: Device(config)# logging host 172.25.33.20 vrf Mgmt-vrf	Logs system messages and debug output to a remote host.
Step 25	crypto pki trustpoint SLA-TrustPoint Example: Device(config)# crypto pki trustpoint SLA-TrustPoint Device(ca-trustpoint)#	(Required) Declares that the product instance should use trustpoint “SLA-TrustPoint” and enters the ca-trustpoint configuration mode. The product instance does not recognize any trustpoints until you declare a trustpoint using this command.
Step 26	enrollment terminal Example: Device(ca-trustpoint)# enrollment terminal	(Required) Specifies the certificate enrollment method.
Step 27	revocation-check none Example: Device(ca-trustpoint)# revocation-check none	(Required) Specifies a method that is to be used to ensure that the certificate of a peer is not revoked. For the SSM On-Prem Deployment topology, enter the none keyword. This means that a revocation check will not be performed and the certificate will always be accepted.

	Command or Action	Purpose
Step 28	end Example: Device (ca-trustpoint) # exit Device (config) # end	Exits the ca-trustpoint configuration mode and then the global configuration mode and returns to privileged EXEC mode.
Step 29	show ip http server session-module Example: Device# show ip http server session-module	(Required) Verifies HTTP connectivity. In the output, check that <code>SL_HTTP</code> is active. Additionally, you can also perform the following checks : <ul style="list-style-type: none"> • From device where SSM On-Prem is installed, verify that you can ping the product instance. A successful ping confirms that the product instance is reachable. • From a Web browser on the device where SSM On-Prem is installed verify <code>https://<product-instance-ip>/</code>. This ensures that the REST API from SSM On-Prem to the product instance works as expected.
Step 30	copy running-config startup-config Example: Device# copy running-config startup-config	Saves your entries in the configuration file.

Setting Up a Connection to CSSM

The following steps show how to set up a Layer 3 connection to CSSM to verify network reachability. Steps marked as "(Required)" are required for all product instances, all other steps may be required or optional, depending the kind of product instance and network requirements. Configure the applicable commands:

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	{ip ipv6} name-server server-address 1 ...server-address 6]	Specifies the address of one or more name servers to use for name and address resolution.

	Command or Action	Purpose
	<p>Example:</p> <pre>Device(config)# ip name-server 209.165.201.1 209.165.200.225 209.165.201.14 209.165.200.230</pre>	<p>You can specify up to six name servers. Separate each server address with a space. The first server specified is the primary server. The device sends DNS queries to the primary server first. If that query fails, the backup servers are queried.</p>
Step 4	<p>ip name-server vrf <i>Mgmt-vrf</i> <i>server-address</i> <i>1...server-address</i> <i>6</i></p> <p>Example:</p> <pre>Device(config)# ip name-server vrf Mgmt-vrf 209.165.201.1 209.165.200.225 209.165.201.14 209.165.200.230</pre>	<p>(Optional) Configures DNS on the VRF interface. You can specify up to six name servers. Separate each server address with a space.</p> <p>Note This command is an alternative to the ip name-server command.</p>
Step 5	<p>ip domain lookup source-interface <i>interface-type</i> <i>interface-number</i></p> <p>Example:</p> <pre>Device(config)# ip domain lookup source-interface Vlan100</pre>	<p>Configures the source interface for the DNS domain lookup.</p>
Step 6	<p>ip domain name <i>domain-name</i></p> <p>Example:</p> <pre>Device(config)# ip domain name example.com</pre>	<p>Configures the domain name.</p>
Step 7	<p>ip host tools.cisco.com <i>ip-address</i></p> <p>Example:</p> <pre>Device(config)# ip host tools.cisco.com 209.165.201.30</pre>	<p>Configures static hostname-to-address mappings in the DNS hostname cache if automatic DNS mapping is not available.</p>
Step 8	<p>interface <i>interface-type-number</i></p> <p>Example:</p> <pre>Device(config)# interface Vlan100 Device(config-if)# ip address 192.0.2.10 255.255.255.0 Device(config-if)# exit</pre>	<p>Configures a Layer 3 interface. Enter an interface type and number or a VLAN.</p>
Step 9	<p>ntp server <i>ip-address</i> [version number] [key <i>key-id</i>] [prefer]</p> <p>Example:</p> <pre>Device(config)# ntp server 198.51.100.100 version 2 prefer</pre>	<p>(Required) Activates the NTP service (if it has not already been activated) and enables the system to synchronize the system software clock with the specified NTP server. This ensures that the device time is synchronized with CSSM.</p> <p>Use the prefer keyword if you need to use this command multiple times and you want to set a preferred server. Using this keyword reduces switching between servers.</p>

	Command or Action	Purpose
Step 10	switchport access vlan <i>vlan_id</i> Example: Device(config)# interface GigabitEthernet1/0/1 Device(config-if)# switchport access vlan 100 Device(config-if)# switchport mode access Device(config-if)# exit OR Device(config)#	Enables the VLAN for which this access port carries traffic and sets the interface as a nontrunking nontagged single-VLAN Ethernet interface. Note This step is to be configured only if the switchport access mode is required. The switchport access vlan command may apply to Catalyst switching product instances, for example, and for routing product instances you may want to configure the ip address <i>ip-address mask</i> command instead.
Step 11	ip route <i>ip-address ip-mask subnet mask</i> Example: Device(config)# ip route 192.0.2.0 255.255.255.255 192.0.2.1	Configures a route on the device. You can configure either a static route or a dynamic route.
Step 12	ip http client source-interface <i>interface-type-number</i> Example: Device(config)# ip http client source-interface Vlan100	(Required) Configures a source interface for the HTTP client. Enter an interface type and number or a VLAN.
Step 13	exit Example: Device(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.
Step 14	copy running-config startup-config Example: Device# copy running-config startup-config	Saves your entries in the configuration file.

Configuring Smart Transport Through an HTTPs Proxy

To use a proxy server to communicate with CSSM when using the Smart transport mode, complete the following steps:

Procedure

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. Enter your password, if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	license smart transport smart Example: Device(config)# license smart transport smart	Enables Smart transport mode.
Step 4	license smart url default Example: Device(config)# license smart transport default	Automatically configures the Smart URL (https://smartreceiver.cisco.com/licservice/license). For this option to work as expected, the transport mode in the previous step must be configured as smart .
Step 5	license smart proxy { address address_hostname port port_num } Example: Device(config)# license smart proxy address 192.168.0.1 Device(config)# license smart proxy port 3128	Configures a proxy for the Smart transport mode. When a proxy is configured, licensing messages are sent to the proxy along with the final destination URL (CSSM). The proxy sends the message on to CSSM. Configure the proxy address and port number separately: <ul style="list-style-type: none"> • address address_hostname: Specifies the proxy address. Enter the IP address or hostname of the proxy server. • port port_num: Specifies the proxy port. Enter the proxy port number. <p>Note the change in the criteria for the acceptance of proxy servers, starting with Cisco IOS XE Bengaluru 17.6.1: only the status code of the proxy server response is verified by the system and not the reason phrase. The RFC format is status-line = HTTP-version SP status-code SP reason-phrase CRLF. For more information about the status line, see section 3.1.2 of RFC 7230.</p>

Configuring the Call Home Service for Direct Cloud Access

The Call Home service provides email-based and web-based notification of critical system events to CSSM. To configure the transport mode, enable the Call Home service, and configure a destination profile (A destination profile contains the required delivery information for an alert notification. At least one destination profile is required.), complete the following steps:

Note All steps are required unless specifically called-out as “(Optional)”.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	license smart transport callhome Example: Device (config)# license smart transport callhome	Enables Call Home as the transport mode.
Step 4	license smart url url Example: Device (config)# license smart url https://tools.cisco.com/its/service/otbe/services/DOEService	For the callhome transport mode, configure the CSSM URL exactly as shown in the example.
Step 5	service call-home Example: Device (config)# service call-home	Enables the Call Home feature.
Step 6	call-home Example: Device (config)# call-home	Enters Call Home configuration mode.
Step 7	no http secure server-identity-check Example: Device (config-call-home)# no http secure server-identity-check	Disables server identity check when HTTP connection is established.
Step 8	contact-email-address email-address Example: Device (config-call-home)# contact-email-addr username@example.com	Assigns customer's email address and enables Smart Call Home service full reporting capability and sends a full inventory message from Call-Home TAC profile to Smart Call Home server to start full registration process. You can enter up to 200 characters in email address format with no spaces.

	Command or Action	Purpose
Step 9	<p>profile name</p> <p>Example:</p> <pre>Device(config-call-home)# profile CiscoTAC-1 Device(config-call-home-profile)#</pre>	<p>Enters the Call Home destination profile configuration submode for the specified destination profile.</p> <p>By default:</p> <ul style="list-style-type: none"> • The CiscoTAC-1 profile is inactive. To use this profile with the Call Home service, you must enable the profile. • The CiscoTAC-1 profile sends a full report of all types of events subscribed in the profile. The alternative is to additionally configure <pre>Device(cfg-call-home-profile)# anonymous-reporting-only anonymous-reporting-only.</pre> When this is set, only crash, inventory, and test messages will be sent. <p>Use the show call-home profile all command to check the profile status.</p>
Step 10	<p>active</p> <p>Example:</p> <pre>Device(config-call-home-profile)# active</pre>	Enables the destination profile.
Step 11	<p>destination transport-method http {email http}</p> <p>Example:</p> <pre>Device(config-call-home-profile)# destination transport-method http AND Device(config-call-home-profile)# no destination transport-method email</pre>	<p>Enables the message transport method. In the example, Call Home service is enabled via HTTP and transport via email is disabled.</p> <p>The no form of the command disables the method.</p>
Step 12	<p>destination address { email email_address http url}</p> <p>Example:</p> <pre>Device(config-call-home-profile)# destination address http https://tools.cisco.com/its/service/otbe/services/DCEService AND Device(config-call-home-profile)# no destination address http https://tools.cisco.com/its/service/otbe/services/DCEService</pre>	<p>Configures the destination e-mail address or URL to which Call Home messages are sent. When entering a destination URL, include either http:// (default) or https://, depending on whether the server is a secure server.</p> <p>In the example provided here, a http:// destination URL is configured; and the no form of the command is configured for https://.</p>

	Command or Action	Purpose
Step 13	exit Example: Device (config-call-home-profile) # exit	Exits Call Home destination profile configuration mode and returns to Call Home configuration mode.
Step 14	exit Example: Device (config-call-home) # end	Exits Call Home configuration mode and returns to privileged EXEC mode.
Step 15	copy running-config startup-config Example: Device# copy running-config startup-config	Saves your entries in the configuration file.
Step 16	show call-home profile { <i>name</i> all }	Displays the destination profile configuration for the specified profile or all configured profiles.

Configuring the Call Home Service for Direct Cloud Access through an HTTPs Proxy Server

The Call Home service can be configured through an HTTPs proxy server. This configuration requires no user authentication to connect to CSSM.

Note Authenticated HTTPs proxy configurations are not supported.

To configure and enable the Call Home service through an HTTPs proxy, complete the following steps:

Note All steps are required unless specifically called-out as “(Optional)”.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	license smart transport callhome Example: Device(config)# license smart transport callhome	Enables Call Home as the transport mode.
Step 4	service call-home Example: Device(config)# service call-home	Enables the Call Home feature.
Step 5	call-home Example: Device(config)# call-home	Enters Call Home configuration mode.
Step 6	http-proxy proxy-address proxy-port port-number Example: Device(config-call-home)# http-proxy 198.51.100.10 port 5000	Configures the proxy server information to the Call Home service. Note the change in the criteria for the acceptance of proxy servers, starting with Cisco IOS XE Bengaluru 17.6.1: only the status code of the proxy server response is verified by the system and not the reason phrase. The RFC format is status-line = HTTP-version SP status-code SP reason-phrase CRLF. For more information about the status line, see section 3.1.2 of RFC 7230 .
Step 7	exit Example: Device(config-call-home)# exit	Exits Call Home configuration mode and enters global configuration mode.
Step 8	exit Example: Device(config)# exit	Exits global configuration mode and enters privileged EXEC mode.
Step 9	copy running-config startup-config Example: Device# copy running-config startup-config	Saves your entries in the configuration file.

Removing and Returning an Authorization Code

To remove and return an SLR authorization code, complete the following steps.

Before you begin

Supported topologies: all

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	show license summary Example: Device# show license summary	Ensure that the license that you want to remove and return is not in-use. If it is in-use, you must first disable the feature.
Step 3	license smart authorization return {all local} {offline [path] online} Example: Device# license smart authorization return all online Enter this return code in Cisco Smart Software Manager portal: UDI: PID:C9800-CL-K9,SN:93BBAH93MGS Return code: CqaUPW-WSPYiq-ZNU2ci-SnWydS-hBCXHP-MuyPqy-PJlGiG-tPTGQj-S2h UDI: PID:C9800-CL-K9,SN:9XECPSUU4XN Return code: CNLwxR-eWiAEJ-XaTEQg-j4rrYW-dSRz9j-37VpcP-imjuLD-mNeA4k-TXA OR Device# license smart authorization return local offline Enter this return code in Cisco Smart Software Manager portal: UDI: PID:C9800-CL-K9,SN:93BBAH93MGS Return code: CqaUPW-WSPYiq-ZNU2ci-SnWydS-hBCXHP-MuyPqy-PJlGiG-tPTGQj-S2h UDI: PID:C9800-CL-K9,SN:9XECPSUU4XN Return code: CNLwxR-eWiAEJ-XaTEQg-j4rrYW-dSRz9j-37VpcP-imjuLD-mNeA4k-TXA OR Device# license smart authorization return local offline bootflash:return-code.txt	Returns an authorization code back to the license pool in CSSM. A return code is displayed after you enter this command. Specify the product instance: <ul style="list-style-type: none"> • all: Performs the action for all connected product instances in a High Availability set-up. • local: Performs the action for the active product instance. This is the default option. Specify if you are connected to CSSM or not: <ul style="list-style-type: none"> • If connected to CSSM, enter online. The code is automatically returned to CSSM and a confirmation is returned and installed on the product instance. If you choose this option, the return code is automatically submitted to CSSM. • If not connected to CSSM, enter offline[path]. If you enter only the offline keyword, you must copy the return code that is displayed on the CLI and enter it in CSSM. If you specify a file name and path, the return code is saved in the specified location. The file format can be any readable format. For example: Device# license smart authorization return local offline bootflash:return-code.txt. For software versions Cisco IOS XE Cupertino 17.7.1 and later only: After you save the return request in a file, you can upload the file to CSSM in the same location and in the same way as you upload a RUM report: #unique_161 .

	Command or Action	Purpose
		To enter the return code in CSSM, complete this task: Removing the Product Instance from CSSM, on page 153 . Proceed with the next step only after you complete this step.
Step 4	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 5	no license smart reservation Example: Device(config)# no license smart reservation	Disables SLR configuration on the product instance. You must complete the authorization code return process in Step 3 above - whether online or offline, before you enter the no license smart reservation command in this step. Otherwise, the return may not be reflected in CSSM or in the show command, and you will have to contact your Cisco technical support representative to rectify the problem.
Step 6	exit Example: Device(config)# exit	Returns to privileged EXEC mode.
Step 7	show license all Example: Device# show license all <output truncated> License Authorizations ===== Overall status: Active: PID:C9800-CL-K9,SN:93BBAH93MGS Status: NOT INSTALLED Last return code: CqUEW-WSPYiq-ZN2ci-SWycS-hBXHP-MYRgy-RJIGiG-tPTGQj-S2h Standby: PID:C9800-CL-K9,SN:9XECPSUU4XN Status: NOT INSTALLED Last return code: QNLwR-eVIAEU-XaTEQy-j4m7W-dSRz9j-37MpcP-imjuLD-mNeMk-IXA <output truncated>	Displays licensing information. Check the License Authorizations header in the output. If the return process is completed correctly, the Last return code: field displays the return code.

Removing the Product Instance from CSSM

To remove a product instance and return all licenses to the license pool, complete the following task:

Before you begin

Supported topologies: No Connectivity to CSSM and No CSLU

If you are removing a product instance that is using reserved licenses (SLR) ensure that you have generated a return code as shown in [Removing and Returning an Authorization Code, on page 151](#). (Enter it in Step 7 in this task).

Procedure

-
- Step 1** Log in to the CSSM Web UI at <https://software.cisco.com> and click **Smart Software Licensing**.
Log in using the username and password provided by Cisco.
- Step 2** Click the **Inventory** tab.
- Step 3** From the **Virtual Account** drop-down list, choose your Virtual Account.
- Step 4** Click the **Product Instances** tab.
The list of product instances that are available is displayed.
- Step 5** Locate the required product instance from the product instances list. Optionally, you can enter a name or product type string in the search tab to locate the product instance.
- Step 6** In the **Actions** column of the product instance you want to remove, click the **Remove** link.
- If the product instance is *not* using a license with an SLR authorization code then the **Confirm Remove Product Instance** window is displayed.
 - If the product instance *is* using a license with an SLR authorization code, then the **Remove Product Instance** window, with a field for return code entry is displayed.
- Step 7** In the **Reservation Return Code** field, enter the return code you generated.
- Note** This step applies only if the product instance is using a license with an SLR authorization code.
- Step 8** Click **Remove Product Instance**.
The license is returned to the license pool and the product instance is removed.
-

Generating a New Token for a Trust Code from CSSM

To generate a token to request a trust code, complete the following steps.

Generate one token for each *Virtual Account* you have. You can use same token for all the product instances that are part of one Virtual Account.

Before you begin

Supported topologies: Connected Directly to CSSM

Procedure

- Step 1** Log in to the CSSM Web UI at <https://software.cisco.com> and click **Smart Software Licensing**.
Log in using the username and password provided by Cisco.
- Step 2** Click the **Inventory** tab.
- Step 3** From the **Virtual Account** drop-down list, choose the required virtual account
- Step 4** Click the **General** tab.
- Step 5** Click **New Token**. The **Create Registration Token** window is displayed.
- Step 6** In the **Description** field, enter the token description
- Step 7** In the **Expire After** field, enter the number of days the token must be active.
- Step 8** (Optional) In the **Max. Number of Uses** field, enter the maximum number of uses allowed after which the token expires.
- Step 9** Click **Create Token**.
- Note** If you enter a value here, ensure that you stagger the installation of the trust code on the product instances, which is the next part of the process. If you want to simultaneously install the trust code on a large number of product instances, we recommend that you leave this field blank. Entering a limit here and simultaneously installing it on a large number of devices causes a bottleneck in the processing of these requests in CSSM and installation on some devices may fail, with the following error: `Failure Reason: Server error occurred: LS_LICENGINE_FAIL_TO_CONNECT.`
- Step 10** You will see your new token in the list. Click **Actions** and download the token as a `.txt` file.

Installing a Trust Code

To manually install a trust code, complete the following steps

Before you begin

Supported topologies:

- Connected Directly to CSSM

Procedure

	Command or Action	Purpose
Step 1	<code>#unique_157</code>	In case you have not completed this already, generate and download a trust code file from CSSM.
Step 2	enable Example: <code>Device> enable</code>	Enables privileged EXEC mode. Enter your password, if prompted

	Command or Action	Purpose
Step 3	<p>license smart trust idtoken <i>id_token_value</i>{local all} [force]</p> <p>Example:</p> <pre>Device# license smart trust idtoken NGMwMjk5mYtNZaxMS00NzMZmtgWm all force</pre>	<p>Enables you to establish a trusted connection with CSSM. For <i>id_token_value</i>, enter the token you generated in CSSM.</p> <p>Enter one of following options:</p> <ul style="list-style-type: none"> • local: Submits the trust request only for the active device in a High Availability set-up. This is the default option. • all: Submits the trust request for all devices in a High Availability set-up. <p>Enter the force keyword to submit the trust code request in spite of an existing trust code on the product instance.</p> <p>Trust codes are node-locked to the UDI of the product instance. If a UDI is already registered, CSSM does not allow a new registration for the same UDI. Entering the force keyword sets a force flag in the message sent to CSSM to create a new trust code even if one already exists.</p>
Step 4	<p>show license status</p> <p>Example:</p> <pre><output truncated> Trust Code Installed: Active: PID:C9800-CL-K9,SN:93BBAH93MGS INSTALLED on Nov 02 08:59:26 2020 IST Standby: PID:C9800-CL-K9,SN:9XECPSUU4XN INSTALLED on Nov 02 09:00:45 2020 IST</pre>	<p>Displays date and time if trust code is installed. Date and time are in the local time zone. See field <code>Trust Code Installed:</code>.</p>

Downloading a Policy File from CSSM

If you have requested a custom policy or if you want to apply a policy that is different from the default that is applied to the product instance, complete the following task:

Before you begin

Supported topologies:

- No Connectivity to CSSM and No CSLU
- CSLU Disconnected from CSSM

Procedure

- Step 1** Log in to the CSSM Web UI at <https://software.cisco.com> and click **Smart Software Licensing**.
Log in using the username and password provided by Cisco.
- Step 2** Follow this directory path: **Reports > Reporting Policy**.
- Step 3** Click **Download**, to save the `.xml` policy file.
You can now install the file on the product instance. See [#unique_164](#)
-

Uploading Data or Requests to CSSM and Downloading a File

You can use this task to:

- To upload a RUM report to CSSM and download an ACK.
- To upload a SLAC or SLR authorization code return request.

This applies only to the *No Connectivity to CSSM and No CSLU* topology and is supported starting with Cisco IOS XE Cupertino 17.7.1.

To upload a RUM report to CSSM and download an ACK *when the product instance is not connected to CSSM or CSLU*, complete the following task:

Before you begin

Supported topologies:

- No Connectivity to CSSM and No CSLU
- CSLU Disconnected from CSSM
- SSM On-Prem Deployment (Product instance-initiated communication and SSM On-Prem-initiated communication)

Procedure

- Step 1** Log in to the CSSM Web UI at <https://software.cisco.com>.
Log in using the username and password provided by Cisco.
- Step 2** Select the **Smart Account** (upper left-hand corner of the screen) that will receive the report.
- Step 3** Select **Smart Software Licensing** → **Reports** → **Usage Data Files**.
- Step 4** Click **Upload Usage Data**. Browse to the file location (RUM report in tar format), select, and click **Upload Data**.
Upload a RUM report (`.tar` format), or a SLAC return request file (`.txt` format).
You cannot delete a usage report in CSSM, after it has been uploaded.

Step 5 From the Select Virtual Accounts pop-up, select the **Virtual Account** that will receive the uploaded file. The file is uploaded to Cisco and is listed in the Usage Data Files table in the Reports screen showing the File Name, time it was Reported, which Virtual Account it was uploaded to, the Reporting Status, Number of Product Instances reported, and the Acknowledgement status.

Step 6 In the Acknowledgement column, click **Download** to save the `.txt` ACK file for the report you uploaded. Wait for the ACK to appear in the Acknowledgement column. If there are many RUM reports or requests to process, CSSM may take a few minutes.

Depending on the topology you have implemented, you can now install the file on the product instance, or transfer it to CSLU, or import it into SSM On-Prem.

Installing a File on the Product Instance

To install a SLAC, or policy, or ACK, on the product instance *when the product instance is not connected to CSSM or CSLU*, complete the following task:

Before you begin

Supported topologies: No Connectivity to CSSM and No CSLU

You must have the corresponding file saved in a location that is accessible to the product instance.

- For a policy, see [#unique_205](#)
- For an ACK, see [#unique_161](#)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted
Step 2	copy source bootflash:file-name Example: Device# copy tftp://10.8.0.6/example.txt bootflash:	Copies the file from its source location or directory to the flash memory of the product instance. <ul style="list-style-type: none"> • source: This is the location of the source file or directory to be copied. The source can be either local or remote • bootflash: This is the destination for boot flash memory.
Step 3	license smart import bootflash: file-name Example: Device# license smart import bootflash:example.txt	Imports and installs the file on the product instance. After installation, a system message displays the type of file you just installed.

	Command or Action	Purpose
Step 4	show license all Example: Device# <code>show license all</code>	Displays license authorization, policy and reporting information for the product instance.

Setting the Transport Type, URL, and Reporting Interval

To configure the mode of transport for a product instance, complete the following task:

Before you begin

Supported topologies: all

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	
Step 3	license smart transport { automatic callhome cslu off smart } Example: Device(config)# <code>license smart transport cslu</code>	Configures a mode of transport for the product instance to use. Choose from the following options: <ul style="list-style-type: none"> • automatic: Sets the transport mode cslu. • callhome: Enables Call Home as the transport mode. • cslu: This is the default transport mode. Enter this keyword if you are using CSLU or SSM On-Prem, with product instance-initiated communication. While the transport mode keyword is the same for CSLU and SSM On-Prem, the transport URLs are different. See license smart url cslu cslu_or_on-prem_url in the next step. • off: Disables all communication from the product instance. • smart: Enables Smart transport.

	Command or Action	Purpose
Step 4	<p>license smart url { <i>url</i> cslu <i>cslu_or_on-prem_url</i> default smart <i>smart_url</i> utility <i>utility_smart_url</i> }</p> <p>Example:</p> <pre>Device(config)# license smart url cslu http://192.168.0.1:8182/cslu/v1/pi</pre>	<p>Sets a URL for the configured transport mode. Depending on the transport mode you've chosen in the previous step, configure the corresponding URL here:</p> <ul style="list-style-type: none"> • url: If you have configured the transport mode as callhome, configure this option. Enter the CSSM URL exactly as follows: <p><code>https://tools.cisco.com/its/service/otbe/services/DCService</code></p> <p>The no license smart url url command reverts to the default URL.</p> • cslu cslu_or_on-prem_url: If you have configured the transport mode as cslu, configure this option with the URL for CSLU or SSM On-Prem, as applicable. <ul style="list-style-type: none"> • If you are using CSLU, enter the URL as follows: <p><code>http://<cslu_ip_or_host>:8182/cslu/v1/pi</code></p> <p>For <code><cslu_ip_or_host></code>, enter the hostname or the IP address of the windows host where you have installed CSLU. 8182 is the port number and it is the only port number that CSLU uses.</p> <p>The no license smart url cslu cslu_url command reverts to <code>http://cslu-local:8182/cslu/v1/pi</code></p> • If you are using SSM On-Prem, enter the URL as follows: <p><code>http://<ip>/cslu/v1/pi/<tenant ID></code></p> <p>For <code><ip></code>, enter the hostname or the IP address of the server where you have installed SSM On-Prem. The <code><tenantID></code> must be the default local virtual account ID.</p> <p>Tip You can retrieve the entire URL from SSM On-Prem. See Retrieving the Transport URL (SSM On-Prem UI), on page 137</p>

	Command or Action	Purpose
		<p>The no license smart url cslu <i>cslu_url</i> command reverts to <code>http://cslu-local:8182/cslu/v1/pi</code></p> <ul style="list-style-type: none"> • default: Depends on the configured transport mode. Only the smart and cslu transport modes are supported with this option. <p>If the transport mode is set to cslu, and you configure license smart url default, the CSLU URL is configured automatically (<code>https://cslu-local:8182/cslu/v1/pi</code>).</p> <p>If the transport mode is set to smart, and you configure license smart url default, the Smart URL is configured automatically (<code>https://smartreceiver.cisco.com/licservice/license</code>).</p> <ul style="list-style-type: none"> • smart <i>smart_url</i>: If you have configured the transport type as smart, configure this option. Enter the URL exactly as follows: <code>https://smartreceiver.cisco.com/licservice/license</code> <p>When you configure this option, the system automatically creates a duplicate of the URL in license smart url <i>url</i>. You can ignore the duplicate entry, no further action is required.</p> <p>The no license smart url smart_{smart_url} command reverts to the default URL.</p> <ul style="list-style-type: none"> • utility <i>smart_url</i>: Although available on the CLI, this option is not supported.
Step 5	<p>license smart usage interval <i>interval_in_days</i></p> <p>Example:</p> <pre>Device(config)# license smart usage interval 40</pre>	<p>(Optional) Sets the reporting interval in days. By default the RUM report is sent every 30 days. The valid value range is 1 to 3650.</p> <p>If you do not configure an interval, the reporting interval is determined entirely by the policy value.</p>
Step 6	<p>exit</p> <p>Example:</p> <pre>Device(config)# exit</pre>	<p>Exits global configuration mode and returns to privileged EXEC mode.</p>
Step 7	<p>copy running-config startup-config</p> <p>Example:</p>	<p>Saves your entries in the configuration file.</p>

	Command or Action	Purpose
	Device# <code>copy running-config startup-config</code>	

Configuring an AIR License

In the Smart Licensing Using Policy environment, you can use this task to configure a license, or change the license being used on the product instance, or configure an add-on license on the product instance. For example, if you are currently using AIR Network Advantage and you also want to use features available with a corresponding Digital Networking Architecture (DNA) Advantage license, you can configure the same using this task. Or for example, if you do not want to use an add-on license any more, reconfigure this command to use only the AIR Network Advantage license.

Information about available licenses can be found Smart Account or Virtual Account. The available licenses may be one of the following:

- AIR Network Essential
- AIR Network Advantage
- AIR DNA Essential
- AIR DNA Advantage

To configure or change the license in-use, follow this procedure:

Before you begin

Supported topologies: all

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> <code>enable</code>	Enables the privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters the global configuration mode.
Step 3	license air level {air-network-advantage [addon air-dna-advantage] air-network-essentials [addon air-dna-essentials] } Example: Device(config)# <code>license air level air-network-essentials addon air-dna-essentials</code>	Activates the configured license on the product instance. In the accompanying example, the product instance activates the AIR DNA Essentials (along with the AIR Network Essential) license after reload.

	Command or Action	Purpose
Step 4	exit Example: Device(config)# exit	Returns to the privileged EXEC mode.
Step 5	copy running-config startup-config Example: Device# copy running-config startup-config	Saves configuration changes.
Step 6	reload Example: Device# reload	Reloads the device.
Step 7	show version Example: Device# show version Cisco IOS XE Software, Version 17.03.02 Cisco IOS Software [Amsterdam], C9800-CL Software (C9800-CL-K9_IOSXE), Version 17.3.2, RELEASE SOFTWARE <output truncated> AIR License Level: AIR DNA Essentials Next reload AIR license Level: AIR DNA Essentials Smart Licensing Status: Registration Not Applicable/Not Applicable <output truncated>	Displays currently used license and the license that is effective at the next reload information.

What to do next

After you configure a license level, the change is effective after a reload. To know if reporting is required, refer to the output of the **show license status** privileged EXEC command and check the **Next ACK deadline:** and **Next report push:** fields.

Note The change in license usage is recorded on the product instance. The next steps relating to reporting - if required - depend on your current topology.

- Connected to CSSM Through CSLU
 - Product Instance-initiated communication: The product instance triggers reporting and installs the returning ACK. CSLU sends the RUM report to CSSM and collects the ACK from CSSM.
 - CSLU-initiated communication: You have to collect usage from the CSLU interface: [#unique_151](#). CSLU sends the RUM report to CSSM and collects the ACK from CSSM.
- Connected Directly to CSSM: The product instance triggers reporting and installs the returning ACK.
- CSLU Disconnected from CSSM:

- Product Instance-initiated communication: The product instance triggers reporting. You then have to report usage in the disconnected mode: `#unique_160 > #unique_161 > #unique_162`.
- CSLU-initiated communication: You have to collect usage from the CSLU interface and report usage in the disconnected mode: `#unique_151 > #unique_160 > #unique_161 > #unique_162`.
- No Connectivity to CSSM and No CSLU: License usage is recorded on the product instance. You must save RUM reports to a file on the product instance, and from a workstation that has connectivity to the internet, and Cisco, upload it to CSSM: Enter **license smart save usage** privileged EXEC command to save usage `> #unique_161 > #unique_164`.

Sample Resource Utilization Measurement Report

The following is a sample Resource Utilization Measurement (RUM) report, in XML format (See [#unique_107](#)). Several such reports may be concatenated to form one report.

```
<?xml version="1.0" encoding="UTF-8"?>
<smartLicense>
```

```
[REDACTED]
```

```
</smartLicense>
```

Troubleshooting Smart Licensing Using Policy

This section provides the list of Smart Licensing Using Policy-related system messages you may encounter, possible reasons for failure, and recommended action.

System Message Overview

The system software sends system messages to the console (and, optionally, to a logging server on another system). Not all system messages mean problems with your system. Some messages are informational, and others can help diagnose problems with communications lines, internal hardware, or the system software.

How to Read System Messages

System log messages can contain up to 80 characters. Each system message begins with a percent sign (%) and is structured as follows:

```
%FACILITY-SEVERITY-MNEMONIC: Message-text
```

%FACILITY

Two or more uppercase letters that show the facility to which the message refers. A facility can be a hardware device, a protocol, or a module of the system software

SEVERITY

A single-digit code from 0 to 7 that reflects the severity of the condition. The lower the number, the more serious the situation.

Table 11: Message Severity Levels

Severity Level	Description
0 - emergency	System is unusable.
1 - alert	Immediate action required.
2 - critical	Critical condition.
3 - error	Error condition.
4 - warning	Warning condition.
5 - notification	Normal but significant condition.
6 - informational	Informational message only.
7 - debugging	Message that appears during debugging only.

MNEMONIC

A code that uniquely identifies the message.

Message-text

Message-text is a text string describing the condition. This portion of the message sometimes contains detailed information about the event, including terminal port numbers, network addresses, or addresses that correspond to locations in the system memory address space. Because the information in these variable fields changes from message to message, it is represented here by short strings enclosed in square brackets ([]). A decimal number, for example, is represented as [dec].

Table 12: Variable Fields in Messages

Severity Level	Description
[char]	Single character
[chars]	Character string
[dec]	Decimal number
[enet]	Ethernet address (for example, 0000.FEED.00C0)
[hex]	Hexadecimal number
[inet]	Internet address (for example, 10.0.2.16)
[int]	Integer
[node]	Address or node name
[t-line]	Terminal line number in octal (or in decimal if the decimal-TTY service is enabled)
[clock]	Clock (for example, 01:20:08 UTC Tue Mar 2 1993)

System Messages

This section provides the list of Smart Licensing Using Policy-related system messages you may encounter, possible reasons for failure (in case it is a failure message), and recommended action (if action is required).

For all error messages, if you are not able to solve the problem, contact your Cisco technical support representative with the following information:

The message, exactly as it appears on the console or in the system log.

The output from the **show license tech support**, **show license history message**, and the **show platform software sl-infra** privileged EXEC commands.

- %SMART_LIC-3-POLICY_INSTALL_FAILED
- %SMART_LIC-3-AUTHORIZATION_INSTALL_FAILED
- %SMART_LIC-3-COMM_FAILED
- %SMART_LIC-3-COMM_RESTORED
- %SMART_LIC-3-POLICY_REMOVED
- %SMART_LIC-3-TRUST_CODE_INSTALL_FAILED
- %SMART_LIC-4-REPORTING_NOT_SUPPORTED
- %SMART_LIC-6-POLICY_INSTALL_SUCCESS
- %SMART_LIC-6-AUTHORIZATION_INSTALL_SUCCESS
- %SMART_LIC-6-AUTHORIZATION_REMOVED
- %SMART_LIC-6-REPORTING_REQUIRED
- %SMART_LIC-6-TRUST_CODE_INSTALL_SUCCESS
- %IOSXE_RP_EWLC_NOT-2-MSGDEVICENOTREG
- %CAPWAPAC_TRACE_MSG-3-MAX_LICENSE_AP_LIMIT_REACHED

Error Message %SMART_LIC-3-POLICY_INSTALL_FAILED: The installation of a new licensing policy has failed: [chars].

Explanation: A policy was installed, but an error was detected while parsing the policy code, and installation failed. [chars] is the error string with details of the failure.

Possible reasons for failure include:

- A signature mismatch: This means that the system clock is not accurate.
- A timestamp mismatch: This means the system clock on the product instance is not synchronized with CSSM.

Note The device should have a valid clock and the NTP configuration.

Recommended Action:

For both possible failure reasons, ensure that the system clock is accurate and synchronized with CSSM. Configure the **ntp server** command in global configuration mode. For example:

```
Device(config)# ntp server 198.51.100.100 version 2 prefer
```

If the above does not work and policy installation still fails, and contact your Cisco technical support representative.

```
Error Message %SMART_LIC-3-AUTHORIZATION_INSTALL_FAILED: The install of a new
licensing authorization code has failed on [chars]: [chars].
```

This message is not applicable to Cisco Catalyst Access, Core, and Aggregation Switches, because there are no enforced or export-controlled licenses on these product instances.

```
Error Message %SMART_LIC-3-COMM_FAILED: Communications failure with the [chars] :
[chars]
```

Explanation: Smart Licensing communication either with CSSM, or CSLU, or SSM On-Prem failed. The first [chars] is the currently configured transport type, and the second [chars] is the error string with details of the failure. This message appears for every communication attempt that fails.

Possible reasons for failure include:

- CSSM, CSLU, SSM On-Prem is not reachable: This means that there is a network reachability problem.
- 404 host not found: This means the CSSM server is down.
- A TLS or SSL handshake failure caused by a missing client certificate. The certificate is required for TLS authentication of the two communicating sides. A recent server upgrade may have cause the certificate to be removed. This reason applies only to a topology where the product instance is directly connected to CSSM.

Note If the error message is displayed for this reason, there is no actual configuration error or disruption in the communication with CSSM.

For topologies where the product instance initiates the sending of RUM reports (Connected to CSSM Through CSLU: Product Instance-Initiated Communication, Connected Directly to CSSM, CSLU Disconnected from CSSM: Product Instance-Initiated Communication, and SSM On-Prem Deployment: Product Instance-Initiated Communication) if this communication failure message coincides with scheduled reporting (**license smart usage interval** *interval_in_days* global configuration command), the product instance attempts to send out the RUM report for up to four hours after the scheduled time has expired. If it is still unable to send out the report (because the communication failure persists), the system resets the interval to 15 minutes. Once the communication failure is resolved, the system reverts the reporting interval to last configured value.

Recommended Action:

Troubleshooting steps are provided for when CSSM is not reachable or there is a missing client certificate, when CSLU is not reachable, and when SSM On-Prem is not reachable.

- If a client certificate is missing and there is no actual configuration error or disruption in the communication with CSSM:

To resolve the error, configure the **ip http client secure-trustpoint** *trustpoint-name* command in global configuration mode. For *trustpoint-name*, enter only `SLA-TrustPoint`. This command specifies that the secure HTTP client should use the certificate associated with the trustpoint indicated by the trustpoint-name argument.

- If CSSM is not reachable and the configured transport type is **smart**:
 1. Check if the smart URL is configured correctly. Use the **show license status** command in privileged EXEC mode, to check if the URL is exactly as follows: <https://smartreceiver.cisco.com/licservice/license>. If it is not, reconfigure the **license smart url smart** *smar_URL* command in global configuration mode.

2. Check DNS resolution. Verify that the product instance can ping `smartreceiver.cisco.com` or the nslookup translated IP. The following example shows how to ping the translated IP

```
Device# ping 171.70.168.183
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 171.70.168.183, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/2 ms
```

- If CSSM is not reachable and the configured transport type is **callhome**:
 1. Check if the URL is entered correctly. Use the **show license status** command in privileged EXEC mode, to check if the URL is exactly as follows: <https://tools.cisco.com/its/service/oddce/services/DDCEService>.
 2. Check if Call Home profile `CiscoTAC-1` is active and destination URL is correct. Use the **show call-home profile all** command in privileged EXEC mode:

```
Current smart-licensing transport settings:
Smart-license messages: enabled
Profile: CiscoTAC-1 (status: ACTIVE)
Destination URL(s): https://tools.cisco.com/its/service/oddce/services/DDCEService
```

3. Check DNS Resolution. Verify that the product instance can ping `tools.cisco.com`, or the nslookup translated IP.

```
Device# ping tools.cisco.com
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 173.37.145.8, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 41/41/42 ms
```

If the above does not work check the following: if the product instance is set, if the product instance IP network is up. To ensure that the network is up, configure the **no shutdown** command in interface configuration mode.

Check if the device is subnet masked with a subnet IP, and if the DNS IP is configured.

4. Verify that the HTTPs client source interface is correct.

Use the **show ip http client** command in privileged EXEC mode to display current configuration. Use **ip http client source-interface** command in global configuration mode to reconfigure it.

In case the above does not work, double-check your routing rules, and firewall settings.

- If CSLU is not reachable:

1. Check if CSLU discovery works.

- Zero-touch DNS discovery of `cslu-local` or DNS discovery of your domain..

In the **show license all** command output, check if the `Last ACK received:` field. If this has a recent timestamp it means that the product instance has connectivity with CSLU. If it is not, proceed with the following checks:

Check if the product instance is able to ping `cslu-local`. A successful ping confirms that the product instance is reachable.

If the above does not work, configure the name server with an entry where hostname `cslu-local` is mapped to the CSLU IP address (the windows host where you installed CSLU). Configure the **ip domain name** `domain-name` and **ip name-server** `server-address` commands in global configuration mode. Here the CSLU IP is 192.168.0.1 and name-server creates entry `cslu-local.example.com`:

```
Device(config)# ip domain name example.com
Device(config)# ip name-server 192.168.0.1
```

- CSLU URL is configured.

In the **show license all** command output, under the `Transport:` header check the following: The `Type:` must be `cslu` and `Cslu address:` must have the hostname or the IP address of the windows host where you have installed CSLU. Check if the rest of the address is configured as shown below and check if the port number is 8182.

```
Transport:
  Type: cslu
  Cslu address: http://192.168.0.1:8182/cslu/v1/pi
```

If it is not, configure the **license smart transport cslu** and **license smart url cslu** `http://<cslu_ip_or_host>:8182/cslu/v1/pi` commands in global configuration mode

2. For CSLU-initiated communication, in addition to the CSLU discovery checks listed above, check the following:

Verify HTTP connectivity. Use the **show ip http server session-module** command in privileged EXEC mode. In the output, under header `HTTP server current connections:`, check that `SL_HTTP` is active. If it is not re-configure the **ip http** commands as mentioned in [#unique_150](#)

From a Web browser on the device where CSLU is installed, verify `https://<product-instance-ip>/`. This ensures that the REST API from CSLU to the product instance works as expected.

- If SSM On-Prem is not reachable:

1. For product instance-initiated communication, check if the SSM On-Prem transport type and URL are configured correctly.

In the **show license all** command output, under the `Transport:` header check the following: The `Type:` must be `cslu` and `Cslu address:` must have the hostname or the IP address of the server where you have installed SSM On-Prem and `<tenantID>` of the *default* local virtual account. See the example below:

```
Transport:
  Type: cslu
  Cslu address: https://192.168.0.1/cslu/v1/pi/on-prem-default
```

Check if you have the correct URL from SSM On-Prem ([Retrieving the Transport URL \(SSM On-Prem UI\)](#), on page 137) and then configure **license smart transport cslu** and **license smart url cslu http://<ip>/cslu/v1/pi/<tenant ID>** commands in global configuration mode.

Check that you have configured any other required commands for your network as mentioned in [Ensuring Network Reachability for Product Instance-Initiated Communication](#), on page 134.

2. For SSM On-Prem-initiated communication, check HTTP's connectivity.

Use the **show ip http server session-module** command in privileged EXEC mode. In the output, under header `HTTP server current connections:`, check that `SL_HTTP` is active. If it is not re-configure the **ip http** commands as mentioned in [Ensuring Network Reachability for SSM On-Prem-Initiated Communication](#), on page 139.

3. Check trustpoint and that certificates are accepted.

For both forms of communication in an SSM On-Prem Deployment, ensure that the correct trustpoint is used and that the necessary certificates are accepted:

```
Device(config)# crypto pki trustpoint SLA-TrustPoint
Device(ca-trustpoint)#
Device(ca-trustpoint)# enrollment terminal
Device(ca-trustpoint)# revocation-check none
Device(ca-trustpoint)# end
Device# copy running-config startup-config
```

If the above does not work and policy installation still fails, contact your Cisco technical support representative.

```
-----
-----
Error Message %SMART_LIC-3-COMM_RESTORED: Communications with the [chars] restored.
[chars] - depends on the transport type
         - Cisco Smart Software Manager (CSSM)
         - Cisco Smart License utility (CSLU)
Smart Agent communication with either the Cisco Smart Software Manager (CSSM) or the Cisco
Smart License
utility (CSLU) has been restored. No action required.
```

Explanation: Product instance communication with either the CSSM, or CSLU, or SSM On-Prem is restored.

Recommended Action: No action required.

```
-----
-----
Error Message %SMART_LIC-3-POLICY_REMOVED: The licensing policy has been removed.
```

Explanation: A previously installed *custom* licensing policy has been removed. The Cisco default policy is then automatically effective. This may cause a change in the behavior of smart licensing.

Possible reasons for failure include:

If you have entered the **license smart factory reset** command in privileged EXEC mode all licensing information including the policy is removed.

Recommended Action:

If the policy was removed intentionally, then no further action is required.

If the policy was removed inadvertently, you can reapply the policy. Depending on the topology you have implemented, follow the corresponding method to retrieve the policy:

- Connected Directly to CSSM:

Enter **show license status**, and check field `Trust Code Installed`. If trust is established, then CSSM will automatically return the policy again. The policy is automatically re-installed on product instances of the corresponding Virtual Account.

If trust has not been established, complete these tasks: [#unique_157](#) and [#unique_158](#). When you have completed these tasks, CSSM will automatically return the policy again. The policy is then automatically installed on all product instances of that Virtual Account.

- Connected to CSSM Through CSLU:

- For product instance-initiated communication), enter the **license smart sync** command in privileged EXEC mode. The synchronization request causes CSLU to push the missing information (a policy or authorization code) to the product instance.

- For CSLU-initiated communication, complete this task: [#unique_151](#). This causes CSLU to detect and re-furnish the missing policy in an ACK response.

- CSLU Disconnected from CSSM:

- For product instance-initiated communication), enter the **license smart sync** command in privileged EXEC mode. The synchronization request causes CSLU to push the missing information (a policy or authorization code) to the product instance. Then complete these tasks in the given order: [#unique_160 > Uploading Data or Requests to CSSM and Downloading a File, on page 157](#) > [#unique_162](#).

- For CSLU-initiated communication, complete this task: [#unique_151](#). This causes CSLU to detect and re-furnish the missing policy in an ACK response. Then complete these tasks in the given order: [#unique_160 > Uploading Data or Requests to CSSM and Downloading a File, on page 157](#) > [#unique_162](#).

- No Connectivity to CSSM and No CSLU

If you are in an entirely air-gapped network, from a workstation that has connectivity to the internet and CSSM complete this task: [#unique_205](#).

Then complete this task on the product instance: [#unique_164](#).

- SSM On-Prem Deployment

- For product instance-initiated communication), enter the **license smart sync** command in privileged EXEC mode. The causes the product instance to synchronize with SSM On-Prem and restore any required or missing information. Then synchronize SSM On-Prem with CSSM if required:

- For SSM On-Prem-initiated communication: In the SSM On-Prem UI, navigate to **Reports > Synchronization pull schedule with the devices > Synchronize now with the device**.

For both forms of communication in an SSM On-Prem Deployment, synchronize with CSSM using either option:

- SSM On-Prem is connected to CSSM: In the SSM On-Prem UI, Smart Licensing workspace, navigate to **Reports > Usage Schedules > Synchronize now with Cisco**.

- SSM On-Prem is not connected to CSSM: [Exporting and Importing Usage Data \(SSM On-Prem UI\), on page 137](#).

```
-----
-----
Error Message %SMART_LIC-3-TRUST_CODE_INSTALL_FAILED: The install of a new licensing
trust code has failed on [chars]: [chars].
```

Explanation: Trust code installation has failed. The first [chars] is the UDI where trust code installation was attempted. The second [chars] is the error string with details of the failure.

Possible reasons for failure include:

- A trust code is already installed: Trust codes are node-locked to the UDI of the product instance. If the UDI is already registered, and you try to install another one, installation fails.
- Smart Account-Virtual Account mismatch: This means the Smart Account or Virtual Account (for which the token ID was generated) does not include the product instance on which you installed the trust code. The token generated in CSSM, applies at the Smart Account or Virtual Account level and applies only to all product instances in that account.
- A signature mismatch: This means that the system clock is not accurate.
- Timestamp mismatch: This means the product instance time is not synchronized with CSSM, and can cause installation to fail.

Recommended Action:

- A trust code is already installed: If you want to install a trust code in spite of an existing trust code on the product instance, re-configure the **license smart trust idtoken id_token_value {local | all} [force]** command in privileged EXEC mode, and be sure to include the **force** keyword this time. Entering the **force** keyword sets a force flag in the message sent to CSSM to create a new trust code even if one already exists.

- Smart Account-Virtual Account mismatch:

Log in to the CSSM Web UI at <https://software.cisco.com> and click **Smart Software Licensing>Inventory > Product Instances**.

Check if the product instance on which you want to generate the token is listed in the selected Virtual Account. If it is, proceed to the next step. If not, check and select the correct Smart Account and Virtual Account. Then complete these tasks again: [#unique_157](#) and [#unique_158](#).

- Timestamp mismatch and signature mismatch: Configure the **ntp server** command in global configuration mode. For example:

```
Device(config)# ntp server 198.51.100.100 version 2 prefer
```

```
-----
-----
Error Message %SMART_LIC-4-REPORTING_NOT_SUPPORTED: The CSSM OnPrem that this
product instance is connected to is down rev and does not support the enhanced policy and
usage
reporting mode.
```

Explanation: Cisco Smart Software Manager On-Prem (formerly known as Cisco Smart Software Manager satellite) is supported in the Smart Licensing Using Policy environment starting with Cisco IOS XE Amsterdam

17.3.3 only (See [SSM On-Prem, on page 63](#)). In *unsupported* releases, the product instance will behave as follows:

- Stop sending registration renewals and authorization renewals.
- Start recording usage and saving RUM reports locally.

Recommended Action:

You have the following options:

- Refer to and implement one of the supported topologies instead. See: [#unique_96](#).
- Upgrade to a release where SSM On-Prem is supported with Smart Licensing Using Policy. See [Migrating to a Version of SSM On-Prem That Supports Smart Licensing Using Policy, on page 119](#).

```
Error Message %SMART_LIC-6-POLICY_INSTALL_SUCCESS: A new licensing policy
was successfully installed.
```

Explanation: A policy was installed in one of the following ways:

- Using Cisco IOS commands.
- CSLU-initiated communication.
- As part of an ACK response.

Recommended Action: No action is required. If you want to know which policy is applied (the policy in-use) and its reporting requirements, enter the **show license all** command in privileged EXEC mode.

```
Error Message %SMART_LIC-6-AUTHORIZATION_INSTALL_SUCCESS: A new licensing
authorization code was successfully installed on: [chars].
```

This message is not applicable to Cisco Catalyst Access, Core, and Aggregation Switches, because there are no enforced or export-controlled licenses on these product instances.

```
Error Message %SMART_LIC-6-AUTHORIZATION_REMOVED: A licensing authorization code has
been removed from [chars]
```

Explanation: [chars] is the UDI where the authorization code was installed. The authorization code has been removed. This removes the licenses from the product instance and may cause a change in the behavior of smart licensing and the features using licenses.

Recommended Action: No action is required. If you want to see the current state of the license, enter the **show license all** command in privileged EXEC mode.

Error Message %SMART_LIC-6-REPORTING_REQUIRED: A Usage report acknowledgement will be required in [dec] days.

Explanation: This is an alert which means that RUM reporting to Cisco is required. [dec] is the amount of time (in days) left to meet this reporting requirements.

Recommended Action: Ensure that RUM reports are sent within the requested time. The topology you have implemented determines the reporting method.

- Connected to CSSM Through CSLU
 - For product instance-initiated communication: Enter the **license smart sync** command in privileged EXEC mode. If CSLU is currently logged into CSSM the reports will be automatically sent to the associated Smart Account and Virtual Account in CSSM.
 - For CSLU-initiated communication, complete this task: [#unique_151](#).
- Connected Directly to CSSM: Enter the **license smart sync** command in privileged EXEC mode.
- Connected to CSSM Through a Controller: If the product instance is managed by a controller, the controller will send the RUM report at the scheduled time.

If you are using Cisco Catalyst Center as the controller, you have the option of ad-hoc reporting. See the [Cisco Catalyst Center Administrator Guide](#) of the required release (Release 2.2.2 onwards) > *Manage Licenses* > *Upload Resource Utilization Details to CSSM*.

- CSLU Disconnected from CSSM: If the product instance is connected to CSLU, synchronize with the product instance as shown for "Connected to CSSM Through CSLU" above, then complete these tasks: [#unique_160](#), [#unique_161](#), and [#unique_162](#).
- No Connectivity to CSSM and No CSLU: Enter the **license smart save usage** command in privileged EXEC mode, to save the required usage information in a file. Then, from a workstation where you have connectivity to CSSM, complete these tasks: [#unique_161](#) > [#unique_164](#).
- SSM On-Prem Deployment:
Synchronize the product instance with SSM On-Prem:
 - For product instance-initiated communication: Enter the **license smart sync** command in privileged EXEC mode. If CSLU is currently logged into CSSM the reports will be automatically sent to the associated Smart Account and Virtual Account in CSSM.
 - For SSM On-Prem-initiated communication, complete this task: In the SSM On-Prem UI, navigate to **Reports** > **Synchronization pull schedule with the devices** > **Synchronize now with the device**.

Synchronize usage information with CSSM (*choose one*)

- SSM On-Prem is connected to CSSM: In the SSM On-Prem UI, Smart Licensing workspace, navigate to **Reports** > **Usage Schedules** > **Synchronize now with Cisco**.
 - SSM On-Prem is not connected to CSSM: [Exporting and Importing Usage Data \(SSM On-Prem UI\), on page 137](#).
-

```
Error Message %SMART_LIC-6-TRUST_CODE_INSTALL_SUCCESS: A new licensing trust code
was successfully installed on [chars].
```

Explanation: [chars] is the UDI where the trust code was successfully installed.

Recommended Action: No action is required. If you want to verify that the trust code is installed, enter the **show license status** command in privileged EXEC mode. Look for the updated timestamp under header **Trust Code Installed:** in the output.

```
Error Message %IOSXE_RP_EWLC_NOT-2-MSGDEVICENOTREG: Unregistered 9800-CL can only
be used in lab. For production usage, please register this device in [int] days. Failure
to do so
will result in a limited number [50] of Access Points being allowed post this.
```

Explanation: An ACK is required on this product instance. [int] is the amount of time left to install an ACK on the product instance.

This system message is displayed only if the product instance is a Cisco Catalyst 9800-CL Wireless Controller running Cisco IOS XE Cupertino 17.7.1 or a later release. For more information, see [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller, on page 121](#) .

This system message is displayed once everyday, until the first ACK is made available on the product instance.

Recommended Action:

Implement one of the supported topologies and complete usage reporting. The method you can use to send the RUM report to CSSM and ACK installation depends on the topology you implement. See: [Supported Topologies, on page 69](#) and [How to Configure Smart Licensing Using Policy: Workflows by Topology](#) , on page 86.

```
Error Message %CAPWAPAC_TRACE_MSG-3-MAX_LICENSE_AP_LIMIT_REACHED: Chassis 1 R0/0:
wncmgrd: Ap MAC: [enet] is not allowed to join. Please start reporting licensing to Cisco
to get the
ACK for resumption of usual operation.
```

Explanation: The ACK deadline for this product instance has passed and an ACK has still not been installed. [enet] is the MAC address of the AP that is trying to join the Cisco Catalyst 9800-CL Wireless Controller but is not allowed because the requisite ACK is not installed.

This system message is displayed only if the product instance is a Cisco Catalyst 9800-CL Wireless Controller running Cisco IOS XE Cupertino 17.7.1 or a later release. For more information, see [RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller, on page 121](#) .

Recommended Action:

Implement one of the supported topologies and complete usage reporting. The method you can use to send the RUM report to CSSM and ACK installation depends on the topology you implement. See: [Supported Topologies, on page 69](#) and [How to Configure Smart Licensing Using Policy: Workflows by Topology](#) , on page 86.

Additional References for Smart Licensing Using Policy

Topic	Document Title
For complete syntax and usage information for the commands used in this chapter, see the Command Reference of the corresponding release.	Cisco Catalyst 9800 Series Wireless Controller Command Reference

Feature History for Smart Licensing Using Policy

This table provides release and related information for features explained in this module.

These features are available on all releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.10.1	Smart Licensing	A cloud-based, software license management solution that allows you to manage and track the status of your license, hardware, and software usage trends.

Release	Feature	Feature Information
Cisco IOS XE Amsterdam 17.3.2a	Smart Licensing Using Policy	<p>An enhanced version of Smart Licensing, with the overarching objective of providing a licensing solution that does not interrupt the operations of your network, rather, one that enables a compliance relationship to account for the hardware and software licenses you purchase and use.</p> <p>Starting with this release, Smart Licensing Using Policy is automatically enabled on the device. This is also the case when you upgrade to this release.</p> <p>By default, your Smart Account and Virtual Account in CSSM is enabled for Smart Licensing Using Policy.</p>
	Cisco Catalyst Center Support for Smart Licensing Using Policy	<p>Cisco Catalyst Center supports Smart Licensing Using Policy functionality starting with Cisco Catalyst Center Release 2.2.2. When you use Cisco Catalyst Center to manage a product instance, Cisco Catalyst Center connects to CSSM, and is the interface for all communication to and from CSSM.</p> <p>For information about the compatible controller and product instance versions, see Controller, on page 62.</p> <p>For information about this topology, see Connected to CSSM Through a Controller, on page 74 and Workflow for Topology: Connected to CSSM Through a Controller, on page 93.</p>
Cisco IOS XE Amsterdam 17.3.3	Smart Software Manager On-Prem (SSM On-Prem) Support for Smart Licensing Using Policy	<p>SSM On-Prem is an asset manager, which works in conjunction with CSSM. It enables you to administer products and licenses on your premises instead of having to directly connect to CSSM.</p> <p>For information about the compatible SSM On-Prem and product instance versions, see: SSM On-Prem, on page 63.</p> <p>For an overview of this topology, and to know how to implement it see SSM On-Prem Deployment, on page 77 and Workflow for Topology: SSM On-Prem Deployment, on page 95.</p> <p>For information about migrating from an existing version of SSM On-Prem, to one that supports Smart Licensing Using Policy, see Migrating to a Version of SSM On-Prem That Supports Smart Licensing Using Policy, on page 119.</p>

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.7.1	RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller	<p>If you are using a Cisco Catalyst 9800-CL Wireless Controller, you must complete RUM reporting and ensure that the Acknowledgment (ACK) is made available on the product instance - at least once. This is to ensure that correct and up-to-date usage information is reflected in CSSM.</p> <p>For more information, see RUM Reporting and Acknowledgment Requirement for Cisco Catalyst 9800-CL Wireless Controller, on page 121.</p>
	Factory-installed trust code	<p>For new hardware orders, a trust code is now installed at the time of manufacturing. Note: You cannot use a factory-installed trust code to communicate with CSSM.</p> <p>See: Overview, on page 60 and Trust Code, on page 68.</p>
	Support for trust code in additional topologies	<p>A trust code is automatically obtained in topologies where the product instance initiates the sending of data to <i>CSLU</i> and in topologies where the product instance is in an air-gapped network.</p> <p>See:</p> <ul style="list-style-type: none"> • Trust Code, on page 68 • Connected to CSSM Through CSLU, on page 69, #unique_117 unique_117_Connect_42_section_d3n_5dq_1nb. • CSLU Disconnected from CSSM, on page 73, #unique_120 unique_120_Connect_42_section_gb1_jdr_1nb. • No Connectivity to CSSM and No CSLU, on page 75, Workflow for Topology: No Connectivity to CSSM and No CSLU, on page 94.
	RUM Report optimization and availability of statistics	

Release	Feature	Feature Information
		<p>RUM report generation and related processes have been optimized. This includes a reduction in the time it takes to process RUM reports, better memory and disk space utilization, and visibility into the RUM reports on the product instance (how many there are, the processing state each one is in, if there are errors in any of them, and so on).</p> <p>See RUM Report and Report Acknowledgement, on page 67.</p> <p>Also see the show license rum, show license all, and show license tech commands in the command reference of the applicable release.</p>
	Support to collect software version in a RUM report	<p>If version privacy is disabled (no license smart privacy version global configuration command), the Cisco IOS-XE software version running on the product instance and Smart Agent version information is <i>included</i> in the RUM report.</p> <p>See the license smart global configuration command in the command reference of the applicable release.</p>
	Account information included in the ACK and show command outputs	<p>A RUM acknowledgement (ACK) includes the Smart Account and Virtual Account that was reported to, in CSSM. You can then display account information using various show commands. The account information that is displayed is always as per the latest available ACK on the product instance.</p> <p>See the show license all, show license summary, show license status, and show license tech commands in the command reference of the applicable release.</p>
	CSLU support for Linux	<p>CSLU can now be deployed on a machine (laptop or desktop) running Linux.</p> <p>See CSLU, on page 61, Workflow for Topology: Connected to CSSM Through CSLU, on page 86, and CSLU Disconnected from CSSM, on page 73.</p>

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.9.1	RUM Report Throttling	<p>For all topologies where the product instance initiates communication, the minimum reporting frequency is throttled to one day. This means the product instance does not send more than one RUM report a day.</p> <p>The affected topologies are: <i>Connected Directly to CSSM</i>, <i>Connected to CSSM Through CSLU</i> (product instance-initiated communication), <i>CSLU Disconnected from CSSM</i> (product instance-initiated communication), and <i>SSM On-Prem Deployment</i> (product instance-initiated communication).</p> <p>You can override the reporting frequency throttling, by entering the license smart sync command in privileged EXEC mode. This triggers an on-demand synchronization with CSSM or CSLU, or SSM On-Prem, to send and receive any pending data.</p> <p>RUM report throttling also applies to the Cisco IOS XE Amsterdam 17.3.6 and later releases of the 17.3.x train, and Cisco IOS XE Bengaluru 17.6.4 and later releases of the 17.6.x train. From Cisco IOS XE Cupertino 17.9.1, RUM report throttling is applicable to <i>all</i> subsequent releases.</p> <p>See: Connected to CSSM Through CSLU, on page 69, Connected to CSSM Through CSLU, on page 69, CSLU Disconnected from CSSM, on page 73, and SSM On-Prem Deployment, on page 77.</p>

CHAPTER 6

Management over Wireless

- [Information About Management over Wireless, on page 181](#)
- [Restrictions on Management over Wireless, on page 181](#)
- [Enabling Management over Wireless on Controller \(GUI\) , on page 181](#)
- [Enabling Management over Wireless on Controller \(CLI\), on page 182](#)

Information About Management over Wireless

The Management over Wireless feature allows operators to monitor and configure the controller using wireless clients connected to the wireless controller network.

Note By default, the Management over Wireless feature is disabled. You will need to keep the Management over Wireless feature disabled, if security is a concern.

This feature blocks the wireless management access to the same controller that the wireless client device is currently associated with. It does not prevent management access to a wireless client associated with another controller entirely. To completely block management access to wireless clients based on VLAN and so on, we recommend that you use Access Control Lists (ACLs) or a similar mechanism.

Restrictions on Management over Wireless

- The Management over Wireless feature does not work for Embedded Wireless Controller (EWC).

Enabling Management over Wireless on Controller (GUI)

Procedure

- Step 1** Choose **Configuration > Wireless > Wireless Global**.
- Step 2** Check the **Management via Wireless** check box.

Step 3 Click **Apply**.

Enabling Management over Wireless on Controller (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless mgmt-via-wireless Example: Device(config)# wireless mgmt-via-wireless	Enables management over wireless. Use the no form of this command to disable the management over wireless.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.

CHAPTER 7

Boot Integrity Visibility

- [Overview of Boot Integrity Visibility, on page 183](#)
- [Verifying Software Image and Hardware, on page 183](#)
- [Verifying Platform Identity and Software Integrity, on page 184](#)

Overview of Boot Integrity Visibility

Boot Integrity Visibility allows the Cisco platform identity and software integrity information to be visible and actionable. Platform identity provides the platform's manufacturing installed identity. Software integrity exposes boot integrity measurements that can be used to assess whether the platform has booted trusted code.

During the boot process, the software creates a checksum record of each stage of the bootloader activities.

You can retrieve this record and compare it with a Cisco-certified record to verify if your software image is genuine. If the checksum values do not match, you may be running a software image that is either not certified by Cisco or has been altered by an unauthorized party.

Verifying Software Image and Hardware

This task describes how to retrieve the checksum record that was created during a switch bootup. Enter the following commands in privileged EXEC mode.

Note On executing the following commands, you might see the message **% Please Try After Few Seconds** displayed on the CLI. This does not indicate a CLI failure, but indicates setting up of underlying infrastructure required to get the required output. We recommend waiting for a few minutes and then try the command again.

The messages **% Error retrieving SUDI certificate** and **% Error retrieving integrity data** signify a real CLI failure.

Procedure

	Command or Action	Purpose
Step 1	<code>show platform sudi certificate [sign [nonce nonce]]</code>	Displays checksum record for the specific SUDI.

	Command or Action	Purpose
	Example: Device# show platform sudi certificate sign nonce 123	<ul style="list-style-type: none"> • (Optional) sign - Show signature. • (Optional) nonce - Enter a nonce value.
Step 2	show platform integrity [sign [nonce nonce]] Example: Device# show platform integrity sign nonce 123	Displays checksum record for boot stages. <ul style="list-style-type: none"> • (Optional) sign - Show signature. • (Optional) nonce - Enter a nonce value.

Verifying Platform Identity and Software Integrity

Verifying Platform Identity

The following example displays the Secure Unique Device Identity (SUDI) chain in PEM format. Encoded into the SUDI is the Product ID and Serial Number of each individual device such that the device can be uniquely identified on a network of thousands of devices. The first certificate is the Cisco Root CA 2048 and the second is the Cisco subordinate CA (ACT2 SUDI CA). Both certificates can be verified to match those published on <https://www.cisco.com/security/pki/>. The third is the SUDI certificate.

Important All the CLI outputs provided here are intended only for reference. The output differs based on the configuration of the device.

```
Device# show platform sudi certificate sign nonce 123

veel+8LmeiE/209h6qGHPPDacCaXA2oJCDHveAt8iPTG
-----END CERTIFICATE-----
```

Signature version: 1

Signature:

The optional RSA 2048 signature is across the three certificates, the signature version and the user-provided nonce.

```
RSA PKCS#1v1.5 Sign {<Nonce (UINT64)> || <Signature Version (UINT32)> || <Cisco Root CA
2048 cert (DER)> ||
<Cisco subordinate CA (DER)> || <SUDI certificate (DER)> }
```

Cisco management solutions are equipped with the ability to interpret the above output. However, a simple script using OpenSSL commands can also be used to display the identity of the platform and to verify the signature, thereby ensuring its Cisco unique device identity.

```
[linux-host:~]openssl x509 -in sudi_id.pem -subject -noout
subject= /serialNumber=PID:C9600-SUP-1 SN:CAT2239L06B/CN=C9600-SUP-1-70b3171eaa00
```

Verifying Software Integrity

The following example displays the checksum record for the boot stages. The hash measurements are displayed for each of the three stages of software successively booted. These hashes can be compared against

Cisco-provided reference values. An option to sign the output gives a verifier the ability to ensure the output is genuine and is not altered. A nonce can be provided to protect against replay attacks.

Note Boot integrity hashes are not MD5 hashes. For example, if you run **verify /md5 cat9k_iosxe.16.10.01.SPA.bin** command for the bundle file, the hash will not match.

The following is a sample output of the **show platform integrity sign nonce 123** command. This output includes measurements of each installed package file.

```
Device# show platform integrity sign nonce 123
Platform: C9800-L-F-K9
Boot 0 Version: R04.1173930452019-06-11
Boot 0 Hash: A6C92C44976FC77DD42234444FFD87798FB9036A2762FAA4999A190A0258B18C
Boot Loader Version: 16.12(1r)

```

Note Only OS and package hashes are supported.

CHAPTER 8

SUDI99 Certificate Support

- [SUDI99 Certificate Support](#), on page 187
- [Disabling SUDI99 Migration \(GUI\)](#), on page 189

SUDI99 Certificate Support

Cisco Catalyst 9800 Series Wireless Controllers use Secure Unique Device Identity (SUDI) certificates as device certificates for authentication during secure connection handshakes. These certificates are provisioned in a secure hardware chip, which can hold multiple certificates, during the manufacturing process.

Note Some of the certificates used in the controller and AP platforms are expiring in May 2029 and require migration to a new set of certificates. SUDI99 certificate support is addressing this migration scenario. SUDI99 is valid until December 2099.

The Cisco IOS XE software supports two slots for initializing SUDI certificates from the secure hardware chip. This SUDI99 migration change will rearrange certificate-to-trustpoint mapping as follows:

Table 13: Existing Software Selection for SUDI Trustpoint Certificates

Trustpoint Name	Software Selection Among Programmed Certificate Chains
CISCO_IDEVID_SUDI	CMCA2 SHA2 SUDI (SHA2-2037)
CISCO_IDEVID_SUDI_LEGACY	CMCA SHA1 SUDI

Table 14: New Software Selection for SUDI Trustpoint Certificates

Trustpoint Name	Software Selection Among Programmed Certificate Chains
CISCO_IDEVID_SUDI	CMCA-III SHA2 SUDI99
CISCO_IDEVID_SUDI_LEGACY	CMCA2 SHA2 SUDI (SHA2-2037)

Caution Performing device authentication using expired certificates may lead to service disruption.

The following table lists the SUDI99 certificate and software support:

Table 15: SUDI99 Certificate and Software Support

Cisco Catalyst 9800 Controllers	SUDI99 Certificate Support	Software Support for SUDI99 Migration
Cisco Catalyst 9800-CL Wireless Controller for Cloud	Not supported.	—
Cisco Catalyst 9800 Series Wireless Controllers <ul style="list-style-type: none"> • 9800-40 • 9800-80 • 9800-L 	Supported	Yes. From Cisco IOS XE Cupertino 17.7.1.
Cisco Embedded Wireless Controller on Catalyst Access Points. <ul style="list-style-type: none"> • 9105AXI • 9115AXI • 9115AXE • 9117AXI • 9120AXI • 9120AXE • 9120AXP • 9130AXI • 9130AXE 	Supported	Yes. From Cisco IOS XE Cupertino 17.7.1.
Cisco Embedded Wireless Controller on Catalyst Switches <ul style="list-style-type: none"> • 9300 Series • 9400 Series • 9500 Series • 9500H Series 	Not supported.	—

Backward Compatibility

The Cisco Catalyst 9800 Series Wireless Controllers have a default wireless management trustpoint. Some applications use this management trustpoint certificate. If a device (AP or controller) cannot validate the SUDI99 certificate, then the controller uses an older certificate (SHA2-2037) as its device certificate for that particular connection.

For NMSP-TLS connections with Cisco CMX, the client certificate is not validated in default security mode. However, in FIPS mode, Cisco CMX validates the controller certificate.

If Cisco CMX is deployed in FIPS mode, explicitly install the new SUDI CA certificates on the Cisco CMX running the earlier version of Cisco CMX or upgrade Cisco CMX to the latest version.

Some applications, such as HTTPS, RADSEC, and WebAuth, do not use SUDI certificate as their default trustpoint. But, it is possible to configure SUDI trustpoint explicitly in them. The SUDI refresh program alters the certificate selection for such services. However, there is no functional impact.

Restrictions

If a SUDI99 certificate is incorrectly programmed in a device, it is rejected during trustpoint initialization at bootup, and trustpoint-to-certificate mapping falls back to the old behaviour. User can verify the SUDI certificate status using the **show platform sudi pki** command.

Disabling SUDI99 Migration Using CLI

The SUDI99 certificate is set as the default trustpoint in supported hardware units. You can disable it using the **no platform sudi cmca3** command. In high availability (HA) deployments, form the HA pair, and then run the command. Then, save the configuration and reload the controller to disable the SUDI certificate and fall back to the older trustpoint certificate.

To check the certificate validation status, use the **show platform sudi pki** command.

Disabling SUDI99 Migration (GUI)

SHA1 SUDI certificates on hardware controllers have an imminent expiry date and devices using expired certificates face disruption in service. To ensure a smooth migration to the latest SUDI99 certificate issued by CMCA-III authority, the controllers have been programmed with newer certificates in their secure hardware chip. These certificates are enabled by default and are valid till December 2099.

Follow the procedure given below, if you do not wish to migrate at this point.

Procedure

-
- | | |
|---------------|---|
| Step 1 | On the Configuration > Security > PKI Management > Trustpoint tab, go to the SUDI Status section. |
| Step 2 | Disable the Cisco Manufacturing CA III certificate to continue using the older certificate that is mapped to an existing Trustpoint. |
| Step 3 | Click Apply |
-

What to do next

Reload the device for the configuration to take effect.

CHAPTER 9

Link Aggregation Group

- [Information About Link Aggregation Group, on page 191](#)

Information About Link Aggregation Group

A link aggregation group (LAG) bundles all of the controller's distribution system ports into a single 802.3ad port channel. This reduces the number of IP addresses required to configure the ports on your controller. When LAG is enabled, the system dynamically manages port redundancy and load balances access points transparently to the corresponding user.

LAG simplifies controller configuration because you no longer have to configure ports for each interface. If any of the controller ports fail, traffic is automatically migrated to one of the other ports. As long as at least one controller port is functioning, the system continues to operate, access points remain connected to the network, and wireless clients continue to send and receive data.

Note The wireless management VLAN can only be part of one port channel.

Note LACP is supported on a standalone controller from Cisco IOS XE Gibraltar 16.12.x release. LACP is supported on an SSO pair from Cisco IOS XE Amsterdam 17.1.1s onwards.

Link Aggregation Control Protocol

Link Aggregation Control Protocol (LACP) is a part of an IEEE specification (802.3ad) that allows you to bundle several physical ports together to form a single logical channel. LACP allows a switch to negotiate an automatic bundle by sending LACP packets to a peer. By using the LACP, the wireless controller learns the identity of peers that are capable of supporting LACP, and the capabilities of each port. The LACP then dynamically groups similarly configured ports into a single logical link (channel or aggregate port). Similarly, configured ports are grouped based on hardware, administrative, and port parameter constraints. If any of the controller ports fail, traffic is automatically migrated to one of the other ports. As long as at least one controller port is functioning, the system continues to operate, access points remain connected to the network, and wireless clients continue to send and receive data.

Configuring LAG Using LACP

To configure LAG using LACP, multiple port-channel interfaces must be created, and these interfaces should be added to the corresponding port bundle. LACP should also be configured on the uplink switch for the LACP bundle to come up.

- [Create a port-channel interface](#)
- [Add interface to the port-channel](#)
- [Add VLAN to LAG](#)
- [Add interface to the port-channel](#)

Port Aggregation Protocol

Port Aggregation Protocol (PAgP) is a Cisco-proprietary protocol that you can run on controllers. PAgP facilitates the automatic creation of EtherChannels by exchanging PAgP packets between Ethernet ports. PAgP packets are sent between Fast EtherChannel-capable ports in order to form a channel. When any of the active ports fail, a standby port becomes active.

By using PAgP, the controller learns the identity of partners that are capable of supporting PAgP and the capabilities of each port. PAgP then dynamically groups similarly configured ports (on a single device in a stack) into a single logical link (channel or aggregate port). Similarly, configured ports are grouped based on hardware, administrative, and port parameter constraints.

Configuring LAG Using PAgP

To configure LAG using PAgP, multiple port-channel interfaces must be created, and these interfaces should be added to the corresponding port bundle. PAgP should also be configured on the uplink switch for the PAgP bundle to come up.

- [Create a port-channel interface](#)
- [Add interface to the port-channel](#)

Information About Port Channel Interface Number

From Cisco IOS XE Bengaluru 17.5.1 onwards, the flexibility to number the port channel interface numbers between 1 and 64 is supported on the following Cisco Catalyst 9800 Series Wireless Controllers:

- Cisco Catalyst 9800-CL Wireless Controller for Cloud: The available range on the CLI is 1 to 64. The maximum supported port channel interfaces are 64.
- Cisco Catalyst 9800-L Wireless Controller: The available range on the CLI is 1 to 64. The maximum supported port channel interfaces are 14.
- Cisco Catalyst 9800-40 Wireless Controller: The available range on the CLI is 1 to 64. The maximum supported port channel interfaces are 16.
- Cisco Catalyst 9800-80 Wireless Controller: The available range on the CLI is 1 to 64. The maximum supported port channel interfaces are 64.

For example on the Cisco Catalyst 9800-L Wireless Controller, port-channel interface numbers can be anywhere between 1 and 64, as long as the total number of port-channel interfaces are 14 or lesser.

Note If you have configured 16 port-channel interfaces on the Cisco Catalyst 9800-40 Wireless Controller, and if the configured port-channel interfaces have reached their limitation, the following error message is displayed when you try to configure the 17th port-channel interface:

```
Device(config)#  
Dec 15 08:58:22.209 CST: %ETC-5-CANNOT_ALLOCATE_AGGREGATOR: Aggregator limit reached, cannot  
allocate aggregator for group 17
```

When you downgrade from Cisco IOS XE Bengaluru 17.5.1 to an earlier version, and if the port channels are configured with a higher range than the supported range in the earlier version, the following errors are displayed when the earlier version is started. The non supported port channels disappear after the downgrade is completed.

```
interface Port-channel29  
^% Invalid input detected at '^' marker.  
interface Port-channel35  
^% Invalid input detected at '^' marker.
```

Note that the HA pairing remains intact after downgrade.

Configuring LAG in ON Mode

To configure LAG in ON mode, multiple port-channel interfaces must be created, and these interfaces should be added to the corresponding port bundle. LACP should also be configured on the uplink switch for the LACP bundle to come up.

- [#unique_237](#)

Multichassis Link Aggregation Group

From Cisco IOS XE Amsterdam 17.2.1, Multichassis Link Aggregation Group (multi-LAG), which provides flexibility in connecting the controller to a switch's infrastructure is supported. Using multi-LAG, you can connect the multiple uplinks from the controller to the separated uplink switches. The controller supports VLAN-based traffic splitting when connected to a multiswitch topology. This provides the ability to distribute traffic on different uplinks, based on VLANs, for example, supporting a use case where guest traffic can be completely isolated to a different switch or network from the enterprise network. Same VLAN cannot be configured on both the uplinks.

You can connect a LAG to a single switch. However, different VLANs must be connected to different LAGs. The redundancy port must be connected to the same distribution switch as the uplinks, or back to back.

Multi-LAG is supported in LAG ON mode, LACP, and PAGP modes.

Prerequisites for Multi-LAG

- Each LAG must be connected to a single switch.
- Different VLANs must be assigned to different LAGs.

Restrictions for Multi-LAG

- If the primary LAG fails, automatic failover to secondary LAG is not supported.
- The interface on the controller does not come up when you shut or unshut the port on the switch port.

Note This is specific to Cisco Catalyst 9800-CL Cloud Wireless Controller in KVM environment for SR-IOV.

Supported Topologies

The Cisco Catalyst 9800-80 Wireless Controller has eight ports, while the Cisco Catalyst 9800-40 and Cisco Catalyst 9800-L wireless controllers have four ports each. You can create multi-LAGs of ports with similar capabilities, for example, 2.5 G and 2.5 G, or 10 G and 10 G. You cannot have a 2.5 G and a 10 G port in a port channel group with a minimum of two ports in one LAG.

Configuring a Port Channel Interface (GUI)

Procedure

-
- Step 1** Choose **Configuration > Interface > Logical**.
- Step 2** Click the **Port Channel** tab to configure the Port Channel interface.
The **Port Channel** tab lists all the logical port-channel interfaces on the device.
- Step 3** Click **Add** to add to a new logical port channel interface.
The **Add Port Channel Interface** window is displayed.
- Step 4** In the **Add Port Channel Interface** complete the following procedure:
- In the **Port Channel Number** field, enter the port channel number. The valid values are between 1 to 64.
 - In the **Description** field, enter the port channel description.
 - Click the **Admin Status** toggle button to set the admin status as *UP* or *DOWN*.
 - Click the **Enable Layer 3 Address** toggle button to enable the Layer 3 address.
 - In the Port Members section, select the port members from the list displayed in the **Available** list box, and add it to the **Associated** list.
 - From the **Switchport Mode** drop-down list, choose a switch mode for the interface.

- If you choose *access* as the switch mode, enter the access VLAN ID in the **Access VLAN** field.
- If you choose *trunk* as the switch mode, enter the VLAN IDs that you want to assign as trunk links. To allow all VLAN IDs as trunk links, set the **Allowed VLANs** to **All**. Specify a native VLAN.
- If you choose *dynamic auto* or *dynamic desirable* as the switch mode, enter the access VLAN ID. Enter the VLAN IDs you want to assign as trunk links. To allow all VLAN IDs as trunk links, set the **Allowed VLANs** to **All**. Specify a native VLAN.

g) Click **Update & Apply to Device**.

Create a Port-Channel Interface

Follow the procedure given below to create a port-channel interface.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	interface port-channel <i>port-channel</i> Example: Device(config)# <code>interface port-channel 2</code>	Configures the port channel and enters interface configuration mode. The valid values for the port channel number ranges from 1 to 64.
Step 3	switchport mode trunk Example: Device(config-if)# <code>switchport mode trunk</code>	Configures the port as trunk.
Step 4	no shutdown Example: Device(config-if)# <code>no shutdown</code>	Enables the interface.

Configuring LAG in ON Mode

Follow the procedure given below to configure LAG in ON mode.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	interface TenGigabitEthernet <i>port-slot</i> Example: Device(config)# interface TenGigabitEthernet0/0/0	Configures the port.
Step 3	switchport mode trunk Example: Device(config-if)# switchport mode trunk	Configures the port as trunk.
Step 4	no shutdown Example: Device(config-if)# no shutdown	Disables the interface.
Step 5	channel-group <i>group-number</i> mode on Example: Device(config-if)# channel-group 3 mode on	Assigns the port to a channel group, and specifies the ON mode. The valid values for the port channel number ranges from 1 to 64.
Step 6	switchport trunk allowed vlan <i>vlan-id</i> Example: Device(config-if)# switchport trunk allowed vlan 16,17	Assigns the allowed VLAN ID to the port when it is in trunking mode.

Add an Interface to a Port Channel (LACP)

Follow the procedure given below to add an interface to a port channel using the LACP.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface TenGigabitEthernet <i>port-slot</i> Example: Device(config)# interface TenGigabitEthernet0/0/0	Configures the port.
Step 3	channel-group <i>group-number</i> {active passive} Example: Device(config-if)# channel-group 1 mode active	Assigns the port to a channel group, and specifies the LACP mode. The valid values for the port channel number ranges from 1 to 64.

	Command or Action	Purpose
Step 4	switchport mode trunk Example: Device(config-if)# switchport mode trunk	Configures the port as trunk.

Add an Interface to a Port Channel (PAgP)

Follow the procedure given below to add an interface to a port channel using the PAgP.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface TenGigabitEthernet <i>port-slot</i> Example: Device(config)# interface TenGigabitEthernet0/0/0	Configures the TenGigabit Ethernet interface.
Step 3	channel-group <i>group-number</i> {auto desirable} Example: Device(config-if)# channel-group 1 mode auto	Assigns the port to a channel group, and specifies the PAgP mode. The valid values for the port channel number ranges from 1 to 64.
Step 4	switchport mode trunk Example: Device(config-if)# switchport mode trunk	Configures the port as trunk.

Add a VLAN to a Port Channel

Follow the procedure given below to add different VLANs under a port channel.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface port-channel <i>port-channel</i> Example:	Configures the port channel.

	Command or Action	Purpose
	Device(config)# interface port-channel 1	Valid values for the port channel number range from 1 to 64.
Step 3	switchport trunk allowed vlan <i>vlan-id</i> Example: Device(config-if)# switchport trunk allowed vlan 10,30,50	Adds VLANs to the list of allowed VLANs.

Remove a Port Channel Group from a Physical Interface

Perform this task to remove a port channel group from a physical port.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface TenGigabitEthernet <i>port-slot</i> Example: Device(config)# interface TenGigabitEthernet0/0/0	Enters the TenGigabit Ethernet interface.
Step 3	no channel-group Example: Device(config-if)# no channel-group	Removes the port channel group from the physical port.
Step 4	end Example: Device(config-if)# end	Exits interface configuration mode.

Verify the LAG Configuration

To view a port channel's state, use the following command:

```
Device# show etherchannel summary
```

```
Flags: D - down          P - bundled in port-channel
       I - stand-alone  s - suspended
       H - Hot-standby (LACP only)
       R - Layer3       S - Layer2
       U - in use       f - failed to allocate aggregator

       M - not in use, minimum links not met
       u - unsuitable for bundling
       w - waiting to be aggregated
       d - default port
```

```

      A - formed by Auto LAG
Number of channel-groups in use: 1
Number of aggregators:          1
Group  Port-channel  Protocol  Ports
-----+-----+-----+-----+-----
3      Po3(SU)        LACP    Tw0/0/0(P)  Tw0/0/1(P)
4      Po4(SU)        LACP    Tw0/0/2(P)  Tw0/0/3(P)

```

To verify an LACP or PAgP configuration, use the following commands:

```
Device# show running-config interface tenGigabitEthernet 0/0/0
```

```
Building configuration...
```

```
Current configuration : 114 bytes
!
interface TwoGigabitEthernet0/0/0
 switchport trunk allowed vlan 16,17
 switchport mode trunk
 speed 1000
 no negotiation auto
 no snmp trap link-status
 channel-group 3 mode on

```

```
Device# show running-config interface port-channel 1
```

```
Building configuration...
```

```
Current configuration : 54 bytes
!
interface Port-channell
 switchport mode trunk
 switchport trunk allowed vlan 10,30,50
end

```

CHAPTER 10

Reload Reason History

- [Feature History for Reload Reason History](#), on page 201
- [Information About Reload Reason History](#), on page 201
- [Verifying Reload Reason History](#), on page 201
- [Requesting Reload Reason History using YANG](#), on page 204

Feature History for Reload Reason History

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 16: Feature History for Reload Reason History

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.11.1	Reload Reason History	The Reload Reason History feature tracks the reasons for controller reload. This is done for the last 10 reloads. In Cisco IOS-XE Dublin 17.10.x and earlier releases, it was possible to track only the reason for the last reload.

Information About Reload Reason History

The Reload Reason History feature tracks the reasons for controller reload. This is done for the last 10 reloads. You will be able to view the history using the show version and the Network Configuration Protocol (NETCONF). This history is useful for serviceability and troubleshooting.

Verifying Reload Reason History

To view the reload history details, use the following command:

```
Device# show reload-history
```

```

Requesting Reload Reason History using YANG

Use YANG with NETCONF and RESTCONF to provide the desired solution for automated and programmable network operations.

Use the following RPC to create a NETCONF GET request for reload history data:

```

<nc:rpc xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0"
message-id="urn:uuid:da15955f-5bb7-437c-aeb5-0fc7901a1e9e">
  <nc:get>
    <nc:filter>
      <device-hardware-data
xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-device-hardware-oper">
        <device-hardware>
          <device-system-data>
            <reload-history/>
          </device-system-data>
        </device-hardware>
      </device-hardware-data>
    </nc:filter>
  </nc:get>
</nc:rpc>

<rpc-reply message-id="urn:uuid:da15955f-5bb7-437c-aeb5-0fc7901a1e9e"
xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <device-hardware-data xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-device-hardware-oper">

      <device-hardware>
        <device-system-data>
          <reload-history>

CHAPTER 11

Best Practices

- [Introduction, on page 207](#)

Introduction

This chapter covers the best practices recommended for configuring a typical Cisco Catalyst 9800 Series wireless infrastructure. The objective is to provide common settings that you can apply to most wireless network implementations. However, not all networks are the same. Therefore, some of the tips might not be applicable to your installation. Always verify them before you perform any changes on a live network.

For more information, see [Cisco Catalyst 9800 Series Configuration Best Practices](#) guide.

PART II

System Upgrade

- [Software Maintenance Upgrade, on page 229](#)
- [Efficient Image Upgrade, on page 247](#)
- [Predownloading an Image to an Access Point, on page 259](#)
- [N+1 Hitless Rolling AP Upgrade, on page 267](#)
- [NBAR Dynamic Protocol Pack Upgrade, on page 283](#)
- [Wireless Sub-Package for Switch, on page 285](#)

CHAPTER 12

Upgrading the Cisco Catalyst 9800 Wireless Controller Software

- [Overview of Upgrading the Controller Software, on page 211](#)
- [Upgrading the Controller Software \(GUI\), on page 212](#)
- [Upgrade the Controller Software \(CLI\), on page 213](#)
- [Converting From Bundle-Mode to Install-Mode, on page 214](#)
- [Copying a WebAuth Tar Bundle to the Standby Controller, on page 217](#)

Overview of Upgrading the Controller Software

This section describes the upgrade process and the methods to upgrade the Cisco Catalyst 9800 Series Wireless Controller Software.

Newer versions of the controller software are released at regular intervals. This includes major releases as well as rebuild releases that focus on bug fixes. The version of the AP software is also tied to the controller software release. Every major Cisco IOS XE software release contains new sets of features that are essential for the enterprise-class customers.

Each Cisco IOS XE software release is classified as either a Standard-Support release or an Extended-Support release.

Standard-Support Release

- A sustaining support lifetime of 12 months from First Customer Shipment (FCS) with two scheduled rebuilds
- Rebuilds are typically released at 6 months intervals after FCS.

Extended-Support release Details

- A sustaining support lifetime of 36 months from FCS with ten scheduled rebuilds.
- These rebuilds are at 3, 4, 4, 6, 7 months intervals after FCS or via SMU support. Last 12 months of support will be via SMU.

Based on your requirement, such as upgrading the full image or applying a software patch for bugs, you can go for an appropriate software upgrade, using either GUI or CLI.

- [Upgrade the Controller Software \(GUI\)](#)

- [Upgrade the Controller Software \(CLI\)](#)

Software Upgrade Options

- **Software Maintenance Upgrade:** This method installs a software package on the system to provide a patch fix or a security resolution to a released image. This upgrade package is provided on a per release and per component basis, and is specific to the platform.
- **Hitless Upgrade:** This method allows the APs to be upgraded in a staggered manner, while still being connected to the same controller. This avoids upgrade downtime even for N+1 networks.
- **In-Service Software Upgrade:** This method upgrades a wireless controller image to a later release while the network forwards packets. This feature is supported only within and between major releases.

Note We recommend In-Service Software Upgrade if you are upgrading the entire image or cold controller SMU. Use [Software Maintenance Upgrade](#) for software patches or bug fixes.

The software upgrade time is estimated to be less than 6 hours for a large network. However, the upgrade time depends on factors such as the number of APs, the percentage of APs to upgrade in each iteration, the controller type (9800-80, 9800-L, and so on), and the connectivity between the controller and the APs.

Device Upgrade Options

The following device upgrade options are available:

- **NBAR Dynamic Protocol Pack Upgrade:** Protocol packs are software packages that update the Network-Based Application Recognition (NBAR) engine protocol support on a device without replacing the Cisco software on the device. A protocol pack contains information on applications that are officially supported by NBAR, and are compiled and packed together.
- **Field Programmable Upgrade:** These are hardware programmable packages released by Cisco to upgrade the hardware programmable firmware. Hardware programmable package upgrade is necessary only when a system message indicates that one of the field programmable devices needs an upgrade or when a Cisco technical support representative suggests an upgrade.

Upgrading the Controller Software (GUI)

Before you begin

Clean up the old installation files using the **Remove Inactive Files** link.

Note For GUI options such as *Software Maintenance Upgrade*, *AP Service Package*, and *AP Device Package*, see the respective feature sections.

Procedure

Step 1 Choose **Administration > Software Management** .

Step 2 Choose an option from the **Upgrade Mode** drop-down list:

- **INSTALL**: The Install mode uses a package-provisioning file named *packages.conf* in order to boot a device.
- **BUNDLE**: The Bundle mode uses monolithic Cisco IOS images to boot a device. The Bundle mode consumes more memory than the Install mode because the packages are extracted from the bundle and copied to RAM.

Note You get to view the **Destination** field only for BUNDLE upgrade mode.

Step 3 From the **Transport Type** drop-down list, choose the transfer type to transfer the software image to your device as **TFTP**, **SFTP**, **FTP**, **Device**, or **Desktop (HTTP)**.

- If you choose **TFTP** as the **Transport Type**, enter the **Server IP Address** of the TFTP server that you want to use. Also, enter the complete **File Path**.

In controllers, the IP TFTP source is mapped to the service port by default.

- If you choose **SFTP** as the **Transport Type**, enter the **Server IP Address** of the SFTP server that you want to use. Also, enter the **SFTP Username**, **SFTP Password**, and the complete **File Path**.
- If you choose **FTP** as the **Transport Type**, enter the **Server IP Address** of the FTP server that you want to use. Also, enter the **FTP Username**, **FTP Password**, and the complete **File Path**.
- If you choose **Device** as the **Transport Type**, choose the **File System** from the drop-down list. In the **File Path** field, browse through the available images or packages from the device and select one of the options, and click **Select**.
- If you choose **Desktop (HTTPS)** as the **Transport Type**, choose the **File System** from the drop-down list. In the **Source File Path** field, click **Select File** to select the file, and click **Open**.

Step 4 Click **Download & Install**.

Step 5 To boot your device with the new software image, click **Save Configuration & Activate**.

Step 6 Click **Commit** after the device reboots to make the activation changes persistent across reloads.

Note For 17.4 and later releases, this step is mandatory for the upgrade to be persistent. If you do not click **Commit**, the auto-timer terminates the upgrade operation after 6 hours, and the controller reverts back to the previous image.

Upgrade the Controller Software (CLI)

Before you begin

- Determine the Cisco IOS release that is currently running on your controller, and the filename of the system image using the **show version** command in user EXEC or privileged EXEC mode.

- Clean up the old installation files using the **install remove inactive** command.
- Use the **show version | include Installation mode** to verify the boot mode.

Note We recommend that you use install mode for the software upgrade.

For steps on converting the device from bundle-mode to install-mode, see [Converting from Bundle-Mode to Install-Mode](#).

Procedure

Step 1 Download the software from Cisco.com: <https://software.cisco.com/download/home/286322524>

- Click IOS XE Software link.
- Select the release number you want to install, for example Gibraltar-16.12.3.

Note Cisco recommended release is selected by default. For release designation information, see: <https://software.cisco.com/download/static/assets/i18n/reldesignation.html?context=sds>

- Click **Download**.

Step 2 Copy the new image to flash using the command: **copy tftp:image flash:**

Step 3 Verify that the image has been successfully copied to flash using the command: **dir flash:**

Step 4 Upgrade the software by choosing an upgrade process from the options that are currently supported.

For a list of upgrade options, see [#unique_268 unique_268_Connect_42_sw_upgrade_opt](#).

Converting From Bundle-Mode to Install-Mode

Use the procedure given below to boot in install-mode:

Before you begin

- Clean up the old installation files using the command **install remove inactive**
- Verify the boot mode using the command: **show version | include Installation mode**
- Download the software image from Cisco.com.

For steps on how to download the software, see *Upgrading the Controller Software (CLI)* .

Procedure

Step 1 Copy the new image to flash using the command: **copy tftp:image flash:**

```
Device# copy tftp://xx.x.x.x//C9800-universalk9_wlc.xx.xx.xx.SSA.bin flash:
```

```

Destination filename [C9800-universalk9_wlc.xx.xx.xx.SSA.bin]?
Accessing tftp://xx.x.x.x/C9800-universalk9_wlc.xx.xx.xx.SSA.bin...
Loading /C9800-universalk9_wlc.xx.xx.xx.SSA.bin from xx.x.x.x (via GigabitEthernet0/0):
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
[OK - 601216545 bytes]
601216545 bytes copied in 50.649 secs (11870255 bytes/sec)

```

Step 2 Verify that the image has been successfully copied to flash using the command: **dir flash:**

```

Device# dir flash:*.bin

Directory of bootflash:/*.bin

On Active

Directory of bootflash:/

   12 -rw- 1231746613 Jun 11 2020 23:15:49 +00:00

   18 -rw- 1232167230 Jun 8 2020 02:42:22 +00:00
C9800-universalk9_wlc.BLD_POLARIS_DEV_LATEST_20200607_002322.SSA.bin
24811823104 bytes total (16032391168 bytes free)

On Standby
Directory of stby-bootflash:/*.bin

Directory of stby-bootflash:/

   18 -rw- 1232167230 Jun 8 2020 02:42:22 +00:00
C9800-universalk9_wlc.BLD_POLARIS_DEV_LATEST_20200607_002322.SSA.bin
   20 -rw- 1231746613 Jun 11 2020 23:15:49 +00:00
C9800-universalk9_wlc.BLD_POLARIS_DEV_LATEST_20200611_101837.SSA.bin
   17 -rw- 1232457039 Jun 9 2020 21:14:40 +00:00
C9800-universalk9_wlc.BLD_POLARIS_DEV_LATEST_20200609_031801.SSA.bin
   16 -rw- 1219332990 Jun 10 2020 02:06:14 +00:00
C9800-universalk9_wlc.BLD_V173_THROTTLE_LATEST_20200608_003622_V17_3_0_183.SSA.bin
26462998528 bytes total (17686335488 bytes free)

```

Step 3 Set the boot variable to **bootflash:packages.conf**.

```
Device(config)# boot sys flash bootflash:packages.conf
```

Step 4 Save your changes by entering this command: **write memory**.

```
Device(config)# write memory
```

Step 5 Verify whether the boot variable is set to **bootflash:packages.conf** using the command: **show boot**

```

Device# show boot

BOOT variable = bootflash:packages.conf,12;
CONFIG_FILE variable =
BOOTLDR variable does not exist
Configuration register is 0x2102

Standby BOOT variable = bootflash:packages.conf,12;
Standby CONFIG_FILE variable =

```

```
Standby BOOTLDR variable does not exist
Standby Configuration register is 0x2102
```

Step 6 Move the device from bundle-mode to install-mode using the command: **install add file image.bin location activate commit**

```
Device# install add file bootflash:C9800-universalk9_wlc.xx.xx.xx.SPA.bin activate commit

install_add_activate_commit: START Thu Dec 6 15:43:57 UTC 2018
Dec 6 15:43:58.669 %INSTALL-5-INSTALL_START_INFO: R0/0: install_engine: Started install

Install will reload the system now!
SUCCESS: install_add_activate_commit Thu Dec 6 15:49:21 UTC 2018
Dec 6 15:49:21.294 %INSTALL-5-INSTALL_COMPLETED_INFO: R0/0: install_engine: Completed
install one-shot PACKAGE bootflash:C9800-xx-universalk9.xx.xx.xx.SPA.bin
```

Note The system reloads automatically after executing the **install add file activate commit** command. You do not have to manually reload the system.

If upgrade fails, cleanup is required before attempting the upgrade procedure again. An upgrade failure may occur due lack of disk space, validation failure of extracted image, system crashes, and so on. Should a system failure occurs during upgrade process, wait till the system is back in service and check the system image version.

- If it is a new image, check for the stability and functionality of the system, and decide whether to commit and complete the upgrade procedure or discard the upgrade procedure.
- If it is a new image, use the cleanup procedure and reattempt the upgrade procedure.

Step 7 Click **yes** to all the prompts.

Step 8 Verify the boot mode using the command: **show version**

```
Device# show version | in Installation mode is  
  
Installation mode is INSTALL
```

Copying a WebAuth Tar Bundle to the Standby Controller

Use the following procedure to copy a WebAuth tar bundle to the standby controller, in a high-availability configuration.

Procedure

Step 1 Choose **Administration > Management > Backup & Restore**.

Step 2 From the **Copy** drop-down list, choose **To Device**.

Step 3 From the **File Type** drop-down list, choose **WebAuth Bundle**.

Step 4 From the **Transfer Mode** drop-down list, choose **TFTP**, **SFTP**, **FTP**, or **HTTP**.

The **Server Details** options change based on the file transfer option selected.

- **TFTP**

- **IP Address (IPv4/IPv6)**: Enter the server IP address (IPv4 or IPv6) of the TFTP server that you want to use.
- **File Path**: Enter the file path. The file path should start with slash a (*/path*).
- **File Name**: Enter a file name.

The file name should not contain spaces. Underscores (`_`) and hyphen (`-`) are the only special characters that are supported. Ensure that file name ends with `.tar`, for example, `webauthbundle.tar`.

- **SFTP**

- **IP Address (IPv4/IPv6)**: Enter the server IP address (IPv4 or IPv6) of the SFTP server that you want to use.

- **File Path:** Enter the file path. The file path should start with slash a (*/path*).
- **File Name:** Enter a file name.
The file name should not contain spaces. Underscores (`_`) and hyphen (`-`) are the only special characters that are supported. Ensure that file name ends with `.tar`, for example, `webauthbundle.tar`.
- **Server Login UserName:** Enter the SFTP server login user name.
- **Server Login Password:** Enter the SFTP server login passphrase.

- **FTP**

- **IP Address (IPv4/IPv6):** Enter the server IP address (IPv4 or IPv6) of the TFTP server that you want to use.
- **File Path:** Enter the file path. The file path should start with slash a (*/path*).
- **File Name:** Enter a file name.
The file name should not contain spaces. Underscores (`_`) and hyphen (`-`) are the only special characters that are supported. Ensure that file name ends with `.tar`, for example, `webauthbundle.tar`.
- **Logon Type:** Choose the login type as either **Anonymous** or **Authenticated**. If you choose **Authenticated**, the following fields are activated:
 - **Server Login UserName:** Enter the FTP server login user name.
 - **Server Login Password:** Enter the FTP server login passphrase.

- **HTTP**

- **Source File Path:** Click **Select File** to select the configuration file, and click **Open**.

Step 5 Click the **Yes** or **No** radio button to back up the existing startup configuration to Flash.

Save the configuration to Flash to propagate the WebAuth bundle to other members, including the standby controller. If you do not save the configuration to Flash, the WebAuth bundle will not be propagated to other members, including the standby controller.

Step 6 Click **Download File**.

CHAPTER 13

In-Service Software Upgrade

- [Information About In-Service Software Upgrade, on page 219](#)

Information About In-Service Software Upgrade

In-Service Software Upgrade (ISSU) is a procedure to upgrade a wireless controller image to a later release while the network continues to forward packets. ISSU helps network administrators avoid a network outage when performing a software upgrade.

ISSU can also be used to apply cold patches without impacting the active network.

ISSU is supported only on the following Cisco Catalyst 9800 Series Wireless Controllers, and supports only upgrade.

- Cisco Catalyst 9800-80 Wireless Controller
- Cisco Catalyst 9800-40 Wireless Controller
- Cisco Catalyst 9800-L Wireless Controller
- Cisco Catalyst 9800-CL Wireless Controller (Private Cloud)

High-Level Workflow of ISSU

1. Onboard the controller software image to the flash memory.
2. Download the AP image to the AP.
3. Install the controller software image.
4. Commit the changes.

Prerequisites for Performing In-Service Software Upgrade

- Ensure that both Active and Standby controllers are in install mode and are booted from *bootflash:/packages.conf*.
- Ensure that the network or device is not being configured during the upgrade.
- Schedule the upgrade when your network is stable and steady.
- Ensure uninterrupted power supply. A power interruption during upgrade procedure might corrupt the software image.

Guidelines and Restrictions for In-Service Software Upgrade

- If you do not run the **install commit** command within 6 hours of the **install activate issu** command, the system will revert to the original commit position. You can choose to delay the commit using the [Delayed Commit](#) procedure.
- During ISSU upgrade, while AP rolling upgrade is in progress, the **install abort** command won't work. You should use the **install abort issu** command, instead to cancel the upgrade.
- During ISSU upgrade, the system displays a warning message similar to:

```
found 46 disjoint TDL objects
```

. You can ignore the warning message because it doesn't have any functional impact.
- During ISSU upgrade, if both the controllers (active and standby) have different images after the power cycle, an auto cancel of ISSU is triggered to bring both the controllers to the same version. The following is a sample scenario: Install Version1 (V1) software on the active controller and then apply a SMU hot patch and perform a commit. Now, upgrade the software to Version2 using ISSU, and then power cycle the active controller. At this point, the system has a version mismatch (V1 and V2). The active controller reloads at this stage, after the completion of bulk synchronization. Now, both the controllers come up with the same version (V1 and V1).
- An ISSU upgrade that is canceled because of configuration synchronization failure on the standby controller rolls back to V1 of the software image. However, this information isn't available in the **show install** command log. Run the **show issu state detail** command to see the current ISSU state.
- To enable the **clear install** command, you should first run the **service internal** command in global configuration mode, and then run the **clear install** command in privileged EXEC mode.
- Image rollback could be affected if the controller has a stale rollback history and the stack gets formed afterwards. We recommend that you run the **clear install state** command to clear stale information and boot the controller in bundle mode.
- The **clear install state** command doesn't delete the SMU file from flash or storage. To remove a SMU, use either the **install remove file** command or the **install remove inactive** command.
- When the new active controller comes up, after the image upgrade, it doesn't retain the old logs on web GUI window as part of show logs.

- If a stateful switchover (SSO) or a high-availability (HA) event occurs during the rolling AP upgrade procedure of the ISSU feature, the rolling AP upgrade stops. You should then use the **ap image upgrade** command to restart the upgrade process.
- If HA fails to form after the ISSU procedure, you should reload any one chassis again to form HA again.
- Use clear **ap predownload statistics** command before using the **show ap image** command. This ensures that you get the right data after every pre-download.
- Manually cancel the ISSU process using the **install issu abort** command in the scenarios given below, to avoid a software version mismatch between the active controller and the standby controller.
 - An RP link is brought down after standby HOT during an ISSU procedure and the links remains down even after the auto-abort timer expiry.
 - An RP link is brought down before the standby controller reaches standby HOT during an ISSU procedure.
- Cisco TrustSec (CTS) is not supported on the RMI interfaces.
- If a switchover occurs while performing an AP upgrade using ISSU, the upgrade process will restart automatically after the switchover.

Upgrading Software Using In-Service Software Upgrade

Use the following procedure to perform a complete image upgrade, that is, from one image to another.

Note ISSU is supported only within and between major releases, for example, 17.3.x to 17.3.y, 17.6.x to 17.6.y (within a major release) and 17.3.x to 17.6.x, 17.3.x to 17.9.x (among major releases), that is, for two releases after the current supported release. ISSU is NOT supported within and between minor releases or between minor and major releases, for example 17.4.x to 17.4.y or 17.4.x to 17.5.x or 17.3.x to 17.4.x.

ISSU downgrade is not supported for Cisco Catalyst 9800 Series Wireless Controller platforms.

Note We recommend that you configure the percentage of APs to be upgraded by using the **ap upgrade staggered** command.

Procedure

	Command or Action	Purpose
Step 1	install add file <i>file-name</i> Example:	The controller software image is added to the flash and expanded.

	Command or Action	Purpose
	Device# install add file <>	Note In Cisco Catalyst 9800 Wireless Controller for Switch, run the install add file sub-package-file-name command to expand the wireless subpackage file.
Step 2	ap image predownload Example: Device# ap image predownload	Performs predownload of the AP image. To see the progress of the predownload, use the show ap image command.
Step 3	install activate issu [auto-abort-timer timer] Example: Device# install activate issu	Runs compatibility checks, installs the package, and updates the package status details. Optionally, you can configure the time limit to cancel the addition of new software without committing the image. Valid values are from 30 to 1200 minutes.
Step 4	Run either of the following commands: • install abort issu Device# install abort issu Cancels the upgrade process and returns the device to the previous installation state. This is applicable for both controller and the AP. • install commit Device# install commit Commits the activation changes to be persistent across reloads. Note If you do not run the install commit command within 6 hours of completing the previous step, the system will revert to the original commit position.	

Upgrading Software Using ISSU (GUI)

Before you begin

1. The device should be in Install mode.
2. The device should have an HA pair. The standby controller should be online and is in SSO mode.

You can verify the details using **show issu state detail** command.

Procedure

-
- Step 1** Choose **Administration > Software Management**.
 - Step 2** Under the **Software Upgrade** tab, check the **ISSU Upgrade (HA Upgrade) (Beta)** check box.
 - Step 3** In the **AP Upgrade Configuration** section, from the **AP Upgrade per Iteration** drop-down list choose the percentage of APs to be upgraded.
 - Step 4** Click **Download & Install**.

This initiates the upgrade process and you can view the progress in the **Status** dialog box.

Click the **Show Logs** link to view the upgrade process details.

Note An SSO takes place while activating the image on the active controller. After the SSO, you should login again to the controller.

- Step 5** The system enables the **Commit** and **ISSU Abort** buttons after the upgrade.
Click **Commit** to commit the activation changes, or **ISSU Abort** to terminate the upgrade process and return the device to the previous installation state.
-

Upgrading Software Using In-Service Software Upgrade with Delayed Commit

Use this procedure to upgrade the controller software with delayed commit, which will help you to run and test the new software without committing the image.

Procedure

	Command or Action	Purpose
Step 1	install add file <i>file-name</i> Example: Device# install add file <file>	Adds and expands the controller software image to the flash. Note In Cisco Catalyst 9800 Wireless Controller for Switch, run the install add file <i>sub-package-file-name</i> command to expand the wireless subpackage file.
Step 2	ap image predownload Example: Device# ap image predownload	Performs predownload of the AP image.

	Command or Action	Purpose
Step 3	install auto-abort-timer stop Example: Device# install auto-abort-timer stop	Stops the termination timer so that the upgrade process is not terminated after the default termination time of 6-8 hours.
Step 4	install activate issu Example: Device# install activate issu	Runs compatibility checks, installs the package, and updates the package status details.
Step 5	install commit Example: Device# install commit	Commits the activation changes to be persistent across reloads.

Monitoring In-Service Software Upgrade

To view the ISSU state after the install add ISSU and before the install activate ISSU, use the following command:

```
Device# show issu state detail

-- Starting local lock acquisition on chassis 1 ---
Finished local lock acquisition on chassis 1
Current ISSU Status: Enabled
Previous ISSU Operation: Abort Successful
=====
System Check Status
-----
Platform ISSU Support Yes
Standby Online Yes
Autoboot Enabled Yes
SSO Mode Yes
Install Boot Yes
Valid Boot Media Yes
=====
No ISSU operation is in progress
show install summary
[ Chassis 1 2 ] Installed Package(s) Information:
State (St): I - Inactive, U - Activated & Uncommitted,
C - Activated & Committed, D - Deactivated & Uncommitted
-----
Type St Filename/Version
-----
IMG I 17.1.1.0.432
IMG C 16.12.2.0.2707
-----
Auto abort timer: inactive
-----
```

To view the ISSU state after activating ISSU, use the following command:

```
Device# show issu state detail

Current ISSU Status: In Progress
Previous ISSU Operation: Abort Successful
=====
```

```

System Check Status
-----
Platform ISSU Support Yes

State transition: Added -> Standby activated -> Active switched-over -> Activated ->
Timeout-error
Auto abort timer: inactive
Running image: bootflash:packages.conf
Operating mode: sso, terminal state reached
```

To view the summary of the active packages in a system, use the following command:

```
Device# show install summary

[ Chassis 1 2 ] Installed Package(s) Information:
State (St): I - Inactive, U - Activated & Uncommitted,
C - Activated & Committed, D - Deactivated & Uncommitted
-----
Type St Filename/Version
-----
IMG C 16.12.2.0.2707
-----
Auto abort timer: inactive
-----
```

Troubleshooting ISSU

Using **install activate issu** command before completing AP pre-download.

The following scenario is applicable when you run the **install activate issu** command before completing AP pre-download. In such instances, you should run the **ap image predownload** command and then proceed with the activation.

```
Device# install activate issu
```

```
install_activate: START Wed Jan  8 04:48:04 UTC 2020
System configuration has been modified.
Press Yes(y) to save the configuration and proceed.
Press No(n) for proceeding without saving the configuration.
Press Quit(q) to exit, you may save configuration and re-enter the command. [y/n/q]
y
Building configuration...
[OK]Modified configuration has been saved
install_activate: Activating ISSU
NOTE: Going to start Activate ISSU install process
STAGE 0: System Level Sanity Check

CHAPTER 14

Software Maintenance Upgrade

- [Introduction to Software Maintenance Upgrade, on page 229](#)
- [Information About AP Device Package, on page 234](#)
- [Information About Per Site or Per AP Model Service Pack \(APSP\), on page 237](#)

Introduction to Software Maintenance Upgrade

Software Maintenance Upgrade (SMU) is a package that can be installed on a system to provide a patch fix or a security resolution to a released image. A SMU package is provided for each release and per component basis, and is specific to the corresponding platform.

A SMU provides a significant benefit over classic Cisco IOS software because it allows you to address the network issue quickly while reducing the time and scope of the testing required. The Cisco IOS XE platform internally validates the SMU compatibility and does not allow you to install noncompatible SMUs.

All the SMUs are integrated into the subsequent Cisco IOS XE software maintenance releases. A SMU is an independent and self-sufficient package and does not have any prerequisites or dependencies. You can choose which SMUs to install or uninstall in any order.

Note SMUs are supported only on Extended Maintenance releases and for the full lifecycle of the underlying software release.

Note You can activate the file used in the **install add file** command only from the filesystems of the active device. You cannot use the file from the standby or member filesystems; the **install add file** command will fail in such instances.

Note When the SMU file is deleted and a reboot is performed, the device may display the following error message:

```
--- Starting SMU Add operation ---
Performing SMU_ADD on all members
  FAILED: Improper State./bootflash/<previously-installed-smu-filename>.smu.bin not
present. Please restore file for stability.
Checking status of SMU_ADD on [1/R0]
SMU_ADD: Passed on []. Failed on [1/R0]
Finished SMU Add operation
FAILED: add_activate_commit /bootflash/<tobeinstalled-wlc-smu-filename>.smu.bin Wed Aug 02
08:30:18 UTC 2023.
```

This error occurs because the previous SMU file was not properly removed from the controller. It may lead to functional errors, such as the inability to install new SMU or APSP files.

We recommend that you use the `install remove file` command to remove previous instances of APSP or SMU files from the bootflash.

SMU infrastructure can be used to meet the following requirements in the wireless context:

- Controller SMU: Controller bug fixes or Cisco Product Security Incident Response information (PSIRT).
- APSP: AP bug fixes, PSIRTs, or minor features that do not require any controller changes.
- APDP: Support for new AP models without introduction of new hardware or software capabilities.

Note The `show ap image` command displays cumulative statistics regarding the AP images in the controller. We recommend that you clear the statistics using the `clear ap predownload statistics` command, before using the `show ap image` command, to ensure that correct data is displayed.

SMU Workflow

The SMU process should be initiated with a request to the SMU committee. Contact your customer support to raise an SMU request. During the release, the SMU package is posted on the Cisco Software Download page and can be downloaded and installed.

SMU Package

An SMU package contains the metadata and fix for the reported issue the SMU is requested for.

SMU Reload

The SMU type describes the effect on a system after installing the corresponding SMU. SMUs can be nontraffic-affecting or can result in device restart, reload, or switchover.

A controller cold patch require a cold reload of the system during activation. A cold reload is the complete reload of the operating system. This action affects the traffic flow for the duration of the reload (~5 min). This reload ensures that all the processes are started with the correct libraries and files that are installed as part of the corresponding SMU.

Controller hot patching support allows the SMU to be effective immediately after activation, without reloading the system. After the SMU is committed, the activation changes are persistent across reloads. Hot patching

SMU packages contain metadata that lists all processes that need to be restarted in order to activate the SMU. During SMU activation, each process in this list will be restarted one at a time until the SMU is fully applied.

Installing a SMU (GUI)

Procedure

-
- Step 1** Choose **Administration > Software Management** and click the **Software Maintenance Upgrade** tab.
- Step 2** Click **Add** to add a SMU image.
- Step 3** From the **Transport Type** drop-down list, choose the transfer type to transfer the software image to your device as TFTP, SFTP, FTP, Device, or Desktop (HTTP).
- If you choose **TFTP** as the **Transport Type**, you need to enter the **Server IP Address (IPv4/IPv6)**, **File path** and choose a **File System** from the drop-down list. For example, if the SMU file is at the root of the TFTP server you can enter `/C9800-universalk9_wlc.17.03.02a.CSCvw55275.SPA.smu.bin` in the **File path** field.
 - If you choose **SFTP** as the **Transport Type**, you need to enter the **Server IP Address (IPv4/IPv6)**, **SFTP Username**, **SFTP Password**, **File path** and choose a **File System** from the drop-down list.
 - If you choose **FTP** as the **Transport Type**, you need to enter the **Server IP Address (IPv4/IPv6)**, **FTP Username**, **FTP Password**, **File path**, and choose a **File System** from the drop-down list.
 - If you choose **Device** as the **Transport Type**, you need to enter the **File path** and choose a **File System** from the drop-down list. This is possible when the software is already present on the device due to an earlier download and activation, followed by a subsequent deactivation.

Note The File System depends upon the kind of device you are using. On physical controllers, you have the option to store the file to the bootflash or hard disk, whereas in case of virtual controllers, you can only store it in the bootflash.
 - If you choose **Desktop (HTTPS)** as the **Transport Type**, you need to choose a **File System** from the drop-down list and click **Select File** to navigate to the **Source File Path**.
- Step 4** Enter the **File Name** and click **Add File**.
- This operation copies the maintenance update package from the location you selected above to the device and performs a compatibility check for the platform and image versions and adds the SMU package for all the members. After a SMU is successfully added to the system, a message is displayed about the successful operation and that the SMU can be activated on the device. The message displays the name of the package (SMU) that is now available to be activated. It lists the SMU Details - Name, Version, State (active or inactive), Type (reload, restart, or non-reload) and other compatibility details. If SMU is of the Type - reload, then any operation (activate, deactivate or rollback) will cause the device to reload; restart involves only a process restart and if it is non reload- no change in process takes place.
- Step 5** Select the SMU and click on **Activate** to activate the SMU on the system and install the package, and update the package status details.
- Step 6** Select the SMU and click **Commit** to make the activation changes persistent across reloads.
- The Commit operation creates commit points. These commit points are similar to snapshots using which you can determine which specific change you want to be activated or rolled back to, in case there is any issue with

the SMU. The commit can be done after activation when the system is up, or after the first reload. If a package is activated, but not committed, it remains active after the first reload, but not after the second reload.

Installing SMU

Procedure

	Command or Action	Purpose
Step 1	install add file bootflash: <i>filename</i> Example: Device# install add file bootflash:<Filename>	Copies the maintenance update package from a remote location to the device, and performs a compatibility check for the platform and image versions. This command runs base compatibility checks on a file to ensure that the SMU package is supported on the platform. It also adds an entry in the package/SMU.sta file, so that its status can be monitored and maintained.
Step 2	install activate file bootflash: <i>filename</i> Example: Device# install activate file bootflash:<Filename>	Runs compatibility checks, installs the package, and updates the package status details. For a restartable package, the command triggers the appropriate post-install scripts to restart the necessary processes, and for non-restartable packages it triggers a reload.
Step 3	install commit Example: Device# install commit	Commits the activation changes to be persistent across reloads. The commit can be done after activation while the system is up, or after the first reload. If a package is activated but not committed, it remains active after the first reload, but not after the second reload.
Step 4	show version Example: Device# show version	Displays the image version on the device.
Step 5	show install summary Example: Device# show install summary	Displays information about the active package. The output of this command varies according to the install commands that are configured.

Roll Back an Image (GUI)

Procedure

-
- Step 1** Choose **Administration > Software Management**.
 - Step 2** Go to **SMU, APSP** or **APDP**.
 - Step 3** Click **Rollback**.
 - Step 4** In the **Rollback to** drop-down list, choose **Base, Committed** or **Rollback Point**.
 - Step 5** Click **Add File**.
-

Rollback SMU

Procedure

	Command or Action	Purpose
Step 1	install rollback to { base committed id committed } <i>committed ID</i> Example: Device(config)# install rollback to id 1234	Returns the device to the previous installation state. After the rollback, a reload is required.
Step 2	install commit Example: Device# install commit	Commits the activation changes to be persistent across reloads.

Deactivate SMU

Procedure

	Command or Action	Purpose
Step 1	install deactivate file bootflash: <i>filename</i> Example: Device# install deactivate file bootflash:<Filename>	Deactivates an active package, updates the package status, and triggers a process to restart or reload.
Step 2	install commit Example: Device# install commit	Commits the activation changes to be persistent across reloads.

Configuration Examples for SMU

The following is sample of the SMU configuration, after the install add for the SMU is done:

```
Device#show install summary

[ Chassis 1 2 ] Installed Package(s) Information:
State (St): I - Inactive, U - Activated & Uncommitted,
           C - Activated & Committed, D - Deactivated & Uncommitted
-----
Type  St   Filename/Version
-----
IMG   C    16.8.1.0.39751
-----
Auto abort timer: inactive
-----
```

Information About AP Device Package

The controller supports rolling out critical bug fixes using Software Maintenance Upgrade (SMU). Similarly, if any new AP hardware model is introduced, the AP models need to be connected to the existing wireless network.

Currently, when a new AP hardware model is introduced, those get shipped along with the corresponding controller related major software version. Then you need to wait for the release of a corresponding controller version relative to the new AP model and upgrade the entire network.

From 16.11.1 onwards, you can introduce the new AP model into your wireless network using the SMU infrastructure without the need to upgrade to the new controller version. This solution is termed as AP Device Package (APDP).

SMU Process or Workflow

The SMU process builds APDP to detect code changes and build APDP. It also supports addition of a new file (AP image file) to APDP and inclusion of those AP images into APDP.

The workflow is as follows:

- install add
- install activate
- install commit

For more details, see *Managing AP Device Package*.

Note To ensure completion of the APSP or APDP activation or deactivation process, ensure that you run the **install commit** command after the **install activate** or **install deactivate** command. Failing to do so within 6 hours of the deactivate operation terminates the deactivate operation and moves it back to the original commit position.

SMU Package

A SMU package contains the metadata that carry AP model and its capability related details.

AP Image Changes

When new AP models are introduced, there may or may not be corresponding new AP images. This means that AP images are mapped to the AP model families. If a new AP model belongs to an existing AP model family then you will have existing AP image entries (Example: ap3g3, ap1g5, and so on). For instance, if an AP model belongs to either ap3g3 or ap1g5, the respective image file is updated with the right AP image location. Also, the corresponding metadata file is updated with the new AP model capability information.

If a new AP model belongs to a new AP model family and new image file, the new image entry file is created in the right AP image location. Also, the corresponding metadata file is updated with the new AP model capability information.

During AP image bundling and packaging of APDP, the new AP model images and metadata file are packaged into APDP.

Note The APDP images must not be renamed to avoid impact on its functionality.

Installing AP Device Package (GUI)

Procedure

- Step 1** Choose **Administration > Software Management**.
- Step 2** Click **AP Device Package (APDP)** tab.
- Step 3** Click **Add**.
- Step 4** From the **Transport Type** drop-down list, choose the transfer type to transfer the software image to your device as TFTP, SFTP, FTP, Device, or Desktop (HTTP).
- a) If you choose **TFTP** as the **Transport Type**, you need to enter the **Server IP Address (IPv4/IPv6)**, **File path** and choose a **File System** from the drop-down list.
 - b) If you choose **SFTP** as the **Transport Type**, you need to enter the **Server IP Address (IPv4/IPv6)**, **SFTP Username**, **SFTP Password**, **File path** and choose a **File System** from the drop-down list.
 - c) If you choose **FTP** as the **Transport Type**, you need to enter the **Server IP Address (IPv4/IPv6)**, **FTP Username**, **FTP Password**, **File path**, and choose a **File System** from the drop-down list.
 - d) If you choose **Device** as the **Transport Type**, you need to enter the **File path** and choose a **File System** from the drop-down list.
 - e) If you choose **Desktop (HTTPS)** as the **Transport Type**, you need to choose a **File System** from the drop-down list and click **Select File** to navigate to the **Source File Path**.
- Step 5** Enter the **File Name** and click **Add File**.
- Step 6** From the **AP Upgrade Configuration** section, choose the percentage of APs to be included from the **AP Upgrade per iteration** drop-down list.
- Step 7** Click **Apply**.
-

Installing AP Device Package (CLI)

Procedure

	Command or Action	Purpose
Step 1	install add file bootflash: filename Example: Device# install add file bootflash:<Filename>	Extracts AP images from APDP and places them in SMU or APDP specific mount location. Note Here, the SMU does not trigger the Wireless module.
Step 2	install activate file bootflash: filename Example: Device# install activate file bootflash:<Filename>	Adds the AP software in APDP to the existing current active AP image list. Also, updates the capability information for the new AP models in the controller . Note Even if the new AP module supports new hardware capabilities, the controller recognizes only the capability information that its base version supports. At this point, the controller accepts the new connection from the new AP model. The new AP model then joins the controller .
Step 3	install commit Example: Device# install commit	Commits the new AP software to be persistent across reloads. The commit can be done after activation while the system is up, or after the first reload. If a package is activated but not committed, it remains active after the first reload, but not after the second reload.
Step 4	install deactivate file bootflash: filename Example: Device# install deactivate file bootflash:<Filename>	(Optional) Deactivates an active APDP, updates the package status, and triggers a process to restart or reload.
Step 5	show version Example: Device# show version	Displays the image version on the device.

Verifying APDP on the Controller

To verify the status of APDP packages on the controller , use the following command:

```

Device# show install summary

[ Chassis 1 ] Installed Package(s) Information:
State (St): I - Inactive, U - Activated & Uncommitted,
           C - Activated & Committed, D - Deactivated & Uncommitted
-----
Type  St  Filename/Version
-----
APDP  I   bootflash:apdp_CSCvp12345.bin
IMG   C   17.1.0.0
-----
Auto abort timer: inactive
-----

```

Note The output of this command varies based on the packages, and the package states that are installed.

Information About Per Site or Per AP Model Service Pack (APSP)

The controller supports critical updates to the access points (APs) using Software Maintenance Update (SMU). Using the Per Site or Per AP Model Service Pack feature, you can roll out critical AP bug fixes to a subset of APs, on a site or group of sites, using SMU in a staggered manner.

This feature allows to control the propagation of a SMU in your network by selecting the sites, to be included in the SMU activation, using Per Site AP SMU rollout. However, all sites should be brought to the same SMU level before a new SMU can be rolled out to a subset of sites or for a subsequent image upgrade to be initiated on the system..

Using Per AP model SMU, you can limit the update to only certain AP models. The software is predownloaded and is activated only to certain AP models, within a site. Note that if a certain number of model images are included in a SMU, all the future updates must contain software images for those models.

This feature is supported in the flex-connect mode, local mode, and Software-Defined Access (SD-Access) wireless scenarios.

Note After applying the AP site filter for per site SMU upgrade, a new image installation will not be allowed without applying the site filter to all the other sites, or removing the existing site filter.

Restrictions

- If APs are not configured to a primary controller, the APs will see the same discovery response from controllers with the APSP image and without the APSP image, causing the APs to flap between two controllers.

Workflow of AP SMU Upgrade

- Run a query to check whether there are ongoing activities, such as AP image predownload or AP rolling upgrade.
- Identify the site or sites to install the SMU in, and set up a site filter.

- Trigger the predownload of SMU to the sites in the site filter.
- Activate the SMU after the predownload is complete.
- Commit the update.

Note You can add more sites to a filter after setting up the filter. However, you have to apply the filter again using the **ap image site-filter file *file-name* apply** command. If you clear the site filter, the update is made on all the remaining sites. Deactivation and rollback of the images are not filtered per site, and are applicable to all the sites.

Rolling AP Upgrade

Rolling AP upgrade is a method of upgrading the APs in a staggered manner such that some APs are always up in the network and provide seamless coverage to clients, while the other APs are selected to be upgraded.

Note The AP images should be downloaded before the rolling upgrade is triggered, so that all the APs that are to be upgraded have the new image version.

Note The time required to complete Rolling AP upgrade depends on factors such as the number of APs, the percentage of APs in each iteration, the controller type, and the connectivity between the controller and the APs. In general, Rolling AP upgrade completion time is the max iteration time (where each iteration can take up to 5 minutes) * expected number of iterations. You use the *iteration expiry time* field of the **show ap upgrade** command output to see the end time.

Rolling AP Upgrade Process

Rolling AP upgrade is done on a per controller basis. The number of APs to be upgraded at a given time, is the percentage of the total number of APs that are connected to the controller. The percentage is capped at a user configured value. The default percentage is 15. The non-client APs will be upgraded before the actual upgrade of APs begin.

The upgrade process is as follows:

1. Candidate AP Set Selection

In this stage, a set of AP candidates are selected based on neighboring AP information. For example, if you identify an AP for upgrade, a certain number (N) of its neighbors are excluded from candidate selection. The N values are generated in the following manner:

If the user configurable capped percentage is 25%, then N=6 (Expected number of iterations =5)

If the user configurable capped percentage is 15%, then N=12 (Expected number of iterations=12)

If the user configurable capped percentage is 5%, then N=24 (Expected number of iterations =22)

If the candidates cannot be selected using the neighboring AP information, select candidates from indirect neighbors. If you still are not able to select candidates, the AP will be upgraded successfully without any failure.

Note After the candidates are selected, if the number of candidates are more than the configured percentage value, the extra candidates are removed to maintain the percentage cap.

2. Client Steering

Clients that are connected to the candidate APs are steered to APs that are not there in the candidate AP list, prior to rebooting the candidate APs. The AP sends out a request to each of its associated clients with a list of APs that are best suited for them. This does not include the candidate APs. The candidate APs are marked as unavailable for neighbor lists. Later, the markings are reset in the AP rejoin and reload process.

3. AP Rejoin and Reload Process

After the client steering process, if the clients are still connected to the candidate AP, the clients are sent a de-authorization and the AP is reloaded and comes up with a new image. A three-minute timer is set for the APs to rejoin. When this timer expires, all the candidates are checked and marked if they have either joined the controller or the mobility peer. If 90% of the candidate APs have joined, the iteration is concluded; if not, the timer is extended to three more minutes. The same check is repeated after three minutes. After checking thrice, the iteration ends and the next iteration begins. Each iteration may last for about 10 minutes.

For rolling AP upgrade, there is only one configuration that is required. It is the number of APs to be upgraded at a time, as a percentage of the total number of APs in the network.

Default value will be 15.

```
Device (config)#ap upgrade staggered <25 | 15 | 5>
```

Use the following command to trigger the rolling AP upgrade:

```
Device#ap image upgrade [test]
```

Note Rolling AP upgrade is not resumed after an SSO. You should run the **ap image upgrade** command to restart the rolling AP upgrade from the beginning and it affects all the APs, including the Mesh APs.

Installing AP Service Package (GUI)

Procedure

- Step 1** Choose **Administration > Software Management**.
- Step 2** Click **AP Service Package (APSP)** tab.
- Step 3** Click **Add**.
- Step 4** From the **Transport Type** drop-down list, choose the transfer type to transfer the software image to your device as TFTP, SFTP, FTP, Device, or Desktop (HTTP).

- a) If you choose **TFTP** as the **Transport Type**, you need to enter the **Server IP Address (IPv4/IPv6)**, **File path** and choose a **File System** from the drop-down list.
- b) If you choose **SFTP** as the **Transport Type**, you need to enter the **Server IP Address (IPv4/IPv6)**, **SFTP Username**, **SFTP Password**, **File path** and choose a **File System** from the drop-down list.
- c) If you choose **FTP** as the **Transport Type**, you need to enter the **Server IP Address (IPv4/IPv6)**, **FTP Username**, **FTP Password**, **File path**, and choose a **File System** from the drop-down list.
- d) If you choose **Device** as the **Transport Type**, you need to enter the **File path** and choose a **File System** from the drop-down list.
- e) If you choose **Desktop (HTTPS)** as the **Transport Type**, you need to choose a **File System** from the drop-down list and click **Select File** to navigate to the **Source File Path**.

Step 5 Enter the **File Name** and click **Add File**.

Step 6 From the **AP Upgrade Configuration** section, choose the percentage of APs to be included from the **AP Upgrade per iteration** drop-down list.

Step 7 Click **Apply**.

Installing AP Service Package (CLI)

Use the following procedure to roll out critical bug fixes to a subset of APs using SMU.

Procedure

	Command or Action	Purpose
Step 1	install add file <i>file-name</i> Example: Device# install add file flash:<file-name>	Checks for ongoing activities, such as AP image predownload or AP rolling upgrade. If there are no such activities, populates the predownload directory to install a package file to the system.
Step 2	ap image site-filter file <i>file-name</i> add <i>site-tag</i> Example: Device# ap image site-filter file flash:<file-name> add bgl18	Adds a site tag to a site filter.
Step 3	ap image site-filter file <i>file-name</i> remove <i>site-tag</i> Example: Device# ap image site-filter file flash:<file-name> remove bgl18	(Optional) Removes a site tag from a site filter.
Step 4	ap image predownload Example: Device# ap image predownload	(Optional) Performs predownload of an AP image. This image predownload will be filtered by the site filter, set up in the previous step.
Step 5	install activate file <i>file-name</i> Example:	Triggers the AP upgrade in rolling a staggered fashion for the APs added in site filter.

	Command or Action	Purpose
	Device# install activate file flash:<file-name>	
Step 6	install commit Example: Device# install commit	Commits the image update. During the commit, the mapping from file to site is saved in the persistent database so that it is available even after a reload.

Adding a Site to a Filter

Procedure

	Command or Action	Purpose
Step 1	ap image site-filter file <i>file-name</i> add <i>site-tag</i> Example: Device# ap image site-filter file flash:<file-name> add bgl18	Adds a site tag to a site filter. Repeat this step again to set up a multisite filter.
Step 2	ap image site-filter file <i>file-name</i> apply Example: Device# ap image site-filter file flash:<file-name> apply	Predownloads the image and upgrades the APs based on the site filter.
Step 3	ap image site-filter file <i>file-name</i> clear Example: Device# ap image site-filter file flash:<file-name> clear	Clears the site filter table and predownloads the image and does a rolling AP upgrade to all sites where it is not active.

Deactivating an Image

Procedure

	Command or Action	Purpose
Step 1	install deactivate file flash <i>file-name</i> Example: Device# install deactivate file flash:<file-name>	Performs rolling AP upgrade based on the AP models present in the prepare file. Deactivation is not filtered by site. Therefore, deactivation applies to all the sites. Note Action is taken if the APs in a site are not running the SMU that is being deactivated. Only internal tables are updated to remove the SMU.

Roll Back APSP

Procedure

	Command or Action	Purpose
Step 1	install add profile <i>rollback_profile-name</i> Example: Device# install add profile rollback_id1	(Optional) Moves back to any rollback points in a graceful way with AP image predownload support. Note To get a list of available rollback profile names, use show install profile command.
Step 2	ap image predownload Example: Device# ap image predownload	(Optional) Performs predownload of an AP image. This image predownload will be filtered by the site filter, set up in the previous step.
Step 3	install rollback to <i>rollback_id</i> Example: Device# install rollback to rollback_id1	Performs rollback of the image for the affected AP models. The roll back action is not filtered by site. Therefore, rollback applies to all the sites. Note The APs that are in the base image or in a point before the rollback action takes effect are not affected.

Canceling the Upgrade

Procedure

	Command or Action	Purpose
Step 1	install abort Example: Device# install abort	Aborts the upgrade by resetting the APs in rolling fashion.

Verifying the Upgrade

To see the summary of the AP software install files, use the following command:

```
Device# show ap image file summary
```

```
AP Image Active List
=====
Install File Name: base_image.bin

Efficient Image Upgrade

Efficient Image upgrade is an optimized method of predownloading images to FlexConnect APs. For each Site Tag with FlexConnect APs joined, one AP per model in that Site Tag is selected as the primary AP, and downloads its image from the controller through the WAN link. Once the primary AP has the downloaded image, the APs in that Site Tag start downloading the image from the primary AP, via TFTP. At most three subordinate APs can download simultaneously from the primary. This reduces load on the WAN link.

Note Make sure that all APs joined via a Site Tag are at the same location, before enabling this feature.

Enable Pre-Download (GUI)

Procedure

- Step 1** Choose **Configuration** > **Wireless** > **Access Points**.
- Step 2** In the **Access Points** page, expand the **All Access Points** section and click the name of the AP to edit.

- Step 3** In the **Edit AP** page, click the **Advanced** tab and from the **AP Image Management** section, click **Predownload**.
- Step 4** Click **Update & Apply to Device**.

Enable Pre-Download (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	wireless profile flex <i>flex-profile</i> Example: Device(config)# wireless profile flex rr-xyz-flex-profile	Configures a flex profile and enters the flex profile configuration mode.
Step 3	predownload Example: Device(config-wireless-flex-profile)# predownload	Enables predownload of the image.
Step 4	end Example: Device(config-wireless-flex-profile)# end	Exits the configuration mode and returns to privileged EXEC mode.

Configuring a Site Tag (CLI)

Follow the procedure given below to configure a site tag:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag site <i>site-name</i> Example:	Configures a site tag and enters site tag configuration mode.

	Command or Action	Purpose
	Device(config)# wireless tag site rr-xyz-site	
Step 3	flex-profile <i>flex-profile-name</i> Example: Device(config-site-tag)# flex-profile rr-xyz-flex-profile	Configures a flex profile. Note You cannot remove the flex profile configuration from a site tag if local site is configured on the site tag. Note The no local-site command needs to be used to configure the Site Tag as Flexconnect, otherwise the Flex profile config does not take effect.
Step 4	description <i>site-tag-name</i> Example: Device(config-site-tag)# description "default site tag"	Adds a description for the site tag.
Step 5	end Example: Device(config-site-tag)# end	Saves the configuration and exits configuration mode and returns to privileged EXEC mode.
Step 6	show wireless tag site summary Example: Device# show wireless tag site summary	(Optional) Displays the number of site tags. Note To view detailed information about a site, use the show wireless tag site detailed <i>site-tag-name</i> command. Note The output of the show wireless loadbalance tag affinity wncd <i>wncd-instance-number</i> command displays default tag (site-tag) type, if both site tag and policy tag are not configured.

Attaching Policy Tag and Site Tag to an AP (CLI)

Follow the procedure given below to attach a policy tag and a site tag to an AP:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap mac-address Example: Device(config)# ap F866.F267.7DFB	Configures a Cisco AP and enters AP profile configuration mode. Note The <i>mac-address</i> should be a wired mac address.
Step 3	policy-tag policy-tag-name Example: Device(config-ap-tag)# policy-tag rr-xyz-policy-tag	Maps a policy tag to the AP.
Step 4	site-tag site-tag-name Example: Device(config-ap-tag)# site-tag rr-xyz-site	Maps a site tag to the AP.
Step 5	rf-tag rf-tag-name Example: Device(config-ap-tag)# rf-tag rf-tag1	Associates the RF tag.
Step 6	end Example: Device(config-ap-tag)# end	Saves the configuration, exits configuration mode, and returns to privileged EXEC mode.
Step 7	show ap tag summary Example: Device# show ap tag summary	(Optional) Displays AP details and the tags associated to it.
Step 8	show ap name <ap-name> tag info Example: Device# show ap name ap-name tag info	(Optional) Displays the AP name with tag information.
Step 9	show ap name <ap-name> tag detail Example: Device# show ap name ap-name tag detail	(Optional) Displays the AP name with tag details.

Trigger Predownload to a Site Tag

Follow the procedure given below to trigger image download to the APs:

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> configure terminal	Enters the privileged EXEC mode.
Step 2	ap image predownload site-tag <i>site-tag</i> start Example: Device# ap image predownload site-tag rr-xyz-site start	Instructs the primary APs to start image predownload.
Step 3	show ap master list Example: Device# show ap master list	Displays the list of primary APs per AP model per site tag.
Step 4	show ap image Example: Device# show ap image	Displays the predownloading state of primary and subordinate APs . Note To check if Flexefficient image upgrade is enabled in the AP, use the show capwap client rcb command on the AP console.

The following sample outputs display the functioning of the Efficient Image Upgrade feature:

The following output displays the primary AP.

```
Device# show ap master list
AP Name                               WTP Mac           AP Model           Site Tag
-----

Feature History for Out-of-Band AP Image Download

This table provides release and related information for the feature explained in this module.

This feature is available in all the releases subsequent to the one in which it is introduced in, unless noted otherwise.

Table 17: Feature History for Out-of-Band AP Image Download

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.11.1	Out-of-Band AP Image Download	The AP image upgrade method is enhanced to make the upgrades faster and more flexible.

Information About Out-of-Band AP Image Download

In WLAN deployments, the APs gather their software image and configuration from the controller (in-band) during the join, predownload, and upgrade phases over the CAPWAP control path. This mechanism has limitations in the context of CAPWAP window size, processing of CAPWAP packets, and parallel image downloads. With image upgrade being a significant activity in the lifecycle of APs, upgrades become a time-consuming activity when the deployment size increases, especially for remote deployments, because the image always comes from the controller, irrespective of the deployment types.

To make upgrades faster and more flexible, the AP image upgrade method is enhanced in Cisco IOS XE Dublin 17.11.1 release. An enhanced webserver (nginx) running on the controller helps the AP image downloads to be available out of the CAPWAP path (out of band).

Note

- HTTPS configuration done at the global level applies to all the APs joining the controller.
- When AP image download over an Out-of-Band method fails, the download falls back to the CAPWAP method, as a result of which the APs will not be stranded.
- AP image download over HTTPS may fail if the HTTPS server Trustpoint has a chain of CA certificates.
- Before you downgrade from Cisco IOS XE Dublin 17.11.1 to an earlier version, ensure that the Out-of-Band AP Image Download feature is disabled, as it is not supported in previous releases.

Restrictions for Out-of-Band AP Image Download

This feature is not supported on the following platforms:

- Cisco Embedded Wireless Controller on Catalyst Access Points
- Cisco Embedded Wireless Controller on Catalyst Switches
- Cisco Wave 1 Access Points

Download AP Image from Controller Using HTTPS (CLI)

Before you begin

- HTTPS configuration must be enabled.
- The nginx server must be running on the controller. Use the **show platform software yang-management process** command to check whether the nginx server is running.
- The custom-configured port must be reachable between the controller and the corresponding AP.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	ap upgrade method https Example: Device(config)# ap upgrade method https	Configures the corresponding AP to download the image over HTTPS from the controller if the AP supports out-of-band AP image download method. You can check whether the AP supports efficient download method using the show ap config general command. Use the no form of this command to disable out-of-band AP image download method.
Step 3	ap file-transfer https port <i>port_number</i> Example: Device(config)# ap file-transfer https port 8445	Configures a custom port for image download from the nginx server running on the controller. For HTTPS port, the valid values range from 0 to 65535, with a default of 8443. You cannot use port 443 for AP file transfers because it is the default port used for other HTTPS requests. Also, avoid configuring standard and well-known ports because the configuration may fail. By default, the Efficient AP image download feature uses port 8443 for HTTPS. If the same port is configured for HTTPS access for controller GUI, then GUI access will not work.

	Command or Action	Purpose
		<p>In such instances, use a port number other than 8443 for controller GUI Access or configure a different port for AP file transfer over HTTPS instead of 8443.</p> <p>The port 8443 is customazible. A sample config is given below:</p> <pre>Source= wireless controller Destination= Access Point Protocol=HTTPS Destination Port=8443 Source Port=any Description= "Out of Band AP Image Download"</pre>
Step 4	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.

Download AP Image from Controller Using HTTPS (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Wireless Global**.
- Step 2** In the **AP Image Upgrade** section, enable the **HTTPS Method** to allow image download on APs from the controller, over HTTPS. This out-of-band file transfer is an efficient method for AP image upgrade.
- Note** The AP should support out-of-band image download. You can verify this in the **Configuration > Wireless > Access Points** window. Select the AP, and in the **Edit AP > Advanced** tab, view the details of the support in the **AP Image Management** section.
- Step 3** Enter the **HTTPS Port** to designate AP file transfers on that port. Valid values range from 0 to 65535, with the default being 8443. Note that you cannot use port 443 for AP file transfers because that is the default port for other HTTPS requests.
- By default, the Efficient AP image download feature uses port 8443 for HTTPS. If the same port is configured for HTTPS access for controller GUI, then GUI access will not work. In such instances, use a port number other than 8443 for controller GUI Access or configure a different port for AP file transfer over HTTPS instead of 8443.
- Step 4** Click **Apply to Device** to save the configuration.
-

Verifying Image Upgrade

To check whether an AP supports efficient download method, use the following command:

```
Device# show ap config general

Cisco AP Name : AP002C.C862.E880
=====

Cisco AP Identifier : 002c.c88b.0300
Country Code : Multiple Countries : IN,US
Regulatory Domain Allowed by Country : 802.11bg:-A 802.11a:-ABDN
AP Country Code : US - United States
AP Regulatory Domain
802.11bg : -A
AP Upgrade Out-Of-Band Capability : Enabled
AP statistics : Disabled
```

To view the AP image download statistics, use the following command.

Use the **show ap image** command to see the detailed output.

```
Device# show ap image summary

Total number of APs : 1
Number of APs
  Initiated           : 0
  Downloading         : 0
  Predownloading      : 0
  Completed downloading : 0
  Completed predownloading : 0
  Not Supported       : 0
  Failed to Predownload : 0
  Predownload in progress : No
```

To view the method used to download the AP image, use the following command:

```
Device# show wireless stats ap image-download

AP image download info for last attempt
AP Name Count ImageSize StartTime          EndTime          Diff(secs) Predownload Aborted
Method
-----
mysore1 1      40509440 08/23/21 22:17:59 08/23/21 22:19:06 67          No          No
      CAPWAP
```

To view the method used to download the AP image, use the following command:

```
Device# show ap upgrade method

AP upgrade method HTTPS : Disabled
```

To view the port used for the AP image transfer, use the following command:

```
Device# show ap file-transfer https summary

Configured port      : 8443
Operational port     : 8443
```

!If different ports are shown under 'Configured port' and 'Operations port'
!that means custom port configuration has failed and is continuing with the previous port.

!The failure reason could be the input port, which is a well-known port and already in use.

To view the whether an AP supports image download over HTTPS, use the following command:

```
Device# show ap name AP2800 config general | sec Upgrade
AP Upgrade Out-Of-Band Capability           : Enabled
```

To view the detailed output an AP's pre-image, use the following command:

```
Device# show ap image

Total number of APs   : 2
Number of APs
  Initiated           : 0
  Downloading         : 0
  Predownloading      : 0
  Completed downloading : 2
  Completed predownloading : 0
  Not Supported       : 0
  Failed to Predownload : 0
  Predownload in progress : No
AP Name      Primary Image Backup Image Predownload Status Predownload Version Next Retry
Time Retry  Count Method
-----
AP_3800_1   17.11.0.69   17.11.0.71   None           0.0.0.0           N/A
  0         HTTPS
AP2800      17.11.0.69   17.11.0.71   None           0.0.0.0           N/A
  0         HTTPS
```

!The 'method' column indicates the download method used by the AP.

CHAPTER 16

Predownloading an Image to an Access Point

Information About Predownloading an Image to an Access Point

To minimize network outages, download an upgrade image to an access point from the device without resetting the access point or losing network connectivity. Previously, you could download an upgrade image to the device and reset it, causing the access point to go into discovery mode. After the access point discovered the controller with the new image, the access point would download the new image, reset it, go into discovery mode, and rejoin the device.

You can now download the upgrade image to the controller. When the controller is up with the upgrade image, the AP joins the controller and moves to Registered state, because the AP image has been predownloaded to the AP.

Restrictions for Predownloading an Image to an Access Point

The following are the restrictions for predownloading an image to an access point:

- The maximum number of concurrent predownloads are limited to 100 per wncd instance (25 for 9800-L) in the controller. However, the predownloads are triggered in sets of 16 per wncd instance at the start, and is repeated every 60 seconds.
- Access points with 16-MB total available memory may not have enough free memory to download an upgrade image and may automatically delete crash information files, radio files, and backup images, if any, to free up space. However, this limitation does not affect the predownload process because the predownload image replaces backup image, if any, on the access point.

- All of the primary, secondary, and tertiary controllers should run the same images. Otherwise, the feature will not be effective.
- At the time of reset, you must make sure that all of the access points have downloaded the image.
- An access point can store only 2 software images.
- The Cisco Wave 1 APs may download the image twice while moving from Cisco AireOS Release 8.3 to Cisco IOS XE Gibraltar 16.10.1. This increases the AP downtime during migration.
- The **show ap image** command displays cumulative statistics regarding the AP images in the controller. We recommend that you clear the statistics using the **clear ap predownload statistics** command, before using the show ap image command, to ensure that correct data is displayed.
- Cisco Catalyst 9800-CL Wireless Controller supports only self-signed certificates and does not support Cisco certificates. When you move the access points between Cisco Catalyst 9800-CL Wireless Controllers, and if the AP join failure occurs on the Cisco Catalyst 9800-CL controller, execute the **capwap ap erase all** command to remove the hash string stored on the APs.
- During AP image pre-download, the WNCN CPU may rise to 99 percent, which is normal and doesn't cause a crash or client or AP disconnect problems.

Predownloading an Image to Access Points (CLI)

Before you begin

There are some prerequisites that you must keep in mind while predownloading an image to an access point:

- Predownloading can be done only when the device is booted in the install mode.

Note Predownload of the AP image is based on the AP model rather than the image type. Predownload is allowed only when the model exists in the new capability XML file. Also, with appropriate modification of the capability XML, the controller can override the existing AP image for a particular model.

- You can copy the new image either from the TFTP server, flash image, or USB.
- If the latest upgrade image is already present in the AP, predownload will not be triggered. Check whether the primary and backup image versions are the same as the upgrade image, using the **show ap image** command.
- The **show ap image** command displays cumulative statistics regarding the AP images in the controller. We recommend that you clear the statistics using the **clear ap predownload statistics** command, before using the **show ap image** command, to ensure that correct data is displayed.
- AP continues to be in predownloading state, if AP flaps post SSO during AP predownload. We recommended that you issue the **ap image predownload abort** command and then the **clear ap predownload stats** command only then the predownload can be initiated again.

Procedure

	Command or Action	Purpose
Step 1	install add file bootflash:file-name Example: Device# install add file bootflash:image.bin	The controller software image is added to the flash and expanded.
Step 2	ap image predownload or ap name ap-name image predownload Example: Device# ap image predownload Device# ap name ap1 image predownload	Downloads the new image to all the access points or a specific access point connected to the device.
Step 3	show ap image Example: Device# show ap image	Verifies the access point's predownload status. This command initially displays the status as Predownloading and then moves to Completed, when download is complete.
Step 4	show ap name ap-name image Example: Device# show ap name ap1 image	Provides image details of a particular AP.
Step 5	ap image swap or ap name ap-name image swap or ap image swap completed Example: Device# ap image swap	Swaps the images of the APs that have completed predownload. Note You can swap the AP images using ap image swap command even without pre-downloading a new image to the AP and there are no restrictions or prerequisites to swap the image.
Step 6	install activate Example: Device# install activate	Runs compatibility checks, installs the package, and updates the package status details. For a restartable package, the command triggers the appropriate post-install scripts to restart the necessary processes, and for non-restartable packages it triggers a reload. Note This step reloads the complete controller stack (both primary and secondary controllers, if HA is used).
Step 7	install commit Example: Device# install commit	Commits the activation changes to be persistent across reloads. The commit can be done after activation while the system is up, or after the first reload. If the

	Command or Action	Purpose
		package is activated but not committed, it remains active after the first reload, but not after the second reload.

Predownloading an Image to Access Points (GUI)

Procedure

-
- Step 1** Choose **Administration** > **Software Management** and click the **Software Upgrade** tab.
Note that you must be in the Install Mode to continue with the following steps.
- Step 2** Select the **Transport Type, File System and File Path** of your choice to from receive the file.
- Step 3** Select the **AP Image Predownload** check box.
If you already have an inactive image file on your device, a dialog box prompts you to remove the unused image and proceed with the latest image download.
- Step 4** Click **Download & Install**.
This initiates the upgrade process and you can view and verify the predownload progress in the **Status** dialog box. You can also check the progress log by clicking on **Show Logs** icon.
- Step 5** Click the **Save Configuration & Activate** button after the predownload operation is successful.
- Step 6** Click **Yes** to confirm the activate operation.
This operation runs compatibility checks, installs the package, and updates the package status details. The device reloads after a successful activation. If there are uncommitted files, you are prompted to remove those.
- Step 7** Click the **Commit** button to complete the upgrade process.
-

Predownloading an Image to Access Points (YANG)

YANG can be used with NETCONF and RESTCONF to provide the desired solution of automated and programmable network operations.

The following RPC is used for Predownloading an Image to an Access Point:

```
<rpc xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="101">
  <set-rad-predownload-all
xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-access-point-cmd-rpc">
    <uuid>12312341231234</uuid>
  </set-rad-predownload-all>
</rpc>
```

For more information on the YANG models, see the Cisco IOS XE Programmability Configuration Guide and YANG Data Models on Github at <https://github.com/YangModels/yang/tree/master/vendor/cisco/xe>.

You can contact the Developer Support Community for NETCONF/YANG features using the following link:

<https://developer.cisco.com/>

Monitoring the Access Point Predownload Process

This section describes the commands that you can use to monitor the access point predownload process.

While downloading an access point predownload image, enter the **show ap image** command to verify the predownload progress on the corresponding access point:

```
Device# show ap image
Total number of APs : 1
```

```
Number of APs
  Initiated           : 1
  Predownloading      : 1
  Completed predownloading : 0
  Not Supported       : 0
  Failed to Predownload : 0
```

AP Name	Primary Image	Backup Image	Predownload Status
Predownload Ver...	Next Retry Time	Retry Count	
AP1 10.0.1.67	10.0.1.66	10.0.1.66	Predownloading
	NA	0	

```
Device# show ap image
Total number of APs : 1
```

```
Number of APs
  Initiated           : 1
  Predownloading      : 0
  Completed predownloading : 1
  Not Supported       : 0
  Failed to Predownload : 0
```

AP Name	Primary Image	Backup Image	Predownload Status
Predownload Ver...	Next Retry Time	Retry Count	
AP1 10.0.1.67	10.0.1.66	10.0.1.67	Complete
	NA	0	

Use the following command to view the image details of a particular AP:

```
Device# show ap name APe4aa.5dd1.99b0 image
```

```
AP Name : APe4aa.5dd1.99b0
Primary Image : 16.6.230.46
Backup Image : 3.0.51.0
Predownload Status : None
Predownload Version : 000.000.000.000
Next Retry Time : N/A
Retry Count : 0
```

Information About AP Image Download Time Enhancement (OEAP or Teleworker Only)

The wireless controller and the access point (AP) communicate with each other using CAPWAP. The CAPWAP has two channels, namely control and data. The control channel is used to send configuration messages, download images and client keys, or the context to the AP. The control channel has a single window in the current implementation. A single window means that every message that is sent from the controller has to be acknowledged by the AP. The next control packet is not transmitted till the earlier one is acknowledged by the AP.

The AP Image Download Time Enhancement feature adds support to multiple sliding windows for control packets going from controller to AP. The sliding window can be set to N (static) instead of a single window. The request queue size is decided based on the maximum window size the AP supports.

Table 18: Recommended Window Size

Link Bandwidth ⁶	Less than 200 ms RTT	Greater than 200 ms RTT
More than 20 Mbps	10	15
Between 5 and 20 Mbps	10	15
Between 1 and 5 Mbps	5	10
Less than 1 Mbps	3	5

⁶ The window size recommendation provided in the table is for packet loss of less than one percent (< 1%). If the network supporting the CAPWAP link has packet loss of more than one percent (> 1%), use a smaller value for window size. For good links with round-trip time (RTT) of about 100ms and packet drops of less than half a percent (< 0.5%), use a window size of up to 20 for better performance.

Note

- The window size can be changed only during the AP join process.
- All image upgrades should be in the **install** mode for faster upgrade. Image upgrade should be done from the **one-shot** command to include OEAP predownload.
- Configure the window size only for AP profiles that are exclusively used for Teleworker or Office Extend Access Points (OEAP).
- An AP reload is not required after disabling this feature.
- This feature is supported only on the OEAP profiles.
- GUI does not support AP predownload. Therefore, the AP downloads after disjoining the controller during CAPWAP join phase. This causes a long disruption in the network as the Image download for AP can take upto one hour.

Important If you downgrade the software to Cisco IOS XE Gibraltar 16.12.4 or earlier from Cisco IOS XE Amsterdam 17.3.1, you should reset the CAPWAP multi window to a single window prior to the downgrade. Failure to do so necessitates a manual AP recovery.

High-Level Workflow of AP Image Download Time Enhancement

1. Select an existing AP join profile or create a new one.
2. Set the CAPWAP window size.
3. Associate the AP join profile to an existing site tag or new one.
4. Apply the site tag to the AP using: Static, Filter, Location, AP, or Default mapping method.

Configuring AP Image Download Time Enhancement (GUI)

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > AP Join > CAPWAP > Advanced**.
- Step 2** In the **CAPWAP Window Size** field, enter the unit of measurement of the window.
- Step 3** Click **Save & Apply to Device**.

Configuring AP Image Download Time Enhancement (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	ap-profile <i>ap-profile</i> Example: Device(config)# ap profile capwap_multiwindow	Configures an AP profile.
Step 3	capwap window size <i>window-size</i> Example:	Configures the AP CAPWAP control packet transmit queue size.

	Command or Action	Purpose
	Device(config-ap-profile)# capwap window size 20	<p>Note Configure the window size only for AP profiles that are exclusively used for teleworker or OEAP.</p> <p>Be aware that any change in window size may impact other APs.</p>
Step 4	<p>end</p> <p>Example:</p> <pre>Device(config-ap-profile)# end</pre>	Returns to privileged EXEC mode.

Verifying AP Image Download Time Enhancement Configuration

To view the CAPWAP window size present in an AP profile, use the following command:

```
Device# show ap profile name default-ap-profile detailed | in wind
Capwap window size : 10
```

To view the CAPWAP status and modes, use the following command:

```
Device# show capwap client rcb

OperationState           : UP
Name                     : AP4001.7A39.2D5A
MwarHwVer                : 0.0.0.0
Location                 : default location
ApMode                   : Remote Bridge
ApSubMode                : Not Configured
CAPWAP Path MTU         : 1485
Software Initiated Reload Reason : Reload command
CAPWAP Sliding Window
Active Window Size       : 10
Last Request Send To Application : 184
Expected Seq Num        : 185
Received Seq Num        : 184
Request Packet Count    : 42424
Out Of Range Packets Count : 0
Window Moved Packets Count : 0
In Range Packets Count  : 960
Expected Packets Count  : 41464
```

To view the AP configuration details, including the CAPWAP window size, use the following command:

```
Device# show ap config general | in Wind

Capwap Active Window Size : 5
Capwap Active Window Size : 10
Capwap Active Window Size : 1
```

N+1 Hitless Rolling AP Upgrade

The existing CAPWAP implementation on the Cisco Catalyst 9800 Series Wireless Controller requires that the controller and all its associated APs have the same software version. It is possible to upgrade a set of APs using the N+1 Hitless Rolling AP Upgrade feature. However, all the APs cannot be upgraded at the same time without network downtime.

You can upgrade wireless networks without network downtime when the same version skew is supported between the controller and the APs. This enables the APs to be upgraded in a staggered manner, while still being connected to the same controller. The version skew method can avoid upgrade downtime even for N+1 networks by using N+1 Hitless Rolling AP Upgrade feature and a spare controller.

The following is the workflow for the N+1 Hitless Rolling AP Upgrade feature:

1. Establish a mobility tunnel from the controller (WLC1) to a mobility member (WLC2).
2. Upgrade the controller software (WLC1) using the command **install add file bootflash:new_version.bin**.
3. Optionally, you can also upgrade the AP image. For more information, see [Predownloading an Image to an Access Point](#) chapter.

4. Use the **ap image upgrade destination** *controller-name controller-ip report-name* privileged EXEC command to upgrade and move all the APs from WLC1 (source) to WLC2 (destination).
5. Activate the new image in WLC1 using the **install activate** command.
6. Commit the changes using the **install commit** command.
7. Move the APs back to WLC1 from WLC2 using the **ap image move destination** *controller-name controller-ip report-name* command.

Note The **ap image upgrade destination** command does not work without an image pre-download. If you do not perform an image pre-download, use the **ap image move** command to move the APs. When APs download the image and join the destination controller, you must set the iteration time as high. Also, you can customize the iteration time by configuring the **ap upgrade staggered iteration timeout** command.

Configuring Hitless Upgrade

Follow the procedure given below to achieve a zero downtime network upgrade in an N+1 deployment.

Before you begin

- Ensure that the hostname and wireless management IP of the destination controller is provided in the privileged EXEC command.
- Ensure that access points are predownloaded with the image running on the destination controller.

Procedure

	Command or Action	Purpose
Step 1	ap image upgrade destination <i>wlc-name wlc-ip</i> Example: Device# ap image upgrade destination wlc2 10.7.8.9	Moves APs to the specified destination controller with the swap and reset command. After this, the parent controller activates new image, and reloads with the new image. After the mobility tunnel comes up, APs are moved back to the parent controller without a swap and reset. Note Ensure that you establish a mobility tunnel from controller (WLC1) to a mobility member (WLC2) before image upgrade.
Step 2	ap image upgrade destination <i>wlc-name wlc-ip</i> Example: Device# ap image upgrade destination wlc2 10.7.8.9	(Optional) Moves APs to the specified destination controller with a swap and reset command. Note Perform Steps 2 to 4 only if you are not performing Step 1.

	Command or Action	Purpose
Step 3	ap image move destination <i>wlc-name wlc-ip</i> Example: Device# ap image move destination wlc1 10.7.8.6	Move the APs back to the parent controller.
Step 4	ap image upgrade destination <i>wlc-name wlc-ip [fallback]</i> Example: Device# ap image upgrade destination wlc2 10.7.8.9 fallback	(Optional) Moves APs to the specified destination controller with a swap and reset command. After that, APs are moved back to the parent controller (without a swap and reset) after manual install activate of the new image and reloading of the parent controller.
Step 5	ap image upgrade destination <i>wlc-name wlc-ip [reset]</i> Example: Device# ap image upgrade destination wlc2 10.7.8.9 reset	(Optional) Moves APs to the specified destination controller with a swap and reset command. After this, the parent controller activates the new image and reloads with the new image.

Verifying Hitless Upgrade

Use the following **show** commands to verify hitless upgrade.

To view all the upgrade report names, use the following command:

```
Device# show ap upgrade summary
```

```
Report Name      Start time
```

```
-----  
AP_upgrade_from_VIGK_CSR_2042018171639 05/20/2018 17:16:39 UTC
```

To view AP upgrade information based on the upgrade report name, use the following command:

```
Device# show ap upgrade name test-report
```

```
AP upgrade is complete  
From version: 16.10.1.4  
To version: 16.10.1.4  
Started at: 05/20/2018 17:16:39 UTC

Feature History for Site-Based Rolling AP Upgrade in N+1 Networks

This table provides release and related information for the features explained in this module.

These features are available in all releases subsequent to the one they were introduced in, unless noted otherwise.

Table 19: Feature History for Site-Based Rolling AP Upgrade in N+1 Networks

Release	Feature	Feature Information
Cisco IOS XE 17.9.1	Site-Based Rolling AP Upgrade in N+1 Network	This feature helps to achieve a zero downtime network upgrade in N+1 networks.

Information About Site-Based Rolling AP Upgrade in N+1 Network

The Site-Based Rolling AP Upgrade in an N+1 Network feature allows you to perform a staggered upgrade of APs in each site in an N+1 deployment.

This feature helps you to effectively achieve a zero-downtime network upgrade in an N+1 network. The existing site filter functionality allows you to perform a software upgrade of a site or all the sites managed by the controller.

In a typical scenario, the software of the APs belonging to a site is upgraded and the network is monitored to see whether it is functioning as intended, before adding more sites to the site filter. If the upgrade fails to meet the objectives, all the sites in the site filter can be removed using the **ap image site-filter file any-image remove-all** command. The **ap image site-filter** command is modified to include the **any-image** keyword as a substitute for the image file name to support the N+1 AP move site filter.

Prerequisites for Site-Based Rolling AP Upgrade in N+1 Networks

- The source and destination controllers should be in the same mobility group (preferably running the latest image) but with different AP image versions.

- Image of the destination controller should be available on the source controller.
- Both the source and destination controllers should be in INSTALL mode.

Restrictions for Site-Based Rolling AP Upgrade in N+1 Networks

- Site filter operations are supported only for N+1 upgrade and N+1 move; **fallback** and **reset** options of the **ap image upgrade destination** command are not supported.
- APs can only move across the controllers having the same software.
- The **any** and **remove-all** keywords of the **ap image site-filter** command work only for the N+1 AP upgrade or move. It will not work for other site filter operations such as AP Model Service Pack (APSP) or AP Device Package (APDP).
- A reboot of the source or the destination controller during the N+1 upgrade requires a re-execution of the procedure.

Use Cases

The N+1 deployments are more common compared to 1+1 redundancy deployments. In the N+1 deployments, spare controllers are used and APs can fail over to it whenever their primary controller goes down. For local mode networks, this results in a small network downtime (30 to 40 seconds), during which APs re-discover and re-join the network. However, during network upgrades, the downtime is much longer, and all the devices have to reboot and converge. The feature can effectively provide a zero-downtime network upgrade in an N+1 deployment.

N+1 Upgrade and Move to Destination Controller

Note

- Run all the commands only on the source controller.
- By default, the Rolling AP Upgrade feature sends a basic service set (BSS) transition message to 11v clients to notify them that the AP they are connected to is going down, along with a list of alternate APs. In scenarios where clients are sensitive to roaming, this feature can cause unnecessary packet drops. In such instances, you can disable the 11v message using the **no ap upgrade staggered client-steering** command.

Before you begin

See the *Prerequisites for Site-based Rolling AP Upgrade in an N+1 Network* section.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	no ap upgrade staggered client-steering Example: Device# no ap upgrade staggered client-steering	(Optional) Disables client steering.
Step 3	ap upgrade staggered iteration completion <i>min-percent</i> Example: Device(config)# ap upgrade staggered iteration completion 50	(Optional) Configures the minimum percentage of APs that must join the destination controller to signal iteration completion.
Step 4	ap upgrade staggered iteration error action stop Example: Device(config)# ap upgrade staggered iteration error action stop	(Optional) Configures the action to be taken when APs are missing after an iteration during AP upgrade.
Step 5	ap upgrade staggered iteration timeout <i>timeout-duration</i> Example: Device(config)# ap upgrade staggered iteration timeout 18	(Optional) Configures the maximum time allowed per iteration during AP upgrade. Valid values range from 9 to 60.
Step 6	exit Example: Device(config)# exit	Returns to privileged EXEC mode.
Step 7	ap image site-filter any-image add <i>site-tag</i> Example: Device# ap image site-filter any-image add site1	Adds a site tag to a site filter. You can repeat this step to set up a multisite filter.
Step 8	ap image move destination <i>controller-name</i> <i>controller-ip</i> Example:	Moves the APs to a different controller in the mobility group.

	Command or Action	Purpose
	Device# ap image move destination controller2 10.9.34.4	<p>Note It is preferable to move the APs to a different controller running the same image.</p> <p>Wait for the upgrade to complete.</p> <p>If upgrade is not completed successfully, you can use the ap image upgrade destination or ap image move destination commands to restart the upgrade process.</p>
Step 9	<p>ap image site-filter any-image add <i>site-tag</i></p> <p>Example:</p> <pre>Device# ap image site-filter file any-image add site2</pre>	Adds additional site tag to a site filter.
Step 10	<p>ap image site-filter any-image apply</p> <p>Example:</p> <pre>Device# ap image site-filter file any-image apply</pre>	<p>Predownloads the image and upgrades the APs based on the site filter.</p> <p>Note Wait for the upgrade to complete.</p>
Step 11	<p>ap image site-filter any-image clear</p> <p>Example:</p> <pre>Device# ap image site-filter file any-image clear</pre>	(Optional) Clears the site filter table and predownloads the image and does a rolling AP upgrade to all the sites.
Step 12	<p>ap image site-filter file any-image remove-all</p> <p>Example:</p> <pre>Device# ap image site-filter file any-image remove-all</pre>	(Optional) Removes all the site filters.

N+1 Move to Destination Controller

Note Run all the commands only on the source controller.

Before you begin

See the *Prerequisites for Site-based Rolling AP Upgrade in an N+1 Network* section.

Procedure

	Command or Action	Purpose
Step 1	ap image site-filter any-image add <i>site-tag</i> Example: Device# ap image site-filter any-image add site1	Adds a site tag to a site filter.
Step 2	ap image move destination <i>image-name</i> <i>controller-ip</i> Example: Device# ap image move destination controller2 10.9.34.2	Moves the APs back to the parent controller. Note Wait for the upgrade to complete.
Step 3	ap image site-filter any-image add <i>site-tag</i> Example: Device# ap image site-filter any-image add site2	Adds an additional site tag to a site filter.
Step 4	ap image site-filter any-image apply Example: Device# ap image site-filter any-image apply	Upgrades the APs based on the site filter. Note Wait for the upgrade to complete. If upgrade is not completed successfully, use the ap image upgrade destination or ap image move destination command to restart the upgrade process.
Step 5	ap image site-filter any-image clear Example: Device# ap image site-filter any-image clear	(Optional) Clears the site filter table and predownloads the image and does a rolling AP upgrade to all the sites where it is not active.

Hitless Software Upgrade (N+1 Upgrade)

Hitless software upgrade uses the concept of N+1 high availability using a spare controller to upgrade the CAPWAP infrastructure comprising controllers and access points (AP). Depending on what you choose, the APs are upgraded in a staggered fashion, per site, or on all sites, using the Rolling AP upgrade feature thereby avoiding network disruption. This ensures that the clients are serviced by the neighboring APs while one or the selected APs undergo the upgrade process.

The upgrade workflow is as follows :

1. Initiate upgrade on the source controller. You can choose to upgrade all sites or per site based on your preference.
2. Move the APs to the destination controller. APs are upgraded in a staggered fashion using the rolling AP upgrade algorithm.

3. Once all the APs move to the destination controller in multiple iterations, activate the target image on the source controller.
4. The source controller reloads for the new image to take effect.
5. (Optional) Move the APs back to the source controller using the cli commands.

Before you begin

- The controller should be in **INSTALL** mode.
- The controller should be paired with another controller and both should be part of the same mobility group.

The spare controller should be upgraded with the target image.

Procedure

-
- Step 1** Choose **Administration > Software Management** .
- Step 2** From the Software Upgrade tab check the **One-Shot Install Upgrade** checkbox.
- Step 3** From the **Transport Type** drop-down list, choose an option.
- a) If you choose **My Desktop** as the transport type, click **Select File** to navigate to the file from the **Source File Path** field.
 - b) If you choose **SFTP** as the transport type, enter the source IP address, SFTP username, SFTP password, file path, and select the destination.
 - c) If you choose **FTP** as the transport type, enter the source IP address, FTP username, FTP password, file path, and select the destination.
 - d) If you choose **TFTP** as the transport type, enter the source IP address, file path, and select the destination.
- Note** In controllers, the IP TFTP source is mapped to the service port by default.
- e) If you choose **Device** as the transport type, choose the file system and file path.
- Note** In the **File Path** field, enter the complete path from where you want to download the software image file, including the name of the file.
- Step 4** Check the **Enable Hitless Upgrade** check box to allow the APs and the controller to be upgraded.
- Step 5** From the **Site Filter** drop-down list, choose **All Sites** or one or more **Custom Sites**.
- In case you choose to upgrade for **All Sites**, you can optionally enable **Fallback after Upgrade** so that the APs move back to the parent controller after the new image has been activated and the parent controller has reloaded.
- In case you choose a **Custom Site**, select the site from the **Site Tags** drop-down list. In this case, the APs do not move back to the parent controller automatically and you will have to manually move them using CLIs.
- Step 6** In the **Controller IP Address (IPv4/IPv6)** field, enter the source controller's IPv4/IPv6 address.
- Step 7** In the **Controller Name** field, enter the source controller's name.
- Step 8** In the **AP Upgrade Configuration** section, use the **AP Upgrade per Iteration** drop-down list to select the percentage of APs to be upgraded per iteration. This configures the minimum percentage of APs that must join the destination controller to signal completion of iteration.

- Step 9** Check the **Client Steering** check box to move clients attached to APs undergoing an upgrade to other APs. If the clients still persist on the candidate APs, they are disconnected and the APs will reload with the new image.
- Step 10** In the **Accounting Percentage** field, choose the percentage of APs that should join the destination controller after each iteration (of the staggered AP upgrade) to consider the iteration as successful. The default value is 90%.
- Step 11** Tap to select the type of **Accounting Action** to configure for the APs. If you enable **Terminate**, the upgrade is terminated if the configured percentage of APs does not join the mobility peer, and a notification is sent via Syslog message. If you choose **Ignore**, the upgrade continues irrespective of whether the configured percentage of APs are joining the controller or not.
- Step 12** In the **Iteration Expiry** field, select the number of minutes from the drop-down list to configure the expiry time for each iteration.
- Step 13** Click **Download & Install**.
- Step 14** Click **Save Configuration & Activate**.
- Step 15** Click **Commit** to make the activation changes persistent across reloads.

Verifying Site-based Rolling AP Upgrade in a N+1 Network

Use the following **show** commands to check the progress of the upgrade and debugging:

- **show ap summary**
- **show ap tag summary**
- **show ap status**
- **show wireless mobility summary**
- **show ap image**
- **show ap upgrade**
- **show ap upgrade site**
- **show ap upgrade site summary**
- **show ap upgrade name** *report-name*
- **show wireless mobility ap-list**

To view the summary of all the connected Cisco APs, use the following command:

```
Device# show ap summary
```

```
Number of APs: 8
```

Information About Client Steering Enhancement

When access points (APs) of a wireless network are upgraded in a staggered manner, the clients connected to those APs are moved to other APs. During this period, clients that are unaware of an ongoing upgrade may try to reassociate with the same AP. Similarly, new clients may also try to join the AP. To avoid this scenario, Cisco IOS XE Dublin 17.11.1 introduces the option to not deauthenticate clients connected to the APs that are selected for the upgrade. Using the **no ap upgrade staggered client-death** command, you can stop deauthenticating clients before the AP performs an upgrade.

Deauthenticate Clients

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	no ap upgrade staggered client-death Example: Device(config)# no ap upgrade staggered client-death	Stops deauthentication of the clients associated with the AP before the AP starts to upgrade. Client deauthentication affects both the 802.11v clients and non-802.11v clients. If client steering is enabled, then 802.11v clients are sent Basic Set Service (BSS) transition frames. If client steering is disabled and client deauthentication is enabled, deauthentication message is sent to 802.11v clients as well.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.

CHAPTER 18

NBAR Dynamic Protocol Pack Upgrade

- [NBAR Dynamic Protocol Pack Upgrade, on page 283](#)
- [Upgrading the NBAR2 Protocol Pack, on page 284](#)

NBAR Dynamic Protocol Pack Upgrade

Protocol packs are software packages that update the Network-Based Application Recognition (NBAR) engine protocol support on a device without replacing the Cisco software on the device. A protocol pack contains information on applications that are officially supported by NBAR, and are compiled and packed together. In each application, the protocol pack includes information on application signatures and application attributes. Each software release has a built-in protocol pack bundled with it.

The Application Visibility and Control (AVC) feature (used for deep-packet inspection [DPI]) supports wireless products using a distributed approach that benefits from NBAR running on the access points (AP) or controller whose goal is to run DPI and report the result using NetFlow messages.

The AVC DPI technology supports the ability to update recognized traffic and to define the custom type of traffic (known as custom applications). The NBAR runs on the controller in local mode, and on the APs in Flex and Fabric modes. In local mode, all the traffic coming from the APs are tunneled towards the wireless controller.

Note

- Although NBAR is supported in all the modes, upgrade of NBAR protocol packs is supported only in local mode (central switching) and in FlexConnect mode (central switching).
- Custom applications are available only in local mode (central switching) and in FlexConnect mode (central switching).
- When you upgrade the AVC protocol pack, copy the protocol pack to both RPs (active and standby). Otherwise, the protocol pack on the standby upgrade will fail and cause the synchronization failure crash.

Protocol packs provide the following features:

- They can be loaded easily and quickly.
- They can be upgraded to a later version protocol pack or revert to an earlier version protocol pack.
- Device reload is not required.

- They do not disrupt any service.

Protocol Pack Upgrade

Using protocol pack upgrades, you can update the NBAR engine to recognize new types of protocols or traffic without updating the entire switch or appliance image. It also eliminates the need to restart the entire system.

NBAR protocol packs are available for download from Cisco Software Center: <https://software.cisco.com/download/navigator.html>

Custom Applications

Using custom applications, you can force the NBAR engine to recognize traffic based on a set of custom rules, for example, destination IP, hostname, URL, and so on.

The custom application names then appear in the web UI or in the NetFlow collector.

Upgrading the NBAR2 Protocol Pack

Follow the procedure given below to upgrade the NBAR2 protocol pack:

Before you begin

Download the protocol pack from [Software Download](#) page and copy it into the bootflash.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ip nbar protocol-pack bootflash:pack-name Example: Device(config)# ip nbar protocol-pack bootflash:mypp.pack	Loads the protocol pack.

CHAPTER 19

Wireless Sub-Package for Switch

- [Introduction to Wireless Sub-package, on page 285](#)
- [Booting in Install Mode, on page 286](#)
- [Installing Sub-Package in a Single Step \(GUI\), on page 287](#)
- [Installing Sub-Package in a Single Step, on page 287](#)
- [Multi-step Installation of Sub-Package, on page 288](#)
- [Installing on a Stack, on page 288](#)
- [Upgrading to a Newer Version of Wireless Package, on page 289](#)
- [Deactivating the Wireless Package, on page 289](#)
- [Enabling or Disabling Auto-Upgrade, on page 289](#)

Introduction to Wireless Sub-package

Wireless-only Fabric uses fabric constructs to garner the benefits of a fabric. In this architecture, a fabric is built on top of existing traditional network designs such as multi-tier, Routed Access, and VSS network. It uses a LISP control plane together with VXLAN encapsulation for the overlay data plane traffic. The wireless control plane remains intact with CAPWAP tunnels initiating on the APs and terminating on a Cisco Catalyst 9800 Series Wireless Controller or AireOS controller. The Cisco Catalyst 9800 Series Wireless Controller can function in a dedicated appliance, directly in a switch, or in a VM.

Cisco Catalyst 9800 Wireless Controller for Switch delivers all the benefits of a centralized control and management plane (easy to configure, upgrade, troubleshoot, etc) and the maximum throughput or performance of a distributed forwarding plane. The distributed data plane allows services such as AVC to scale. In this new model, the wireless control plane is not split between MC and MA. The switch is detached from the wireless control plane and the controller takes care of the wireless function and the traffic switching is done by the Cisco Access Switch.

Since the wireless functionality is required to be enabled only on few nodes of the network, you can install Cisco Catalyst 9800 Series Wireless Controller as a separate package on the switch on a need basis. The sub-package is installed on top of the base image and a reload is required to activate the sub-package.

Note The sub-package is an optional binary that contains the entire Cisco Catalyst 9800 Series Wireless Controller software.

Note SNMP is not supported on Catalyst 9800 Embedded Wireless Controller for Switch.

How to Install Wireless Package

1. Install the base image (without wireless) on the switch.
2. Install the wireless package on the switch.
3. Upgrade the AP image.
4. Reload the switch.
5. Enable wireless on the switch using the **wireless-controller** configuration command, and configure wireless features.

How to Remove Wireless Package

1. Uninstall the wireless package from the switch.
2. Reload the switch.
3. Run the **write** command. This removes the wireless configuration from the startup-configuration.

Upgrading to a Newer Version of Wireless Package

1. Install the base image (without wireless) on the switch.
2. Install the updated wireless package.
3. Reload the switch.
4. Commit the installation.

Booting in Install Mode

Use the procedure given below to boot the switch in install-mode:

Before you begin

The sub-package does not work in bundle-mode. Use the **show version** command to verify the boot mode.

Procedure

Step 1 **install add file** *image.bin* **location activate commit.**

This command moves the switch from bundle-mode to install-mode. Note that *image.bin* is the base image.

Step 2 Click **yes** to all the prompts.

Step 3 **reload**

Reloads the switch. Ensure that you boot from *flash:packages.conf*. After the reload, the switch will be in install-mode.

Note During Install mode image upgrade/downgrade, “Install add file” with `flash:<file_name>` command is not supported. Instead of that “bootflash:<filename>” needs to be used.

```
Install add file bootflash:<file_name> activate commit
```

What to do next

Verify the boot mode using the **show version** command.

Installing Sub-Package in a Single Step (GUI)

Procedure

- Step 1** Choose **Administration > Software Management > Software Upgrade**.
 - Step 2** Choose the upgrade mode from the **Upgrade Mode** drop-down list, the transport type from the **Transport Type** drop-down list and enter the **Server IP Address (IPv4/IPv6)**, the **File System** and choose the location from the **Source File Path** drop-down list.
 - Step 3** Click **Download & Install**.
-

Installing Sub-Package in a Single Step

Use the procedure given below to install sub-package in a single step:

Before you begin

- Ensure that the switch is in install-mode.
- Ensure that you boot only from *flash:packages.conf*.

Procedure

- Step 1** **install add file *flash:<controller>.bin* activate commit**
Installs the Cisco Catalyst 9800 Wireless Controller for Switch sub-package.
Note The sub-package (`flash:<controller>.bin`) is available on www.cisco.com. You can also install the sub-package directly from TFTP server.
 - Step 2** Click **yes** to all the prompts.
-

What to do next

Use the **show install summary** command to verify the installed image or package.

Multi-step Installation of Sub-Package

Use the procedure given below to install sub-package:

Before you begin

- Ensure that the switch is in install-mode.
- Ensure that you boot only from *flash:packages.conf*.

Procedure

Step 1 **install add file** *flash:<controller>.bin*

The sub-package is added to the flash and expanded.

Step 2 **install activate file** *flash:<controller>.bin*

Installs the sub-package.

Step 3 **install commit**

Completes the installation by writing the files.

What to do next

Use the **show install summary** command to verify the installed image or package.

Installing on a Stack

You can install the package on a stack using either [Single-step Package Installation](#) or [#unique_349](#).

If a new member joins the stack, the two possible scenarios are:

- **If auto-upgrade is enabled:** The required software is installed on to the new member. It will match the version of software running on the stack as well as the wireless package.
- **If auto-upgrade is disabled:** As the software version is not the same as in the stack, the new member will remain in version mismatch state and it will not join the stack. You have to manually run the **install autoupgrade** command in EXEC mode to initiate the auto-upgrade procedure.

Upgrading to a Newer Version of Wireless Package

Use the procedure given below to upgrade to a newer version of wireless package:

Procedure

-
- Step 1** **install add file** *flash:<base-image>.bin*
- The base image (without wireless) is added to the flash and expanded.
- Step 2** **install add file** *flash:<controller-sub-package>.bin*
- The sub-package is added to the flash and expanded.
- Step 3** **install active**
- Installs the base image and sub-package and triggers a reload. However, you can also rollback to the previous state after the reload.
- Step 4** **install commit**
- Completes the installation by writing the files.
-

Deactivating the Wireless Package

Follow the procedure given below to deactivate the wireless sub-package:

Procedure

	Command or Action	Purpose
Step 1	install deactivate file <i>flash:<controller>.bin</i> Example: Device# install deactivate file flash:<controller>.bin	Removes the package and forces the switch to reboot.
Step 2	install commit Example: Device# install commit	Commits the switch without wireless package.

Enabling or Disabling Auto-Upgrade

Follow the procedure given below to enable or disable auto-upgrade:

Procedure

	Command or Action	Purpose
Step 1	software auto-upgrade enable Example: Device(config)# software auto-upgrade enable	Enables software auto-upgrade.
Step 2	no software auto-upgrade enable Example: Device(config)# no software auto-upgrade enable	Disables software auto-upgrade.

CHAPTER 20

Countries and Regulations

- [Information About Country Codes](#), on page 293
- [Prerequisites for Configuring Country Codes](#), on page 293
- [Configuring Country Codes \(GUI\)](#), on page 294
- [Configuring Country Codes \(CLI\)](#), on page 294
- [Configuration Examples for Configuring Country Codes](#), on page 296
- [Information About Regulatory Compliance Domain](#), on page 297
- [Configuring Country Code for Rest of the World \(CLI\)](#) , on page 317

Information About Country Codes

Controllers and access points are designed for use in many countries with varying regulatory requirements. The radios within the access points are assigned to a specific regulatory domain at the factory (such as -E for Europe), but the country code enables you to specify a particular country of operation (such as FR for France or ES for Spain). Configuring a country code ensures that each radio's broadcast frequency bands, interfaces, channels, and transmit power levels are compliant with country-specific regulations.

Information About Japanese Country Codes

Country codes define the channels that can be used legally in each country. These country codes are available for Japan:

- J2: Allows only -P radios to join the controller
- J4: Allows 2.4G JPQU and 5G PQU to join the controller.

Prerequisites for Configuring Country Codes

- Generally, you should configure one country code per device; you configure one code that matches the physical location of the device and its access points. You can configure up to 200 country codes per device. This multiple-country support enables you to manage access points in various countries from a single device.
- When the multiple-country feature is used, all the devices that are going to join the same RF group must be configured with the same set of countries, configured in the same order.

- Access points are capable of using all the available legal frequencies. However, access points are assigned to the frequencies that are supported in their relevant domains.
- The country list configured on the RF group leader determines which channels the members will operate on. This list is independent of which countries have been configured on the RF group members.
- For devices in the Japan regulatory domain, you should have one or more Japan country codes (JP, J2, or J3) configured on your device at the time you last booted your device.
- For devices in the Japan regulatory domain, you should have one or more Japan country codes (J2, or J4) configured on your device at the time you last booted your device.
- For devices in the Japan regulatory domain, you must have at least one access point with a -J regulatory domain joined to your device.
- You cannot delete any country code using the configuration command **wireless country country-code** if the specified country was configured using the **ap country list** command and vice-versa.

Configuring Country Codes (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points > Country**.
- Step 2** On the **Country** page, select the check box for each country where your access points are installed. If you selected more than one check box, a message is displayed indicating that RRM channels and power levels are limited to common channels and power levels.
- Step 3** Click **Apply**.
-

Configuring Country Codes (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	show wireless country supported Example: Device# show wireless country supported	Displays a list of all the available country codes.
Step 3	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Device# configure terminal	
Step 4	ap dot11 { 24ghz 5ghz 6ghz } shutdown Example: Device(config)# ap dot11 5ghz shutdown	Disables the 802.11b/g network, if you use 24ghz. Disables the 802.11a network, if you use 5ghz. Disables the 802.11 6GHz network, if you use 6ghz.
Step 5	ap country <i>country_code</i> Example: Device(config)# ap country IN	Configures country code on the controller, so that access points joining controller matches the country code and its corresponding regulatory domain codes for the AP. Note More than one country code can be configured.
Step 6	wireless country <i>country_code</i> Example: Device(config)# wireless country IN	Configures 200 country codes per device. Note This CLI is applicable for deployments having more than 20 countries.
Step 7	exit Example: Device(config)# exit	Returns to privileged EXEC mode.
Step 8	show wireless country configured Example: Device# show wireless country configured	Displays the configured countries.
Step 9	show wireless country channels Example: Device# show wireless country channels	Displays the list of available channels for the country codes configured on your device. Note Perform Steps 9 through 17 only if you have configured multiple country codes in Step 6.
Step 10	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 11	no ap dot11 { 24ghz 5ghz 6ghz } shutdown Example: Device(config)# no ap dot11 5ghz shutdown	Enables the 802.11b/g network, if you use 24ghz. Enables the 802.11a network, if you use 5ghz. Enables the 802.11 6-GHz network, if you use 6ghz.

	Command or Action	Purpose
Step 12	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 13	ap name cisco-ap shutdown Example: Device# ap name AP02 shutdown	Disables the access point. Note Ensure that you disable only the access point for which you are configuring country codes.
Step 14	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 15	ap name cisco-ap country country_code Example: Device# ap name AP02 country US	Assigns each access point with a country code from the controller country code list. Note <ul style="list-style-type: none"> • Ensure that the country code that you choose is compatible with the regulatory domain of at least one of the access point's radios. • Disable the access point before changing country code.
Step 16	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 17	ap name cisco-ap no shutdown Example: Device# ap name AP02 no shutdown	Enables the access point.

Configuration Examples for Configuring Country Codes

Viewing Channel List for Country Codes

This example shows how to display the list of available channels for the country codes on your device:

```
Device# show wireless country channels
```

```
Configured Country.....: US - United States
KEY: * = Channel is legal in this country and may be configured manually.
```

```

A = Channel is the Auto-RF default in this country.
. = Channel is not legal in this country.
C = Channel has been configured for use by Auto-RF.
x = Channel is available to be configured for use by Auto-RF.
(-,-) = (indoor, outdoor) regulatory domain allowed by this country.
-----:+++++-----
802.11bg      :

```

Information About Regulatory Compliance Domain

Controllers and access points (AP) are designed for use in many countries with varying regulatory requirements. Country code enables to specify a particular country of operation (such as FR for France or ES for Spain). Configuring a country code ensures that each radio's broadcast frequency bands, interfaces, channels, and transmit power levels are compliant with country-specific regulations.

This feature helps to reduce the number of regulatory domains by modifying the existing pre-provision domains workflow to determine the regulatory domain at runtime for each country code. A new Rest of World (RoW) domain has been introduced and merged to include the nine pre-existing domains. Every AP can determine its own regulatory domain from one of these domains, with the regulated power table and the allowed radio channels.

Note The transmission power value in the TPC IE of the beacon can differ from that of the transmission power value of the AP displayed in the **show controllers dot11radio** command, by a maximum difference of 2 dB. The maximum deviation allowed in TPC IE of beacon is 2 dB.

Global Country-Level Domains

Table 20: Power Table and Supported Channels of Countries in Global Domain (2.4-GHz and 5-GHz)

Country and Code	Outdoor Power Table 2.4-GHz	Outdoor Power Table 5-GHz	Supported Channels 2.4-GHz	Supported Primary Channels 5-GHz	Supported Secondary Channels 5-GHz

⁷ From Cisco IOS XE 17.14.1, Israel has rejected the RoW domain standard and requires the usage of the following:

- Outdoor APs:
 - -I, effective July 2024

- Development of a Cisco Catalyst 9124 and 9163 domains that conform to Israel's outdoor AP requirements
- Indoor APs: Add Israel to the country list in the controller for -E domain APs
- Usage of -E on pre-RoW Wi-Fi 6 APs

Applicable post-RoW indoor APs: Cisco Catalyst 9136, 9162, 9164, and 9166 APs

Applicable pre-RoW indoor APs: Cisco Catalyst 9105, 9115, 9120, and 9130 APs

Restrictions on Regulatory Compliance Domain

- Cisco Catalyst 9124 AXE APs (9124AXE-F) are not supported in Indonesia. The AP radios are operationally down.

Countries Supporting 6-GHz Radio Band

The table below list the countries that support 802.11 6-GHz radio band:

The following APs support 6-GHz radio band:

- Cisco Catalyst 9136 Access Points
- Cisco Catalyst 9162 Series Access Points
- Cisco Catalyst 9164 Series Access Points
- Cisco Catalyst 9166 Series Access Points

From Cisco IOS XE Dublin 17.11.1, Albania, Iceland, Lichtenstein, Norway, and Switzerland are added to the list of countries that supports 6-GHz radio band.

From Cisco IOS XE Dublin 17.12.1, Australia, Brazil, Costa Rica, Honduras, Hong Kong, Japan, Jordan, Kenya, Malaysia, Morocco, New Zealand, Peru, Qatar, Saudi Arabia, and United Arab Emirates are added to the list of countries that supports 6-GHz radio band.

⁸ From Cisco IOS XE 17.14.1, Israel has rejected the RoW domain standard and requires the usage of the following:

- Outdoor APs:
 - -I, effective July 2024
 - Development of a Cisco Catalyst 9124 and 9163 domains that conform to Israel's outdoor AP requirements
- Indoor APs: Add Israel to the country list in the controller for -E domain APs
- Usage of -E on pre-RoW Wi-Fi 6 APs

Applicable post-RoW indoor APs: Cisco Catalyst 9136, 9162, 9164, and 9166 APs

Applicable pre-RoW indoor APs: Cisco Catalyst 9105, 9115, 9120, and 9130 APs

Rest of World Domain

Until Cisco IOS XE Bengaluru 17.5.1, APs used the global controller country list to configure and validate the country codes. From Cisco IOS XE Bengaluru 17.6.1 onwards, RoW domain support was added.

The following APs support RoW domain:

- Cisco Catalyst 9124AX outdoor Access Points
- Cisco Catalyst 9136 Access Points
- Cisco Catalyst 9164 Series Access Points
- Cisco Catalyst 9166 Series Access Points

From Cisco IOS XE Cupertino 17.9.1, the following countries are added to the RoW domain:

- Belarus
- Brunei
- Iraq
- Kazakhstan
- Kuwait
- Nigeria
- Pakistan
- Qatar
- Ukraine
- Uruguay

From Cisco IOS XE Dublin 17.11.1, the following countries are added to the RoW domain:

- Afghanistan
- Angola
- Bhutan
- Cambodia
- Democratic Republic of the Congo
- Ethiopia
- Georgia
- Honduras
- Ivory Coast
- Kosovo
- Laos
- Moldova

- Myanmar
- Nepal
- Nicaragua
- San Marino
- Sudan
- Vatican City State
- Yemen
- Zimbabwe

Note From Cisco IOS XE 17.14.1, Israel has rejected the RoW domain standard and requires the usage of the following:

- Outdoor APs:
 - -I, effective July 2024
 - Development of a Cisco Catalyst 9124 and 9163 domains that conform to Israel's outdoor AP requirements
- Indoor APs: Add Israel to the country list in the controller for -E domain APs
- Usage of -E on pre-RoW Wi-Fi 6 APs

Applicable post-RoW indoor APs: Cisco Catalyst 9136, 9162, 9164, and 9166 APs

Applicable pre-RoW indoor APs: Cisco Catalyst 9105, 9115, 9120, and 9130 APs

Configuring Country Code for Rest of the World (CLI)

This configuration is mandatory for the RoW.

Follow the procedure given below to configure the country code.

Before you begin

- Before configuring the country code in the AP profile, ensure that the country is present in the global country list. If the configured country code is not present in the global list, the AP retains the previous country code configuration. In addition, the misconfigured operation triggers a default flag and brings the radio operations down.
- If the configured country code does not match with the regulatory domain of one or more radio slots, the AP retains the previous country code configuration. In addition, the misconfigured operation triggers a default flag and brings the radio operations down.
- When a country is configured in an AP profile, a per AP country configuration on an AP mapped to that profile is not allowed.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# ap profile default-ap-profile	Configures an AP profile and enters AP profile configuration mode. Note The Cisco Embedded Wireless Controller (EWC) supports only the default AP profile.
Step 3	country <i>code</i> Example:	Sets the country code. Use the no form of this command to delete the country code.

	Command or Action	Purpose
	Device(config-ap-profile)# country IN	Note From Cisco IOS XE Bengaluru 17.6.1, the ap country code command was modified. The ap keyword was removed. The modified command is country code .
Step 4	end Example: Device(config-ap-profile)# end	Returns to privileged EXEC mode.
Step 5	show ap profile name default-ap-profile detailed Example: Device# show ap profile name default-ap-profile detailed AP Profile Name : default-ap-profile Description : default ap profile . . Country code : IN	Displays the AP country code for the AP join profile. If a country is not configured in the AP join profile, the country code will be displayed as "Not configured". The regulatory domain of RoW APs will be displayed as ROW.

Information about Sniffer

The controller enables you to configure an access point as a network “sniffer”, which captures and forwards all the packets on a particular channel to a remote machine that runs packet analyzer software. These packets contain information on time stamps, signal strength, packet sizes, and so on.

Sniffers allow you to monitor and record network activity, and detect problems.

The packet analyzer machine configured receives the 802.11 traffic encapsulated using the Airopeek protocol from the controller management IP address with source port UDP/5555 and destination UDP/5000.

You must use **Clear** in AP mode to return the AP back to client-serving mode, for example the local mode or FlexConnect mode depending on the remote site tag configuration.

Note It is recommended not to use the AP command to change the CAPWAP mode.

Information About XOR Radio Role Sniffer Support

The XOR radio in APs like Cisco 2800, 3800, 4800, and the 9100 series AP models support sniffer role in single radio interface.

The XOR radio offers the ability to operate as a single radio interface in many modes. This eliminates the need to place the entire AP into a mode. When this concept is applied to a single radio level, it is termed as role.

From this release onwards, Sniffer is the new supported role along with the Client Serving and Monitor roles.

Note The radio role is supported in Local and FlexConnect modes.

Feature History for Sniffer Mode

This table provides release and related information for features explained in this module.

These features are available on all releases subsequent to the one they were introduced in, unless noted otherwise.

Table 23: Feature History for Sniffer Mode

Release	Feature	Feature Information
Cisco IOS XE 17.8.1	XOR Radio Role Sniffer Support on the Access Point	The XOR radio in APs like Cisco 2800, 3800, 4800, and the 9100 series AP models support sniffer role in single radio interface.

Prerequisites for Sniffer

To perform sniffing, you need the following hardware and software:

- A dedicated access point—An access point configured as a sniffer cannot simultaneously provide wireless access service on the network. To avoid disrupting coverage, use an access point that is not part of your existing wireless network.
- A remote monitoring device—A computer capable of running the analyzer software.
- Software and supporting files, plug-ins, or adapters—Your analyzer software may require specialized files before you can successfully enable.

Restrictions on Sniffer

- Supported third-party network analyzer software applications are as follows:

- Wildpackets Omnipcap or Airocap
 - AirMagnet Enterprise Analyzer
 - Wireshark
- The latest version of Wireshark can decode the packets by going to the Analyze mode. Select **decode as**, and switch UDP5555 to decode as PEEKREMOTE..
 - Sniffer mode is not supported when the controller L3 interface is the Wireless Management Interface (WMI).
 - When an AP or a radio operates in the sniffer mode, irrespective of its current channel width settings, the AP sniffs or captures only on the primary channel.

Note As both Cisco Catalyst 9166I and 9166D APs have XOR radios, a Board Device File (BDF) has to be loaded to initialize radio 2 for the radios of these APs to work as expected. While the BDF is being loaded and for the file to be loaded correctly, the firmware has to be made non-operational and radios have to be reset. This operation of radio reset due to firmware being non-operational for the purposes of loading the BDFs is deliberate and is an expected behavior. This operation can be observed in both the controller and Cisco Catalyst Center. We recommend that you ignore the core dump that is generated due to this deliberate operation.

How to Configure Sniffer

Configuring an Access Point as Sniffer (GUI)

Procedure

- Step 1** Choose **Configuration > Wireless > Access Points**.
- Step 2** On the **General** tab, update the name of the AP. The AP name can be ASCII characters from 33 to 126, without leading and trailing spaces.
- Step 3** Specify the physical location where the AP is present.
- Step 4** Choose the **Admin Status** as **Enabled** if the AP is to be in enabled state.
- Step 5** Choose the mode for the AP as *Sniffer*.
- Step 6** In the **Tags** section, specify the appropriate policy, site, and RF tags that you created on the **Configuration > Tags & Profiles > Tags** page.

Note If the AP is in sniffer mode, you do not want to assign any tag.

- Step 7** Click **Update & Apply to Device**.
- Step 8** Choose the mode for the AP as **Clear** to return the AP back to the client-serving mode depending on the remote site tag configuration.

Note All the radios will be set to manual mode when you change the AP mode to Sniffer mode. Simultaneously, a warning message will be displayed informing you to convert the radio submode back to AUTO, if required, while changing the mode from Sniffer to other.

Configuring an Access Point as Sniffer (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device>enable	Enables privileged EXEC mode.
Step 2	ap name <i>ap-name</i> mode sniffer Example: Device# ap name access1 mode sniffer	Configures the access point as a sniffer. Where, <i>ap-name</i> is the name of the Cisco lightweight access point. Use the no form of this command to disable the access point as a sniffer.

Enabling or Disabling Sniffing on the Access Point (GUI)

Before you begin

Change the access point AP mode to sniffer mode.

Procedure

- Step 1** Choose **Configuration > Wireless > Access Points**.
- Step 2** On the **Access Points** page, click the AP name from the 6 GHz, 5 GHz, or 2.4 GHz list.
- Step 3** In the **Role Assignment** section, select the **Assignment Method** as *Sniffer*.
- Step 4** In the **Sniffer Channel Assignment** section, check the **Sniffer Channel Assignment** checkbox to enable.
Uncheck the checkbox to disable sniffing on the access point.

- Step 5** From the **Sniff Channel** drop-down list, select the channel.

Note By default, the **Snif Channel** is set to 36 for the 5 GHz and 1 for the 2.4 GHz.

- Step 6** Enter the IP address in the **Sniffer IP** field.

To validate the IP address, click **Update & Apply to Device**. If the IP address is valid, the **Sniffer IP Status** displays *Valid*.

Step 7 Click **Update & Apply to Device**.

Enabling or Disabling Sniffing on the Access Point (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode.
Step 2	ap name <i>ap-name</i> sniff { dot11 6Ghz slot 3 channel server-ip-address dot11a channel server-ip-address dot11b channel server-ip-address dual-band channel server-ip-address } Example: Device# ap name access1 sniff dot11b 19.9.48.5	Enables sniffing on the access point. <ul style="list-style-type: none"> • <i>channel</i> is the valid channel to be sniffed. For 802.11a, the range is 36 to 165. For 802.11b, the range is 1 to 14. For dot11 6Ghz, the range is between 1 and 233. • <i>server-ip-address</i> is the IP address of the remote machine running Omnipcap, Airopeek, AirMagnet, or Wireshark software.
Step 3	ap name <i>ap-name</i> no sniff { dot116Ghz dot11a dot11b dual-band } Example: Device# ap name access1 no sniff dot116ghz	Disables sniffing on the access point.

Configuring XOR Radio Role Sniffer Support on the Access Point (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	ap name <i>ap-name</i> dot11 { dual-band } shutdown Example: Device# ap name AP687D.B45C.189C dot11 dual-band shutdown	Shutdown the XOR radio.
Step 3	ap name <i>ap-name</i> dot11 { dual-band } role manual { client-serving }	Converts the XOR radio role to manual.

	Command or Action	Purpose
	Example: <pre>Device# ap name ap-name dot11 dual-band role manual client-serving</pre>	
Step 4	ap name <i>ap-name</i> dot11 {dual-band} band {5ghz 24ghz} Example: <pre>Device# ap name AP687D.B45C.189C dot11 dual-band band 5ghz</pre>	Configures XOR radio to manually operate in a specific band.
Step 5	ap name <i>ap-name</i> dot11 {dual-band} radio role manual sniffer channel <i>channel-number</i> ip <i>ip-address</i> Example: <pre>Device# ap name AP687D.B45C.189C dot11 dual-band radio role manual sniffer channel 100 ip 9.4.197.85</pre>	Enables XOR radio role Sniffer support on AP from the controller. Where, <ul style="list-style-type: none"> • <i>ap-name</i> is the name of the Cisco lightweight access point. • <i>channel-number</i> is the channel number.
Step 6	ap name <i>ap-name</i> no dot11 {dual-band} shutdown Example: <pre>Device# ap name AP687D.B45C.189C no dot11 dual-band shutdown</pre>	Unshuts the XOR radio.
Step 7	end Example: <pre>Device# end</pre>	Returns to privileged EXEC mode. Note When configuring the radio to work as a Sniffer in the 5-GHz band, you will need to change the band of the radio manually as in Step 4 .

Verifying Sniffer Configurations

Table 24: Commands for verifying sniffer configurations

Commands	Description
show ap name <i>ap-name</i> config dot11 {24ghz 5ghz 6ghz dual-band}	Displays the sniffing details.
show ap name <i>ap-name</i> config slot <i>slot-ID</i>	Displays the sniffing configuration details. <i>slot-ID</i> ranges from 0 to 3. All access points have slot 0 and 1.

Verifying XOR Radio Role Sniffer Configuration

To verify the XOR radio role sniffer configuration for a given AP, use the following command:

```
Device# show ap name AP687D.B45C.189C config slot 0

Sniffing : Enabled
Sniff Channel : 6
Sniffer IP : 9.4.197.85
Sniffer IP Status : Valid
ATF Mode : Disable
ATE Optimization : N/A
AP Submode : Not Configured
Remote AP Debug : Disabled
Logging Trap Severity Level : information
Software Version : 17.9.0.18
Boot Version : 1.1.2.4
Mini IOS Version : 0.0.0.0
Stats Reporting Period : 60
primary_discovery_timer : 120
LED State : Enabled
LED Flash State : Enabled
LED Flash Timer : 0
PoE Pre-Standard Switch : Disabled
PoE Power Injector MAC Address : Disabled
Power Type/Mode : PoE/Full Power
Number of Slots : 4
AP Model : C9136I-B
IOS Version : 17.9.0.18
Reset Button : Disabled
AP Serial Number : FOC25322JJZ
AP Certificate Type : Manufacturer Installed Certificate
AP Certificate Expiry-time : 08/09/2099 20:58:26
AP Certificate issuer common-name : High Assurance SUDI CA
AP Certificate Policy : Default
AP CAPWAP-DTLS LSC Status
    Certificate status : Not Available
AP 802.1x LSC Status
    Certificate status : Not Available
AP User Name : admin
AP 802.1X User Mode : Global
AP 802.1X User Name : Not Configured
Cisco AP System Logging Host : 255.255.255.255
AP Up Time : 4 hours 20 minutes 55 seconds
AP CAPWAP Up Time : 4 hours 16 minutes 17 seconds
Join Date and Time : 01/19/2022 03:06:12

Attributes for Slot 0
Radio Type : 802.11ax - 2.4 GHz
Radio Mode : Sniffer
Radio Role : Sniffer
Maximum client allowed : 400
Radio Role Op : Manual
Radio SubType : Main
Administrative State : Enabled
Operation State : Up
```

Examples for Sniffer Configurations and Monitoring

This example shows how to configure an access point as Sniffer:

```
Device# ap name access1 mode sniffer
```

This example shows how to enable sniffing on the access point:

```
Device# ap name access1 sniff dot11b 1 9.9.48.5
```

This example shows how to disable sniffing on the access point:

```
Device# ap name access1 no sniff dot11b
```

This example shows how to display the sniffing configuration details:

```
Device# show ap name access1 config dot11 24ghz  
Device# show ap name access1 config slot 0
```

Introduction to Monitor Mode

To optimize the monitoring and location calculation of RFID tags, you can enable tracking optimization on up to four channels within the 2.4-GHz band of an 802.11b/g/x access point radio. This feature allows you to scan only the channels on which tags are usually programmed to operate (such as channels 1, 6, and 11).

Note You can move an AP to a particular mode (sensor mode to local mode or flex mode) using the site tag with the corresponding mode. If the AP is not tagged to any mode, it will fall back to the mode specified in the default site tag.

You must use clear in AP mode to return the AP back to client-serving mode, for example the local mode or FlexConnect mode depending on the remote site tag configuration.

Enable Monitor Mode (GUI)

Procedure

- Step 1** Choose **Configuration > Wireless > Access Points**.
- Step 2** In the **Access Points** page, expand the **All Access Points** section and click the name of the AP to edit.
- Step 3** In the **Edit AP** page, click the **General** tab and from the **AP Mode** drop-down list, choose **Monitor**.
- Step 4** Click **Update & Apply to Device**.

- Step 5** Choose the mode for the AP as **clear** to return the AP back to the client-serving mode depending on the remote site tag configuration.

Enable Monitor Mode (CLI)

Procedure

	Command or Action	Purpose
Step 1	ap name <i>ap-name</i> mode monitor Example: Device# ap name 3602a mode monitor	Enables monitor mode for the access point.
Step 2	ap name <i>ap-name</i> monitor tracking-opt Example: Device# ap name 3602a monitor tracking-opt	Configures the access point to scan only the Dynamic Channel Assignment (DCA) channels supported by its country of operation.
Step 3	ap name <i>ap-name</i> monitor-mode dot11b fast-channel [<i>first-channel second-channel third-channel fourth-channel</i>] Example: Device# ap name 3602a monitor dot11b 1 2 3 4	Chooses up to four specific 802.11b channels to be scanned by the access point. In the United States, you can assign any value from 1 to 11 (inclusive) to the channel variable. Other countries support additional channels. You must assign at least one channel.
Step 4	ap name <i>ap-name</i> dot11 6ghz slot 3 radio role manual monitor Example: Device# ap name cisco-ap dot11 6ghz slot 3 radio role manual monitor	slot 3 radio role manual monitor Configures the 802.11 6-GHz radio role manual monitor
Step 5	show ap dot11 {24ghz 5ghz 6ghz} channel Example: Device# show ap dot11 5ghz channel	Shows configuration and statistics of 802.11a or 802.11b or 6-GHz channel assignment.
Step 6	show ap dot11 6ghz summary Example: Device# show ap dot11 6ghz summary	Shows configuration and statistics summary of 6 the GHz band Cisco APs.

Feature History for Management Mode Migration in Cisco Catalyst Wireless 916X Access Points

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 25: Feature History for Management Mode Migration in Cisco Wireless Catalyst Wireless 916X Series Access Points

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.9.1	Management Mode Migration in Cisco Catalyst Wireless 916X Series Access Points	This feature allows you to convert the AP mode between DNA Management mode and Meraki Management mode, depending on your requirements. Note The document explains the conversion from DNA Management mode to Meraki Management mode and not vice versa.

Information About Management Mode Migration in Cisco Catalyst Wireless 916X Series Access Points

Cisco Catalyst Wireless 916x APs (CW9164I-x and CW9166I-x) support both cloud and controller architecture. You can migrate between cloud and controller deployments, depending on your requirements. The CW916x APs join and operate either in the DNA Management mode or in the Meraki Management mode. You can configure the management mode migration with the help of CLI commands in the privileged EXEC mode, at the AP level, and from the controller GUI.

CW916x APs support dual-band slot 3 radios, which in turn support both 6-GHz and 5-GHz bands.

Note The section explains the migration from DNA Management mode to the Meraki Management mode and not vice versa.

Regulatory Domain

For regulatory domain support, Cisco Catalyst 916x (CW916x) supports Rest of the World (RoW) and a few other fixed domains as shown here:

- -B
- -E
- -A
- -Z
- -Q
- -I
- -R

During the AP join flow, the regulatory domain details and the details of the country that is configured is passed on to the controller from the AP. The controller assigns or validates the right country of operation. After the country is validated based on the decision tree, the controller informs the AP about which country the AP should be configured with.

The following are the scenarios that determine the country that an AP should be configured with:

AP Configured with Non-RoW Regulatory Domain

Case 1: AP does not report a country as part of the join procedure.

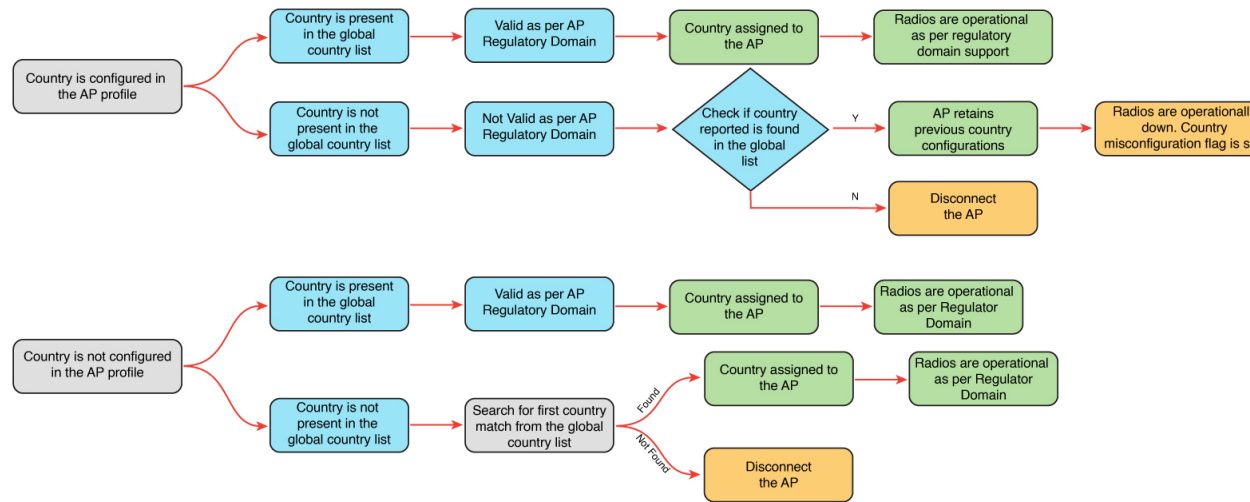

In the non-RoW regulatory domain, when an AP does not report a country as part of the join procedure, the following takes place:

- AP profile has a country configured.
 - If the country configured in the AP profile is present in the global country list, and is valid as per the AP regulatory domain, the country that is configured in the AP profile is assigned to the AP. Radios become operational as per the country or regulatory domain support.
 - If the country configured the AP profile is not present in the global country list, and is not valid as per the AP regulatory domain, the AP is disconnected.
- AP profile does not have a country configured. Find a valid country from the global country list (the first match), as per the AP regulatory domain.
 - If the country is found, the country is assigned to the AP and the radios become operational as per the country or regulatory domain support.
 - If the country is not found, the AP is disconnected.

Case 2: AP reports a country as part of the join procedure.

AP Reports Country as Part of the Join Procedure

In the non-RoW regulatory domain, when an AP reports a country as part of the join procedure, the following takes place:

- The AP profile has a country configured.
 - If the country configured in the AP profile is present in the global country list, and it is valid as per the AP regulatory domain, the country that is configured in the AP profile is assigned to the AP. Radios become operational as per the country or regulatory domain support.
 - If the country configured in the AP profile is not present in the global country list, and is not valid as per the AP regulatory domain, check the global country list to confirm if the country is present in the list. If the country is present in the global list, the AP retains the previous country configuration and the radios are not operational with the country misconfiguration flag set. If the country is not located in the global list, the AP is disconnected.
- The AP profile does not have a country configured.
 - If the country reported by the AP is found in the global country list, and is valid as per the AP regulatory domain, the country is assigned to the AP and the radios become operational as per the country or regulatory domain support.
 - If the country is not present in the list, search for the first country match from the global list. If the country is found, the country is assigned to the AP and the radios become operational. If the country is not found, the AP is disconnected.

AP Configured with RoW Regulatory Domain

Case 1: The AP does not report a country as part of the join procedure.

AP Does Not Report a Country as Part of the Join Procedure

In the RoW regulatory domain, when an AP does not report a country as part of the join procedure, the following takes place:

- The AP profile has a country configured.
 - If the country configured in the AP profile is present in the global country list, and is valid as per the AP regulatory domain, country that is configured in the AP profile is assigned to the AP. Radios become operational as per the country or regulatory domain support.
 - If the country configured in the AP profile is not present in the global country list, and is not valid as per the AP regulatory domain, country is not assigned to the AP and radios are not operational, and the country misconfiguration flag is set.
- If the AP profile does not have a country configured, the country is not assigned to the AP and radios are not operational, and the country misconfiguration flag is set.

Case 2: The AP reports a country as part of the join procedure.

AP Reports a Country as Part of the Join Procedure

In the RoW regulatory domain, when an AP reports a country as part of the join procedure, the following takes place:

- The AP profile has a country configured.

- If the country configured in the AP profile is present in the global country list, and it is valid as per the AP regulatory domain, the country that is configured in the AP profile is assigned to the AP. Radios become operational as per the country or regulatory domain support.
- If the country configured in the AP profile is not present in the global country list, and is not valid as per the AP regulatory domain, the AP retains the previous country configuration and the radios are not operational with the country misconfiguration flag set.
- The AP retains the previous country configuration and the radios are not operational with the country misconfiguration flag set.

Configuring Management Mode Migration (GUI)

Before you begin

The country code must be configured on the AP profile. To configure the country code, navigate to **Configuration > Tags & Profiles > AP Join** page. Click an AP profile to edit. In the **General** tab, select the country code from the drop-down list.

Procedure

-
- Step 1** Choose **Configuration > Wireless > Migrate to Meraki Management Mode**.
 - Step 2** Select the required APs by clicking on the check box(es), from the displayed APs. The **Migrate to Meraki Management Mode** button is enabled.
 - Step 3** Click **Migrate to Meraki Management Mode** button to perform a validation check on the selected APs. If the validation check is successful, the **Next** button is enabled.
 - Step 4** Click **Next** to start the process.
 - Step 5** On the **Confirm Management Mode Migration** window, do the following:
 - a. Select the **Agree and continue** check box.
 - b. Click **Yes** to confirm.
- The **Management Mode Migration Successful** section displays the APs that were migrated to the Meraki management mode. The **Management Mode Migration Failed** section displays the APs that were retained in DNA management mode.
- Step 6** Click **Restart Workflow** to restart the workflow for APs that did not migrate from DNA management mode to Meraki management mode.

Exporting Meraki Management Mode-Migrated APs (GUI)

You can export the details about the Meraki management mode-migrated APs either from the **Change to Meraki Persona** tab after the workflow is completed or from the **Previously changed APs** tab.

Procedure

	Command or Action	Purpose
Step 1	Choose Configuration > Wireless > Migrate to Meraki Management Mode .	
Step 2	Click the Export button to export the list of APs.	
Step 3	Select whether you want to export only the current page or all pages. Click Yes to continue.	
Step 4	On the Export window, select the export method. The available options are:	<ul style="list-style-type: none"> • Serial Number • JSON • Export to Meraki Dashboard <p>Note We recommend the Export to Meraki Dashboard option as you can directly export the migrated APs information into the Meraki Dashboard.</p>
Step 5	Click Copy to copy the migrated APs. Click Download and save the file location.	

Configuring the AP Management Mode (CLI)

Before you begin

- Ensure that the AP is Meraki-capable to run any of the EXEC commands. To view the list of Meraki-capable APs, use the **show ap management-mode meraki capability summary** command.

Note If the country code is misconfigured, the change of management mode will not be allowed for any of the EXEC commands, except the **force** command.

If the regulatory domain is misconfigured for any slot, the change of management mode is not allowed for any of the EXEC commands, except the **force** command.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter the password, if prompted.

	Command or Action	Purpose
Step 2	ap name Cisco-AP-name management-mode meraki [force] [noprompt] Example: Device# ap name Cisco-AP-name management-mode meraki Device# ap name Cisco-AP-name management-mode meraki force Device# ap name Cisco-AP-name management-mode meraki noprompt Device# ap name Cisco-AP-name management-mode meraki force noprompt	Changes the AP management mode to Meraki. Here, force skips the validations at the controller and attempts Meraki management mode change at the AP. noprompt skips the user prompt for attempting AP management mode change.
Step 3	(Optional) clear ap meraki stats Example: Device# clear ap meraki stats	Clears the Meraki AP-related data.

Verifying the Management Mode Migration Details

To view the summary of the Meraki-capable AP information, run the following command:

```
Device# show ap management-mode meraki capability summary
AP Name          AP Model          Radio MAC          MAC Address          AP Serial
Number          Meraki Serial Number
-----
APXXXX.BXXX.1XXX    CW9162I          6XXd.bXXe.eXX0    6XXd.bXXe.eXX0    FOCXXXXXB90
                   FOCXXXXXB90
```

To view the failure summary of the AP along with the migration attempt timestamp, run the following command:

```
Device# show ap management-mode meraki failure summary
AP Name          AP Model          Radio MAC          MAC Address          Conversion Attempt
AP Serial Number Meraki Serial Number Reason Code
-----
APXXXX.BXXC.1    CW9162I          6XXd.bXXe.eXX0    6XXd.bXXe.eXX0    03/03/2022 17:17:42
IST FOCXXXXXB90    FOCXXXXXB90          Regulatory domain not set
```

To view the successful Meraki management mode migration attempts of all the APs, run the following command:

```
Device# show ap management-mode meraki change summary
AP Name          AP Model          Radio MAC          MAC Address          Conversion
Timestamp        AP Serial Number Meraki Serial Number
-----
APXXXX.3XXX.EXXX    CW9166I-B          1XXX.2XXX.1100    ccXX.3XXX.eXX0    05/02/2022
07:48:56 CST      KWC2XXXXX5G          Q5XX-4XXX-K7XX
```

Information About FlexConnect

FlexConnect is a wireless solution for branch office and remote office deployments. It enables customers to configure and control access points (AP) in a branch or remote office from the corporate office through a wide area network (WAN) link without deploying a controller in each office. The FlexConnect access points

can also switch client data traffic locally and perform client authentication locally when their connection to the controller is lost. When they are connected to the controller, they can also send traffic back to the controller. FlexConnect access points support multiple SSIDs. In the connected mode, the FlexConnect access point can also perform local authentication.

Figure 16: FlexConnect Deployment

The controller software has a more robust fault tolerance methodology to FlexConnect access points. In previous releases, whenever a FlexConnect access point disassociates from a controller, it moves to the standalone mode. The clients that are centrally switched are disassociated. However, the FlexConnect access point continues to serve locally switched clients. When the FlexConnect access point rejoins the controller (or a standby controller), all the clients are disconnected and are authenticated again. This functionality has been enhanced and the connection between the clients and the FlexConnect access points are maintained intact and the clients experience seamless connectivity. When both the access point and the controller have the same configuration, the connection between the clients and APs is maintained.

After the client connection is established, the controller does not restore the original attributes of the client. The client username, current rate and supported rates, and listen interval values are reset to the default or new configured values only after the session timer expires.

The controller can send multicast packets in the form of unicast or multicast packets to an access point. In FlexConnect mode, an access point can receive only multicast packets.

In Cisco Catalyst 9800 Series Wireless Controller, you can define a flex connect site. A flex connect site can have a flex site connect profile associate with it. You can have a maximum of 100 access points for each flex connect site.

FlexConnect access points support a 1-1 network address translation (NAT) configuration. They also support port address translation (PAT) for all features except true multicast. Multicast is supported across NAT boundaries when configured using the Unicast option. FlexConnect access points also support a many-to-one NAT or PAT boundary, except when you want true multicast to operate for all centrally switched WLANs.

Workgroup bridges and Universal Workgroup bridges are supported on FlexConnect access points for locally switched clients.

FlexConnect supports IPv6 clients by bridging the traffic to local VLAN, similar to an IPv4 operation. FlexConnect supports Client Mobility for a group of up to 100 access points.

An access point does not have to reboot when moving from local mode to FlexConnect mode and vice-versa.

FlexConnect Authentication

When an access point boots up, it looks for a controller. If it finds one, it joins the controller, downloads the latest software image and configuration from the controller, and initializes the radio. It saves the downloaded configuration in nonvolatile memory for use in standalone mode.

Note Once the access point is rebooted after downloading the latest controller software, it must be converted to the FlexConnect mode.

Note 802.1X is not supported on the AUX port for Cisco Aironet 2700 series APs.

A FlexConnect access point can learn the controller IP address in one of these ways:

- If the access point has been assigned an IP address from a DHCP server, it can discover a controller through the regular CAPWAP or LWAPP discovery process.

Note OTAP is not supported.

- If the access point has been assigned a static IP address, it can discover a controller through any of the discovery process methods except DHCP option 43. If the access point cannot discover a controller through Layer 3 broadcast, we recommend DNS resolution. With DNS, any access point with a static IP address that knows of a DNS server can find at least one controller.
- If you want the access point to discover a controller from a remote network where CAPWAP or LWAPP discovery mechanisms are not available, you can use priming. This method enables you to specify (through the access point CLI) the controller to which the access point is to connect.

Note The LEDs on the access point change as the device enters different FlexConnect modes. See the hardware installation guide for your access point for information on LED patterns.

When a client associates to a FlexConnect access point, the access point sends all authentication messages to the controller and either switches the client data packets locally (locally switched) or sends them to the controller (centrally switched), depending on the WLAN configuration. With respect to client authentication (open, shared, EAP, web authentication, and NAC) and data packets, the WLAN can be in any one of the following states depending on the configuration and state of controller connectivity:

Note For the FlexConnect local switching, central authentication deployments, whenever passive client is enabled, the IP Learn timeout is disabled by default.

- central authentication, central switching—In this state, the controller handles client authentication, and all client data is tunneled back to the controller. This state is valid only in connected mode.

- central authentication, local switching—In this state, the controller handles client authentication, and the FlexConnect access point switches data packets locally. After the client authenticates successfully, the controller sends a configuration command with a new payload to instruct the FlexConnect access point to start switching data packets locally. This message is sent per client. This state is applicable only in connected mode.
- local authentication, local switching—In this state, the FlexConnect access point handles client authentication and switches client data packets locally. This state is valid in standalone mode and connected mode.

In connected mode, the access point provides minimal information about the locally authenticated client to the controller. The following information is not available to the controller:

- Policy type
- Access VLAN
- VLAN name
- Supported rates
- Encryption cipher

Local authentication is useful where you cannot maintain a remote office setup of a minimum bandwidth of 128 kbps with the round-trip latency no greater than 100 ms and the maximum transmission unit (MTU) no smaller than 576 bytes. In local authentication, the authentication capabilities are present in the access point itself. Local authentication reduces the latency requirements of the branch office.

- Notes about local authentication are as follows:
 - Guest authentication cannot be done on a FlexConnect local authentication-enabled WLAN.
 - Local RADIUS on the controller is not supported.
 - Once the client has been authenticated, roaming is only supported after the controller and the other FlexConnect access points in the group are updated with the client information.
- authentication down, switch down—In this state, the WLAN disassociates existing clients and stops sending beacon and probe requests. This state is valid in both standalone mode and connected mode.
- authentication down, local switching—In this state, the WLAN rejects any new clients trying to authenticate, but it continues sending beacon and probe responses to keep existing clients alive. This state is valid only in standalone mode.

When a FlexConnect access point enters standalone mode, WLANs that are configured for open, shared, WPA-PSK, or WPA2-PSK authentication enter the “local authentication, local switching” state and continue new client authentications. This configuration is also correct for WLANs that are configured for 802.1X, WPA-802.1X, WPA2-802.1X, or Cisco Centralized Key Management, but these authentication types require that an external RADIUS server be configured.

Other WLANs enter either the “authentication down, switching down” state (if the WLAN was configured for central switching) or the “authentication down, local switching” state (if the WLAN was configured for local switching).

When FlexConnect access points are connected to the controller (rather than in standalone mode), the controller uses its primary RADIUS servers and accesses them in the order specified on the RADIUS Authentication Servers page or in the **config radius auth add** CLI command (unless the server order is overridden for a

particular WLAN). However, to support 802.1X EAP authentication, FlexConnect access points in standalone mode need to have their own backup RADIUS server to authenticate clients.

Note A controller does not use a backup RADIUS server. The controller uses the backup RADIUS server in local authentication mode.

You can configure a backup RADIUS server for individual FlexConnect access points in standalone mode by using the controller CLI or for groups of FlexConnect access points in standalone mode by using either the GUI or CLI. A backup server configured for an individual access point overrides the backup RADIUS server configuration for a FlexConnect.

When web-authentication is used on FlexConnect access points at a remote site, the clients get the IP address from the remote local subnet. To resolve the initial URL request, the DNS is accessible through the subnet's default gateway. In order for the controller to intercept and redirect the DNS query return packets, these packets must reach the controller at the data center through a CAPWAP connection. During the web-authentication process, the FlexConnect access points allows only DNS and DHCP messages; the access points forward the DNS reply messages to the controller before web-authentication for the client is complete. After web-authentication for the client is complete, all the traffic is switched locally.

When a FlexConnect access point enters into a standalone mode, the following occurs:

- The access point checks whether it is able to reach the default gateway via ARP. If so, it will continue to try and reach the controller.

If the access point fails to establish the ARP, the following occurs:

- The access point attempts to discover for five times and if it still cannot find the controller, it tries to renew the DHCP on the ethernet interface to get a new DHCP IP.
- The access point will retry for five times, and if that fails, the access point will renew the IP address of the interface again, this will happen for three attempts.
- If the three attempts fail, the access point will fall back to the static IP and will reboot (only if the access point is configured with a static IP).
- Reboot is done to remove the possibility of any unknown error the access point configuration.

Once the access point reestablishes a connection with the controller, it disassociates all clients, applies new configuration information from the controller, and allows client connectivity again.

Guidelines and Restrictions for FlexConnect

- FlexConnect mode can support only 16 VLANs per AP.
- You can deploy a FlexConnect access point with either a static IP address or a DHCP address. In the context of DHCP, a DHCP server must be available locally and must be able to provide the IP address for the access point at bootup.
- FlexConnect supports up to 4 fragmented packets, or a minimum 576-byte maximum transmission unit (MTU) WAN link.

- Round-trip latency must not exceed 300 milliseconds (ms) between the access point and the controller, and CAPWAP control packets must be prioritized over all other traffic. In scenarios where you cannot achieve the 300-ms round-trip latency, configure the access point to perform local authentication.
- Client connections are restored only for locally switched clients that are in the RUN state when the access point moves from standalone mode to connected mode. After the access point moves, the access point's radio is also reset.
- When multiple APs come from standalone mode to connected mode on FlexConnect and all the APs send the client entry in hybrid-REAP payload to the controller. In this scenario, the controller sends disassociation messages to the WLAN client. However, the WLAN client comes back successfully and joins the controller.
- When APs are in standalone mode, if a client roams to another AP, the source AP cannot determine whether the client has roamed or is just idle. So, the client entry at source AP will not be deleted until idle timeout.
- The configuration on the controller must be the same between the time the access point went into standalone mode and the time the access point came back to connected mode. Similarly, if the access point is falling back to a secondary or backup controller, the configuration between the primary and the secondary or backup controller must be the same.
- A newly connected access point cannot be booted in FlexConnect mode.
- FlexConnect mode requires that the client send traffic before learning the client's IPv6 address. Compared to in local mode where the controller learns the IPv6 address by snooping the packets during Neighbor Discovery to update the IPv6 address of the client.
- 802.11r fast transition roaming is not supported on APs operating in local authentication.
- The primary and secondary controllers for a FlexConnect access point must have the same configuration. Otherwise, the access point might lose its configuration, and certain features, such as WLAN overrides, VLANs, static channel number, and so on, might not operate correctly. In addition, make sure you duplicate the SSID of the FlexConnect access point and its index number on both controllers.
- If you configure a FlexConnect access point with a syslog server configured on the access point, after the access point is reloaded and the native VLAN other than 1, at the time of initialization, a few syslog packets from the access point are tagged with VLAN ID 1.
- MAC filtering is not supported on FlexConnect access points in standalone mode. However, MAC filtering is supported on FlexConnect access points in connected mode with local switching and central authentication. Also, Open SSID, MAC Filtering, and RADIUS NAC for a locally switched WLAN with FlexConnect access points is a valid configuration, where MAC is checked by Cisco ISE.
- FlexConnect does not display any IPv6 client addresses in the Client Detail window.
- FlexConnect access points with locally switched WLANs cannot perform IP source guard and prevent ARP spoofing. For centrally switched WLANs, the wireless controller performs IP source guard and ARP spoofing.
- To prevent ARP spoofing attacks in FlexConnect APs with local switching, we recommend that you use ARP inspection.
- Proxy ARP for VM clients (with any wireless host) does not work since the client includes many IP addresses for the same MAC. To avoid this issue, disable the ARP-caching option in the Flex profile.

- When you enable local switching on policy profile for FlexConnect APs, the APs perform local switching. However, for the APs in local mode, central switching is performed.

In a scenario where the roaming of a client between FlexConnect mode AP and Local mode AP is not supported, the client may not get the correct IP address due to VLAN difference after the move. Also, L2 and L3 roaming between FlexConnect mode AP and Local mode AP are not supported.

FlexConnect local switching is not supported on Cisco Aironet Cisco 1810T and 1815T (Teleworker) Access Points.

- Cisco Centralized Key Management (CCKM) is not supported in FlexConnect standalone mode. Hence, CCKM enabled client will not be able to connect when AP is in FlexConnect standalone mode.
- For Wi-Fi Protected Access Version 2 (WPA2) in FlexConnect standalone mode or local authentication in connected mode or Cisco Centralized Key Management fast roaming in connected mode, only Advanced Encryption Standard (AES) is supported.
- For Wi-Fi Protected Access (WPA) in FlexConnect standalone mode or local-auth in connected mode or Cisco Centralized Key Management fast-roaming in connected mode, only Temporal Key Integrity Protocol (TKIP) is supported.
- WPA2 with TKIP and WPA with AES is not supported in standalone mode, local-auth in connected mode, and Cisco Centralized Key Management fast-roaming in connected mode.
- WPA with TKIP is supported in non-FIPS mode.
- Only open, WPA (PSK and 802.1x), and WPA2 (AES) authentication is supported on the Cisco Aironet 1830 Series and 1850 Series APs.
- Only 802.11r fast-transition roaming is supported on the Cisco Aironet 1830 Series and 1850 Series APs.
- AVC on locally switched WLANs is supported on second-generation APs.
- Local authentication fallback is not supported when a user is not available in the external RADIUS server.
- For WLANs configured for FlexConnect APs in local switching and local authentication, synchronization of dot11 client information is supported.
- DNS override is not supported on the Cisco Aironet 1830 Series and 1850 Series APs.
- The Cisco Aironet 1830 Series and 1850 Series APs do not support IPv6. However, a wireless client can pass IPv6 traffic across these APs.
- VLAN group is not supported in Flex mode under flex-profile.
- Configuring maximum number of allowed media streams on individual client or radio is not supported in FlexConnect mode.
- The WLAN client association limit will not work when the AP is in FlexConnect mode (connected or standalone) and is performing local switching and local authentication.
- A local switching client on FlexConnect mode will not get IP address for RLAN profile on the Cisco Aironet 1810 Series AP.
- Standard ACL is not supported on FlexConnect AP mode.
- IPv6 RADIUS Server is not configurable for FlexConnect APs. Only IPv4 configuration is supported.
- In Flex mode, IPv4 ACLs configured on WLAN gets pushed to AP but IPv6 ACLs does not.

- The client delete reason counters that are a part of the **show wireless stats client delete reasons** command, will be incremented only when the client record entry persists for join.

For example, when an AP in the FlexConnect mode performs local authentication with ACL mismatch, then the AP deletes the client, and the controller does not create any client record.

- Cisco Centralized Key Management (CCKM) is supported in wave 1 APs in FlexConnect when you use local association.
- If the client roams from one AP to another and the roaming is successful, the following occurs:
 - The client does not send any traffic to the new AP.
 - The client's state is IP LEARN pending.
 - The client is deauthenticated after 180 seconds, if there is no traffic for the entire duration. In case the DHCP Required flag is set, the deauthentication occurs after 60 seconds.
- Using custom VLANs under the policy profile of the FlexConnect locally switched WLANs stops the SSID broadcast. In such scenarios, run the **shut** and **no shut** commands on the policy profile to start the SSID broadcast.

SSIDs are broadcasted when you:

- Perform VLAN name to id mapping under FlexConnect profile and map the custom VLAN name under the policy profile.
- Use VLAN id or standard VLAN name, for example, VLANxxxx.
- In the FlexConnect mode, the group temporal key (GTK) timer is set to 3600 seconds by default on Cisco Wave 2 AP, and this value cannot be reconfigured.
- For Flex mode deployments, local association configured policy profiles are not supported at a given time on the WLAN. Only the local association command must be enabled.
- From Cisco IOS XE Amsterdam 17.1.1 release onwards, the police rate per client in the flex connect APs in the controller, is represented as **rate_out** for Ingress (input) and **rate_in** for Egress (output). To verify police rate on the flex AP, use the **show rate-limit client** command.
- FlexConnect APs do not forward the DHCP packets after Change of Authorization (CoA) and change of VLANs using 802.1X encryption. You must disconnect the client from the WLAN and reconnect the client to enable the client to get an IP address in the second VLAN.
- Cisco Wave 2 and Catalyst Wi-Fi6 APs in FlexConnect local switching mode do not support Layer2(PSK, 802.1X) + Layer3(LWA, CWA, redirection-based posturing) + Dynamic AAA override + NAC.
- In Cisco Catalyst 9136I APs, in FlexConnect local authentication, the ongoing session timeout for a client gets reset after every roam.
- Network access control (NAC) is not supported in FlexConnect local authentication.
- Multicast traffic on an AAA overridden VLAN is not supported. Using this configuration may result in potential traffic leaks between VLANs.

Configuring a Site Tag

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag site <i>site-name</i> Example: Device(config)# wireless tag site default-site-tag	Configures site tag and enters site tag configuration mode.
Step 3	flex-profile <i>flex-profile-name</i> Example: Device(config-site-tag)# flex-profile rr-xyz-flex-profile	Maps a flex profile to a site tag.
Step 4	ap-profile <i>ap-profile</i> Example: Device(config-site-tag)# ap-profile xyz-ap-profile	Assigns an AP profile to the wireless site.
Step 5	description <i>site-tag-name</i> Example: Device(config-site-tag)# description "default site tag"	Adds a description for the site tag.
Step 6	no local-site Example: Device(config-site-tag)# no local-site	Moves the access point to FlexConnect mode.
Step 7	end Example: Device(config-site-tag)# end	Saves the configuration, exits the configuration mode, and returns to privileged EXEC mode.
Step 8	show wireless tag site summary Example: Device# show wireless tag site summary	(Optional) Displays the summary of site tags.

Configuring a Policy Tag (CLI)

Follow the procedure given below to configure a policy tag:

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	wireless tag policy <i>policy-tag-name</i> Example: Device(config-policy-tag)# wireless tag policy default-policy-tag	Configures policy tag and enters policy tag configuration mode. Note When performing LWA, the clients connected to a controller gets disconnected intermittently before session timeout.
Step 4	description <i>description</i> Example: Device(config-policy-tag)# description "default-policy-tag"	Adds a description to a policy tag.
Step 5	remote-lan <i>name</i> policy <i>profile-policy-name</i> {<i>ext-module</i> <i>port-id</i> } Example: Device(config-policy-tag)# remote-lan rr-xyz-rlan-aa policy rr-xyz-rlan-policy1 port-id 2	Maps a remote-LAN profile to a policy profile.
Step 6	wlan <i>wlan-name</i> policy <i>profile-policy-name</i> Example: Device(config-policy-tag)# wlan rr-xyz-wlan-aa policy rr-xyz-policy-1	Maps a policy profile to a WLAN profile. Note Ensure that the WLAN profile is not used by any other profiles. If the AP uses the default profile, ensure that the no central switching command is configured on other profiles.
Step 7	end Example: Device(config-policy-tag)# end	Exits policy tag configuration mode, and returns to privileged EXEC mode.

	Command or Action	Purpose
Step 8	show wireless tag policy summary Example: Device# show wireless tag policy summary	(Optional) Displays the configured policy tags. Note To view detailed information about a policy tag, use the show wireless tag policy detailed policy-tag-name command.

Attaching a Policy Tag and a Site Tag to an Access Point (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
 - Step 2** Click the **Access Point** name.
 - Step 3** Go to the **Tags** section.
 - Step 4** Choose the **Policy Tag** from the **Policy** drop-down list.
 - Step 5** Choose the **Site Tag** from the **Site** drop-down list.
 - Step 6** Click **Update and Apply to Device**.
-

Attaching Policy Tag and Site Tag to an AP (CLI)

Follow the procedure given below to attach a policy tag and a site tag to an AP:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap mac-address Example: Device(config)# ap F866.F267.7DFB	Configures a Cisco AP and enters AP profile configuration mode. Note The <i>mac-address</i> should be a wired mac address.
Step 3	policy-tag policy-tag-name Example: Device(config-ap-tag)# policy-tag rr-xyz-policy-tag	Maps a policy tag to the AP.

	Command or Action	Purpose
Step 4	site-tag <i>site-tag-name</i> Example: Device(config-ap-tag)# site-tag rr-xyz-site	Maps a site tag to the AP.
Step 5	rf-tag <i>rf-tag-name</i> Example: Device(config-ap-tag)# rf-tag rf-tag1	Associates the RF tag.
Step 6	end Example: Device(config-ap-tag)# end	Saves the configuration, exits configuration mode, and returns to privileged EXEC mode.
Step 7	show ap tag summary Example: Device# show ap tag summary	(Optional) Displays AP details and the tags associated to it.
Step 8	show ap name <ap-name> tag info Example: Device# show ap name ap-name tag info	(Optional) Displays the AP name with tag information.
Step 9	show ap name <ap-name> tag detail Example: Device# show ap name ap-name tag detail	(Optional) Displays the AP name with tag details.

Linking an ACL Policy to the Defined ACL (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Flex**.
 - Step 2** Click **Add**.
 - Step 3** In the **General** tab, enter the **Name** of the Flex Profile. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
 - Step 4** In the **Policy ACL** tab, click **Add**.
 - Step 5** Select the ACL from the **ACL Name** drop-down list and click **Save**.
 - Step 6** Click **Apply to Device**.
-

Applying ACLs on FlexConnect

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex <i>flex-profile-name</i> Example: Device(config)# wireless profile flex Flex-profile-1	Configures a wireless flex profile and enters wireless flex profile configuration mode.
Step 3	acl-policy <i>acl-policy-name</i> Example: Device(config-wireless-flex-profile)# acl-policy ACL1	Configures an ACL policy. Access control lists (ACLs) perform packet filtering to control the movement of packets through a network.
Step 4	exit Example: Device(config-wireless-flex-profile-acl)# exit	Returns to wireless flex profile configuration mode.
Step 5	native-vlan-id Example: Device(config-wireless-flex-profile)# native-vlan-id 25	Configures native vlan-id information.
Step 6	vlan <i>vlan-name</i> Example: Device(config-wireless-flex-profile)# vlan-name VLAN0169	Configures a VLAN.
Step 7	acl <i>acl-name</i> Example: Device(config-wireless-flex-profile-vlan)# acl ACL1	Configures an ACL for the interface.
Step 8	vlan-id <i>vlan-id</i> Example: Device(config-wireless-flex-profile-vlan)# vlan-id 169	Configures VLAN information.

Configuring FlexConnect

Configuring a Switch at a Remote Site

Procedure

- Step 1** Attach the access point, which will be enabled for FlexConnect, to a trunk or access port on the switch.
- Note** The sample configuration in this procedure shows the FlexConnect access point connected to a trunk port on the switch.
- Step 2** The following example configuration shows you how to configure a switch to support a FlexConnect access point.
- In this sample configuration, the FlexConnect access point is connected to the trunk interface FastEthernet 1/0/2 with native VLAN 100. The access point needs IP connectivity on the native VLAN. The remote site has local servers or resources on VLAN 101. A DHCP pool is created in the local switch for both the VLANs in the switch. The first DHCP pool (NATIVE) is used by the FlexConnect access point, and the second DHCP pool (LOCAL-SWITCH) is used by the clients when they associate to a WLAN that is locally switched.

```
.
.
.
ip dhcp pool NATIVE
  network 209.165.200.224 255.255.255.224

Configuring the Controller for FlexConnect

You can configure the controller for FlexConnect in two environments:

- Centrally switched WLAN
- Locally switched WLAN

The controller configuration for FlexConnect consists of creating centrally switched and locally switched WLANs. This table shows three WLAN scenarios.

Table 26: WLAN Scenarios

WLAN	Security	Authentication	Switching	Interface Mapping (GUEST VLAN)
Employee	WPA1+WPA2	Central	Central	Management (centrally switched GUEST VLAN)
Employee-local	WPA1+WPA2 (PSK)	Local	Local	101 (locally switched GUEST VLAN)
Guest-central	Web authentication	Central	Central	Management (centrally switched GUEST VLAN)
Employee-local-auth	WPA1+WPA2	Local	Local	101 (locally switched VLAN)

Configuring Local Switching in FlexConnect Mode (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Policy**.
 - Step 2** On the **Policy Profile** page, click the name of a policy profile to edit it or click **Add** to create a new one.
 - Step 3** In the **Add/Edit Policy Profile** window that is displayed, uncheck the **Central Switching** check box.
 - Step 4** Click **Update & Apply to Device**.
-

Configuring Local Switching in FlexConnect Mode (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy rr-xyz-policy-1	Configures WLAN policy profile and enters the wireless policy configuration mode.
Step 3	no central switching Example: Device(config-wireless-policy)# no central switching	Configures the WLAN for local switching.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Central Switching in FlexConnect Mode (GUI)

Before you begin

Ensure that the policy profile is configured. If the policy profile is not configured, see *Configuring a Policy Profile (GUI)* section.

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Policy**.
 - Step 2** On the **Policy Profile** page, select a policy.
 - Step 3** In the **Edit Policy Profile** window, in General Tab, use the slider to enable or disable **Central Switching**.
 - Step 4** Click **Update & Apply to Device**.
-

Configuring Central Switching in FlexConnect Mode

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# <code>wireless profile policy rr-xyz-policy-1</code>	Configures WLAN policy profile and enters the wireless policy configuration mode.
Step 3	central switching Example: Device(config-wireless-policy)# <code>central switching</code>	Configures the WLAN for central switching.
Step 4	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring an Access Point for FlexConnect

For more information, see *Configuring a Site Tag (CLI)* topic in New Configuration Model chapter.

Configuring an Access Point for Local Authentication on a WLAN (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Policy**.
 - Step 2** In the **Policy Profile** page, select a policy profile name. The **Edit Policy Profile** window is displayed.
 - Step 3** In the General tab, deselect **Central Authentication** check box.
 - Step 4** Click **Update & Apply to Device**.
-

Configuring an Access Point for Local Authentication on a WLAN (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# <code>wireless profile policy rr-xyz-policy-1</code>	Configures WLAN policy profile and enters the wireless policy configuration mode.
Step 3	no central authentication Example: Device(config-wireless-policy)# <code>no central authentication</code>	Configures the WLAN for local authentication.
Step 4	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Connecting Client Devices to WLANs

Follow the instructions for your client device to create profiles to connect to the WLANs you created, as specified in the [#unique_414](#).

In the example scenarios (see [#unique_414](#)), there are three profiles on the client:

1. To connect to the *employee* WLAN, create a client profile that uses WPA or WPA2 with PEAP-MSCHAPV2 authentication. After the client is authenticated, the client is allotted an IP address by the management VLAN of the controller.
2. To connect to the *local-employee* WLAN, create a client profile that uses WPA or WPA2 authentication. After the client is authenticated, the client is allotted an IP address by VLAN 101 on the local switch.
3. To connect to the *guest-central* WLAN, create a client profile that uses open authentication. After the client is authenticated, the client is allocated an IP address by VLAN 101 on the network local to the access point. After the client connects, a local user can enter any HTTP address in the web browser. The user is automatically directed to the controller to complete the web authentication process. When the web login window appears, the user should enter the username and password.

Configuring FlexConnect Ethernet Fallback

Information About FlexConnect Ethernet Fallback

You can configure an AP to shut down its radio when the Ethernet link is not operational. When the Ethernet link comes back to operational state, you can configure the AP to set its radio back to operational state. This feature is independent of the AP being in connected or standalone mode. When the radios are shut down, the AP does not broadcast the WLANs, and therefore, the clients cannot connect to the AP, either through first association or through roaming.

Configuring FlexConnect Ethernet Fallback

Before you begin

This feature is not applicable to APs with multiple ports.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex <i>flex-profile-name</i> Example: Device(config)# wireless profile flex test	Configures a wireless flex profile and enters wireless flex profile configuration mode.
Step 3	fallback-radio-shut Example: Device(config-wireless-flex-profile)# fallback-radio-shut	Enables radio interface shutdown.
Step 4	end Example: Device(config-wireless-flex-profile)# end	Exits configuration mode and returns to privileged EXEC mode.
Step 5	show wireless profile flex detailed <i>flex-profile-name</i> Example: Device# show wireless profile flex detailed test	(Optional) Displays detailed information about the selected profile.

Flex AP Local Authentication (GUI)

Procedure

Step 1 Choose **Configuration** > **Tags & Profiles** > **Flex**.

Step 2 In the **Flex** page, click the name of the **Flex Profile** or click **Add** to create a new one.

Step 3 In the **Add/Edit Flex Profile** window that is displayed, click the **Local Authentication** tab.

When local authentication and association is enabled in Access Point with Flex mode, the following occurs:

- AP handles the authentication.
- AP handles the rejection of client joins (in Mobility).

Note The controller does not increment statistics when AP rejects client association.

Step 4 Choose the server group from the **RADIUS Server Group** drop-down list.

Step 5 Use the **Local Accounting RADIUS Server Group** drop down to select the RADIUS server group.

Step 6 Check the **Local Client Roaming** check box to enable client roaming.

Step 7 Choose the profile from the **EAP Fast Profile** drop-down list.

Step 8 Choose to enable or disable the following:

- LEAP: Lightweight Extensible Authentication Protocol (LEAP) is an 802.1X authentication type for wireless LANs and supports strong mutual authentication between the client and a RADIUS server using a logon password as the shared secret. It provides dynamic per-user, per-session encryption keys.
- PEAP: Protected Extensible Authentication Protocol (PEAP) is a protocol that encapsulates the Extensible Authentication Protocol (EAP) within an encrypted and authenticated Transport Layer Security (TLS) tunnel.
- TLS: Transport Layer Security (TLS) is a cryptographic protocol that provide communications security over a computer network.
- RADIUS: Remote Authentication Dial-In User Service (RADIUS) is a networking protocol that provides centralized Authentication, Authorization, and Accounting (AAA or Triple A) management for users who connect and use a network service.

Step 9 In the **Users** section, click **Add**.

Step 10 Enter username and password details and click **Save**.

Step 11 Click **Save & Apply to Device**.

Flex AP Local Authentication (CLI)

Note The Cisco Catalyst 9800 Series Wireless Controller + FlexConnect local authentication + AP acting as RADIUS are not supported on Cisco COS and IOS APs.

Procedure

	Command or Action	Purpose
Step 1	aaa new-model Example: Device(config)# aaa new-model	Creates a AAA authentication model.
Step 2	aaa session-id common Example: Device(config)# aaa session-id common	Ensures that all the session IDs information that is sent out from the RADIUS group for a given call are identical.
Step 3	dot1x system-auth-control Example: Device(config)# dot1x system-auth-control	Enables system authorization control for the RADIUS group.
Step 4	eap profile name Example: Device(config)# eap profile aplocal-test	Creates an EAP profile.
Step 5	method fast Example: Device(config-eap-profile)# method fast	Configures the FAST method on the profile.
Step 6	exit Example: Device(config-radius-server)# exit	Returns to configuration mode.
Step 7	wireless profile flex flex-profile Example: Device(config)# wireless profile flex default-flex-profile	Configures the flex policy.
Step 8	local-auth ap eap-fast name Example: Device(config-wireless-flex-profile)# local-auth ap eap-fast aplocal-test	Configures EAP-FAST profile details.

	Command or Action	Purpose
Step 9	local-auth ap leap Example: Device(config-wireless-flex-profile)# local-auth ap leap	Configures the LEAP method.
Step 10	local-auth ap peap Example: Device(config-wireless-flex-profile)# local-auth ap peap	Configures the PEAP method.
Step 11	local-auth ap username <i>username</i> Example: Device(config-wireless-flex-profile)# local-auth ap username test1 test1	Configures username and password.
Step 12	local-auth ap username <i>username password</i> Example: Device(config-wireless-flex-profile)# local-auth ap username test2 test2	Configures another username and password.
Step 13	exit Example: Device(config-wireless-flex-profile)# exit	Returns to configuration mode.
Step 14	wireless profile policy <i>policy-profile</i> Example: Device(config)# wireless profile policy default-policy-profile	Configures profile policy.
Step 15	shutdown Example: Device(config-wireless-policy)# shutdown	Disables the policy profile.
Step 16	no central authentication Example: Device(config)# no central authentication	Disables central (controller) authentication.
Step 17	vlan-id <i>vlan-id</i> Example: Device(config)# vlan-id 54	Configures VLAN name or VLAN ID.
Step 18	no shutdown Example: Device(config)# no shutdown	Enables the configuration.

Flex AP Local Authentication with External Radius Server

In this mode, an access point handles client authentication and switches client data packets locally. This state is valid in standalone mode and connected mode.

Procedure

	Command or Action	Purpose
Step 1	aaa new-model Example: Device(config)# aaa new-model	Creates a AAA authentication model.
Step 2	aaa session-id common Example: Device(config)# aaa session-id common	Ensures that all the session ID's information that is sent out, from the RADIUS group for a given call are identical.
Step 3	dot1x system-auth-control Example: Device(config)# dot1x system-auth-control	Enables the system authorization control for the RADIUS group.
Step 4	radius server <i>server-name</i> Example: Device(config)# radius server Test-SERVER1	Specifies the RADIUS server name. Note To authenticate clients with freeradius over RADSEC, you should generate an RSA key longer than 1024 bit. Use the crypto key generate rsa general-keys exportable label <i>name</i> command to achieve this. Do not configure key-wrap option under the radius server and radius server group, as it may lead to clients getting stuck in authentication state.
Step 5	address {ipv4 ipv6} <i>ip address</i> {auth-port <i>port-number</i> acct-port <i>port-number</i> } Example: Device(config-radius-server)# address ipv4 124.3.50.62 auth-port 1112 acct-port 1113 Device(config-radius-server)# address ipv6 2001:DB8:0:20::15 auth-port 1812 acct-port 1813	Specifies the primary RADIUS server parameters.

	Command or Action	Purpose
Step 6	key string Example: <pre>Device(config-radius-server)# key test123</pre>	Specifies the authentication and encryption key used between the device and the RADIUS daemon running on the RADIUS server. Note The maximum number of characters allowed for the shared secret is 63.
Step 7	radius server server-name Example: <pre>Device(config)# radius server Test-SERVER2</pre>	Specifies the RADIUS server name.
Step 8	address {ipv4 ipv6} ip address {auth-port port-number acct-port port-number } Example: <pre>Device(config-radius-server)# address ipv4 124.3.52.62 auth-port 1112 acct-port 1113 Device(config-radius-server)# address ipv6 2001:DB8:0:21::15 auth-port 1812 acct-port 1813</pre>	Specifies the secondary RADIUS server parameters.
Step 9	key string Example: <pre>Device(config-radius-server)# key test113</pre>	Specifies the authentication and encryption key used between the device and the RADIUS daemon running on the RADIUS server.
Step 10	exit Example: <pre>Device(config-radius-server)# exit</pre>	Returns to configuration mode.
Step 11	aaa group server radius server-group Example: <pre>Device(config)# aaa group server radius aaa_group_name</pre>	Creates a RADIUS server group identification. Note <i>server-group</i> refers to the server group name. The valid range is from 1 to 32 alphanumeric characters.
Step 12	radius server server-name Example: <pre>Device(config)# radius server Test-SERVER1</pre>	Specifies the RADIUS server name.
Step 13	radius server server-name Example: <pre>Device(config-radius-server)# radius server Test-SERVER2</pre>	Specifies the RADIUS server name.

	Command or Action	Purpose
Step 14	exit Example: Device(config-radius-server)# exit	Exit from RADIUS server configuration mode.
Step 15	wireless profile flex <i>flex-profile</i> Example: Device(config)# wireless profile flex default-flex-profile	Creates a new flex policy.
Step 16	local-auth radius-server-group <i>server-group</i> Example: Device(config-wireless-flex-profile)# local-auth radius-server-group aaa_group_name	Configures the authentication server group name.
Step 17	exit Example: Device(config-wireless-flex-profile)# exit	Returns to configuration mode.
Step 18	wireless profile policy <i>policy-profile</i> Example: Device(config)# wireless profile policy default-policy-profile	Configures a WLAN policy profile.
Step 19	shutdown Example: Device(config-wireless-policy)# shutdown	Disables a policy profile.
Step 20	no central authentication Example: Device(config-wireless-policy)# no central authentication	Disables central (controller) authentication.
Step 21	vlan-id <i>vlan-id</i> Example: Device(config-wireless-policy)# vlan-id 54	Configures a VLAN name or VLAN Id.
Step 22	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables the configuration.

Configuration Example: FlexConnect with Central and Local Authentication

To see configuration example on how to configure a controller for FlexConnect central and local authentication, see the [FlexConnect Configuration with Central and Local Authentication on Catalyst 9800 Wireless Controllers](#) document.

NAT-PAT for FlexConnect

If you want to use a central DHCP server to service clients across remote sites, NAT-PAT should be enabled. An AP translates the traffic coming from a client and replaces the client's IP address with its own IP address.

Note You must enable local switching, central DHCP, and DHCP required using the (**ipv4 dhcp required**) command to enable NAT and PAT.

Configuring NAT-PAT for a WLAN or a Remote LAN

Creating a WLAN

Follow the steps given here to create a WLAN.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan wlan-name wlan-id SSID-name Example: Device(config)# wlan wlan-demo 1 ssid-demo	Enters the WLAN configuration sub-mode. <ul style="list-style-type: none"> • <i>wlan-name</i>—Enter the profile name. The range is from 1 to 32 alphanumeric characters. • <i>wlan-id</i>—Enter the WLAN ID. The range is from 1 to 512. • <i>SSID-name</i>—Enter the Service Set Identifier (SSID) for this WLAN. If the SSID is not specified, the WLAN profile name is set as the SSID.

	Command or Action	Purpose
		Note If you have already configured WLAN, enter <code>wlan wlan-name</code> command.
Step 3	no shutdown Example: <code>Device(config-wlan)# no shutdown</code>	Shut down the WLAN.
Step 4	end Example: <code>Device(config-wlan)# end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring a Wireless Profile Policy and NAT-PAT (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Policy**.
 - Step 2** Click **Add**.
 - Step 3** In the **General** tab, enter the **Name** of the policy.
 - Step 4** Disable the **Central Switching** toggle button.
 - Step 5** Enable the **Central DHCP** toggle button.
 - Step 6** Enable the **Flex NAT/PAT** toggle button.
 - Step 7** In the **Advanced** tab, under the **DHCP Settings**, check the **IPv4 DHCP Required** check box.
 - Step 8** Click **Apply to Device**.
-

Configuring a Wireless Profile Policy and NAT-PAT

Follow the procedure given below to configure a wireless profile policy and NAT-PAT:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: <code>Device# configure terminal</code>	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: <code>Device(config)# wireless profile policy nat-enabled-policy</code>	Configures the policy profile for NAT.

	Command or Action	Purpose
Step 3	no central switching Example: Device(config-wireless-policy)# no central switching	Configures the WLAN for local switching.
Step 4	ipv4 dhcp required Example: Device(config-wireless-policy)# ipv4 dhcp required	Configures the DHCP parameters for WLAN.
Step 5	central dhcp Example: Device(config-wireless-policy)# central dhcp	Configures the central DHCP for locally switched clients.
Step 6	flex nat-pat Example: Device(config-wireless-policy)# flex nat-pat	Enables NAT-PAT.
Step 7	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables policy profile.
Step 8	end Example: Device(config-wireless-policy)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Mapping a WLAN to a Policy Profile

Follow the procedure given below to map a WLAN to a policy profile:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag policy <i>policy-tag-name</i> Example: Device(config)# wireless tag policy demo-tag	Configures a policy tag and enters policy tag configuration mode.

	Command or Action	Purpose
Step 3	wlan <i>wlan-name</i> policy <i>profile-policy-name</i> Example: Device(config-policy-tag)# wlan wlan-demo policy nat-enabled-policy	Maps a policy profile to a WLAN profile.
Step 4	end Example: Device(config-policy-tag)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring a Site Tag

Follow the procedure given below to configure a site tag:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag site <i>site-name</i> Example: Device(config)# wireless tag site flex-site	Configures a site tag and enters site tag configuration mode.
Step 3	no local-site Example: Device(config-site-tag)# no local-site	Moves an access point to FlexConnect mode.
Step 4	end Example: Device(config-site-tag)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Attaching a Policy Tag and a Site Tag to an Access Point (GUI)

Procedure

- Step 1** Choose **Configuration > Wireless > Access Points**.
- Step 2** Click the **Access Point** name.
- Step 3** Go to the **Tags** section.
- Step 4** Choose the **Policy Tag** from the **Policy** drop-down list.
- Step 5** Choose the **Site Tag** from the **Site** drop-down list.

Step 6 Click **Update and Apply to Device**.

Attaching a Policy Tag and a Site Tag to an Access Point

Follow the procedure given below to attach a policy tag and a site tag to an access point:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap mac-address Example: Device(config)# ap F866.F267.7DFB	Configures Cisco APs and enters ap-tag configuration mode.
Step 3	policy-tag policy-tag-name Example: Device(config-ap-tag)# policy-tag demo-tag	Maps a policy tag to the AP.
Step 4	site-tag site-tag-name Example: Device(config-ap-tag)# site-tag flex-site	Maps a site tag to the AP.
Step 5	end Example: Device(config-ap-tag)# end	Returns to privileged EXEC mode.

Split Tunneling for FlexConnect

If a client that connects over a WAN link that is associated with a centrally switched WLAN has to send traffic to a device present in the local site, this traffic should be sent over CAPWAP to the controller, and the same traffic is sent back to the local site either over CAPWAP or with the help of some off-band connectivity.

This process consumes WAN link bandwidth unnecessarily. To avoid this, you can use the Split Tunneling feature, which allows the traffic sent by a client to be classified based on the packet contents. The matching packets are locally switched and the rest of the traffic is centrally switched. The traffic that is sent by the client that matches the IP address of the device present in the local site can be classified as locally switched traffic, and the rest of the traffic as centrally switched.

To configure local split tunneling on an AP, ensure that you have enabled DHCP Required on the policy profile using the (**ipv4 dhcp required**) command. This ensures that the client that is associating with the split WLAN does DHCP.

Note Apple iOS clients need option 6 (DNS) to be set in DHCP offer for split tunneling to work.

- Note**
- FlexConnect split tunneling (vlan-based central switching for FlexConnect) on auto-anchor deployment is not supported.
 - Split tunneling does not work on RLAN clients. When the **split-tunnel** option is enabled on RLAN, traffic denied by the split tunnel ACL is not translated based on the IP address, instead the traffic is sent back to the controller through CAPWAP.
 - URL filter must not be configured with wildcard URLs such as * and *.*
-

Configuring Split Tunneling for a WLAN or Remote LAN

Defining an Access Control List for Split Tunneling (GUI)

Procedure

- Step 1** Choose **Configuration > Security > ACL**.
- Step 2** Click **Add**.
- Step 3** In the **Add ACL Setup** dialog box, enter the **ACL Name**.
- Step 4** Choose the ACL type from the **ACL Type** drop-down list.
- Step 5** Under the **Rules** settings, enter the **Sequence** number and choose the **Action** as either **permit** or **deny**.
- Step 6** Choose the required source type from the **Source Type** drop-down list.
- a) If you choose the source type as **Host**, then you must enter the **Host Name/IP**.
 - b) If you choose the source type as **Network**, then you must specify the **Source IP** address and **Source Wildcard** mask.
- Step 7** Check the **Log** check box if you want the logs.
- Step 8** Click **Add**.
- Step 9** Add the rest of the rules and click **Apply to Device**.
-

Defining an Access Control List for Split Tunneling

Follow the procedure given below to define an Access Control List (ACL) for split tunneling:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ip access-list extended <i>name</i> Example: Device(config)# ip access-list extended split_mac_acl	Defines an extended IPv4 access list using a name, and enters access-list configuration mode.
Step 3	deny ip any host <i>hostname</i> Example: Device(config-ext-nacl)# deny ip any host 9.9.2.21	Allows the traffic to switch centrally.
Step 4	permit ip any any Example: Device(config-ext-nacl)# permit ip any any	Allows the traffic to switch locally.
Step 5	end Example: Device(config-ext-nacl)# end	Exits configuration mode and returns to privileged EXEC mode.

Linking an ACL Policy to the Defined ACL

Follow the procedure given below to link an ACL policy to the defined ACL:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex <i>flex-profile</i> Example: Device(config)# wireless profile flex flex-profile	Configures the Flex profile and enters flex profile configuration mode.
Step 3	acl-policy <i>acl policy name</i> Example: Device(config-wireless-flex-profile)# acl-policy split_mac_acl	Configures an ACL policy for the defined ACL.

	Command or Action	Purpose
Step 4	end Example: Device(config-wireless-flex-profile)# end	Exits configuration mode and returns to privileged EXEC mode.

Creating a WLAN

Follow the procedure given below to create a WLAN.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan wlan-name wlan-id SSID-name Example: Device(config)# wlan wlan-demo 1 ssid-demo	Specifies the WLAN name and ID: <ul style="list-style-type: none"> • <i>wlan-name</i>—Enter the profile name. The range is from 1 to 32 alphanumeric characters. • <i>wlan-id</i>—Enter the WLAN ID. The range is from 1 to 512. • <i>SSID-name</i>—Enter the Service Set Identifier (SSID) for this WLAN. If the SSID is not specified, the WLAN profile name is set as the SSID.
Step 3	no shutdown Example: Device(config-wlan)# no shutdown	Enables the WLAN.
Step 4	end Example: Device(config-wlan)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring a Wireless Profile Policy and a Split MAC ACL Name (GUI)

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > Policy**.
- Step 2** Click **Add**.
- Step 3** In the **General** tab, enter the **Name** of the policy.

- Step 4** Enable the **Central Switching** toggle button.
- Step 5** Enable the **Central DHCP** toggle button.
- Step 6** In the **Advanced** tab, under the **DHCP** settings, check the **IPv4 DHCP Required** check box and enter the **DHCP Server IP Address**.
- Step 7** Under the **WLAN Flex Policy** settings, choose the split MAC ACL from the **Split MAC ACL** drop-down list.
- Step 8** Click **Apply to Device**.

Configuring a Wireless Profile Policy and a Split MAC ACL Name

Follow the procedure given below to configure a wireless profile policy and a split MAC ACL name:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy split-tunnel-enabled-policy	Configures a WLAN policy profile and enters wireless policy configuration mode.
Step 3	flex split-mac-acl <i>split-mac-acl-name</i> Example: Device(config-wireless-policy)# flex split-mac-acl split_mac_acl	Configures a split MAC ACL name. Note You should use the same ACL name for linking the flex and the policy profile.
Step 4	central switching Example: Device(config-wireless-policy)# central switching	Configures WLAN for central switching.
Step 5	central dhcp Example: Device(config-wireless-policy)# central dhcp	Enables central DHCP for centrally switched clients.
Step 6	ipv4 dhcp required Example: Device(config-wireless-policy)# ipv4 dhcp required	Configures the DHCP parameters for a WLAN.
Step 7	ipv4 dhcp server <i>ip_address</i> Example:	Configures the override IP address of the DHCP server.

	Command or Action	Purpose
	Device(config-wireless-policy)# ipv4 dhcp server 9.1.0.100	
Step 8	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables a policy profile.

Mapping a WLAN to a Policy Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Tags**.
 - Step 2** Click **Add**.
 - Step 3** Enter the **Name** of the Tag Policy.
 - Step 4** Under **WLAN-POLICY Maps** tab, click **Add** .
 - Step 5** Choose the WLAN Profile from the **WLAN Profile** drop-down list.
 - Step 6** Choose the Policy Profile from the **Policy Profile** drop-down list.
 - Step 7** Click the **Tick** Icon .
 - Step 8** Click **Apply to Device**.
-

Mapping WLAN to a Policy Profile

Follow the procedure given below to map WLAN to a policy profile.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag policy <i>policy-tag-name</i> Example: Device(config)# wireless tag policy split-tunnel-enabled-tag	Configures a policy tag and enters policy tag configuration mode.
Step 3	wlan <i>wlan-name</i> policy <i>profile-policy-name</i> Example: Device(config-policy-tag)# wlan wlan-demo policy split-tunnel-enabled-policy	Maps a policy profile to a WLAN profile.

	Command or Action	Purpose
Step 4	end Example: Device(config-policy-tag)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring a Site Tag

Follow the procedure given below to configure a site tag:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag site <i>site-name</i> Example: Device(config)# wireless tag site flex-site	Configures a site tag and enters site tag configuration mode.
Step 3	no local-site Example: Device(config-site-tag)# no local-site	Local site is not configured on the site tag.
Step 4	flex-profile <i>flex-profile-name</i> Example: Device(config-site-tag)# flex-profile flex-profile	Configures a flex profile.
Step 5	end Example: Device(config-site-tag)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Attaching a Policy Tag and Site Tag to an Access Point

Follow the procedure given below to attach a policy tag and site tag to an access point.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	ap <i>ethernet-mac-address</i> Example: Device(config)# ap 188b.9dbe.6eac	Configures an AP and enters ap tag configuration mode.
Step 3	policy-tag <i>policy-tag-name</i> Example: Device(config-ap-tag)# policy-tag split-tunnel-enabled-tag	Maps a policy tag to an AP.
Step 4	site-tag <i>site-tag-name</i> Example: Device(config-ap-tag)# site-tag flex-site	Maps a site tag to an AP.
Step 5	end Example: Device(config-ap-tag)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

VLAN-based Central Switching for FlexConnect

In FlexConnect local switching, if the VLAN definition is not available in an access point, the corresponding client does not pass traffic. This scenario is applicable when the AAA server returns the VLAN as part of client authentication.

When a WLAN is locally switched in flex and a VLAN is configured on the AP side, the traffic is switched locally. When a VLAN is not defined in an AP, the VLAN drops the packet.

When VLAN-based central switching is enabled, the corresponding AP tunnels the traffic back to the controller. The controller then forwards the traffic to its corresponding VLAN.

Note

- For VLAN-based central switching, ensure that VLAN is defined on the controller.
- VLAN-based central switching is not supported by mac filter.
- For local switching, ensure that VLAN is defined on the policy profile and FlexConnect profile.
- VLAN-based central switching with central web authentication enabled in Flex profile is not supported.

Configuring VLAN-based Central Switching (GUI)

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > Policy**.

- Step 2** Click the name of the policy profile.
- Step 3** In the **Edit Policy Profile** window, perform these tasks:
- Set **Central Switching** to **Disabled** state.
 - Set **Central DHCP** to **Disabled** state.
 - Set **Central Authentication** to **Enabled** state.
- Step 4** Click the **Advanced** tab.
- Step 5** Under **AAA Policy**, check the **Allow AAA Override** check box to enable AAA override.
- Step 6** Under **WLAN Flex Policy**, check the **VLAN Central Switching** check box, to enable VLAN-based central switching on the policy profile.
- Step 7** Click **Update & Apply to Device**.

Configuring VLAN-based Central Switching (CLI)

Follow the procedure given below to configure VLAN-based central switching.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy default-policy-profile	Configures a wireless policy profile.
Step 3	no central switching Example: Device(config-wireless-policy)# no central switching	Configures a WLAN for local switching.
Step 4	no central dhcp Example: Device(config-wireless-policy)# no central dhcp	Configures local DHCP mode, where the DHCP is performed in an AP.
Step 5	central authentication Example: Device(config-wireless-policy)# central authentication	Configures a WLAN for central authentication.
Step 6	aaa-override Example:	Configures AAA policy override.

	Command or Action	Purpose
	<code>Device(config-wireless-policy)# aaa-override</code>	
Step 7	flex vlan-central-switching Example: <code>Device(config-wireless-policy)# flex vlan-central-switching</code>	Configures VLAN-based central switching.
Step 8	end Example: <code>Device(config-wireless-policy)# end</code>	Returns to privileged EXEC mode.
Step 9	show wireless profile policy detailed default-policy-profile Example: <code>Device# show wireless profile policy detailed default-policy-profile</code>	(Optional) Displays detailed information of the policy profile.

OfficeExtend Access Points for FlexConnect

A Cisco OfficeExtend access point (OEAP) provides secure communications from a controller to a Cisco AP at a remote location, seamlessly extending the corporate WLAN over the Internet to an employee's residence. A user's experience at the home office is exactly the same as it would be at the corporate office. Datagram Transport Layer Security (DTLS) encryption between an access point and the controller ensures that all communications have the highest level of security.

Note Preconfigure the controller IP for a zero-touch deployment with OEAP. All other home users can use the same access point to connect for home use by configuring the local SSID from AP.

Note In releases prior to Cisco IOS XE Amsterdam 17.3.2, when an AP is converted to OEAP, the local DHCP server on the AP is enabled by default. If the DHCP server on home router has a similar configuration, a network conflict occurs and AP will not be able to join back to the controller. In such a scenario, we recommend that you change the default DHCP server on the Cisco AP using OEAP GUI.

Note For OEAP, when configuration changes are made from the OEAP GUI to the following: Radio Status, Radio Interface Status, 802.11 n-mode, 802.11 ac-mode, Bandwidth, and Channel Selection (2.4 GHz or 5 GHz), CAPWAP should be restarted for the configuration sync to take place between the AP and the controller. During this interval, the AP GUI may not respond until the AP rejoins the controller. We recommend that you wait for the AP to rejoin the controller (for about 1-2 minutes), before you make further changes from the OEAP GUI.

Note In Cisco OfficeExtend access point (Cisco OEAP), if the OEAP local DHCP server is enabled and the user configures DNS IP from OEAP GUI, the wireless and wired clients connected to Cisco OEAP will receive that IP as DNS server IP in DHCP ACK.

Configuring OfficeExtend Access Points

Follow the procedure given below to configure OfficeExtend access points.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex <i>flex-profile-name</i> Example: Device(config)# wireless profile flex test	Configures a wireless flex profile and enters wireless flex profile configuration mode.
Step 3	office-extend Example: Device(config-wireless-flex-profile)# office-extend	Enables the OfficeExtend AP mode for a FlexConnect AP.
Step 4	end Example: Device(config-wireless-flex-profile)# end	Exits configuration mode and returns to privileged EXEC mode. Note After creating a flex profile, ensure that OEAP is in flex connect mode and mapped to its corresponding site tag. OfficeExtend is disabled by default. To clear the access point's configuration and return it to the factory-defaults, use the clear ap config cisco-ap command.

Disabling OfficeExtend Access Point

Follow the procedure given below to disable an OfficeExtend access point.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex <i>flex-profile-name</i> Example: Device(config)# wireless profile flex test	Configures a wireless flex profile and enters wireless flex profile configuration mode.
Step 3	no office-extend Example: Device(config-wireless-flex-profile)# no office-extend	Disables OfficeExtend AP mode for a FlexConnect AP.
Step 4	end Example: Device(config-wireless-flex-profile)# end	Exits configuration mode and returns to privileged EXEC mode.

Support for OEAP Personal SSID

Information About OEAP Personal SSID Support

The Cisco OfficeExtend Access Point supports personal SSID. This enables a local home client to use the same OfficeExtend Access Point for local networking and internet connectivity. With the help of the OEAP personal SSID feature, you can enable or disable personal SSID, enable or disable Datagram Transport Layer Security (DTLS) encryption between an access point and the controller, and enable rogue detection, using the knobs that are present on the AP profile page in the GUI. The local network access and DTLS encryption are enabled by default. The configurations described in this chapter is applicable for OEAP or for APs in the OEAP mode.

Configuring OEAP Personal SSID (GUI)

Procedure

-
- Step 1** Choose **Configuration > AP Tags & Profiles > AP Join**.
- The **AP Join Profile** section displays all the AP Join profiles.
- Step 2** To edit the configuration details of an AP Join profile, select APs in the OEAP mode. The **Edit AP Join Profile** window is displayed.
- Step 3** In the **General** tab, under the **OfficeExtend AP Configuration** section, configure the following:
- Check the **Local Access** check box to enable the local network. By default, **Local Access** is enabled. After the AP joins the controller using AP join profile where local access is enabled, the AP will not

broadcast the default personal SSID. Since the local access is enabled, you can login to the AP GUI and configure the personal SSID.

- b) Check the **Link Encryption** check box to enable data DTLS. By default, **Link Encryption** is enabled.
- c) Check the **Rogue Detection** check box to enable rogue detection. Rogue detection is disabled by default for OfficeExtend APs because these APs, deployed in a home environment, are likely to detect a large number of rogue devices.

Configuring OEAP Personal SSID (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# ap profile <i>ap-profile</i>	Configures an AP profile and enters the AP profile configuration mode.
Step 3	[no] oead local-access Example: Device(config-ap-profile)# oead local-access	Enables the local access to AP. Local access consist of local AP GUI, LAN ports and personal SSID. The no form of this command disables the feature. If the local access is disabled, you will not be able to access the AP GUI, the local LAN port will be disabled, and personal SSID will not be broadcasted.
Step 4	[no] oead link-encryption Example: Device(config-ap-profile)# oead link-encryption	Enables DTLS encryption for OEAP APs or APs moving to the OEAP mode. The no form of this command disables the feature. This feature is enabled by default.
Step 5	[no] oead rogue-detection Example: Device(config-ap-profile)# no oead rogue-detection	Enables OEAP DTLS encryption in the AP profile configuration mode. This feature is disabled by default.

Viewing OEAP Personal SSID Configuration

To view the OEAP personal SSID configuration, run the following command.

```
Device# show ap profile name default-ap-profile detailed
.
.
.
OEAP Mode Config
Link Encryption : ENABLED
```

```
Rogue Detection : DISABLED
Local Access : ENABLED
```

Clearing Personal SSID from an OfficeExtend Access Point

To clear the personal SSID from an access point, run the following command:

```
ap name Cisco_AP clear-personal-ssid
```

Example: Viewing OfficeExtend Configuration

This example displays an OfficeExtend configuration:

```
Device# show ap config general

Cisco AP Name      : ap_name

Proxy ARP

Proxy address resolution protocol (ARP) is the most common method for learning about MAC address through a proxy device. Enabling Proxy ARP known as ARP caching in Cisco Catalyst 9800 Series Wireless Controller means that the AP owning client is the destination of the ARP request, replies on behalf of that client and therefore does not send the ARP request to the client over the air. Access points not owning the destination client and receiving an ARP request through their wired connection will drop the ARP request. When the ARP caching is disabled, the APs bridge the ARP requests from wired-to-wireless and vice-versa increasing the air time usage and broadcasts over wireless.

The AP acts as an ARP proxy to respond to ARP requests on behalf of the wireless clients.

Enabling Proxy ARP for FlexConnect APs (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Flex**.
 - Step 2** Click **Add**.
 - Step 3** In the **General** tab, enter the **Name** of the Flex Profile and check the **ARP Caching** check box. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
 - Step 4** Click **Apply to Device**.
-

Enabling Proxy ARP for FlexConnect APs

Follow the procedure given below to configure proxy ARP for FlexConnect APs.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex flex-policy Example: Device(config)# wireless profile flex flex-test	Configures WLAN policy profile and enters wireless flex profile configuration mode.
Step 3	arp-caching Example: Device(config-wireless-flex-profile)# arp-caching	Enables ARP caching. Note Use the no arp-caching command to disable ARP caching.

	Command or Action	Purpose
Step 4	end Example: Device(config-wireless-flex-profile)# end	Returns to privileged EXEC mode.
Step 5	show running-config section wireless profile flex Example: Device# show running-config section wireless profile flex	Displays ARP configuration information.
Step 6	show wireless profile flex detailed <i>flex-profile-name</i> Example: Device# show wireless profile flex detailed flex-test	(Optional) Displays detailed information of the flex profile.
Step 7	show arp summary Example: Device# show arp summary	(Optional) Displays ARP summary.

Overlapping Client IP Address in Flex Deployment

Overview of Overlapping Client IP Address in Flex Deployment

In flex deployments, you can use cookie cutter configuration across sites and branches which also includes local DHCP servers configured with the same subnet. In this topology, controllers detect multiple client sessions with the same IP as IP THEFT and clients are put in blocked list.

The Overlapping Client IP Address in Flex Deployment feature offers overlapping IP address across various flex sites and provides all the functionalities that are supported in flex deployments.

Enabling Overlapping Client IP Address in Flex Deployment (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Flex** and click **Add**.
 - Step 2** On the **Add Flex Profile** window and **General** tab.
 - Step 3** Check the **IP Overlap** check box to enable overlapping client IP Address in Flex deployment.
 - Step 4** Click **Apply to Device**.
-

Enabling Overlapping Client IP Address in Flex Deployment

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex <i>flex-profile</i> Example: Device(config)# wireless profile flex flex1	Configures a Flex profile and enters Flex profile configuration mode.
Step 3	[no] ip overlap Example: Device(config-wireless-flex-profile)# [no] ip overlap	Enables overlapping client IP address in flex deployment. Note By default, the configuration is disabled.

Verifying Overlapping Client IP Address in Flex Deployment (GUI)

Procedure

-
- Step 1** Choose **Monitoring > Wireless > Clients**.
- Step 2** Click the client in the table to view properties and statistics for each client.
- Step 3** On the **Client** window and **General** tab, click **Client Statistics** tab to view the following details:
- Number of Bytes Received from Client
 - Number of Bytes Sent to Client
 - Number of Packets Received from Client
 - Number of Packets Sent to Client
 - Number of Policy Errors
 - Radio Signal Strength Indicator
 - Signal to Noise Ratio
 - IP - Zone ID Mapping
- Step 4** Click **OK**.
-

Verifying Overlapping Client IP Address in Flex Deployment

To verify if the overlapping client IP address in Flex deployment feature is enabled or not, use the following command:

```
Device# show wireless profile flex detailed flex1
Fallback Radio shut      : DISABLED
ARP caching              : ENABLED
Efficient Image Upgrade  : ENABLED
OfficeExtend AP         : DISABLED
Join min latency        : DISABLED
IP overlap status       : DISABLED
```

To view additional details about the overlapping client IP address in Flex deployment feature, use the following command:

```
Device# show wireless device-tracking database ip
```

IP	ZONE-ID	STATE	DISCOVERY	MAC
9.91.59.154	0x00000002	Reachable	IPv4 Packet	
6038.e0dc.3182				
1000:1:2:3:90d8:dd1a:11ab:23c0	0x00000002	Reachable	IPv6 Packet	
58ef.680d.c6c3				
1000:1:2:3:f9b5:3074:d0da:f93b	0x00000002	Reachable	IPv6 Packet	
58ef.680d.c6c3				
2001:9:3:59:90d8:dd1a:11ab:23c0	0x00000002	Reachable	IPv6 NDP	
58ef.680d.c6c3				
2001:9:3:59:f9b5:3074:d0da:f93b	0x00000002	Reachable	IPv6 NDP	
58ef.680d.c6c3				
fe80::f9b5:3074:d0da:f93b	0x80000001	Reachable	IPv6 NDP	
58ef.680d.c6c3				

To view APs in various site tags, use the following command:

```
Device# show ap tag summary
Number of APs: 5
```

AP Name	AP Mac	Site Tag Name	Policy Tag Name	RF Tag Name	Misconfigured Tag	Source
AP3802	70b3.17f6.37aa	flex_ip_overlap-site-tag-auto-3	flex_ip_overlap_policy_tag_1	flex_ip_overlap_policy_tag_1		
default-rf-tag	No Static					
AP-9117AX	0cd0.f894.0f8c	default-site-tag	default-policy-tag	default-rf-tag	No Default	
AP1852JJ9	38ed.18ca.2b48	flex_ip_overlap-site-tag-auto-2	flex_ip_overlap_policy_tag_2	flex_ip_overlap_policy_tag_2		
default-rf-tag	No Static					
AP1852I	38ed.18cc.61c0	flex_ip_overlap-site-tag-auto-1	flex_ip_overlap_policy_tag_1	flex_ip_overlap_policy_tag_1		
default-rf-tag	No Static					
AP1542JJ9	700f.6a84.1b30	flex_ip_overlap-site-tag-auto-2	flex_ip_overlap_policy_tag_2	flex_ip_overlap_policy_tag_2		
default-rf-tag	No Static					

To view APs in FlexConnect mode, use the following command:

```
Device# show ap status
AP Name      Status      Mode          Country
-----
AP3802      Disabled   FlexConnect   IN
AP1852I     Enabled    FlexConnect   US
AP-9117AX   Enabled    FlexConnect   IN
AP1542JJ9   Disabled   FlexConnect   US
AP1852JJ9   Enabled    FlexConnect   US
```

Troubleshooting Overlapping Client IP Address in Flex Deployment

To verify the WNCID instance for each of the APs, use the following command:

```
Device# show wireless loadbalance ap affinity wncid 0
AP Mac                Discovery Timestamp    Join Timestamp          Tag
-----
0cd0.f894.0f8c        10/27/20 22:11:05     10/27/20 22:11:14     default-site-tag
38ed.18ca.2b48        10/27/20 22:06:09     10/27/20 22:06:19     flex_ip_overlap-site-tag-auto-2
700f.6a84.1b30        10/27/20 22:25:03     10/27/20 22:25:13     flex_ip_overlap-site-tag-auto-2
```

Information About FlexConnect High Scale Mode

This feature helps to scale up the FlexConnect site capacity to accommodate 300 APs and 3000 802.1x clients per site. The FlexConnect site capability is scaled up by using the Pairwise Master Key (PMK) option to skip Extensible Authentication Protocol (EAP) exchange while performing client roaming.

When a client associates with an AP under an 802.1x authentication architecture, an EAP exchange takes place, followed by a four-way handshake to verify the encryption keys. Using PMK caching, an AP can cache the PMK identifier of the EAP exchange, and for the subsequent client join. In PMK caching, the EAP exchange process is eliminated, and the authentication time process is decreased.

The PMK propagation feature is disabled by default. Until Cisco IOS XE Cupertino 17.7.1, the wireless controller used to push the PMK cache to every FlexConnect AP in the site. From Cisco IOS XE Cupertino 17.8.1 onwards, when PMK propagation is enabled, the controller pushes the PMK cache only to selective FlexConnect APs. These FlexConnect APs then forward the PMK identifier to the other FlexConnect APs within the same site.

Enabling PMK Propagation (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex test-flex-profile Example: Device(config)# wireless profile flex test-flex-profile	Creates a FlexConnect profile.
Step 3	pmk propagate Example: Device(config-wireless-flex-profile)# pmk propagate	Propagates PMK information to the other APs in the site. Note The PMK propagation feature is disabled by default.

Examples

```
Device# configure terminal
Device(config)# wireless profile flex test-flex-profile
Device(config-wireless-flex-profile)# pmk propagate
```

Flex Resilient with Flex and Bridge Mode Access Points

Information About Flex Resilient with Flex and Bridge Mode Access Points

The Flex Resilient with Flex and Bridge Mode Access Points describe how to set up a controller with Flex+Bridge mode Access Points (APs) and Flex Resilient feature. The Flex Resilient feature works only in Flex+Bridge mode APs. The feature resides in Mesh link formed between RAP - MAP, once the link is UP and RAP loses connection to the CAPWAP controller, both RAP and MAP continue to bridge the traffic. A child Mesh AP (MAP) maintains its link to a parent AP and continues to bridge till the parent link is lost. A child MAP cannot establish a new parent or child link till it reconnects to the CAPWAP controller.

Note Existing wireless clients in locally switching WLAN can stay connected with their AP in this mode. No new or disconnected wireless client can associate to the Mesh AP in this mode. Client traffic in Flex+Bridge MAP is dropped at RAP switchport for the locally switched WLANs.

Configuring a Flex Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Flex**.
 - Step 2** Click a **Flex Profile Name**. The **Edit Flex Profile** dialog box appears.
 - Step 3** Under the **General** tab, choose the **Flex Resilient** check box to enable the Flex Resilient feature.
 - Step 4** Under the **VLAN** tab, choose the required VLANs.
 - Step 5** (Optionally) Under the **Local Authentication** tab, choose the desired server group from the **Local Accounting RADIUS Server Group** drop-down list. Also, choose the **RADIUS** check box.
 - Step 6** Click **Update & Apply to Device**.
-

Configuring a Flex Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	wireless profile flex <i>flex-profile</i> Example: Device(config)# wireless profile flex new-flex-profile	Configures a Flex profile and enters Flex profile configuration mode.
Step 3	arp-caching Example: Device(config-wireless-flex-profile)# arp-caching	Enables ARP caching.
Step 4	description <i>description</i> Example: Device(config-wireless-flex-profile)# description "new flex profile"	Enables default parameters for the Flex profile.
Step 5	native-vlan-id Example: Device(config-wireless-flex-profile)# native-vlan-id 2660	Configures native vlan-id information.
Step 6	resilient Example: Device(config-wireless-flex-profile)# resilient	Enables the resilient feature.
Step 7	vlan-name <i>vlan_name</i> Example: Device(config-wireless-flex-profile)# vlan-name VLAN2659	Configures VLAN name.
Step 8	vlan-id <i>vlan_id</i> Example: Device(config-wireless-flex-profile)# vlan-id 2659	Configures VLAN ID. The valid VLAN ID ranges from 1 to 4096.
Step 9	end Example: Device(config-wireless-flex-profile)# end	Exits configuration mode and returns to privileged EXEC mode.

Configuring a Site Tag (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	wireless tag site <i>site-name</i> Example: Device(config)# wireless tag site new-flex-site	Configures a site tag and enters site tag configuration mode.
Step 3	flex-profile <i>flex-profile-name</i> Example: Device(config-site-tag)# flex-profile new-flex-profile	Configures a flex profile.
Step 4	no local-site Example: Device(config-site-tag)# no local-site	Local site is not configured on the site tag.
Step 5	site-tag <i>site-tag-name</i> Example: Device(config-site-tag)# site-tag new-flex-site	Maps a site tag to an AP.
Step 6	end Example: Device(config-site-tag)# end	Exits configuration mode and returns to privileged EXEC mode.

Configuring a Mesh Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	wireless profile mesh <i>profile-name</i> Example: Device(config)# wireless profile mesh Mesh_Profile	Configures a Mesh profile and enters the Mesh profile configuration mode.

	Command or Action	Purpose
Step 3	no ethernet-vlan-transparent Example: Device(config-wireless-profile-mesh)# no ethernet-vlan-transparent	Disables VLAN transparency to ensure that the bridge is VLAN aware.
Step 4	end Example: Device(config-wireless-profile-mesh)# end	Exits configuration mode and returns to privileged EXEC mode.

Associating Wireless Mesh to an AP Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	ap profile <i>ap-profile-name</i> Example: Device(config)# ap profile new-ap-join-profile	Configures the AP profile and enters AP profile configuration mode.
Step 3	mesh-profile <i>mesh-profile-name</i> Example: Device(config-ap-profile)# mesh-profile Mesh_Profile	Configures the Mesh profile in AP profile configuration mode.
Step 4	ssh Example: Device(config-ap-profile)# ssh	Configures the Secure Shell (SSH).
Step 5	mgmtuser username <i>username</i> password {0 8} <i>password</i> Example: Device(config-ap-profile)# mgmtuser username Cisco password 0 Cisco secret 0 Cisco	Specifies the AP management username and password for managing all of the access points configured to the controller. <ul style="list-style-type: none"> • 0: Specifies an UNENCRYPTED password. • 8: Specifies an AES encrypted password. <p>Note While configuring an username, ensure that special characters are not used as it results in error with bad configuration.</p>

	Command or Action	Purpose
Step 6	end Example: Device(config-ap-profile)# end	Exits configuration mode and returns to privileged EXEC mode.

Attaching Site Tag to an Access Point (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	ap mac-address Example: Device(config)# ap F866.F267.7DFB	Configures Cisco APs and enters ap-tag configuration mode.
Step 3	site-tag site-tag-name Example: Device(config-ap-tag)# site-tag new-flex-site	Maps a site tag to the AP. Note Associating Site Tag causes the associated AP to reconnect.
Step 4	end Example: Device(config-ap-tag)# end	Exits configuration mode and returns to privileged EXEC mode.

Configuring Switch Interface for APs (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	interface interface-id Example: Device(config)# interface <int-id>	Enters the interface to be added to the VLAN.
Step 3	switchport trunk native vlan vlan-id Example:	Assigns the allowed VLAN ID to the port when it is in trunking mode.

	Command or Action	Purpose
	Device(config-if)# switchport trunk native vlan 2660	
Step 4	switchport trunk allowed vlan <i>vlan-id</i> Example: Device(config-if)# switchport trunk allowed vlan 2659,2660	Assigns the allowed VLAN ID to the port when it is in trunking mode.
Step 5	switchport mode trunk Example: Device(config-if)# switchport mode trunk	Sets the trunking mode to trunk unconditionally. Note When the controller works as a host for spanning tree, ensure that you configure portfast trunk, using spanning-tree portfast trunk command, in the uplink switch to ensure faster convergence.
Step 6	end Example: Device(config-if)# end	Exits configuration mode and returns to privileged EXEC mode.

Verifying Flex Resilient with Flex and Bridge Mode Access Points Configuration

To view the AP mode and model details, use the following command:

```
Device# show ap name <ap-name> config general | inc AP Mode
AP Mode                : Flex+Bridge
AP Model               : AIR-CAP3702I-A-K9
```

To view the MAP mode details, use the following command:

```
Device# show ap name MAP config general | inc AP Mode
AP Mode                : Flex+Bridge
AP Model               : AIR-CAP3702I-A-K9
```

To view the RAP mode details, use the following command:

```
Device# show ap name RAP config general | inc AP Mode
AP Mode                : Flex+Bridge
AP Model               : AIR-AP2702I-A-K9
```

To view if the Flex Profile - Resilient feature is enabled or not, use the following command:

```
Device# show wireless profile flex detailed FLEX_TAG | inc resilient
Flex resilient        : ENABLED
```

Feature History for OEAP Link Test

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 27: Feature History for OEAP Link Test

Release	Feature	Feature Information
Cisco IOS XE Bengaluru 17.5.1	OEAP Link Test	The Cisco OEAP Link Test feature allows you to determine the DTLS upload, link latency, and jitter of the link between an AP and the controller.

Information About OEAP Link Test

The Cisco OEAP Link Test feature allows you to determine the DTLS upload speed of the link between an AP and the controller. This feature helps in identifying network bottlenecks and reasons for functionality failures. You can determine the link latency by running a test on demand.

A link test is used to determine the quality of the link between the controller and an AP in OEAP mode. The AP sends synthetic packets to the controller and the controller echoes them back to the AP, which can then estimate the link quality.

Feature Scenarios

Cisco OfficeExtend Access Point (OEAP) users are complaining of poor performance when connected to a teleworker AP.

Use Cases

This feature allows OEAP network admins to troubleshoot low throughput from the Cisco Catalyst 9800 Controller GUI by running OEAP link test.

The OEAP link test provides DTLS upload speed, link latency, and link jitter, all of which help the network administrators to narrow down the problem.

Configuring OEAP Link Test (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enters privileged EXEC mode.
Step 2	ap name <i>ap-name</i> network-diagnostic Example: Device# ap name ap18 network-diagnostic	Triggers network diagnostics on an OfficeExtend AP.

Performing OEAP Link Test (GUI)

Procedure

Step 1 Choose **Monitoring > Wireless > AP Statistics**.

In the list of APs, a **Link Test** icon is displayed in the **AP Name** column for OEAP-capable APs.

Note The **Link Test** icon is displayed only if an AP is OEAP capable and is configured to operate as OEAP.

Step 2 Click **Link Test**.

A link test is run and the results are shown.

Verifying OEAP Link Test

The following example shows how to verify network diagnostics information:

```
Device# show FlexConnect office-extend diagnostics
```

```
Summary of OfficeExtend AP Link Latency
```

```
CAPWAP Latency Heartbeat
```

```
Current: current latency (ms)
```

```
Min: minimum latency (ms)
```

```
Max: maximum latency (ms)
```

```

Feature History for Cisco OEAP Split Tunneling

This table provides release and related information for the feature explained in this module.

This feature is available in all the releases subsequent to the one in which it is introduced in, unless noted otherwise.

Table 28: Feature History for Cisco OEAP Split Tunneling

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.8.1	IPv6 Support	IPv6 addressing is supported on the Cisco OEAP Split Tunneling feature.
Cisco IOS XE Cupertino 17.7.1	Cisco OEAP Split Tunneling	The Split Tunneling feature in Cisco OfficeExtend Access Point (OEAP) provides a mechanism to classify client traffic, based on packet content, using access control lists (ACLs).

Information About Cisco OEAP Split Tunneling

The global pandemic has redefined the way people interact and work. The workplace has shifted from office cubicles to home desks, which requires applications that enable seamless collaboration among the workforce. For home-based workers, access to business services must be reliable, consistent, and secure. It should provide an experience that is similar to the office facility. Routing all of the traffic through the corporate network using traditional VPNs increases the traffic volume, slows down access to resources, and negatively impacts the remote user experience.

Cisco OEAP provides secure communications from a controller to an access point (AP) at a remote location, seamlessly extending the corporate WLAN over the internet to an employee's residence. Cisco OEAP provides segmentation of home and corporate traffic using the Split Tunneling feature, which allows for home device connectivity without security risks to corporate policy.

Split tunneling classifies the traffic sent by a client, based on packet content, using ACLs. Matching packets are switched locally from Cisco OEAP, and other packets are centrally switched over CAPWAP. Clients on a corporate SSID can talk to devices on a local network (printers, wireless devices on a personal SSID, and so on) directly without consuming WAN bandwidth, by sending packets over CAPWAP.

Traffic to Software as a Service (SaaS) applications such as Cisco WebEx, Microsoft SharePoint, Microsoft Office365, Box, Dropbox, and so on that is required as part of the work routine, need not go through the corporate network, by using the Split Tunneling feature.

The Cisco OEAP advertises two SSIDs, one corporate and one personal. Corporate SSID clients obtain their IP address from the central DHCP server in the corporate network. If split tunneling is enabled and a client wants to access a device in the home network, the AP performs NAT (PAT) translation between the wireless client corporate network subnet and the home network where the AP is located.

The personal SSID is configurable by a Cisco OEAP user. Clients will either get their IP address from the home router (when the AP personal SSID firewall is disabled) or from the internal AP DHCP server (when the AP personal SSID firewall is enabled). In the latter scenario, if the clients want to reach the home network devices, the AP perform sNAT (PAT) translation between the wireless client's internal network and the home network where the AP is located.

IPv6 Address Support

From Cisco IOS XE Cupertino 17.8.1, IPv6 addressing is supported. You can disable IPv6 addressing only by disabling the feature.

Note The end-to-end network should support IPv6, that is, both the corporate network (controller, corporate gateway, and so on) and the home network (wireless clients, home router, and so on) should support IPv6.

Prerequisites for Cisco OEAP Split Tunneling

- Cisco Wave 2 APs or Cisco Catalyst 9100AX Series Access Points
- URL filter list that matches the ACL name configured in split tunneling

Restrictions for Cisco OEAP Split Tunneling

- Cisco OEAPs are not supported when Cisco Embedded Wireless Controller on Catalyst Access Points (EWC) is used as a controller.
- Mesh topology is not supported.
- Clients connected on personal SSID or on home network (AP native VLAN) cannot discover devices on the corporate network.
- Split tunnelling is not supported in standalone mode.
- URL split tunnelling supports only up to 512 URLs.
- Action (deny or permit) can be specified only on the URL filter list, not for each individual entry.
- If URL-based ACL contains wild-card URLs, a maximum of 10 URLs are supported.
- The amount of snooped DNS IP addresses is limited as follows:
 - An AP can snoop 4095 IP addresses per DNS response, if IP addresses are less than 150,000.
 - An AP can snoop 10 IP addresses per DNS response, if IP addresses are between 150,000 and 200,000.
 - An AP can snoop five IP addresses per DNS response, if IP addresses are between 200,000 and 250,000.
 - An AP can snoop one IP address per DNS response, if IP addresses are greater than 250,000.
- A maximum of 128 IP address ACE (rules) can be used in the IP ACL for split tunnelling.
- URL-based split tunnelling only works with IPv4 addresses.
- The following restrictions are specific to IPv6 addressing
 - Multihoming (multiple router advertisement prefixes) is not supported (If a home network receives multiple prefixes, the one used by the AP that is connected to the controller is used.)
 - Roaming is not supported.
 - Filtering is not supported on the upstream traffic towards the wireless client.

- Split tunneling is disabled for clients with duplicate IPv6 addresses. Traffic for these clients is forwarded centrally to the controller.
- DHCPv6 prefix delegation is not supported for wireless clients.
- If the corporate prefix length is smaller than the home prefix length, split tunneling for a particular client is disabled.

Use Cases for Cisco OEAP Split Tunneling

Before Release 17.7.1, split tunneling used IP ACLs. This meant that cloud services such as Cisco Webex were accessed directly without going through the corporate network. The network administrator maintained the list of IP addresses that Cisco Webex used, which was a daunting task. From Release 17.7.1, using the Cisco OEAP Split Tunneling feature, the network administrator needs to provide only the DNS names that Cisco Webex uses. The AP ensures that traffic from these DNS names is routed directly to the internet without using the corporate network.

Workflow to Configure Cisco OEAP Split Tunneling

1. Create an IP address ACL or URL ACL
2. Add ACL to FlexConnect Profile
3. Enable Split Tunneling on Policy Profile
4. Verify the Configuration

Create an IP Address ACL (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ip access-list extended name Example: Device(config)# ip access-list extended vlan_oeap	Defines an extended IPv4 access list using a name. Note IP ACL can be used to define a default action if there is no match in the URL ACL.
Step 3	seq-num deny ip any host hostname Example:	Denies IP traffic from any host.

	Command or Action	Purpose
	Device(config-ext-nacl)# 10 deny ip any 10.10.0.0 0.0.255.255	
Step 4	<i>seq-num permit ip any any hostname</i> Example: Device(config-ext-nacl)# 20 permit ip any any	Permits IP traffic from any source or destination host.
Step 5	end Example: Device(config-ext-nacl)# end	Exits configuration mode and returns to privileged EXEC mode.

Create a URL ACL (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	urlfilter list list-name Example: Device(config)# urlfilter list vlan_oemap	Configures the URL filter list. The list name must not exceed 32 alphanumeric characters.
Step 3	action permit Example: Device(config-urlfilter-params)# action permit	Configures the action: Permit (traffic is allowed directly on the home network) or Deny (traffic is directed to the corporate network).
Step 4	filter-type post-authentication Example: Device(config-urlfilter-params)# filter-type post-authentication	Configures the URL list as post authentication filter.
Step 5	url url-name Example: Device(config-urlfilter-params)# url wiki.cisco.com	Configures a URL.
Step 6	url url-name Example: Device(config-urlfilter-params)# url example.com	(Optional) Configures a URL. Use this option when you want to add multiple URLs.

	Command or Action	Purpose
Step 7	end Example: Device(config-urlfilter-params)# end	Exits configuration mode and returns to privileged EXEC mode.

Add an ACL to a FlexConnect Profile

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex <i>flex-profile</i> Example: Device(config)# wireless profile flex default-flex-profile	Configures a FlexConnect profile.
Step 3	acl-policy <i>acl-policy-name</i> Example: Device(config-wireless-flex-profile)# acl-policy vlan_oep	Configures an ACL policy.
Step 4	urlfilter list <i>url-filter</i> Example: Device(config-wireless-flex-profile-acl)# urlfilter list vlan_oep	Configures a URL filter list.
Step 5	exit Example: Device(config-wireless-flex-profile-acl)# exit	Returns to FlexConnect profile configuration mode..
Step 6	office-extend Example: Device(config-wireless-flex-profile)# office-extend	Enables the OEAP mode for a FlexConnect AP.
Step 7	end Example: Device(config-wireless-flex-profile)# end	Exits configuration mode and returns to privileged EXEC mode.

Enable Split Tunneling in a Policy Profile

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile flex <i>flex-profile</i> Example: Device(config)# wireless profile flex default-flex-profile	Configures a FlexConnect profile.
Step 3	no central association Example: Device(config-wireless-flex-profile)# no central association	Disables central association and enables local association for locally switched clients.
Step 4	flex split-mac-acl <i>split-mac-acl-name</i> Example: Device(config-wireless-flex-profile)# flex split-mac-acl vlan_oeap	Configures a split MAC ACL name. Note Ensure that you use the same <i>acl-policy-name</i> in the FlexConnect profile.
Step 5	end Example: Device(config-wireless-flex-profile)# end	Exits configuration mode and returns to privileged EXEC mode.

Verifying the Cisco OEAP Split Tunnel Configuration

To verify the split tunneling DNS ACLs per wireless client on the AP side, use the following command:

```
Device# show split-tunnel client 00:11:22:33:44:55 access-list
```

```
Split tunnel ACLs for Client: 00:11:22:33:44:55
```

```
IP ACL: SplitTunnelACL
```

```
Tunnel packets Tunnel bytes NAT packets NAT bytes
           1           242           3           768
```

```
URL ACL: SplitTunnelACL
```

```
Tunnel packets Tunnel bytes NAT packets NAT bytes
           3           778           0           0
```

```
Resolved IPs for Client: 00:11:22:33:44:55 for Split tunnel
```

```

HIT-COUNT      URL           ACTION  IP-LIST
1              base1.com     deny.   20.0.1.1
              base1.com     deny.   20.0.1.10
2              base2.com     deny.   20.0.1.2
3              base3.com     deny.   20.0.1.3

```

To verify the current binding between a WLAN and an ACL, use the following command:

```
Device# show split-tunnel mapping
```

```

VAP-Id      ACL Name
0           SplitTunnelACL

```

To verify the content of the current URL ACL, use the following command:

```
Device# show flexconnect url-acl
```

```

ACL-NAME      ACTION      URL-LIST
SplitTunnelACL  deny       base.com

```

AP Survey Mode

To enable the Cisco Catalyst 9136 Series APs and other upcoming AP models for site survey at customer sites, a new AP command is introduced to help APs to switch to survey mode. When an AP is in survey mode, the AP GUI is enabled and is used for configuring the RF parameters for site survey investigation.

To enable survey mode on an AP, run the **ap-type site-survey** command from the AP CLI.

The following features in the AP GUI are hidden, when the AP is in the survey mode:

- WAN
- Firewall
- Network Diagnostics

Note To make the hidden features visible on the AP GUI, you must switch the AP back to the CAPWAP mode, by running the **ap-type capwap** command from the AP CLI. In CAPWAP mode, the AP GUI becomes available only when the **OfficeExtend AP** field is enabled in the flex profile page associated to that AP.

Note To access the AP survey mode from the GUI, you must enter the default login as 'admin' and the default password as 'admin' (both case sensitive).

When the AP is in survey mode, it broadcasts an SSID by default. The default password to connect to this SSID is 'password' (case sensitive).

Information About AP Deployment Mode

The AP Deployment Mode feature enables you to configure Cisco Catalyst 9124AX Series Outdoor Access Points to operate in Indoor mode (in -E regulatory domain only) to increase the available channel list. The -E regulatory domain specifies the country of operation assigned to the AP. For more information on the regulatory domain, see [Countries and Regulations](#).

The -E regulatory domain currently supports only Unlicensed National Information Infrastructure U-NII-2C channels. This feature configures the Outdoor AP to operate in Indoor mode and expands the channels to include U-NII-1 and U-NII-2 in 5-GHz WLAN. For more information on U-NII-1 and U-NII-2, see https://en.wikipedia.org/wiki/Unlicensed_National_Information_Infrastructure.

Note This feature applies to Cisco Catalyst 9124AX Series Outdoor APs only.

Use Case for AP Deployment Mode

A typical use case is to operate the Cisco Catalyst 9124AX Series Outdoor APs in Indoor mode in greenhouses, walk-in freezers, and so on.

Configuring AP Deployment Mode (GUI)

Procedure

- Step 1** Go to **Configuration > Tags & Profiles > AP Join**.
- To add a new AP join profile, see *Configuring an AP Profile (GUI)*. To modify an existing AP join profile, select the required AP join profile.
- Step 2** Click the **General** tab.
- Step 3** From the **Deployment mode** drop-down list, select one of the following:
- *Default or Outdoor*: Select this option if you want to configure the AP in outdoor mode. By default, Cisco Catalyst 9124AX Series Access Points are configured in outdoor mode.
 - *Indoor*: Select this option if you want to configure the AP in indoor mode for enclosed spaces like green-houses or walk-in freezers.
- Note** When the deployment mode is changed, the system prompts you to confirm the change. Select **Yes** to accept the change.
- Step 4** Click **Apply to Device**.

To view the deployment status, go to **Configuration > Wireless > Access Points**. On the **All Access Points** tab, click on a Cisco Catalyst 9124AX Series Access Point access point. In the **Edit AP** window, select the **Advanced** tab to view the default and current mode of the AP.

Configuring AP Deployment Mode (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	ap profile <i>ap-profile-name</i> Example: Device(config)# ap profile ap-profile1	Configures an AP profile and enters the AP profile configuration mode.
Step 3	dual-mode-ap-deployment-mode indoor Example: Device(config-ap-profile)# dual-mode-ap-deployment-mode indoor	Configures the outdoor AP to operate in Indoor mode.
Step 4	end Example: Device(config-ap-profile)# end	Exits configuration mode and returns to privileged EXEC mode.

Verifying AP Deployment Mode

To verify whether the AP indoor mode is enabled or not, use the following command:

```
Device# show ap name APXXXX.31XX.83XX config general
Cisco AP Name      : APXXXX.31XX.83XX
=====
Cisco AP Identifier          : 4ca6.4d22.f140
Country Code                : Multiple Countries : CZ,US
Regulatory Domain Allowed by Country : 802.11bg:-AE 802.11a:-ABE 802.11
6GHz:-BE
Radio Authority IDs         : None
AP Country Code             : CZ - Czech Republic
AP Regulatory Domain
  802.11bg                  : -E
  802.11a                   : -E
.
.
.AP Indoor Mode             : Enabled
```

To verify the available channel list in AP console, use the following command:

```
AP# show rrm receive configuration
RRM configuration slot 1
=====
Group Id
Switch Id           :0904640500ff
Group Cnt           :57454
IP address          :9.4.100.5
Encrypted           :0
Version             :1
Key                 :ff3fff55ffffff42ffff2cff6d0affff
Domain              :default
Key Name            :Channel Count       :19
TX Chans            :36 40 44 48 52 56 60 64 100 104 108 112 116 120 124 128 132 136 140
```

To view the indoor deployment details in AP console, use the following command:

```
AP# show capwap client configuration
AdminState          : ADMIN_ENABLED(1)
Name                : AP3C57.31C5.9478
Location            : default location
Primary controller name : Rack10_katar
Primary controller IP   : 9.4.100.5
Secondary controller name :
Tertiary controller name :
.
.
.Indoor Deployment   : 2!Indoor Deployment: 2 signifies that the AP is in
Indoor mode.
!Indoor Deployment: 0 signifies that the AP is in Outdoor mode.
```

Information About Data Datagram Transport Layer Security

Data Datagram Transport Layer Security (DTLS) enables you to encrypt CAPWAP data packets that are sent between an access point and the controller using DTLS, which is a standards-track IETF protocol that can encrypt both control and data packets based on TLS. CAPWAP control packets are management packets that are exchanged between a controller and an access point while CAPWAP data packets encapsulate forwarded wireless frames. CAPWAP control and data packets are sent over separate UDP ports: 5246 (control) and 5247 (data).

If an access point does not support DTLS data encryption, DTLS is enabled only for the control plane, and a DTLS session for the data plane is not established.

If an access point supports Data DTLS, it enables data DTLS after receiving the new configuration from the controller. The access point performs a DTLS handshake on port 5247 and after successfully establishing the DTLS session. All the data traffic (from the access point to the controller and the controller to the access point) is encrypted.

Note The throughput is affected for some APs that have data encryption enabled.

The controller does not perform a DTLS handshake immediately after processing client-hello with a cookie, if the following incorrect settings are configured:

- ECDHE-ECDSA cipher in “ap dtls-cipher <>” and RSA-based certificate in “wireless management trustpoint”.
- RSA cipher in “ap dtls-cipher <>” and EC-based certificate in “wireless management trustpoint”.

Note This is applicable when you move from CC -> FIPS -> non-FIPS mode.

Note If the AP’s DHCP lease time is less and the DHCP pool is small, access point join failure or failure in establishing the Data Datagram Transport Layer Security (DTLS) session may occur. In such scenarios, associate the AP with a named site-tag and increase the DHCP lease time for at least 8 days.

Configuring Data DTLS (GUI)

Follow the procedure to enable DTLS data encryption for the access points on the controller :

Procedure

- Step 1** Click **Configuration > Tags and Profile > AP Join**.
 - Step 2** Click **Add** to create a new **AP Join Profile** or click an existing profile to edit it.
 - Step 3** Click **CAPWAP > Advanced**.
 - Step 4** Check **Enable Data Encryption** check box to enable Datagram Transport Layer Security (DTLS) data encryption.
 - Step 5** Click **Update & Apply to Device**.
-

Configuring Data DTLS (CLI)

Follow the procedure given below to enable DTLS data encryption for the access points on the controller :

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	ap profile <i>ap-profile</i> Example: <pre>Device(config)# ap profile test-ap-profile</pre>	Configures an AP profile and enters AP profile configuration mode. Note You can use the default AP profile (default-ap-profile) or create a named AP profile, as shown in the example.
Step 3	link-encryption Example: <pre>Device(config-ap-profile)# link-encryption</pre>	Enables link encryption based on the profile. Answer yes, when the system prompts you with this message: Note If you set stats-timer as as zero (0) under the AP profile, then the AP will not send the link encryption statistics. Enabling link-encryption will reboot the APs with link-encryption. Are you sure you want to continue? (y/n) [y]:
Step 4	end Example: <pre>Device(config-ap-profile)# end</pre>	Returns to privileged EXEC mode.
Step 5	show wireless dtls connections Example: <pre>Device# show wireless dtls connections</pre>	(Optional) Displays the DTLS session established for the AP that has joined this controller.
Step 6	show ap link-encryption Example: <pre>Device# show ap link-encryption</pre>	(Optional) Displays the link encryption-related statistics (whether link encryption is enabled or disabled) counter received from the AP.

Introduction to the 802.1X Authentication

IEEE 802.1X port-based authentication is configure on a device to prevent unauthorized devices from gaining access to the network. The device can combine the function of a router, switch, and access point, depending on the fixed configuration. Any device connecting to a switch port where 802.1X authentication is enabled must go through relevant EAP authentication model to start exchanging traffic.

Currently, the Cisco Wave 2 and Wi-Fi 6 (802.11AX) APs support 802.1X authentication with switch port for EAP-FAST, EAP-TLS and EAP-PEAP methods. Now, you can enable configurations and provide credentials to the AP from the controller .

Note If the AP is dot1x EAP-FAST, when the AP reboots, it should perform an anonymous PAC provision. For performing PAC provision, the ADH cipher suites should be used to establish an authenticated tunnel. If the ADH cipher suites are not supported by radius servers, AP will fail to authenticate on reload.

EAP-FAST Protocol

In the EAP-FAST protocol developed by Cisco, in order to establish a secured TLS tunnel with RADIUS, the AP requires a strong shared key (PAC), either provided via in-band provisioning (in a secured channel) or via out-band provisioning (manual).

Note The EAP-FAST type configuration requires 802.1x credentials configuration for AP, since AP will use EAP-FAST with MSCHAP Version 2 method.

Note Local EAP is not supported on the Cisco 7925 phones.

Note In Cisco Wave 2 APs, for 802.1x authentication using EAP-FAST after PAC provisioning (caused by the initial connection or after AP reload), ensure that you configure the switch port to trigger re-authentication using one of the following commands: **authentication timer restart num** or **authentication timer reauthenticate num**.

Starting from Cisco IOS XE Amsterdam 17.1.1, TLS 1.2 is supported in EAP-FAST authentication protocol.

EAP-TLS/EAP-PEAP Protocol

The EAP-TLS protocol or EAP-PEAP protocol provides certificate based mutual EAP authentication.

In EAP-TLS, both the server and the client side certificates are required, where the secured shared key is derived for the particular session to encrypt or decrypt data. Whereas, in EAP-PEAP, only the server side certificate is required, where the client authenticates using password based protocol in a secured channel.

Note The EAP-PEAP type configuration requires Dot1x credentials configuration for AP; and the AP also needs to go through LSC provisioning. AP uses the PEAP protocol with MSCHAP Version 2 method.

Limitations of the 802.1X Authentication

- 802.1X is not supported on dynamic ports or Ethernet Channel ports.
- 802.1X is not supported in a mesh AP scenario.

- There is no recovery from the controller on credential mismatch or the expiry/invalidity of the certificate on AP. The 802.1X authentication has to be disabled on the switch port to connect the AP back to fix the configurations.
- There are no certificate revocation checks implemented on the certificates installed in AP.
- Only one Locally Significant Certificates (LSC) can be provisioned on the AP and the same certificate must be used for CAPWAP DTLS session establishment with controller and the 802.1X authentication with the switch. If global LSC configuration on the controller is disabled; AP deletes LSC which is already provisioned.
- If clear configurations are applied on the AP, then the AP will lose the 802.1X EAP type configuration and the LSC certificates. AP should again go through staging process if 802.1X is required.
- 802.1X for trunk port APs on multi-host authentication mode is supported. Network Edge Authentication Topology (NEAT) is not supported on COS APs.

Topology - Overview

The 802.1X authentication events are as follows:

1. The AP acts as the 802.1X supplicant and is authenticated by the switch against the RADIUS server which supports EAP-FAST along with EAP-TLS and EAP-PEAP. When dot1x authentication is enabled on a switch port, the device connected to it authenticates itself to receive and forward data other than 802.1X traffic.
2. In order to authenticate with EAP-FAST method, the AP requires the credentials of the RADIUS server. It can be configured at the controller, from where it will be passed on to the AP via configuration update request. For, EAP-TLS or EAP-PEAP the APs use the certificates (device/ID and CA) made significant by the local CA server.

Figure 17: Figure: 1 Topology for 802.1X Authentication

Configuring 802.1X Authentication Type and LSC AP Authentication Type (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
- Step 2** On the **AP Join Profile** page, click **Add**.
The **Add AP Join Profile** page is displayed.
- Step 3** In the **AP > General** tab, navigate to the **AP EAP Auth Configuration** section.
- Step 4** From the **EAP Type** drop-down list, choose the EAP type as *EAP-FAST*, *EAP-TLS*, or *EAP-PEAP* to configure the dot1x authentication type.
- Step 5** From the **AP Authorization Type** drop-down list, choose the type as either **CAPWAP DTLS +** or **CAPWAP DTLS**.
- Step 6** Click **Save & Apply to Device**.
-

Configuring 802.1X Authentication Type and LSC AP Authentication Type

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	ap profile <i>profile-name</i> Example: Device(config)# ap profile new-profile	Specify a profile name.
Step 4	dot1x {max-sessions username eap-type lsc-ap-auth-state} Example: Device(config-ap-profile)# dot1x eap-type	Configures the dot1x authentication type. max-sessions: Configures the maximum 802.1X sessions initiated per AP.

	Command or Action	Purpose
		<p>username: Configures the 802.1X username for all Aps.</p> <p>eap-type: Configures the dot1x authentication type with the switch port.</p> <p>lsc-ap-auth-state: Configures the LSC authentication state on the AP.</p>
Step 5	<p>dot1x eap-type {EAP-FAST EAP-TLS EAP-PEAP}</p> <p>Example:</p> <pre>Device(config-ap-profile)# dot1x eap-type</pre>	Configures the dot1x authentication type: EAP-FAST, EAP-TLS, or EAP-PEAP.
Step 6	<p>dot1x lsc-ap-auth-state {CAPWAP-DTLS Dot1x-port-auth Both}</p> <p>Example:</p> <pre>Device(config-ap-profile)#dot1x lsc-ap-auth-state Dot1x-port-auth</pre>	<p>Configures the LSC authentication state on the AP.</p> <p>CAPWAP-DTLS: Uses LSC only for CAPWAP DTLS.</p> <p>Dot1x-port-auth: Uses LSC only for dot1x authentication with port.</p> <p>Both: Uses LSC for both CAPWAP-DTLS and Dot1x authentication with port.</p>
Step 7	<p>end</p> <p>Example:</p> <pre>Device(config-ap-profile)# end</pre>	Exits the AP profile configuration mode and enters privileged EXEC mode.

Configuring the 802.1X Username and Password (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
 - Step 2** On the **AP Join** page, click the name of the AP Join profile or click **Add** to create a new one.
 - Step 3** Click the **Management** tab and then click the **Credentials** tab.
 - Step 4** Enter the local username and password details.
 - Step 5** Choose the appropriate local password type.
 - Step 6** Enter 802.1X username and password details.
 - Step 7** Choose the appropriate 802.1X password type.
 - Step 8** Enter the time in seconds after which the session should expire.
 - Step 9** Enable local credentials and/or 802.1X credentials as required.
 - Step 10** Click **Update & Apply to Device**.
-

Configuring the 802.1X Username and Password (CLI)

The following procedure configures the 802.1X password for all the APs:

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	ap profile <i>profile-name</i> Example: Device(config)# ap profile new-profile	Specify a profile name.
Step 4	dot1x {max-sessions username eap-type lsc-ap-auth-state} Example: Device(config-ap-profile)# dot1x eap-type	Configures the dot1x authentication type. max-sessions: Configures the maximum 802.1X sessions initiated per AP. username: Configures the 802.1X username for all Aps. eap-type: Configures the dot1x authentication type with the switch port. lsc-ap-auth-state: Configures the LSC authentication state on the AP.
Step 5	dot1x username <username> password {0 8} <password> Example: Device(config-ap-profile)#dot1x username username password 0 password	Configures the dot1x password for all the APs. 0: Specifies an unencrypted password will follow. 8: Specifies an AES encrypted password will follow.

Enabling 802.1X on the Switch Port

The following procedure enables 802.1X on the switch port:

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Device(config)# aaa new-model	Enables AAA.
Step 4	aaa authentication dot1x {default listname} method1[method2...] Example: Device(config)# aaa authentication dot1x default group radius	Creates a series of authentication methods that are used to determine user privilege to access the privileged command level so that the device can communicate with the AAA server.
Step 5	aaa authorization network group Example: aaa authorization network group	Enables AAA authorization for network services on 802.1X.
Step 6	dot1x system-auth-control Example: Device(config)# dot1x system-auth-control	Globally enables 802.1X port-based authentication.
Step 7	interface type slot/port Example: Device(config)# interface fastethernet2/1	Enters interface configuration mode and specifies the interface to be enabled for 802.1X authentication.
Step 8	authentication port-control {auto force-authorized force-unauthorized} Example: Device(config-if)# authentication port-control auto	Enables 802.1X port-based authentication on the interface. auto —Enables IEEE 802.1X authentication and causes the port to begin in the unauthorized state, allowing only EAPOL frames to be sent and received through the port. The authentication process begins when the link state of the port changes from down to up or when an EAPOL-start frame is received. The Device requests the identity of the supplicant and begins relaying authentication messages between the supplicant and the authentication server. Each supplicant

	Command or Action	Purpose
		<p>attempting to access the network is uniquely identified by the Device by using the supplicant MAC address.</p> <p>force-authorized—Disables IEEE 802.1X authentication and causes the port to change to the authorized state without any authentication exchange required. The port sends and receives normal traffic without IEEE 802.1X-based authentication of the client. This is the default setting.</p> <p>force-unauthorized—Causes the port to remain in the unauthorized state, ignoring all attempts by the supplicant to authenticate. The Device cannot provide authentication services to the supplicant through the port.</p>
Step 9	dot1x pae [supplicant authenticator both] Example: Device(config-if)# dot1x pae authenticator	Enables 802.1X authentication on the port with default parameters.
Step 10	end Example: Device(config-if)# end	Enters privileged EXEC mode.

Verifying 802.1X on the Switch Port

The following show command displays the authentication state of 802.1X on the switch port:

```
Device# show dot1x all
Sysauthcontrol          Enabled
Dot1x Protocol Version  2
Dot1x Info for FastEthernet1
-----
PAE                      = AUTHENTICATOR
PortControl              = AUTO
ControlDirection        = Both
HostMode                 = MULTI_HOST
ReAuthentication         = Disabled
QuietPeriod              = 60
ServerTimeout            = 30
SuppTimeout              = 30
ReAuthPeriod             = 3600 (Locally configured)
ReAuthMax                = 2
MaxReq                   = 2
TxPeriod                 = 30
RateLimitPeriod          = 0
Device#
```

Verifying the Authentication Type

The following show command displays the authentication state of an AP profile:

```
Device#show ap profile <profile-name> detailed ?
  chassis Chassis
  |       Output modifiers
  <cr>

Device#show ap profile <profile-name> detailed

AP Profile Name       : default-ap-profile
Description           : default ap profile
...
Dot1x EAP Method      : [EAP-FAST/EAP-TLS/EAP-PEAP/Not-Configured]
LSC AP AUTH STATE    : [CAPWAP DTLS / DOT1x port auth / CAPWAP DTLS + DOT1x port auth
```

Feature History for Access Point Client ACL Counter

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 29: Feature History for Access Point Client ACL Counter

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.13.1	Access Point Client ACL Counter	The AP Client ACL Counter feature provides a statistical count for client ACL rules. This feature allows you to count the number of packets that hit a specific rule in the client ACL.

Information About Access Point Client ACL Counter

From the Cisco IOS XE Dublin 17.13.1 release, the AP Client ACL Counter feature provides a statistical count for client ACL rules. Until the Cisco IOS XE Dublin 17.12.1 release, there was no per-rule counter to determine which rule was passing or dropping the packets.

Use this feature to enable the counter in the AP to count the number of packets that hit a specific rule in the client ACL, using the following AP commands:

- **[no] debug flexconnect access-list counter [all | vlan-acl | client-acl]**
- **[no] debug flexconnect access-list event [all | vlan-acl | client-acl]**
- To clear ACL counters use the following command:
 - **clear counters access-list client <MAC> all**

AP Client ACL Counter is supported in the FlexConnect mode and local switching central authentication sub-mode.

Failover Priority for Access Points

Each controller has a defined number of communication ports for access points. When multiple controllers with unused access point ports are deployed on the same network and one controller fails, the dropped access points automatically poll for unused controller ports and associate with them.

The following are some guidelines for configuring failover priority for access points:

- You can configure your wireless network so that the backup controller recognizes a join request from a higher-priority access point, and if necessary, disassociates a lower-priority access point as a means to provide an available port.
- Failover priority is not in effect during the regular operation of your wireless network. It takes effect only if there are more associations requests to controller than the available AP capacity on the controller.
- AP priority is checked while connecting to the controller when the controller is in full scale or the primary controller fails, the APs fallback to the secondary controller.
- You can enable failover priority on your network and assign priorities to the individual access points.
- By default, all access points are set to priority level 1, which is the lowest priority level. Therefore, you need to assign a priority level only to those access points that warrant a higher priority.

Setting AP Priority (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
 - Step 2** Click the Access Point.
 - Step 3** In the **Edit AP** dialog box, go to **High Availability** tab.
 - Step 4** Choose the priority from the **AP failover priority** drop-down list.
 - Step 5** Click **Update and Apply to Device**.
-

Setting AP Priority

Note Priority of access points ranges from 1 to 4, with 4 being the highest.

Procedure

	Command or Action	Purpose
Step 1	ap name <i>ap-name</i> priority <i>priority</i> Example: Device# ap name AP44d3.ca52.48b5 priority 1	Specifies the priority of an access point.
Step 2	show ap config general Example: Device# show ap config general	Displays common information for all access points.
Step 3	show ap name <i>ap-name</i> config general Example: Device# show ap name AP44d3.ca52.48b5 config general	Displays the configuration of a particular access point.

Overview of Access Point Plug-n-Play

The Plug and Play (PnP) server provides staging parameters to an access point (AP) before it joins a controller. Using this staging configuration, the AP receives the runtime configuration when it joins the controller.

The AP PnP feature enables the PnP server to provide all tag-related information, as part of the preconfigured information to the AP and in turn, to the controller.

You can upload configuration in PNP server in either *TXT* or *JSON* format and also add the AP details. The AP details are then mapped with the details in the *TXT* or *JSON* configuration file. While provisioning AP from PnP server, the AP acquires this configuration details. Based on the configuration details, the AP then joins the corresponding controller with the tag details.

Provisioning AP from PnP Server

You can provision AP from PnP Server in either ways:

- Configure DHCP server or switch with *Option 43*. For example, you can refer to the following code sample:

```
ip dhcp pool vlan10
 network 9.10.10.0 255.255.255.0
 default-router 9.10.10.1
 option 43 ascii 5A1D;B2;K4;|9.10.60.5;J80
```

- Configure DHCP server with DNS. For example, you can refer to the following code sample:

```
ip dhcp pool vlan10
 network 9.10.10.0 255.255.255.0
 default-router 9.10.10.1
 dns-server 9.8.65.5
 domain-name dns.com
```

Verifying AP Tag Configuration

The following example shows how to verify the AP tag configuration:

```
Device# show ap tag summary
Number of APs: 5
```

AP Name RF Tag Name	AP Mac Misconfigured	Site Tag Name Tag Source	Policy Tag Name
APd42c.4482.6102 default-rf-tag	d42c.4482.6102 No	default-site-tag Default	default-policy-tag
AP00c1.64d8.6af0 named-rf-tag	00c1.64d8.6af0 No	named-site-tag AP	named-policy-tag

Note The details in the second row reflect the tag source coming from a PNP server.

Feature History for AP Fallback to Controllers Using AP Priming Profile

This table provides release and related information for the feature explained in this module.

Table 30: Feature History for AP Fallback to Controllers Using AP Priming Profile

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.9.2	AP Fallback to Controllers Using AP Priming Profile	This feature helps to configure primary, secondary, and tertiary controllers for a group of APs matching regular expression or for an individual AP using priming profiles.

Information About AP Fallback to Controllers Using AP Priming Profile

In large networks, accessing every AP console and configuring AP priming for primary, secondary, and tertiary controllers are not easy tasks. The AP Fallback to Controllers Using AP Priming Profile feature allows you to simplify the task of priming APs by using profiles defined in the controller.

Using the AP priming profile under the AP filter profile, you can configure primary, secondary, and tertiary controllers for a group of APs matching regular expressions, or for an individual AP using AP Ethernet MAC. When the AP joins the controller, the AP priming configuration gets pushed to the AP depending on whether priming override is enabled or not.

Note When the controller sends a priming profile to the AP, the AP disconnects from the current controller and joins the controller in the priming profile. A CAPWAP restart or device reboot is not required.

Restrictions for AP Fallback to Controllers Using AP Priming Profile

- Rolling AP upgrade will not work if priming override is enabled.
- The maximum number of priming profiles permitted is 128. The length of each profile can be up to 32 ASCII characters.

Configure AP Priming Profile

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile ap priming <i>profile-name</i> Example: Device(config)# wireless profile ap priming Prime-FX	Configures the profile to prime APs.
Step 3	primary <i>controller-name ip-address</i> Example: Device(config-priming)# primary aaaa 209.165.201.2	Configures name and IP address of the primary controller for AP fallback.
Step 4	secondary <i>controller-name ip-address</i> Example: Device(config-priming)# secondary bbbb 209.165.201.3	Configures name and IP address of the secondary controller for AP fallback.
Step 5	tertiary <i>controller-name ip-address</i> Example: Device(config-priming)# tertiary bbbb 209.165.201.4	Configures name and IP address of the tertiary controller for AP fallback.
Step 6	priming-override Example: Device(config-priming)# priming-override	Sends the priming details to the AP. Priming override is disabled by default. When disabled, information stored in the AP priming profile is not sent to the APs. . Note N+1 upgrade may not work as expected when priming override is enabled. Before using N+1 upgrade, ensure that priming override is disabled using the no priming-override command.

Configure AP Priming Using Filters

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap filter name <i>filter-name</i> type priming Example: Device(config)# ap filter name test-filter type priming	Configures the AP filter and sets the type as priming. Ensure that you set type as priming because the default filter type is tag. Note The existing filter type cannot be modified unless the filter is deleted and created with a different type. Use the no ap filter name command to delete a filter.
Step 3	ap name-regex <i>reg-ex</i> Example: Device(config-ap-pr-filter)# ap name-regex BGL18	Configures the AP name regular expression match.
Step 4	profile <i>profile-name</i> Example: Device(config-ap-pr-filter)# profile Prime-FX	Maps the priming profile to the filter.
Step 5	exit Example: Device(config-ap-pr-filter)# exit	Returns to global configuration.
Step 6	ap filter priority <i>priority</i> filter-name <i>filter-name</i> Example: Device(config)# ap filter priority 12 filter-name test-filter	Configures priority for a named AP filter. You can configure multiple AP priming profiles with unique priority levels. This allows you to set different priority levels for each AP priming profile.

Configure Per-AP Priming

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap mac-address Example: Device(config)# ap 00:00:5e:00:53:af	Enters AP profile configuration mode.
Step 3	priming profile-name Example: Device(config-ap-tag)# priming Prime-FX	Maps a priming profile to an AP.

Verify the Configuration

To view the list of all the priming filters, use the following command:

```
Device# show ap filters all type priming
```

Filter Name	regex	Priming profile
FLR1	*AP-FLOOR-1*	AP-PRIMING-1
FLR2	*AP-FLOOR-2*	AP-PRIMING-2

To view the list of all the active priming filters, use the following command:

```
Device# show ap filters active type priming
```

Priority	Filter Name	regex	Priming profile
0	FLR2	*AP-FLOOR-2*	AP-PRIMING-2
1	FLR1	*AP-FLOOR-1*	AP-PRIMING-1

To view the summary of the priming profiles, use the following command:

```
Device# show wireless profile ap priming summary
```

```
Number of AP Priming Profiles: 2
Priming profile
-----
AP-PRIMING-1
AP-PRIMING-2
```

To view the details of the priming profiles, use the following command:

```
Device# show wireless profile ap priming all
```

Profile Name	Primary Controller Name	Primary Controller IP	Secondary Controller Name	Secondary Controller IP	Tertiary Controller Name	Tertiary Controller IP	Override
AP-PRIMING-1	BGL18-wlc	209.165.201.1	BGL17-wlc	209.165.201.2		0.0.0.0	Disabled
AP-PRIMING-2	BGL18-wlc	209.165.201.2	BGL17-wlc	209.165.201.2	BGL12-wlc	209.165.201.3	Disabled

To view the priming information for each AP, use the following command:

```
Device# show ap ap1 config general | sec Priming
```

```
Priming Profile           : AP-PRIMING-1
Priming Override          : Disabled
Priming Source            : MAC/FILTER/NONE
Filter Name                : FLR1
```

AP Crash File Upload

When a converted access point unexpectedly reboots, the access point stores a crash file on its local flash memory at the time of the crash. After the unit reboots, it sends the reason for the reboot to the device. If the unit rebooted because of a crash, the device pulls up the crash file using the existing CAPWAP messages and stores it in the device flash memory. The crash information copy is removed from the access point's flash memory when the device pulls it from the access point:

Note The system does not generate reports in case of a reload.

During a process crash, the following are collected locally from the device:

- Full process core
- Trace logs
- Cisco IOS syslogs (not guaranteed in case of nonactive crashes)
- System process information
- Bootup logs
- Reload logs

- Certain types of proc information

All this information is stored in separate files, which are then archived and compressed into one bundle. This makes it convenient to get a crash snapshot in one place, and can be then moved off the box for analysis. This report is generated before the device goes down to ROMMON/bootloader.

Note Except for the full core and tracelogs, everything else is a text file.

Configuring AP Crash File Upload (CLI)

Procedure

- Step 1** **enable**
Enters privileged EXEC mode.
- Step 2** **ap name** *ap-name* **crash-file get-crash-data**
Collects AP crash information. The crash file is uploaded automatically after the AP reloads to ready state. Therefore, this command does not have to be manually executed.
- Step 3** **ap name** *ap-name* **crash-file get-radio-core-dump slot** {0 | 1}
Collects the AP core dump file for slot 0 or slot 1.
- Step 4** **ap name** *ap-name* **core-dump tftp-ip** *crash-file* **uncompress**
Uploads the AP crash coredump file to the given TFTP location.
- Step 5** **show ap crash-file**
Displays the AP crash file, as well as the radio crash file.
- Step 6** **dir bootflash**
Displays the crash file in bootflash with .crash extension.
-

Information About LED States for Access Points

In a wireless LAN network where there are a large number of access points, it is difficult to locate a specific access point associated with the controller. You can configure the controller to set the LED state of an access point so that it blinks and the access point can be located. This configuration can be done in the wireless network on a global as well as per-AP level.

The LED state configuration at the global level takes precedence over the AP level.

Note For APs that have Ethernet LEDs in addition to the main system LED, the Ethernet LEDs are enabled or disabled (switched ON or OFF) as per the system LED. For example, if the system LED is ON, the Ethernet LED will also be ON.

Configuring LED State in Access Points (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
- Step 2** Click an AP from the AP list.
The **Edit AP** window is displayed.
- Step 3** In the **General** tab, under the General section, go to **LED Settings**.
- Click the box adjacent to the **LED State** field to enable or disable the LED state.
 - From the **LED Brightness Level** drop-down list, choose a value from 1 to 8.
- Step 4** Under the **Flash Settings** section, perform the following steps:
- Click the box adjacent to the **Flash State** field to enable or disable the flash state.
When the flash state is enabled, the current status of the flash and the flash duration fields are displayed.
 - From the **Flash Duration** drop-down list, choose either **Always ON** or **Timed**.
If you choose the **Timed** option, the **Time Duration** field is displayed.
 - In the **Time Duration** field, specify the flash duration time, in seconds. The default value is one second.
The valid range is between 1 second and 3600 seconds.
- Step 5** Click **Update & Apply to Device**.
-

Configuring LED State for Access Points in the Global Configuration Mode (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: <code>Device> enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	ap name <i>Cisco-AP-name</i> led Example: <code>Device# ap name <i>Cisco-AP-name</i> led</code>	Enables the LED state for Cisco APs, globally.

	Command or Action	Purpose
Step 3	ap name <i>Cisco-AP-name</i> led flash {start duration <i>duration</i> stop} Example: <pre>Device# ap name Cisco-AP-name led flash start duration 20 Device# ap name Cisco-AP-name led flash stop</pre>	Configures the starting and the stopping of the AP LED flash. The valid start duration range is between 0 and 3600 seconds.
Step 4	ap name <i>Cisco-AP-name</i> led-brightness-level 1-8 Example: <pre>Device# ap name Cisco-AP-name led-brightness-level 4</pre>	Configures the LED brightness level. Value of the brightness is from 1 to 8.

Configuring LED State in the AP Profile

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 2	ap profile <i>default-ap-profile</i> Example: <pre>Device(config)#ap profile default-ap-profile</pre>	Enters the AP profile configuration mode.
Step 3	led Example: <pre>Device(config-ap-profile)# led</pre>	Enables the LED-state for all Cisco APs.

Verifying LED State for Access Points

To verify the LED state of the access points, use the following command:

show ap name AXXX-APXXXX.bdXX.f2XX config general

```
Device# show ap name AXXX-APXXXX.bdXX.f2XX config general
Cisco AP Name : AXXX-APXXXX.bdXX.f2XX
=====
Cisco AP Identifier : 0cXX.bdXX.65XX
Country Code : Multiple Countries : FR,IN,US
Regulatory Domain Allowed by Country : 802.11bg:-AE 802.11a:-ABDEN
AP Country Code : US - United States
```

```

Access Point Support Bundle

An access point (AP) support bundle contains core files, crash files, **show run-configuration**, configuration commands, msglogs, and traplogs.

This topic describes how you can retrieve the support bundle information of an AP and export it to the controller or to an external server. (Until Cisco IOS XE, Release 17.2.1, you had to log in to the AP console to retrieve the AP support-bundle information.)

The Access Point Support Bundle feature is supported only on Cisco Wave2 APs and Cisco Catalyst APs.

Exporting an AP Support Bundle (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
- Step 2** Click the corresponding AP name.
The **Edit AP** window is displayed.
- Step 3** Click the **Support Bundle** tab.
- Step 4** From the **Destination** drop-down list, choose one of the following:
- **This Device:** If you choose this, enter the values for the **Server IP**, **Destination File Path**, **Username**, and **Password** fields.
- Note** When you choose **This Device**, a bundle is sent through Secure Copy (SCP) to the controller (if you have configured the **ip scp server enable** command globally on the controller). You can easily retrieve the bundle later from your browser, using the controller file manager.

- **External Server:** If you choose this, from the **Transfer Mode** drop-down list, choose either **scp** or **tftp**.

If you choose the **scp** transfer mode, enter the values for the **Server IP**, **Destination File Path**, **Username**, and **Password** fields.

If you choose the **tftp** transfer mode, enter the values for the **Server IP**, and **Destination File Path** fields.

Note Information about the **Last Export Status**, such as **State**, **Transfer Mode**, **Server IP**, **File Path**, and **Time of Export**, is displayed on the right-hand side of the window.

Step 5 Click **Start Transfer**.

Exporting an AP Support Bundle (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	ap name <i>Cisco-AP-name</i> export support-bundle mode { scp tftp } target ip-address { <i>A.B.C.D</i> <i>X:X:X:X::X</i> } path <i>file-path</i> Example: Device> ap name <i>Cisco-AP-name</i> export support-bundle mode scp target ip-address 10.1.1.1 path <i>file-path</i>	Exports the AP support bundle through the SCP or TFTP transfer modes. If you select the scp , you will be prompted to provide your username and password. For tftp , username and password is not required.

Monitoring the Status of Support Bundle Export

To monitor the status of a support bundle export, run the following command:

```
Device# show ap support-bundle summary
AP Name      Server-IP    Status      Last Successful Time    Path File-name
-----
AP_28XXX     81.1.1.10   Copy Success 04/24/2020 07:27:38 UTC
AP_28XXX_support.17.4.0.2.2020.07XXX.tgz
```

Information About Access Point Memory Information

With the introduction of the Access Point Memory Information feature, you can view the access point (AP) memory type, the CPU type, and the memory size per AP, after single sign-on authentication. APs share the memory information with the controller during the join phase.

To view the memory information of a specific AP, use the `show ap name AP-NAME config general` command.

Verifying Access Point Memory Information

To verify the memory information of a specified AP, including the CPU type, memory type and memory size, use the following command:

```
Device# show ap name AP-NAME config general
Cisco AP Name      : AP-NAME
=====
Cisco AP Identifier      : 00XX.f1XX.e0XX
Country Code           : Multiple Countries : FR,IN,US
Regulatory Domain Allowed by Country : 802.11bg:-AE 802.11a:-ABDEN
AP Country Code        : US - United States
AP Regulatory Domain
  802.11bg              : -A

Information About Access Point Tag Persistency

From Cisco IOS XE Bengaluru 17.6.1 onwards, AP tag persistency is enabled globally on the controller. When APs join a controller with tag persistency enabled, the mapped tags are saved on the APs without having to write the tag configurations on each AP, individually.

Configuring AP Tag Persistency (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Tags**.
 - Step 2** Click the **AP** tab.
 - Step 3** In the **Tag Source** tab, check the **Enable AP Tag Persistency** check box to configure AP Tag persistency globally.

When APs join a controller with the tag persistency enabled, the mapped tags are saved on the AP without having to write the tag configurations on each AP individually.
 - Step 4** Click **Apply to Device**.
-

What to do next

Save tags on an AP.

Saving Tags on an Access Point (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
 - Step 2** Click an AP from the list.
The **Edit AP** page is displayed.
 - Step 3** Click the **General** tab.
 - Step 4** In the **Tags** section, specify the appropriate policy, site, and RF tags that you created in the **Configuration > Tags & Profiles > Tags** page.
 - Step 5** From the **Policy** drop-down list, select a value.
 - Step 6** From the **Site** drop-down list, select a value.
 - Step 7** From the **RF** drop-down list, select a value.
 - Step 8** Check the **Write Tag Config to AP** check box to push the tags to the AP so that the AP can save and remember this information even when the AP is moved from one controller to another.
 - Step 9** Click **Update & Apply to Device**.
-

Deleting Saved Tags on the Access Point

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
 - Step 2** Click an AP from the list of APs.
The **Edit AP** window is displayed.
 - Step 3** In the **Edit AP** window, choose the **Advanced** tab.
 - Step 4** In the **Set to Factory Default** section, check the **Clear Resolved Tag Config** check box to clear the saved tags on an AP.
 - Step 5** Click **Update & Apply to Device**.
-

Configuring AP Tag Persistency (CLI)

Before you begin

For an AP to preserve its policy tag, site tag, and RF tag configured from the primary controller, these tags must also exist on the other controllers that the AP connect to. If all the three tags do not exist, the AP applies

the default policy tag, site tag, and RF tag. Similarly, the tag policy is applicable even if one or two tags exist. AP tag persistency helps in priming an AP in N+1 redundancy scenarios. For more information about configuring tags, see https://www.cisco.com/c/en/us/td/docs/wireless/controller/9800/17-6/config-guide/b_wl_17_6_cg/m_config_model.html.

Note After being enabled, AP tag persistency is performed during AP join. Therefore, if there are any APs that are already joined to the controller, those APs must rejoin the controller.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap tag persistency enable Example: Device(config)# ap tag persistency enable	Configures AP tag persistency.
Step 3	end Example: Device(config)# end	Exits configuration mode and returns to privileged EXEC mode.

Verifying AP Tag Persistency

To verify AP tag persistency in the primary controller, use the following command:

```
Device# show ap tag summary
Number of APs: 1
```

AP Name	AP Mac	Site Tag Name	Policy Tag Name	RF Tag Name
	Misconfigured	Tag Source		
Cisco01_AP	xxxx.xxxx.xxxx	default-site-tag	OpenRoaming	default-rf-tag
No		Static		

Note If the Tag Source displays **Static** or **Filter**, it means that the AP tag mappings were configured on the primary controller. If the source displays **Default**, it means that the AP received the default tags when joining the controller.

To verify the AP tag persistency in the secondary controller, use the following command:

```
Device# show ap tag summary
Number of APs: 1
```

AP Name	AP Mac	Site Tag Name	Policy Tag Name	RF Tag Name
---------	--------	---------------	-----------------	-------------

```

Misconfigured Tag Source
-----
Cisco01_AP    xxxx.xxxx.xxxx  default-site-tag  OpenRoaming      default-rf-tag
No           AP

```

Note If the Tag Source displays **AP**, it means that the policy tag, site tag, and RF tag match what was configured on the primary controller, indicating that the AP tags have persisted across controllers.

Feature History for AP Power Save

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 31: Feature History for AP Power Save

Release	Feature Information
Cisco IOS XE Cupertino 17.8.1	This feature allows a network administrator to force APs to operate in low-power mode to reduce power consumption.
Cisco IOS XE Cupertino 17.9.1	Feature support for the following APs: <ul style="list-style-type: none"> • Cisco Catalyst 9164 Series Access Points • Cisco Catalyst 9166 Series Access Points
Cisco IOS XE Dublin 17.10.1	The following features are supported: <ul style="list-style-type: none"> • Radio spatial streams • Flexible PoE profiles
Cisco IOS XE 17.13.1	AP Power Distribution support in Cisco Catalyst 9124 Series APs.

Information About AP Power Save

The power-save mode in APs allows a network administrator to force APs to operate in low-power mode to reduce power consumption.

The AP Power Save feature is supported in the following APs:

- Cisco Catalyst 9115 Series Access Points
- Cisco Catalyst 9120 Series Access Points
- Cisco Catalyst 9124 Series Access Points
- Cisco Catalyst 9130 Series Access Points

- Cisco Catalyst 9136 Series Access Points
- Cisco Catalyst 9164 Series Access Points
- Cisco Catalyst 9166 Series Access Points
- Cisco Catalyst 9162 Series Access Points

Access Point Power Policy

The access point power policy allows you to define the power budget utilization available for an AP, wherein, you can define a set of policies for different interfaces on an AP. You can manage interfaces such as Wi-Fi radios, USB, and so on, as required.

Cisco Catalyst 9124 AXI/D APs support up to two radio interfaces (single 5 GHz), and Cisco Catalyst 9124 AXE APs support up to three (dual 5 GHz) radio interfaces. When Cisco Catalyst 9124 Series APs operate under 802.3at/PoE+/30W insufficient power condition, the new operating modes support both dual or Tri-Radio mode.

Use Case for AP Power Policy

The following is the use case of an AP power policy:

- You can define a power policy for the available power inputs, such as, 802.3af, 802.3at, 802.3bt (for multiple levels), DC power, and so on. With tri-radio and quad-radio APs, the power requirement has gone beyond the capability of the 802.3at Power over Ethernet (PoE) mode. Therefore, with the AP power policy, for example, we statically predefine an AP operation when provided with non-802.3bt power (such, as TX power, radio chains, USB port, SFP, and so on).

Power-Save Mode

The power-save mode enables an AP to switch to a low-power mode when no clients are associated with the AP. For example, when this mode is enabled in workspaces, the AP falls asleep during after hours, thereby saving power consumption of the AP throughout the night.

From Cisco IOS-XE Cupertino 17.10.1 onwards, you can shut down AP radios or lower the radio spatial streams, to reduce usage of power. You can enforce radio speed by configuring the number of spatial streams on the radios. The combinations for radio spatial stream policies are: 1X1, 2X2, 3X3 (only for Cisco Catalyst 9130 Series Access Points), 4X4, and 8X8.

The following are the advantages of the power-save mode:

- Increases the energy saving per AP: In the power save mode you can reduce AP functions during off-peak hours and save an additional 20% in energy costs compared to the regular idle mode.
- Enables environmentally conscious purchases: Large enterprises and companies track environmental performance as one of their key indices. They have a centralized energy team to monitor their energy efficiency, which magnifies the importance of the power-save feature.

PoE Profiles

- **Fixed PoE Profile:** The APs negotiate the power that is required, from the switches they are connected to. The power required varies from one AP model to another AP model. If an AP is not granted the power it requested, it operates under the power budget. In such conditions, some of the interfaces operate under *degraded conditions*.

For example, some radios may operate at 2SS instead of at 4SS, which they are capable of. The operating conditions for each of the AP interfaces differs from one power level to another. These are referred to as fixed PoE profiles. Fixed PoE profiles are applied when the AP is operating in normal mode, that is, nonpower-save mode. When the AP operates in power-save mode, the configured PoE power policies are applied.

- **PoE Power Policy:** With power policies or profiles, you can configure interfaces that you want to set at certain speeds. With this policy, you can configure a profile of your choice that will be pushed to the AP based on your calendar or timing. For example, on a group of APs in the second floor, push a profile where you want to turn off all APs, except 2.4-GHz radio, from 7 p.m. to 7 a.m.
- **Flexible PoE Profile:** With flexible PoE profiles, you can configure different interfaces and set specific parameter values and states for each interface, instead of following fixed PoE profile rules. If an AP does not get the power it requires, it operates under the power budget by using the flexible PoE profile.

In Cisco IOS XE 17.13.1, PoE-out is a new interface introduced in Cisco Catalyst 9124 Series APs, in addition to the USB, Ethernet, and LAN interfaces. The PoE-out for Cisco Catalyst 9124 Series AP RLAN works only if you have enabled the RLAN port.

Wakeup Threshold for Access Point Power Save Mode

The Wakeup Threshold feature enables you to define the client threshold in the AP power profile configuration to determine when the AP wakes up from the power save mode or enter into the power save mode.

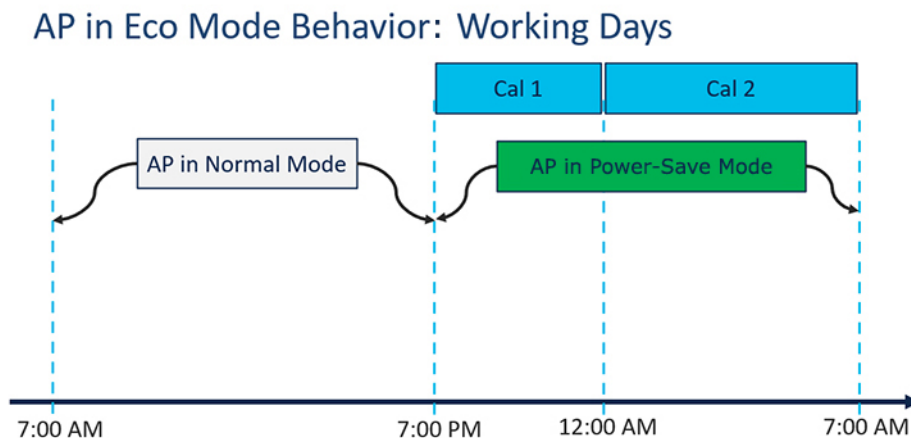

When the AP applies the calendar associated power profile (for an active calendar), and the number of connected clients reach the wakeup threshold, the AP wakes up from power save mode and goes into the Fixed power profile mode or the Regular power profile (insufficient power) mode.

When the AP applies the calendar associated power profile (for an active calendar), and the number of connected clients is less than the wakeup threshold, the AP applies the calendar associated power profile to shut down the interface or to lower the interface speed to save power.

AP Power Save Scenarios

The AP Power Save feature helps APs to enter into a power-save mode or low-power mode by applying a calendar, for example, for after hours, associated with the corresponding power profile. The AP profile is enhanced to associate a PoE power policy with calendar profiles. The following are the scenarios for Eco mode APs:

- **Figure 18: AP in Eco Mode Behavior: Working Days**

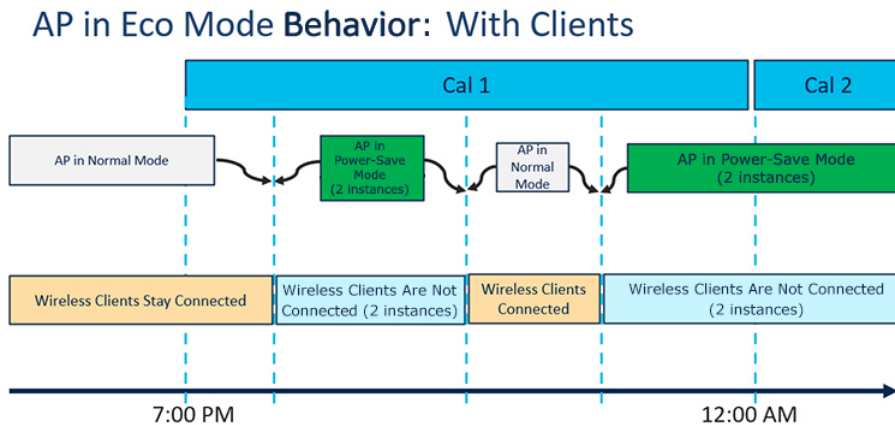

On working days, from 7:00 a.m. to 7:00 p.m., the AP functions in normal mode or fixed mode, when the maximum number of clients are connected to the AP. From 7:00 p.m. to 12:00 a.m., the **Cal1** calendar profile timer starts to put the AP in the power-save mode. Likewise, the **Cal2** calendar profile timer starts, and extends the power-save mode from 12:00 a.m. to 7:00 a.m. Again, at 7:00 a.m., the AP goes into normal mode.

• **Figure 19: AP in Eco Mode Behavior: Nonworking Days**

On nonworking days, the AP goes into power-saving mode from 12:00 a.m. to 11:59:59 p.m. The **Cal3** calendar profile is applied here. This profile defines the timer for the power-save mode. This means that there are no clients connected to the AP, and that the AP is asleep.

• **Figure 20: AP in Eco Mode Behavior: With Clients**

When clients are connected to the AP, the AP automatically switches to the normal mode. For example, in the calendar profile **Cal1**, the AP is in normal mode, because wireless clients are connected to the AP. At 8:00 p.m., clients get dissociated from the AP, and the AP goes into power-save mode. When clients enter the AP coverage area at 9:30 p.m., the AP automatically switches from power-save mode to normal mode of operation.

Configuring Power Policy Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Power Profile**.
- Step 2** Click **Add**.
The **Add Power Profile** window is displayed.
- Step 3** Enter a name and description for the power profile. The name must be ASCII characters of up to 128 characters, without leading or trailing spaces.
- Step 4** Click **Add** to add rules for the power profile.
- Step 5** In the **Sequence number** field, enter a unique sequence number to designate the priority in which power should be disabled for the component. The sequence number of 0 indicates that the component should be disabled first.
- Step 6** From the **Interface** and **Interface ID** drop-down list, choose interface and interface ID to designate to the component for which the power derating rule applies.
- Step 7** From the **Parameter** and **Parameter value** drop-down list, choose the values depending on the interface you chose in step 6.

For example, if you chose **Ethernet** as an interface, you can further customize the rule for the interface by choosing the associated speed. This rule ensures that the AP disables power for the Ethernet interface that is operating at a higher speed, and thereby consuming more power.
- Step 8** Click the check mark to save and then click **Apply to Device**.
-

Configuring a Power Policy Profile (CLI)

Before you begin

You must keep at least one radio interface up and running before you configure a power policy profile.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile power <i>power-profile-name</i> Example: Device(config)# wireless profile power <i>power-profile-name</i>	Configures the power policy profile.

	Command or Action	Purpose
Step 3	<p><i>sequence-number</i> ethernet {GigabitEthernet0 GigabitEthernet1 speed {1000mbps 100mbps 2500mbps 5000mbps} LAN1 LAN2 LAN3 state disable};</p> <p>Example:</p> <pre>Device(config-wireless-power-profile)# 10 ethernet gigabitethernet1 speed 1000mbps</pre>	<p>Configures the power policy for Ethernet.</p> <p><i>sequence-number</i>: The power profile settings are ordered by sequence numbers. AP derating takes place as per the sequence number entered. The same combination of interface identifiers and parameter values does not appear in another sequence number. The same interface with the same parameter can appear multiple times with different parameter values.</p> <p>Note</p> <ul style="list-style-type: none"> • The Ethernet interface is used to join the controller. The uplink interface is not disabled even if it is defined in the power policy. • Ethernet speed configuration is not operational in Cisco IOS XE Cupertino 17.8.1.
Step 4	<p><i>sequence-number</i> radio 24ghz {spatial-stream {1 2 3 4} state shutdown};</p> <p>Example:</p> <pre>Device(config-wireless-power-profile)# 20 radio 24ghz spatial stream 2</pre>	<p>Configures spatial stream for the 2.4-GHz band radio.</p> <p>Here:</p> <p><i>sequence-number</i>: The power profile settings are ordered by sequence numbers. AP derating takes place as per the sequence number entered. The same combination of interface identifiers and parameter values does not appear in another sequence number. The same interface with the same parameter can appear multiple times with different parameter values.</p> <ul style="list-style-type: none"> • 1: Specifies a 1X1 radio spatial stream. • 2 : Specifies a 2X2 radio spatial stream. • 3 : Specifies a 3X3 radio spatial stream. • 4 : Specifies a 4X4 radio spatial stream. <p>state shutdown: Indicates that the radio state is down.</p>
Step 5	<p><i>sequence-number</i> radio 5ghz {spatial-stream {1 2 3 4 8} state shutdown};</p> <p>Example:</p> <pre>Device(config-wireless-power-profile)# 30 radio 5ghz spatial stream 4</pre>	<p>Configures spatial stream for the 5-GHz band radio.</p> <p>Here:</p> <p><i>sequence-number</i>: The power profile settings are ordered by sequence numbers. AP derating takes place as per the sequence number entered.</p>

	Command or Action	Purpose
		<p>The same combination of interface identifiers and parameter values does not appear in another sequence number. The same interface with the same parameter can appear multiple times with different parameter values.</p> <ul style="list-style-type: none"> • 1: Specifies a 1X1 radio spatial stream. • 2 : Specifies a 2X2 radio spatial stream. • 3 : Specifies a 3X3 radio spatial stream. • 4 : Specifies a 4X4 radio spatial stream. • 8 : Specifies a 8X8 radio spatial stream. <p>state shutdown: Indicates that the radio state is down.</p>
Step 6	<p><i>sequence-number</i> radio secondary-5ghz {spatial-stream {1 2 3 4 8} state shutdown}</p> <p>Example:</p> <pre>Device(config-wireless-power-profile)# 40 radio 5ghz spatial stream 4</pre>	<p>Configures spatial stream for a secondary 5-GHz band radio.</p> <p>Here:</p> <p><i>sequence-number:</i> The power profile settings are ordered by sequence numbers. AP derating takes place as per the sequence number entered. The same combination of interface identifiers and parameter values does not appear in another sequence number. The same interface with the same parameter can appear multiple times with different parameter values.</p> <ul style="list-style-type: none"> • 1: Specifies a 1X1 radio spatial stream. • 2 : Specifies a 2X2 radio spatial stream. • 3 : Specifies a 3X3 radio spatial stream. • 4 : Specifies a 4X4 radio spatial stream. • 8 : Specifies a 8X8 radio spatial stream. <p>state shutdown: Indicates that the radio state is down.</p>
Step 7	<p><i>sequence-number</i> radio 6ghz {spatial-stream {1 2 3 4 8} state shutdown}</p> <p>Example:</p> <pre>Device(config-wireless-power-profile)# 50 radio 6ghz spatial stream 2</pre>	<p>Configures spatial stream for the 6-GHz band radio.</p> <p>Here:</p> <p><i>sequence-number:</i> The power profile settings are ordered by sequence numbers. AP derating takes place as per the sequence number entered. The same combination of interface identifiers and parameter values does not appear in another</p>

	Command or Action	Purpose
		<p>sequence number. The same interface with the same parameter can appear multiple times with different parameter values.</p> <ul style="list-style-type: none"> • 1 : Specifies a 1X1 radio spatial stream. • 2 : Specifies a 2X2 radio spatial stream. • 3 : Specifies a 3X3 radio spatial stream. • 4 : Specifies a 4X4 radio spatial stream. • 8 : Specifies a 8X8 radio spatial stream. <p>state shutdown: Indicates that the radio state is down.</p>
Step 8	<p><i>sequence-number</i> usb 0 state disable</p> <p>Example:</p> <pre>Device(config-wireless-power-profile)# 60 usb 0 state disable</pre>	Configures the power policy for USB.

Configuring a Calendar Profile (GUI)

Configure calendar profiles to set up a daily, weekly, or monthly recurrence schedule.

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Calendar**.
- Step 2** Click **Add**.
The **Add Calendar Profile** window is displayed.
- Step 3** Enter a name for the calendar profile. The name must be ASCII characters of up to 32 characters, without leading or trailing spaces.
- Step 4** From the **Recurrence** drop-down list, choose the schedule for which you want to create a profile.
- Step 5** Select the **Start Time** and the **End Time** for the recurrence schedule.

- Note**
- For daily recurrences, you can select the start time and end time. For example, if you want the AP to derate the power on certain interfaces between 7 p.m. to 7 a.m. daily, or if you want the controller to not allow any clients to be associated during this period, you can set up this daily recurrence schedule.

To cover this timespan, you must create two calendar profiles, one for 7 p.m. till 23:59:59, and another one from midnight to 7 a.m. of the next calendar day, and map it to the same power profile. After this, assign it to the AP Join profile.

- For weekly recurrences, select the specific days of the week along with the start and end time.
- For monthly recurrence, select the specific days of the month along with the start and end time.

Step 6 Click **Apply** to save the configuration.

Configuring a Calendar Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless profile calendar-profile name <i>calendar_profile_ap_power</i> Example: Device# <code>wireless profile calendar-profile</code> <code>name ap_power_calendar</code>	Configures a calendar profile. Enters the calendar profile configuration mode. Here, name refers to the name of the calendar profile.
Step 3	recurrence daily Example: Device(config-calendar-profile)# <code>recurrence daily</code>	Configures daily recurrence for daily profile.
Step 4	start start-time end end-time Example: Device(config-calendar-profile)# <code>start</code> <code>16:00:00</code> <code>end 20:00:00</code>	Configures the start time and end time for calendar profile.
Step 5	end Example:	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config-calendar-profile)# end	

Configuring a Power Policy in an AP Join Profile (GUI)

Power policy supports the use of a power profile or a mapped configuration of a power profile and a calendar profile that are pushed to an AP during an AP join session. You can map a maximum of five combination profiles (calendar and power) per AP profile.

Before you begin

Ensure that the power profile and calendar profile are created and displayed in the respective drop-down lists in the GUI.

Procedure

Step 1 Choose **Configuration > Tags & Profiles > AP Join**.

The **Add AP Join Profile** window is displayed.

Step 2 Click the **AP** tab.

Step 3 Under the AP tab, click the **Power Management** tab.

Step 4 From the **Regular Power Profile** drop-down list, choose the power profile.

The AP applies these settings to derate the power based on the configured priority list.

Note If you want the AP to apply the power profile configuration during a specific time period, choose the **Calendar Profile** and map it to the power profile from the drop-down list.

Step 5 Click the check mark to associate the mapping.

Step 6 Click **Apply to Device** to save the configuration.

Mapping a Power Profile Under an AP Profile (CLI)

Before you begin

Ensure that you have defined a calendar profile in the wireless profile, before you map the calendar profile to an AP join profile.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	ap profile <i>ap-profile-name</i> Example: Device(config)# ap profile <i>ap-profile-name</i>	Configures an AP profile and enters AP profile configuration mode.
Step 3	power-profile <i>power-profile-name</i> Example: Device(config-ap-profile)# power-profile <i>power-profile-name</i>	Configures the AP power profile. This power profile is used during non-calendar hours to meet the power budget provided by the switch connected to the AP.
Step 4	calendar-profile <i>calendar-profile-name</i> Example: Device(config-ap-profile)# calendar-profile <i>ap-calendar-profile</i>	Maps a calendar profile to the AP profile. Enters the AP profile calendar configuration mode.
Step 5	[no] action power-saving-mode power-profile <i>power-profile-name</i> Example: Device(config-ap-profile-calendar)# action power-saving-mode power-profile <i>power-profile1</i>	Maps a specific power profile to a specific calendar profile. Maps the power-saving mode action for the calendar profile. Use the no form of this command to disable the command. Note You can have more than one mapping of calendar profile to power profile.

Configuring Client Wakeup Threshold (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile power <i>power-profile-name</i> Example: Device(config)# wireless profile power <i>power-profile1</i>	Configures the power policy profile.
Step 3	power-save-client-threshold <i>client-threshold</i> Example: Device(config-wireless-power-profile)# power-save-client-threshold 5	Configures the client threshold up to which the AP can stay in the power save mode. The valid range is between 1 and 32 clients. The default value is 1.

Configuring PoE-Out Interface in Power Profile (GUI)

Before you begin

Enable the RLAN port for the AP.

Procedure

-
- Step 1** Choose **Configuration** > **Tags & Profiles** > **Power Profile**.
- Step 2** Click **Add**.
The **Add Power Profile** window is displayed.
- Step 3** Enter a name and description for the power profile. The name can contain up to 128 ASCII characters, without leading or trailing spaces.
- Step 4** (Optional) From the **Power Save Client Threshold** counter, select a value to set a limit to the number of client associations with the AP. The default value is 1. The valid range is between 1 to 32.
- Step 5** Click **Add** to create a rule for the PoE-Out interface.
The **Rule** section is displayed in the window.
- Step 6** In the **Rule** section, complete the following steps:
- In the **Sequence number** field, enter a unique sequence number to assign the priority in which power should be disabled for the component. A sequence number of 0 indicates that the component should be disabled first.
 - From the **Interface** drop-down list, choose **Ethernet** as the interface.
 - From the **Interface ID** drop-down list, choose one of the following interfaces: **LAN1**, **LAN2**, or **LAN3**.
 - From the **Parameter** drop-down list, choose **POE-out**.
- A POE-out port on an AP is used to provide power to the another device, for example, a camera. This selection ensures that the power usage of the port is reduced or shut down at the specified sequence.
- Step 7** Click the check mark button to save.
- Step 8** Click **Apply to Device**.
-

Configuring PoE-Out Interface in Power Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	wireless profile power <i>power-profile-name</i> Example: Device(config)# wireless profile power <i>poe-out-power-profile</i>	Configures the power policy profile. Enters the wireless power profile configuration mode.
Step 3	<i>sequence-number</i> ethernet LAN1 poe-out disable Example: Device(config-wireless-power-profile)# 1 ethernet LAN1 poe-out disable	Disables the PoE-out state.

Configuration Example of Power Profile

The following example shows how to define a power save policy:

```
wireless profile power power-save
  10 radio 5ghz state shutdown
  20 radio secondary-5ghz state shutdown
  30 radio 6ghz state shutdown
  40 usb 0 state disable
```

The following example shows how to define a calendar profile:

```
wireless profile calender-profile name eve-to-midnight
  recurrence daily
  start 19:00:00 end 23:59:59
wireless profile calender-profile name midnight-to-morning
  recurrence daily
  start 00:00:00 end 07:00:00
wireless profile calender-profile name weekends
  recurrence weekly
  day Saturday
  day Sunday
  start 00:00:00 end 23:59:59
```

The following example shows how to define an AP join profile and map a calendar profile to a power profile:

```
ap profile wireless-prof-sitel
  calendar-profile eve-to-midnight
  action power-saving-mode power-profile power-save
  calendar-profile midnight-to-morning
  action power-saving-mode power-profile power-save
  calendar-profile weekends
  action power-saving-mode power-profile power-save
```

Verifying Access Point Power Policy (GUI)

To verify the applied configuration on the GUI, follow these steps:

Procedure

- Step 1** Choose **Monitoring > AP Statistics**.
 - Step 2** Click a Cisco Catalyst 9136 series AP from the list of APs.
The **General** window is displayed.
 - Step 3** Click the **Power** tab.
The **Power Operational Status** and the **AP Fixed Power Policy** details are displayed.
 - Step 4** Click **OK**.
-

To verify the AP fixed power policy details from the list of configured APs, follow these steps:

Procedure

- Step 1** Choose **Configuration > Access Points**.
 - Step 2** Click a Cisco Catalyst 9136 series AP from the list of APs.
The **Edit AP** window is displayed.
 - Step 3** Click the **Interfaces** tab.
The **AP Fixed Power Policy** details are displayed.
 - Step 4** Click **Update & Apply**.
-

Verifying the Access Point Power Profile

To view the calendar profile and its mapping, run the following command:

```
Device# show ap profile name default-ap-profile detailed
AP Profile Name           : default-ap-profile
Description                : default ap profile
Power profile name        : power_prof_day
AP packet capture profile : Not Configured
AP trace profile          : Not Configured
Mesh profile name         : default-mesh-profile
Power profile name        : Not Configured
Calendar Profile
  Profile Name             : cal47
  Power saving mode profile name : pow_da
  -----
  Profile Name             : cal48
  Power saving mode profile name : pow23
  -----
```

To view the operational details of the AP, run the following command:

```
Device# show ap name cisco-ap power-profile summary
AP power derate Capability : Capable

Power saving mode
Power saving mode profile : pow2
Associated calendar profile : cal1

AP power profile status : Insufficient De-rating
```

Interface	Interface-ID	Parameter	Parameter value	Status
Radio	5 GHz	State	DISABLED	Success
Radio	6 GHz	State	DISABLED	Not Applicable
Ethernet	LAN1	State	DISABLED	Not Applicable
Radio	2.4 GHz	State	DISABLED	Success
Ethernet	Gig0	Speed	5000 MBPS	Fixed Policy

AP power derate capability is displayed in the output as **Capable** only for those APs that support power policy. For the other APs, it is displayed as **Not Capable**.

In the **show ap name cisco-ap power-profile summary** output, in the power saving mode, the status of the interface configured in the power profile (for example, **pow2**) is applied on the AP, and the AP sends the details (that are displayed in the show command) such as, the name of the power saving profile and the associated calendar profile.

The table that is displayed shows the interfaces and the parameter status of the power saving profile. The AP sends the information as to which of the interfaces are disabled. For example, if the AP does not have a 6-GHz radio interface, the **Status** is displayed as **Not Applicable**. If the interfaces are applied without any errors, then **Success** is displayed.

Note When the AP uses the fixed power policy, due to inactive calendar or client connectivity, the interfaces are not displayed in the power profile summary if their status is UP on the AP.

Verifying Radio Spatial Streams

To view the configuration and operational details of radio spatial stream rules in the power profile, run the following commands:

```
Device# show wireless profile power detailed wireless_pow_profile_name
Power profile name          : wireless_pow_profile_name
-----
Description                  :
.
.
Seq No      Interface      Interface-id      Parameter          Parameter value
-----
100         Radio                6 GHz            Spatial Stream     2 x 2
200         Radio                5 GHz            Spatial Stream     8 x 8
400         USB                  USB0             State              DISABLED
500         Ethernet             Gig0             Speed              100 MBPS
600         Radio                6 GHz            State              DISABLED
700         Radio                2.4 GHz          State              DISABLED
900         Radio                5 GHz            State              DISABLED

Device# show ap name cisco-ap-name power-profile summary
AP power derate Capability   : Capable

AP fixed power policy
-----

Interface      Interface-ID      Parameter          Parameter value    Status
-----
Ethernet       Gig0              Speed              5000 MBPS         Fixed Policy
Radio          2.4 GHz           Spatial Stream     4 x 4             Fixed Policy
Radio          5 GHz             Spatial Stream     8 x 8             Fixed Policy
```

```

Radio          Sec 5 GHz          Spatial Stream  4 x 4          Fixed Policy
USB           USB0              State          DISABLED       Fixed Policy

```

Verifying Client Threshold

To view the client threshold details, run the following command:

```

Device# show wireless profile power detailed profile1
Power profile name          : profile1
-----
Description                  : Power profile 1
Power save client threshold : 5
Seq No      Interface      Interface-id      Parameter      Parameter value
-----
0           Radio          6 GHz           State          DISABLED
1           Radio          5 GHz           Spatial Stream  1 x 1
2           Radio          2.4 GHz         Spatial Stream  2 x 2
3           USB            USB0            State          DISABLED

```

Verifying PoE-Out Details

To view the PoE-out details in the wireless power profile, run the following commands:

```

Device# show wireless profile power detailed poe-out_profile_name
Power profile name          : poe-out_profile_name
-----
Description                  : profile-description
Seq No      Interface      Interface-id      Parameter      Parameter value
-----
10 ...
20          Ethernet      LAN 1            POE_OUT        DISABLED
30 ...

Device# show ap name Cisco-Ap1 power-profile summary
AP power derate Capability  : Capable

AP fixed power policy
-----

Interface      Interface-ID      Parameter      Parameter value      Status
-----
...
Ethernet      LAN 1            POE_OUT        DISABLED              Fixed Policy
...

```

Information About Access Point Real-Time Statistics

From Cisco IOS XE Bengaluru 17.5.1 onwards, you can track the CPU utilization and memory usage of an AP, and monitor the health of an AP, by generating real-time statistics for an AP.

SNMP traps are defined for CPU and memory utilization of APs and the controller. An SNMP trap is sent out when the threshold is crossed. The sampling period and statistics interval can be configured using SNMP, YANG, and CLI.

Statistics interval is used to process the data coming from an AP, and the average CPU utilization and memory utilization is computed over time. You can also configure an upper threshold for these statistics. When a statistic value surpasses the upper threshold, an alarm is enabled, and an SNMP trap is triggered.

From Cisco IOS XE Cupertino 17.7.1 release onwards, for radio monitoring, you can reset the radios based on the statistics sent by the AP for a sampling period. When you configure the radios in the controller, if there is no increment in the Tx or Rx statistics when the radio is up, then the radio reset is triggered.

Feature History for Real Time Access Point Statistics

This table provides release and related information for the feature explained in this module.

Table 38: Feature History for Real Time Access Point Statistics

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.7.1	Real Time Access Point Statistics	This feature is enhanced with the implementation of AP threshold values between 0 and 50 to trigger an alarm.

Restrictions for AP Radio Monitoring Statistics

You cannot reset the radio firmware from the controller. The controller will shut and unshut the radio if the Rx or Tx count is not incremented for a radio slot in a specified period.

Configuring Access Point Real Time Statistics (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
 - Step 2** Click **Add**. The **Add AP Join Profile** page is displayed.
 - Step 3** Under the **AP** tab, click the **AP Statistics** tab.
 - Step 4** In the **System Monitoring** section:
 - a) Enable **Monitor Real Time Statistics** to get calculated statistics and alarms of the AP.
 - b) To receive an alarm when the upper threshold is surpassed for parameters such as CPU utilization and memory, enable **Trigger Alarm for AP**.
 - c) Enter the threshold percentage for CPU and memory usage in the **CPU Threshold to Trigger Alarm** field and **Memory Threshold to Trigger Alarm** fields, respectively. The valid range is between 0 to 50. An SNMP trap is sent out when this threshold is crossed.
 - d) In the **Interval to Hold Alarm** field, enter the time for which the alarm is held before it gets triggered. The valid range is between 0 and 3600 seconds.
 - e) In the **Trap Retransmission Time** field, enter the time between retransmissions of the alarm. The valid range is between 0 and 65535 seconds.

- f) To define how often data should be collected from the AP, enter a value in the **Sampling Interval** field. The valid range is between 720 and 3600 seconds.
- g) To define the interval at which AP statistics are to be calculated, enter a value in the **Statistics Interval** field. The valid range is between 2 and 900 seconds.
- h) To automatically reload the AP when there is high CPU and memory usage in the defined sampling interval, select the **Reload the AP** check box.

Step 5

Under the **Radio Monitoring** section:

- a) Select the **Monitoring of AP Radio stuck** check box to verify that the Tx and Rx statistics of the AP are updated each time the payloads are coming in from the AP to the controller.
- b) To generate an alarm for the radio of the AP when there is no increment in the Tx and RX statistics for the payloads, select the **Alarms for AP Radio stuck** check box.
- c) Select the **Reset the stuck AP Radio** check box to recover the radio from the bad state. A radio admin state payload will be sent from the controller to toggle the radio and the radio will be shut when there is no increment in the Tx and Rx statistics.
- d) To define how often data should be collected from the radio, enter a value in the **Sampling Interval** field. The valid range is between 720 and 3600 seconds.

Step 6

Click **Apply to Device** to save the configuration.

Configuring Real-Time Access Point Statistics (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile-name</i> Example: Device(config)# ap profile <i>doc-test</i>	Configures the AP profile. The default AP join profile name is <i>default-ap-profile</i> .
Step 3	stats-timer <i>frequency</i> Example: Device(config-ap-profile)# stats-timer 60	(Optional) Configures the statistics timer. This command is used to change the frequency of the statistics reports coming from the AP. The valid values range between 0 and 65535 seconds.
Step 4	statistics ap-system-monitoring enable Example: Device(config-ap-profile)# statistics ap-system-monitoring enable	(Optional) Enables monitoring of AP real-time statistics (CPU and memory).

	Command or Action	Purpose
Step 5	statistics ap-system-monitoring alarm-enable Example: <pre>Device(config-ap-profile)# statistics ap-system-monitoring alarm-enable</pre>	Enables alarms for AP real-time statistics (CPU and memory).
Step 6	statistics ap-system-monitoring alarm-hold-time duration Example: <pre>Device(config-ap-profile)# statistics ap-system-monitoring alarm-hold-time 400</pre>	Defines the alarms for AP real-time statistics (CPU and Memory). The valid values range between 0 and 3600 seconds.
Step 7	ap-system-monitoring alarm-retransmit-time duration Example: <pre>Device(config-ap-profile)# ap-system-monitoring alarm-retransmit-time 100</pre>	Defines the interval between retransmissions of the trap alarm. The valid values range between 0 and 65535 seconds.
Step 8	statistics ap-system-monitoring cpu-threshold percentage Example: <pre>Device(config-ap-profile)# statistics ap-system-monitoring cpu-threshold 30</pre>	Defines the threshold for CPU usage on the AP (percentage) to trigger alarms. Note From Cisco IOS XE Cupertino 17.7.1 release onwards, the valid threshold value for CPU on the AP to trigger the alarms is between 0 and 50.
Step 9	ap-system-monitoring mem-threshold percentage Example: <pre>Device(config-ap-profile)# ap-system-monitoring mem-threshold 40</pre>	Defines the threshold for memory usage on AP to trigger alarms. The percentage of threshold for memory usage on the AP to trigger is between 0 and 100. Note From Cisco IOS XE Cupertino 17.7.1 release onwards, the valid threshold value for memory usage on the AP to trigger the alarms is between 0 and 50.
Step 10	ap-system-monitoring sampling-interval duration Example: <pre>Device(config-ap-profile)# statistics ap-system-monitoring sampling-interval 600</pre>	(Optional) Defines the sampling interval. The valid values range between 2 and 900 seconds.
Step 11	exit Example:	Exits from AP profile configuration mode and returns to global configuration mode.

	Command or Action	Purpose
	Device(config-ap-profile)# exit	
Step 12	trapflags ap ap-stats Example: Device(config)# trapflags ap ap-stats	Enables sending AP-related traps. Traps are sent when statistics exceed the configured threshold.

Example

```

Device(config)# ap profile default-policy-profile
Device(config-ap-profile)# statistics ap-system-monitoring enable
Device(config-ap-profile)#statistics ap-system-monitoring sampling-interval 90
Device(config-ap-profile)#statistics ap-system-monitoring stats-interval 120
Device(config-ap-profile)#statistics ap-system-monitoring alarm-enable
Device(config-ap-profile)#statistics ap-system-monitoring alarm-hold-time 3
Device(config-ap-profile)#statistics ap-system-monitoring alarm-retransmit-time 10
Device(config-ap-profile)#statistics ap-system-monitoring cpu-threshold 90
Device(config-ap-profile)#statistics ap-system-monitoring mem-threshold 90
Device(config)# trapflags ap ap-stats

```

Configuring AP Radio Monitoring Statistics

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>profile-name</i> Example: Device(config)# ap profile test1	Configures an AP profile and enters the AP profile configuration mode.
Step 3	statistic ap-radio-monitoring enable Example: (config-ap-profile)#statistic ap-radio-monitoring enable	Enables the monitoring of AP radio stuck statistics.
Step 4	statistic ap-radio-monitoring alarm-enable Example: (config-ap-profile)#statistic ap-radio-monitoring alarm-enable	(Optional) Enables the alarm for AP radio stuck statistics.
Step 5	statistic ap-system-monitoring action reload-ap interval <i>duration</i> Example:	(Optional) Specifies the sampling interval in seconds. The valid values range between 720 and 3600 seconds.

	Command or Action	Purpose
	<code>(config-ap-profile)# statistic ap-radio-monitoring action reload-ap interval850</code>	
Step 6	statistic ap-radio-monitoring action radio-reset Example: <code>(config-ap-profile)# statistic ap-radio-monitoring action radio-reset</code>	(Optional) Generates an alarm and resets the radio if the radio is stuck.
Step 7	statistic ap-system-monitoring action reload-ap Example: <code>(config-ap-profile)# statistic ap-system-monitoring action reload-ap</code>	Reloads the AP.

Example

```
Device(config)# ap profile test1
Device(config-ap-profile)# statistics ap-radio-monitoring enable
Device(config-ap-profile)#statistic ap-radio-monitoring alarm-enable
Device(config-ap-profile)#statistic ap-radio-monitoring sampling-interval 750
Device(config-ap-profile)# statistic ap-radio-monitoring action radio-reset
Device(config-ap-profile)#statistic ap-system-monitoring action reload-ap
```

Monitoring Access Point Real-Time Statistics (GUI)

Procedure

-
- Step 1** Choose **Monitoring > Wireless > AP Statistics**.
 - Step 2** Click the **General** tab.
 - Step 3** Click an AP name. The **General** window is displayed.
 - Step 4** To view the AP Statistics data, click the **AP Statistics** tab.

The following information is displayed:

- **Memory alarm last send time:** Displays the time of the last memory trap sent.
- **Memory Alarm Status:** Displays the state of the memory alarm. An alarm can be **ACTIVE**, **INACTIVE**, **INACTIVE_SOAKING**, **ACTIVE_SOAKING**. An alarm is soaked until the configured hold time has passed.
- **Memory alarm raise time:** Displays the last time the memory alarm was active.
- **Memory alarm clear time:** Displays the last time the memory alarm was inactive.

- **Last statistics received:** Displays the time of the last statistics report received from the AP.
- **Current CPU Usage:** Displays the latest percentage of CPU usage reported.
- **Average CPU Usage:** Displays the average CPU usage calculated.
- **Current Memory Usage:** Displays the latest percentage of memory usage reported.
- **Average Memory Usage:** Displays the average memory usage calculated.
- **Current window size:** Displays the window size. The window size is calculated by dividing the statistics interval by the sampling interval. The average CPU and memory usage is calculated by the window size.
- **CPU alarm last send time:** Displays the time of the last CPU trap sent.
- **CPU Alarm Status:** Displays the state of the CPU alarm. An alarm can be **ACTIVE**, **INACTIVE**, **INACTIVE_SOAKING**, **ACTIVE_SOAKING**. An alarm is soaked until the configured hold time has passed.
- **CPU alarm raise time:** Displays the last time the CPU alarm was active.
- **CPU alarm clear time:** Displays the last time the CPU alarm was inactive.

Step 5 Click OK.

Verifying Access Point Real-Time Statistics

To verify AP real-time statistics, run the **show ap config general | section AP statistics** command:

```
Device# show ap config general | section AP statistics
!Last Statistics
AP statistics : Enabled
Current CPU usage : 4
Average CPU usage : 49
Current memory usage : 35
Average memory usage : 35
Last statistics received : 03/09/2021 15:25:08
!Statistics Configuration
Current window size : 1
Sampling interval : 30
Statistics interval : 300
AP statistics alarms : Enabled
!Alarm State - Active, Inactive, Inactive_Soaking, Inactive_Soaking
Memory alarm status : Active
Memory alarm raise time : 03/09/2021 15:24:29
Memory alarm clear time : NA
Memory alarm last send time : 03/09/2021 15:24:59
CPU alarm status : Inactive
CPU alarm raise time : 03/09/2021 15:24:25
CPU alarm clear time : 03/09/2021 15:25:05
CPU alarm last send time : 03/09/2021 15:25:05
!Alarm Configuration
Alarm hold time : 6
Alarm retransmission time : 30
Alarm threshold cpu : 30
Alarm threshold memory : 32
```

To verify the statistics reporting period, run the **show ap config general | i Stats Reporting Period** command:

```
Device# show ap config general | i Stats Reporting Period
Stats Reporting Period : 10
```

Feature History for Access Point Auto Location Support

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 39: Feature History for Access Point Auto Location Support

Release	Feature Information
Cisco IOS XE Dublin 17.12.1	The Access Point Auto Location Support feature helps to effectively self-locate APs in a global coordinate by combining various ranging technologies and algorithms.
Cisco IOS XE Dublin 17.13.1	The improvized Access Point Auto Location Support feature helps wireless clients to leverage Fine Timing Measurement (FTM) and AP GNSS for indoor navigation.

Information About Access Point Auto Location Support

In all enterprise wireless deployments, AP location is manually entered. In many cases, the AP location is not entered because it is a tedious process to identify the location manually and enter it in the system, or, the AP location is entered only to provide a reference for client location. A Global Positioning System (GPS) or a Global Navigation Satellite System (GNSS) solution is not feasible because of the indoor nature of the deployments.

From Cisco IOS XE Dublin 17.12.1 onwards, a solution to effectively self-locate the APs in a global coordinate by combining various ranging technologies and algorithms, is introduced through the AP Location feature.

Location of an object, by definition, is dependent on a reference point. Here, reference points are based as a few subsets of sparse nodes from a group of nodes serving a continuous RF domain. These are the ones that have visibility to the open sky, namely, the ones located near the windows, or the ones at the periphery of the building or floor.

The AP Auto Location solution delivers accurate, automated, up-to-date AP location leveraging Fine Timing Measurement (FTM) and GNSS when available. If GNSS is not accessible, a few manual anchors need to be provided per floor. This feature requires an AP density such that neighboring APs can hear each other at maximum power. The accuracy of the feature depends on the building type and the distances between APs.

The process includes:

- Segmentation of a large number of APs into smaller segments with floor-level labels and the calculation of the geolocations of all the APs at the end of the process.
- Geolocation of an AP is determined at the controller, Cisco Spaces, or both the controller and Cisco Spaces.

- Highly accurate GNSS positioning of the APs that have good GNSS signal reception and, geolocating the APs with no GNSS reception by running the locationing algorithm to determine the geolocation based on inter-APs ranging data (FTM) to GNSS-enabled APs.

From Cisco IOS XE 17.13.1 onwards, the AP Auto Location Support feature has been improved to help wireless clients to leverage FTM and AP GNSS for indoor navigation.

- **Client FTM:** You can enable the FTM responder in the designated WLANs for indoor navigation. The APs support ranging from unassociated clients through the FTM responders in the 5-GHz and 6-GHz bands.
- **Air Pressure Reporting Updates:** APs send air pressure report to the controller. As an enhancement to this feature, in Cisco IOS XE 17.13.1, remote procedure calls (RPC) and the Privileged EXEC mode commands enable the collection of air pressure details for a specific duration. For example, if you set the duration as 10 minutes, then the AP will send samples every 30 seconds, for 10 minutes.
- **AP Band Filters:** In Cisco IOS XE Dublin 17.12.1, the area optimization for AP-to-AP ranging was triggered on a per site-tag basis. From Cisco IOS XE Dublin 17.13.1 onwards, band filters such as 5 GHz or 6 GHz are enhanced for effective ranging.
- **AP Ranging Completion Notification:** The controller monitors all APs in a given site for ranging completion. Ranging is considered as complete only after the AP sends the ranging report back to the controller, in response to the ranging requests made by the controller.

The controller notifies the APs and Cisco Spaces when ranging is complete for a given site.

- **AP Movement Alarm:** When an AP gets disconnected and later reconnects in a different location, the AP sends an alarm to the controller. The controller prints a syslog and sends an event to Cisco Spaces, to notify the user about the AP movement.

Use Case

A typical use case of the solution in the controller is either self-locating APs in one building or APs in one floor of a building.

Supported Access Points

This feature is supported in the following APs:

- Cisco Catalyst 9130 Series Access Points
- Cisco Catalyst 9136 Series Access Points
- Cisco Catalyst 9164 Series Access Points
- Cisco Catalyst 9166 Series Access Points

Configuring Access Point Geolocation Derivation Using Ranging (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Wireless Global**.
- Step 2** In the **AP Geolocation** section, click the **Geolocation Derivation Using Ranging** toggle button to enable geolocation derivation.
When you enable **Geolocation Derivation Using Ranging**, it allows the corresponding AP to be a part of the location services that use ranging to determine the geolocation of the AP.
- Step 3** Click **Apply**.
-

Configuring Access Point Geolocation Derivation Using Ranging (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	[no] ap geolocation derivation ranging Example: Device(config)# ap geolocation derivation ranging	Enables geolocation derivation using ranging. Use the no form of this command to disable the feature.

Configuring Access Point Ranging Parameters (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
- Step 2** Click **Add**.
- Step 3** In the **General** tab, enter the name and description of the corresponding AP join profile.
- Step 4** Click the **Geolocation** tab.

- Step 5** In the **Fine Time Management (FTM)** section, complete the following:
- Click the **FTM** toggle button to allow APs to use FTM for inter AP ranging.
 - In the **FTM Initiator Burst Size** field, specify the burst size value. The burst size determines the size of the transmitted frames. The valid range is between 2 and 31 frames. The default value is 16 frames per burst.
 - From the **FTM Initiator Burst Duration** drop-down list, choose a value. The burst duration determines the interval of the transmitted frames. The default value is 32 microseconds.
- Step 6** Click **Apply to Device**.

Configuring Access Point Ranging Parameters (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile-name</i> Example: Device(config)# ap profile ap-profile1	Configures an AP profile and enters AP profile configuration mode.
Step 3	[no] geolocation ftm Example: Device(config-ap-profile)# geolocation ftm	Enables geolocation Fine Timing Measurement (FTM).
Step 4	[no] geolocation ftm initiator burst-size <i>burst-size</i> Example: Device(config-ap-profile)# geolocation ftm initiator burst-size 8	Configures the geolocation FTM burst size. The burst size values are 4, 8, 16, 32, and 64 frames. The default value is 8 frames per burst.
Step 5	[no] geolocation ftm initiator burst-duration {128ms 16ms 1ms 250us 2ms 32ms 4ms 500us 64ms 8ms} Example: Device(config-ap-profile)# geolocation ftm initiator burst-duration 32ms	Configures the geolocation FTM burst duration. The default value is 32 microseconds.

Configuring Access Point Coordinates and Floor Information (CLI)

The following steps help you to configure the AP coordinates and the corresponding floor information.

Note There are no corresponding GUI steps for this configuration.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	ap name <i>ap-name</i> geolocation coordinates <i>longitude latitude</i> Example: Device# ap name <i>cisco-ap1</i> geolocation coordinates 90 45	Configures the longitude and latitude of the AP. The value range for longitude is between -180 and 180 degrees. The value range for latitude is between -90 to 90 degrees.
Step 3	ap name <i>ap-name</i> floor <i>floor-id</i> Example: Device# ap name <i>cisco-ap1</i> floor 2147483647	Configures the floor ID for the AP. The floor ID range is between -2147483648 and 2147483647.

Configuring On-Demand Access Point Ranging (CLI)

The following steps help you to configure on-demand AP ranging.

Note There are no corresponding GUI steps for this configuration.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.

	Command or Action	Purpose
Step 2	ap geolocation ranging site <i>ap-site-tag</i> accurate [5ghz 6ghz] Example: Device# ap geolocation ranging site ap-site-tag accurate 5ghz	Enables accurate ranging using the 5-GHz or 6-GHz bands on APs under the configured site tag. Note Client connections may be disrupted.
Step 3	ap geolocation ranging all accurate [5ghz 6ghz] Example: Device# ap geolocation ranging all accurate 5ghz	Enables accurate ranging using the 5-GHz or 6-GHz bands on all APs. Caution Client connections may be disrupted.

Enabling Fine Time Measurement (802.11mc) Responder (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > WLANs**.
- Step 2** Click **Add**.
The **Add WLAN** page is displayed.
- Step 3** In the **General** tab, enter the **Profile Name**, the **SSID**, and the **WLAN ID**.
- Step 4** In the **Advanced** tab, under the **Geolocation** section, click the **Fine Time Measurement (FTM) Responder** toggle button to enable the AP to respond to time measurement queries sent from a client. The client sends time measurement queries to measure its distance to the AP and determine their indoor location. The **Advertise AP Location** field is displayed.
- Step 5** Click the **Advertise AP Location** toggle button to enable the AP to advertise its geolocation coordinates.
- Step 6** Click **Apply to Device** to save the configuration.
-

Configuring Fine Time Measurement (802.11mc) Responder (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan profile-name wlan-id ssid-name <i>profile-name wlan-id ssid-name</i>	Specifies the WLAN name and ID.

	Command or Action	Purpose
	Example: <pre>Device(config)# wlan wlan-profile 36 ssid1</pre>	<ul style="list-style-type: none"> • <i>profile-name</i> is the WLAN name. Valid WLAN names can contain upto 32 alphanumeric characters • <i>wlan-id</i> is the wireless LAN identifier. The valid range is from 1 to 4096. • <i>ssid-name</i> is the SSID which can contain 32 alphanumeric characters.
Step 3	[no] geolocation ftm-responder Example: <pre>Device(config-wlan)# geolocation ftm-responder</pre>	Configures the FTM responder.
Step 4	[no] geolocation ftm-responder advertise-ap-location Example: <pre>Device(config-wlan)# geolocation ftm-responder advertise-ap-location</pre>	Configures the advertisement of AP location to clients.
Step 5	(Optional) clear ap geolocation ranging Example: <pre>Device# clear ap geolocation ranging</pre>	Clears the AP geolocation best known FTM report.

Configuring Air Pressure Reporting (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	ap sensor air-pressure {all site site-tag-name} [duration duration-time] Example: <pre>Device# ap sensor air-pressure site sitetag1 duration 10</pre>	Configures the sensor air pressure data collection for all APs or for APs in a specific site tag. The value range of the duration of the air pressure reporting is between 1 minute and 1440 minutes. The default is 10 minutes.

Verifying Access Point Geolocation Information

To view the AP geolocation ranging report, run the following command:

```

Device# show ap geolocation ranging report
AP RadioMAC      NeighbourMAC    Type  Method  Dist (cm)  Channel  Band      Width
Duration (ms)   RSSIAvg  Frames      Time

```

To view an AP geolocation ranging request, run the following command:

```

Device# show ap geolocation ranging request
Request ID  SiteTag/All APs  Mode      Band  Requests  Responses  Reports
Start Time                End Time
-----
3           ALL APs          Accurate  All   2          2          4
09/22/2023 16:29:28 IST  09/22/2023 16:29:36 IST
2           ALL APs          Normal    All   2          0          0
09/22/2023 16:21:13 IST  09/22/2023 16:21:35 IST
1           ALL APs          Accurate  All   2          2          6
09/22/2023 16:18:39 IST  09/22/2023 16:18:49 IST

```

To view the AP geolocation summary, run the following command:

```

Device# show ap geolocation summary
AP Name      Radio MAC      Location  Location Longitude  Latitude
Major-axis  Minor-axis  Orientation Height Height  Height  Height
(meters)    (degrees)   Type      (meters) Uncertainty Source (degrees) (degrees) (meters)
                                         (meters)
-----
APCC9C.3EF1.0F30  10f9.20fd.f640  Ellipse  Manual  90.000000  90.000000  0
0              0.000000  NA      NA      NA      NA

```

To view the AP geolocation statistics, run the following command:

```

Device# show ap geolocation statistics
Num APs with GNSS      : 1
Num APs with manual height : 0
Num APs with derived geolocation : 0
Last geolocation derivation run : 07/21/2023 08:54:21

```

To view the AP geolocation GNSS-capable summary, run the following command:

```

Device# show ap geolocation gnss-capable summary
-----
AP Name      Radio MAC      GPS Coverage  Antenna Type  Last GPS fix
-----
APCC9C.3EF4.CF00  10f9.20fd.b6e0  No           Internal      NA
-----

```

To view the AP geolocation ranging status, run the following commands:

```

Device# show ap geolocation ranging status
Device# show ap name geolocation ranging status

```

To view the ranging capability of APs, run the following command:

```

Device# show ap geolocation ranging capability
AP Name      FTM Responder  FTM Initiator
-----
AP0001.Cisco.CF00  Yes           Yes

```

Verifying Access Point Geolocation Information

AP0002.Cisco.0F30	Yes	Yes
AP-2800	No	No
AP0003.Cisco.82a0	No	No

Feature History for Configuring the Access Point Console

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 40: Feature History for Configuring the Access Point Console

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.9.1	Configuring the Access Point Console	<p>This feature allows you to configure the Access Point (AP) console from the controller.</p> <p>In Cisco IOS XE Cupertino 17.8.x and earlier releases, the AP console could be disabled from the controller, only by enabling the Federal Information Processing Standard (FIPS) mode or the Common Criteria (CC) mode.</p>

Information About Configuring the Access Point Console

From Cisco IOS XE Cupertino 17.9.1 onwards, a new option (a configuration knob) is introduced to enable the Access Point console from the controller, which is independent of the FIPS mode or the high-security

mode (CC mode). (Until Cisco IOS XE Cupertino 17.8.1, the console was enabled by default). This configuration knob can be activated through the controller GUI and CLI.

Console enablement is isolated from the FIPS mode and is configured through the AP join profile. In the CC mode, the console and SSH are disabled. When you enable the CC mode, it overrides the AP console configurations, if any, done from the AP profile.

Configuring the AP Console (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
 - Step 2** In the **Management** tab, in the **Telnet/SSH Configuration** section, check the **Serial Console** check box.
 - Step 3** Click **Apply to Device**.
-

Configuring the AP Console (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile-name</i> Example: Device(config)# ap profile <i>ap-profile-name</i>	Configures an AP profile and enters AP profile configuration mode.
Step 3	[no] console Example: Device(config-ap-profile)# console	Enables the AP serial console port. Use the no form of this command to disable the AP serial console port.

Verifying the AP Console Status

To verify the AP console status from the controller, run the following command:

```
Device# show ap config general | include ap-Name | console
Cisco AP Name : CiscoAP
=====
```

```
Cisco AP Identifier : 6XXX.bXXX.aXXX
```

```
Country Code : US
Regulatory Domain Allowed by Country : 802.11bg:-A 802.11a:-AB 802.11 6GHz:-B

SSH State : Enabled
Serial Console State : Enabled
```

Information About AP Audit Configuration

The AP Audit Configuration feature helps to detect wireless service synchronization issues between the controller and an AP. In Cisco IOS XE Amsterdam, Release 17.3.1, two methods are implemented to support AP audit configuration.

- **Config Checker:** This functionality helps in auditing the application of wireless policies during the AP join phase. Any discrepancies at this stage is reported on the controller. This is a built-in functionality and you cannot disable the same. When you try to configure any of the AP attributes such as name, IP address, controller information, tag, mode, radio mode, and radio admin state, the AP parses the CAPWAP payload configuration from the controller and reports errors detected back to the controller with proper code. If a discrepancy is detected, the controller flags errors using the syslog.
- **Config Audit:** This functionality helps to perform periodic comparison of operational states between an AP and the controller after the AP join phase and while the corresponding AP is still connected. Discrepancies, if any, are reported immediately on the controller. The consolidated report is available at the controller anytime. This functionality is disabled by default. The periodic auditing interval is a configurable parameter.

Use the **ap audit-report** command to enable and configure audit report parameters. When triggered, AP sends configurations from the database to the controller, and the controller compares the configurations against the current configuration. If a discrepancy is detected, the controller flags the error using the syslog.

Restrictions for AP Audit Configuration

- Config checker alerts are available only through the syslog.
- IOS AP is not supported.

- The audit reports are not synchronized from the active to the standby controller. After SSO, they are not readily available until the next reporting interval of the already-connected APs.
- The audit reports are not available when an AP is in standalone mode.
- This feature is supported only on APs in FlexConnect mode.

Configure AP Audit Parameters (CLI)

The AP Audit Configuration feature helps you compare the operational states between an AP and the controller. The AP sends state view details to the controller, and the controller compares it with what it perceives as the AP state. This feature is disabled by default.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap audit-report enable Example: Device(config)# ap audit-report enable	Enables audit reporting.
Step 3	ap audit-report interval <i>interval</i> Example: Device(config)# ap audit-report interval 1300	Configures AP audit reporting interval. The default value for interval is 1440 minutes. The valid range is from 10 to 43200.

Verifying AP Audit Report Summary

To verify the AP audit report summary, use the **ap audit-report summary** command:

```
Device# show ap audit-report summary
WTP Mac           Radio           Wlan           IPv4 Acl
IPv6 Acl         Last Report Time

2.4-GHz Radio Support

Configuring 2.4-GHz Radio Support for the Specified Slot Number

Before you begin

Note The term *802.11b radio* or *2.4-GHz radio* will be used interchangeably.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap name ap-name dot11 24ghz slot 0 SI Example: Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 SI	Enables Spectrum Intelligence (SI) for the dedicated 2.4-GHz radio hosted on slot 0 for a specific access point. For more information, <i>Spectrum Intelligence</i> section in this guide. Here, 0 refers to the Slot ID.
Step 3	ap name ap-name dot11 24ghz slot 0 antenna {ext-ant-gain antenna_gain_value selection [internal external]}	Configures 802.11b antenna hosted on slot 0 for a specific access point.

	Command or Action	Purpose
	<p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 antenna selection internal</pre>	<ul style="list-style-type: none"> • ext-ant-gain: Configures the 802.11b external antenna gain. <i>antenna_gain_value</i>- Refers to the external antenna gain value in multiples of .5 dBi units. The valid range is from 0 to 4294967295. • selection: Configures the 802.11b antenna selection (internal or external). <p>Note</p> <ul style="list-style-type: none"> • For APs supporting self-identifying antennas (SIA), the gain depends on the antenna, and not on the AP model. The gain is learned by the AP and there is no need for controller configuration. • For APs that do not support SIA, the APs send the antenna gain in the configuration payload, where the default antenna gain depends on the AP model. • Cisco Catalyst 9120E and 9130E APs support self-identifying antennas (SIA). Cisco Catalyst 9115E APs do not support SIA antennas. Although Cisco Catalyst 9115E APs work with SIA antennas, the APs do not auto-detect SIA antennas nor add the correct external gain.
Step 4	<p>ap name <i>ap-name</i> dot11 24ghz slot 0 beamforming</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 beamforming</pre>	Configures beamforming for the 2.4-GHz radio hosted on slot 0 for a specific access point.
Step 5	<p>ap name <i>ap-name</i> dot11 24ghz slot 0 channel {<i>channel_number</i> auto}</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 channel auto</pre>	Configures advanced 802.11 channel assignment parameters for the 2.4-GHz radio hosted on slot 0 for a specific access point.

	Command or Action	Purpose
Step 6	ap name <i>ap-name</i> dot11 24ghz slot 0 cleanair Example: Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 cleanair	Enables CleanAir for 802.11b radio hosted on slot 0 for a specific access point.
Step 7	ap name <i>ap-name</i> dot11 24ghz slot 0 dot11n antenna {A B C D} Example: Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 dot11n antenna A	Configures 802.11n antenna for 2.4-GHz radio hosted on slot 0 for a specific access point. Here, A: Is the antenna port A. B: Is the antenna port B. C: Is the antenna port C. D: Is the antenna port D.
Step 8	ap name <i>ap-name</i> dot11 24ghz slot 0 shutdown Example: Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 shutdown	Disables 802.11b radio hosted on slot 0 for a specific access point.
Step 9	ap name <i>ap-name</i> dot11 24ghz slot 0 txpower {<i>tx_power_level</i> auto} Example: Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 txpower auto	Configures transmit power level for 802.11b radio hosted on slot 0 for a specific access point. <ul style="list-style-type: none"> • <i>tx_power_level</i>: Is the transmit power level in dBm. The valid range is from 1 to 8. • auto: Enables auto-RF.

5-GHz Radio Support

Configuring 5-GHz Radio Support for the Specified Slot Number

Before you begin

Note The term *802.11a radio* or *5-GHz radio* will be used interchangeably in this document.

Procedure

	Command or Action	Purpose
Step 1	enable Example:	Enters privileged EXEC mode.

	Command or Action	Purpose
	Device# enable	
Step 2	ap name <i>ap-name</i> dot11 5ghz slot 1 SI Example: Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 SI	Enables Spectrum Intelligence (SI) for the dedicated 5-GHz radio hosted on slot 1 for a specific access point. Here, 1 refers to the Slot ID.
Step 3	ap name <i>ap-name</i> dot11 5ghz slot 1 antenna ext-ant-gain <i>antenna_gain_value</i> Example: Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 antenna ext-ant-gain	Configures external antenna gain for 802.11a radios for a specific access point hosted on slot 1. <i>antenna_gain_value</i> —Refers to the external antenna gain value in multiples of .5 dBi units. The valid range is from 0 to 4294967295. Note <ul style="list-style-type: none"> • For APs supporting self-identifying antennas (SIA), the gain depends on the antenna, and not on the AP model. The gain is learned by the AP and there is no need for controller configuration. • For APs that do not support SIA, the APs send the antenna gain in the configuration payload, where the default antenna gain depends on the AP model. • Cisco Catalyst 9120E and 9130E APs support self-identifying antennas (SIA). Cisco Catalyst 9115E APs do not support SIA antennas. Although Cisco Catalyst 9115E APs work with SIA antennas, the APs do not auto-detect SIA antennas nor add the correct external gain.
Step 4	ap name <i>ap-name</i> dot11 5ghz slot 1 antenna mode [omni sectorA sectorB] Example: Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 antenna mode sectorA	Configures the antenna mode for 802.11a radios for a specific access point hosted on slot 1.

	Command or Action	Purpose
Step 5	ap name <i>ap-name</i> dot11 5ghz slot 1 antenna selection [internal external] Example: <pre>Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 antenna selection internal</pre>	Configures the antenna selection for 802.11a radios for a specific access point hosted on slot 1.
Step 6	ap name <i>ap-name</i> dot11 5ghz slot 1 beamforming Example: <pre>Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 beamforming</pre>	Configures beamforming for the 5-GHz radio hosted on slot 1 for a specific access point.
Step 7	ap name <i>ap-name</i> dot11 5ghz slot 1 channel {<i>channel_number</i> auto width [20 40 80 160]} Example: <pre>Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 channel auto</pre>	Configures advanced 802.11 channel assignment parameters for the 5-GHz radio hosted on slot 1 for a specific access point. Here, <i>channel_number</i> - Refers to the channel number. The valid range is from 1 to 173.
Step 8	ap name <i>ap-name</i> dot11 5ghz slot 1 cleanair Example: <pre>Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 cleanair</pre>	Enables CleanAir for 802.11a radio hosted on slot 1 for a given or specific access point.
Step 9	ap name <i>ap-name</i> dot11 5ghz slot 1 dot11n antenna {A B C D} Example: <pre>Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 dot11n antenna A</pre>	Configures 802.11n for 5-GHz radio hosted on slot 1 for a specific access point. Here, A - Is the antenna port A. B - Is the antenna port B. C - Is the antenna port C. D - Is the antenna port D.
Step 10	ap name <i>ap-name</i> dot11 5ghz slot 1 rrm channel <i>channel</i> Example: <pre>Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 rrm channel 2</pre>	Is another way of changing the channel hosted on slot 1 for a specific access point. Here, <i>channel</i> - Refers to the new channel created using 802.11h channel announcement. The valid range is from 1 to 173, provided 173 is a valid channel in the country where the access point is deployed.
Step 11	ap name <i>ap-name</i> dot11 5ghz slot 1 shutdown Example:	Disables 802.11a radio hosted on slot 1 for a specific access point.

	Command or Action	Purpose
	Device# <code>ap name AP-SIDD-A06 dot11 5ghz slot 1 shutdown</code>	
Step 12	ap name <i>ap-name</i> dot11 5ghz slot 1 txpower {<i>tx_power_level</i> auto} Example: Device# <code>ap name AP-SIDD-A06 dot11 5ghz slot 1 txpower auto</code>	Configures 802.11a radio hosted on slot 1 for a specific access point. <ul style="list-style-type: none"> • <i>tx_power_level</i>- Is the transmit power level in dBm. The valid range is from 1 to 8. • auto- Enables auto-RF.

6-GHz Radio Support

Configuring 6-GHz Radio Support for the Specified Slot Number

Before you begin

Static channel must be set before changing the channel width.

As there are no external antenna APs, as by regulatory requirements, antennas have to be captive (internal always) for 6-GHz.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# <code>enable</code>	Enters privileged EXEC mode.
Step 2	ap name <i>ap-name</i> dot11 6ghz slot 3 antenna port {A B C D} Example: Device# <code>ap name Cisco-AP dot11 6ghz slot 3 antenna port A</code>	Configures the antenna port for 802.11 6-GHz radios for a specific access point. Here, A: Is the antenna port A. B: Is the antenna port B. C: Is the antenna port C. D: Is the antenna port D.
Step 3	ap name <i>ap-name</i> dot11 6ghz slot 3 antenna selection [internal external] Example:	Configures the antenna selection, either internal or external, for 802.11 6-GHz radios for a specific access point.

	Command or Action	Purpose
	<pre>Device# ap name Cisco-AP dot11 6ghz slot 1 antenna selection internal</pre>	<p>Note</p> <ul style="list-style-type: none"> For APs supporting self-identifying antennas (SIA), the gain depends on the antenna, and not on the AP model. The gain is learned by the AP and there is no need for controller configuration. For APs that do not support SIA, the APs send the antenna gain in the configuration payload, where the default antenna gain depends on the AP model. Cisco Catalyst 9120E and 9130E APs support self-identifying antennas (SIA). Cisco Catalyst 9115E APs do not support SIA antennas. Although Cisco Catalyst 9115E APs work with SIA antennas, the APs do not auto-detect SIA antennas nor add the correct external gain.
Step 4	<p>ap name <i>ap-name</i> dot11 6ghz slot 3 channel {<i>channel_number</i> auto width [160 20 40 80]}</p> <p>Example:</p> <pre>Device# ap name Cisco-AP dot11 6ghz slot 3 channel auto</pre>	<p>Configures advanced 802.11 channel assignment parameters for the 6-GHz radio hosted on slot 3 for a specific access point.</p> <p>Here,</p> <p><i>channel_number</i>: Refers to the channel number. The valid range is from 1 to 233.</p>
Step 5	<p>ap name <i>ap-name</i> dot11 6ghz slot 3 dot11ax bss-color {<i>bss-color-number</i> auto}</p> <p>Example:</p> <pre>Device# ap name Cisco-AP dot11 6ghz slot 3 dot11ax bss-color auto</pre>	<p>Enables basic service set (BSS) color for 802.11 6-GHz radio for a given or specific access point.</p> <p>Here,</p> <p><i>bss-color-number</i>: Refers to the BSS color number. The valid range is from 1 to 63.</p>
Step 6	<p>ap name <i>ap-name</i> dot11 6ghz slot 3 radio role {auto manual {client-serving monitor sniffer}}</p> <p>Example:</p> <pre>Device# ap name Cisco-AP dot11 6ghz slot 3 radio role auto</pre>	<p>Configures the 802.11 6-GHz radio role, which is either auto or manual.</p>

	Command or Action	Purpose
Step 7	ap name <i>ap-name</i> dot11 6ghz slot 3 rrm channel <i>channel</i> Example: <pre>Device# ap name Cisco-AP dot11 6ghz slot 3 rrm channel 1</pre>	Configures a new channel using 802.11h channel announcement. Here, <i>channel</i> : Refers to the new channel created using 802.11h channel announcement. The valid range is from 1 to 233.
Step 8	ap name <i>ap-name</i> dot11 6ghz slot 3 shutdown Example: <pre>Device# ap name Cisco-AP dot11 6ghz slot 3 shutdown</pre>	Disables the 802.11 6-GHz radio on the Cisco AP.
Step 9	ap name <i>ap-name</i> dot11 6ghz slot 3 txpower {<i>tx_power_level</i> auto} Example: <pre># ap name AP-SIDD-A06 dot11 5ghz slot 1 txpower auto</pre>	Configures 802.11 6-GHz Tx power level. <ul style="list-style-type: none"> • <i>tx_power_level</i>: Is the transmit power level in dBm. The valid range is from 1 to 8. • auto: Enables auto-RF.

Information About Dual-Band Radio Support

The Dual-Band (XOR) radio in Cisco 2800, 3800, 4800, and the 9120 series AP models offer the ability to serve 2.4-GHz or 5-GHz bands or passively monitor both the bands on the same AP. These APs can be configured to serve clients in 2.4-GHz and 5-GHz bands, or serially scan both 2.4-GHz and 5-GHz bands on the flexible radio while the main 5-GHz radio serves clients.

Cisco Catalyst Wireless 9166 AP (CW9166) now has XOR function for a dual 5-GHz 4x4 or 5-GHz 4x4 and 6-GHz 4x4 radios. These radios can also be configured as client serving, monitor or as a sniffer interface like the earlier XOR radios.

Note For all countries that do not support 6-GHz spectrum for use of Wi-Fi, when the Cisco Catalyst Wireless 9166I AP operates as dual 5-GHz, the 5-GHz channels will be locked on both the radios even if slot 2 is disabled or set up for monitoring.

Cisco APs models up and through the Cisco 9120 APs are designed to support dual 5-GHz band operations with the *i* model supporting a dedicated Macro/Micro architecture and the *e* and *p* models supporting Macro/Macro. The Cisco 9130AXI APs and the Cisco 9136 APs support dual 5-GHz operations as Micro/Messo cell, and the CW9166I supports as Macro/Macro.

When a radio moves between bands (from 2.4-GHz to 5-GHz and vice versa), clients need to be steered to get an optimal distribution across radios. When an AP has two radios in the 5-GHz band, client steering algorithms contained in the Flexible Radio Assignment (FRA) algorithm are used to steer a client between the same band co-resident radios.

The XOR radio support can be steered manually or automatically:

- Manual steering of a band on a radio—The band on the XOR radio can only be changed manually.

- Automatic client and band steering on the radios is managed by the FRA feature that monitors and changes the band configurations as per site requirements.

Note RF measurement will not run when a static channel is configured on slot 1. Due to this, the dual band radio slot 0 will move only with 5-GHz radio and not to the monitor mode.

When slot 1 radio is disabled, RF measurement will not run, and the dual band radio slot 0 will be only on 2.4-GHz radio.

Note Only one of the 5-GHz radios can operate in the UNII band (100 - 144), due to an AP limitation to keep the power budget within the regulatory limit.

Configuring Default XOR Radio Support

Before you begin

Note The default radio points to the XOR radio hosted on slot 0.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap name <i>ap-name</i> dot11 dual-band antenna ext-ant-gain <i>antenna_gain_value</i> Example: Device# ap name <i>ap-name</i> dot11 dual-band antenna ext-ant-gain 2	Configures the 802.11 dual-band antenna on a specific Cisco access point. <i>antenna_gain_value</i> : The valid range is from 0 to 40.
Step 3	ap name <i>ap-name</i> [no] dot11 dual-band shutdown Example: Device# ap name <i>ap-name</i> dot11 dual-band shutdown	Shuts down the default dual-band radio on a specific Cisco access point. Use the no form of the command to enable the radio.
Step 4	ap name <i>ap-name</i> dot11 dual-band role manual client-serving Example:	Switches to client-serving mode on the Cisco access point.

	Command or Action	Purpose
	Device# ap name <i>ap-name</i> dot11 dual-band role manual client-serving	
Step 5	ap name <i>ap-name</i> dot11 dual-band band 24ghz Example: Device# ap name <i>ap-name</i> dot11 dual-band band 24ghz	Switches to 2.4-GHz radio band.
Step 6	ap name <i>ap-name</i> dot11 dual-band txpower {<i>transmit_power_level</i> auto} Example: Device# ap name <i>ap-name</i> dot11 dual-band txpower 2	Configures the transmit power for the radio on a specific Cisco access point. Note When an FRA-capable radio (slot 0 on 9120 AP[for instance]) is set to Auto, you cannot configure static channel and Txpower on this radio. If you want to configure static channel and Txpower on this radio, you will need to change the radio role to Manual Client-Serving mode. This note is not applicable for Cisco Catalyst Wireless 9166 AP (CW9166).
Step 7	ap name <i>ap-name</i> dot11 dual-band channel <i>channel-number</i> Example: Device# ap name <i>ap-name</i> dot11 dual-band channel 2	Enters the channel for the dual band. <i>channel-number</i> —The valid range is from 1 to 173.
Step 8	ap name <i>ap-name</i> dot11 dual-band channel auto Example: Device# ap name <i>ap-name</i> dot11 dual-band channel auto	Enables the auto channel assignment for the dual-band.
Step 9	ap name <i>ap-name</i> dot11 dual-band channel width {20 MHz 40 MHz 80 MHz 160 MHz} Example: Device# ap name <i>ap-name</i> dot11 dual-band channel width 20 MHz	Chooses the channel width for the dual band.
Step 10	ap name <i>ap-name</i> dot11 dual-band cleanair Example:	Enables the Cisco CleanAir feature on the dual-band radio.

	Command or Action	Purpose
	Device# ap name <i>ap-name</i> dot11 dual-band cleanair	
Step 11	ap name <i>ap-name</i> dot11 dual-band cleanair band {24 GHz 5 GMHz} Example: Device# ap name <i>ap-name</i> dot11 dual-band cleanair band 5 GHz Device# ap name <i>ap-name</i> [no] dot11 dual-band cleanair band 5 GHz	Selects a band for the Cisco CleanAir feature. Use the no form of this command to disable the Cisco CleanAir feature.
Step 12	ap name <i>ap-name</i> dot11 dual-band dot11n antenna {A B C D} Example: Device# ap name <i>ap-name</i> dot11 dual-band dot11n antenna A	Configures the 802.11n dual-band parameters for a specific access point.
Step 13	show ap name <i>ap-name</i> auto-rf dot11 dual-band Example: Device# show ap name <i>ap-name</i> auto-rf dot11 dual-band	Displays the auto-RF information for the Cisco access point.
Step 14	show ap name <i>ap-name</i> wlan dot11 dual-band Example: Device# show ap name <i>ap-name</i> wlan dot11 dual-band	Displays the list of BSSIDs for the Cisco access point.

Configuring XOR Radio Support for the Specified Slot Number (GUI)

Procedure

-
- Step 1** Click **Configuration > Wireless > Access Points**.
- Step 2** In the **Dual-Band Radios** section, select the AP for which you want to configure dual-band radios. The AP name, MAC address, CleanAir capability and slot information for the AP are displayed. If the Hyperlocation method is HALO, the antenna PID and antenna design information are also displayed.
- Step 3** Click **Configure**.
- Step 4** In the **General** tab, set the **Admin Status** as required.
- Step 5** Set the **CleanAir Admin Status** field to Enable or Disable.

Step 6 Click Update & Apply to Device.

Configuring XOR Radio Support for the Specified Slot Number

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap name <i>ap-name</i> dot11 dual-band slot 0 antenna ext-ant-gain <i>external_antenna_gain_value</i> Example: Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 antenna ext-ant-gain 2	Configures dual-band antenna for the XOR radio hosted on slot 0 for a specific access point. <i>external_antenna_gain_value</i> - Is the external antenna gain value in multiples of .5 dBi unit. The valid range is from 0 to 40. Note <ul style="list-style-type: none"> • For APs supporting self-identifying antennas (SIA), the gain depends on the antenna, and not on the AP model. The gain is learned by the AP and there is no need for controller configuration. • For APs that do not support SIA, the APs send the antenna gain in the configuration payload, where the default antenna gain depends on the AP model.
Step 3	ap name <i>ap-name</i> dot11 dual-band slot 0 band {24ghz 5ghz} Example: Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 band 24ghz	Configures current band for the XOR radio hosted on slot 0 for a specific access point.
Step 4	ap name <i>ap-name</i> dot11 dual-band slot 0 channel {<i>channel_number</i> auto width [160 20 40 80]} Example: Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 channel 3	Configures dual-band channel for the XOR radio hosted on slot 0 for a specific access point. <i>channel_number</i> - The valid range is from 1 to 165.

	Command or Action	Purpose
Step 5	<p>ap name <i>ap-name</i> dot11 dual-band slot 0 cleanair band {24Ghz 5Ghz}</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 cleanair band 24Ghz</pre>	Enables CleanAir features for dual-band radios hosted on slot 0 for a specific access point.
Step 6	<p>ap name <i>ap-name</i> dot11 dual-band slot 0 dot11n antenna {A B C D}</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 dot11n antenna A</pre>	<p>Configures 802.11n dual-band parameters hosted on slot 0 for a specific access point.</p> <p>Here,</p> <p>A- Enables antenna port A.</p> <p>B- Enables antenna port B.</p> <p>C- Enables antenna port C.</p> <p>D- Enables antenna port D.</p>
Step 7	<p>ap name <i>ap-name</i> dot11 dual-band slot 0 role {auto manual [client-serving monitor]}</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 role auto</pre>	<p>Configures dual-band role for the XOR radio hosted on slot 0 for a specific access point.</p> <p>The following are the dual-band roles:</p> <ul style="list-style-type: none"> • auto- Refers to the automatic radio role selection. • manual- Refers to the manual radio role selection.
Step 8	<p>ap name <i>ap-name</i> dot11 dual-band slot 0 shutdown</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 shutdown</pre> <pre>Device# ap name AP-SIDD-A06 [no] dot11 dual-band slot 0 shutdown</pre>	<p>Disables dual-band radio hosted on slot 0 for a specific access point.</p> <p>Use the no form of this command to enable the dual-band radio.</p>
Step 9	<p>ap name <i>ap-name</i> dot11 dual-band slot 0 txpower {<i>tx_power_level</i> auto}</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 txpower 2</pre>	<p>Configures dual-band transmit power for XOR radio hosted on slot 0 for a specific access point.</p> <ul style="list-style-type: none"> • <i>tx_power_level</i>- Is the transmit power level in dBm. The valid range is from 1 to 8. • auto- Enables auto-RF.

Receiver Only Dual-Band Radio Support

Information About Receiver Only Dual-Band Radio Support

This feature configures the dual-band Rx-only radio features for an access point with dual-band radios.

This dual-band Rx-only radio is dedicated for Analytics, Hyperlocation, Wireless Security Monitoring, and BLE AoA*.

This radio will always continue to serve in monitor mode, therefore, you will not be able to make any channel and *tx-rx* configurations on the 3rd radio.

Configuring Receiver Only Dual-Band Parameters for Access Points

Enabling CleanAir with Receiver Only Dual-Band Radio on a Cisco Access Point (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
 - Step 2** In the **Dual-Band Radios** settings, click the AP for which you want to configure the dual-band radios.
 - Step 3** In the **General** tab, enable the **CleanAir** toggle button.
 - Step 4** Click **Update & Apply to Device**.
-

Enabling CleanAir with Receiver Only Dual-Band Radio on a Cisco Access Point

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap name <i>ap-name</i> dot11 rx-dual-band slot 2 cleanair band {24Ghz 5Ghz} Example: Device# ap name AP-SIDD-A06 dot11 rx-dual-band slot 2 cleanair band 24Ghz Device# ap name AP-SIDD-A06 [no] dot11 rx-dual-band slot 2 cleanair band 24Ghz	Enables CleanAir with receiver only (Rx-only) dual-band radio on a specific access point. Here, 2 refers to the slot ID. Use the no form of this command to disable CleanAir.

Disabling Receiver Only Dual-Band Radio on a Cisco Access Point (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
 - Step 2** In the **Dual-Band Radios** settings, click the AP for which you want to configure the dual-band radios.
 - Step 3** In the **General** tab, disable the **CleanAir Status** toggle button.
 - Step 4** Click **Update & Apply to Device**.
-

Disabling Receiver Only Dual-Band Radio on a Cisco Access Point

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap name <i>ap-name</i> dot11 rx-dual-band slot 2 shutdown Example: Device# ap name AP-SIDD-A06 dot11 rx-dual-band slot 2 shutdown Device# ap name AP-SIDD-A06 [no] dot11 rx-dual-band slot 2 shutdown	Disables receiver only dual-band radio on a specific Cisco access point. Here, 2 refers to the slot ID. Use the no form of this command to enable receiver only dual-band radio.

Configuring Client Steering (CLI)

Before you begin

Enable Cisco CleanAir on the corresponding dual-band radio.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Device# <code>configure terminal</code>	
Step 3	<p>wireless macro-micro steering transition-threshold balancing-window <i>number-of-clients(0-65535)</i></p> <p>Example:</p> <pre>Device(config)# wireless macro-micro steering transition-threshold balancing-window 10</pre>	Configures the micro-macro client load-balancing window for a set number of clients.
Step 4	<p>wireless macro-micro steering transition-threshold client count <i>number-of-clients(0-65535)</i></p> <p>Example:</p> <pre>Device(config)# wireless macro-micro steering transition-threshold client count 10</pre>	Configures the macro-micro client parameters for a minimum client count for transition.
Step 5	<p>wireless macro-micro steering transition-threshold macro-to-micro <i>RSSI-in-dBm(-128-0)</i></p> <p>Example:</p> <pre>Device(config)# wireless macro-micro steering transition-threshold macro-to-micro -100</pre>	Configures the macro-to-micro transition RSSI.
Step 6	<p>wireless macro-micro steering transition-threshold micro-to-macro <i>RSSI-in-dBm(-128-0)</i></p> <p>Example:</p> <pre>Device(config)# wireless macro-micro steering transition-threshold micro-to-macro -110</pre>	Configures the micro-to-macro transition RSSI.
Step 7	<p>wireless macro-micro steering probe-suppression aggressiveness <i>number-of-cycles(-128-0)</i></p> <p>Example:</p> <pre>Device(config)# wireless macro-micro steering probe-suppression aggressiveness -110</pre>	Configures the number of probe cycles to be suppressed.
Step 8	<p>wireless macro-micro steering probe-suppression hysteresis <i>RSSI-in-dBm</i></p> <p>Example:</p> <pre>Device(config)# wireless macro-micro steering probe-suppression hysteresis -5</pre>	Configures the macro-to-micro probe in RSSI. The range is between -6 to -3.

	Command or Action	Purpose
Step 9	wireless macro-micro steering probe-suppression probe-only Example: Device(config)# wireless macro-micro steering probe-suppression probe-only	Enables probe suppression mode.
Step 10	wireless macro-micro steering probe-suppression probe-auth Example: Device(config)# wireless macro-micro steering probe-suppression probe-auth	Enables probe and single authentication suppression mode.
Step 11	show wireless client steering Example: Device# show wireless client steering	Displays the wireless client steering information.

Verifying Cisco Access Points with Dual-Band Radios

To verify the access points with dual-band radios, use the following command:

```
Device# show ap dot11 dual-band summary
```

```
AP Name Subband Radio      Mac      Status Channel Power Level Slot ID Mode
-----
4800    All 3890.a5e6.f360 Enabled (40)* *1/8      (22 dBm)      0  Sensor
4800    All 3890.a5e6.f360 Enabled N/A      N/A           2  Monitor
```

Information About OFDMA Support for 11ax Access Points

The Cisco Catalyst 9100 series access points are the next generation WiFi 802.11ax access point, which is ideal for high-density high-definition applications.

The IEEE 802.11ax protocol aims to improve user experience and network performance in high density deployments for both 2.4 GHz and 5 GHz. The 802.11ax APs supports transmission or reception to more than one client simultaneously using Orthogonal Frequency Division Multiplexing (OFDMA).

The IEEE 802.11ax supports uplink MU-MIMO and also adds OFDMA for multiple users in the uplink and downlink. All the users in IEEE 802.11ax OFDMA have the same time allocations and it ends at the same time. In MU-MIMO and OFDMA, multiple stations (STAs) either simultaneously transmit to a single STA or simultaneously receive from a single STA independent data streams over the same radio frequencies.

Supported Modes on 11ax Access Points

The following AP modes are supported:

- Local mode
- Flex-connect mode

- Bridge mode
- Flex+Mesh mode

Configuring 11AX (GUI)

You can configure 11ax for the frequencies, 5 GHz and 2.4 GHz.

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > High Throughput**.
- Step 2** Click the **5 GHz Band** tab.
- Expand the **11ax** section.
 - Select the **Enable 11ax** and **Multiple Bssid** check boxes, if required.
 - Check either the **Select All** check box to configure all the data rates or select the desired options from the available data rates list.
- Step 3** Click the **2.4 GHz Band** tab.
- Expand the **11ax** section.
 - Select the **Enable 11ax** and **Multiple Bssid** check boxes, if required.
 - Check either the **Select All** check box to configure all the data rates or select the desired options from the available data rates list.
-

Configuring Channel Width

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	ap dot11 { 24ghz 5ghz } rrm channel dca chan-width 160 Example: Device(config)# ap dot11 5ghz rrm channel dca chan-width 160	Configures channel width for 802.11 radios as 160. Use the no form of the command to disable the configuration. Note Cisco Catalyst 9115 and C9120 series APs do not support 80+80 channel width. Cisco Catalyst 9117 series APs do not support OFDMA in 160 channel width.

	Command or Action	Purpose
Step 3	ap dot11 { 24ghz 5ghz } rf-profile <i>profile-name</i> Example: Device(config)# ap dot11 5ghz rf-profile ax-profile	Configures an RF profile and enters RF profile configuration mode.
Step 4	channel chan-width 160 Example: Device(config-rf-profile)# channel chan-width 160	Configures the RF profile DCA channel width.

Configuring 802.11ax Radio Parameters (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > High Throughput > 5 GHz Band > 11ax**.
 - Step 2** Check or uncheck the **Enable 11 n** check box.
 - Step 3** Check the check boxes for the desired MCS/(data rate) or to select all of them, check the **Select All** check box.
 - Step 4** Click **Apply**.
 - Step 5** Choose **Configuration > Radio Configurations > High Throughput > 2.4 GHz Band > 11ax**.
 - Step 6** Check or uncheck the **Enable 11 n** check box.
 - Step 7** Check the check boxes for the desired MCS/(data rate) or to select all of them, check the **Select All** check box.
 - Step 8** Click **Apply**.
 - Step 9** Choose **Configuration > Wireless > Access Points**.
 - Step 10** Click the Access Point.
 - Step 11** In the **Edit AP** dialog box, enable the **LED State** toggle button and choose the LED brightness level from the **LED Brightness Level** drop-down list.
 - Step 12** Click **Update and Apply to Device**.
-

Configuring 802.11ax Radio Parameters (CLI)

Follow the procedure given below to configure radio parameters:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz } dot11ax Example: Device(config)# ap dot11 6ghz dot11ax	Configures 802.11 6GHz dot11ax parameters. Use the no form of the command to disable the configuration.
Step 3	ap dot11 {24ghz 5ghz 6ghz} dot11ax mcs tx index index spatial-stream spatial-stream-value Example: Device(config)# ap dot11 5ghz dot11ax mcs tx index 11 spatial-stream 8	Enables the 11ax 2.4-GHz, 5-GHz, or 6-GHz band modulation and coding scheme (MCS) transmission rates.
Step 4	ap led-brightness brightness-level Example: Device(config)# ap led-brightness 6	(Optional) Configures the led brightness level.

Setting up the 802.11ax Radio Parameters

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap name ap-name led-brightness-level brightness-level Example: Device# ap name ax-ap led-brightness-level 6	Configures the led brightness level.
Step 3	ap name ap-name dot11 {24ghz 5ghz} dot11n antenna antenna-port Example: Device# ap name ap1 dot11 5ghz dot11n antenna A	Configures the 802.11n - 5 GHz antenna selection. Use the no form of the command to disable the configuration.

	Command or Action	Purpose
Step 4	ap name <i>ap-name</i> dot11 {24ghz 5ghz} channel width <i>channel-width</i> Example: Device# ap name ap1 dot11 5ghz channel width 160	Configures 802.11 channel width.
Step 5	ap name <i>ap-name</i> dot11 {24ghz 5ghz} secondary-80 <i>channel-num</i> Example: Device# ap name ap1 dot11 5ghz secondary-80 12	Configures the advanced 802.11 secondary 80Mhz channel assignment parameters.

Configuring OFDMA on a WLAN

Note For Cisco Catalyst 9115 and 9120 series APs, the configuration given below are per radio, and not per WLAN. This feature remains enabled on the controller, if it is enabled on any of the WLANs.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 2	wlan <i>wlan1</i> Example: Device(config)# wlan wlan1	Enters the WLAN configuration mode.
Step 3	dot11ax <i>downlink-ofdma</i> Example: Device(config-wlan)# dot11ax downlink-ofdma	Enables the downlink connection that uses the OFDMA technology. Use the no form of the command to disable the configuration.
Step 4	dot11ax <i>uplink-ofdma</i> Example: Device(config-wlan)# dot11ax uplink-ofdma	Enables the uplink connection that uses the OFDMA technology .
Step 5	dot11ax <i>downlink-mumimo</i> Example:	Enables the downlink connection that uses the MUMIMO technology.

	Command or Action	Purpose
	Device(config-wlan)# dot11ax downlink-mumimo	
Step 6	dot11ax uplink-mumimo Example: Device(config-wlan)# dot11ax uplink-mumimo	Enables the uplink connection that uses the MUMIMO technology.
Step 7	dot11ax twt-broadcast-support Example: Device (config-wlan)# dot11ax twb-broadcast-support	Enables the TWT broadcast support operation.

Verifying Channel Width

To verify the channel width and other channel information, use the following **show** commands:

```
Device# show ap dot11 5ghz summary
```

```

```

Note For 6-GHz radio, the 802.11ax parameters are taken from the multi BSSID profile tagged to the corresponding 6-GHz RF profile of the AP. So, the WLAN dot11ax parameters are overridden by multi BSSID profile parameters in the case of 6-GHz. There are no changes for 2.4 and 5-GHz band WLANs. They continue to use the WLAN parameters for 802.11ax.

Information About Cisco Flexible Antenna Port

The presence of multiple antennas on the transmitters and the receivers of access points (APs), results in better performance and reliability of the APs. Multiple antennas improve reception through the selection of stronger signals or a combination of individual signals, at the receiver. You can configure the antenna ports to be used in the APs as either dual-band antennas or as single-band antennas to optimize radio coverage.

- Dual-band antenna mode: APs operate in both the 2.4-GHz and 5-GHz bandwidth with all the four antennas—A, B, C, and D. An example of a dual-band antenna mode AP is the Cisco Industrial Wireless 3702 AP.
- Single-band antenna mode: Among the APs, antennas A and B operate in the 2.4-GHz bandwidth, and the antennas C and D operate in the 5-GHz bandwidth. An example of a single-band antenna mode AP is the Cisco Catalyst Industrial Wireless 6300 AP.

Configuring a Cisco Flexible Antenna Port (GUI)

Procedure

- Step 1** Choose **Configuration > Wireless > Access Points**.
- Step 2** Click **AP Name**.
- Step 3** Click the **Advanced** tab.
- Step 4** From the **Antenna Mode** drop-down list, choose the antenna mode.
- Step 5** Click **Apply & Update**.

Configuring a Cisco Flexible Antenna Port (CLI)

Procedure

	Command or Action	Purpose
Step 1	<pre>ap name <i>ap-name</i> antenna-band-mode { dual single}</pre> <p>Example:</p>	Configures antenna band mode as single or dual.

	Command or Action	Purpose
	Device# ap name <i>ap-name</i> antenna-brand-mode single	

Verifying Flexible Antenna Port Configuration

The following is a sample output of the **show ap name *ap-name* config general** command that shows the bands selected on a specific AP:

```
Device# show ap name APXXXX.31XX.83XX config general

Tx                               : Unknown
Rx                               : Unknown
```

Feature History for Environmental Sensors in Access Points

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 41: Feature History for Environmental Sensors on Access Points

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.8.1	Environmental Sensors in Access Points	The Environmental Sensors in Access Points feature helps you collect real-time environmental data, such as, air quality, temperature, and humidity, from the environmental sensors that are embedded in the Cisco Catalyst 9136 Series Access Points.
Cisco IOS XE Cupertino 17.9.1	Environmental Sensors in Access Points	This feature is supported on Cisco Catalyst Wireless 9166I Series Access Points.

Information About Environmental Sensors in Access Points

You can collect real-time environmental data, such as, air quality, temperature, and humidity, from the environmental sensors that are embedded in the Cisco Catalyst 9136 Series Access Points, and make this data available to customers and partners through the Cisco Spaces solution. You can disable, enable, and configure the scan interval of the sensors from the Cisco Catalyst 9800 Series Wireless Controller CLIs.

Note This feature is supported on Cisco Catalyst 9136 Series APs.

In Cisco IOS XE Cupertino 17.9.1, air quality, temperature, and humidity are supported on Cisco Catalyst Wireless 9166I Series Access Points.

Currently, two sensors are added to Cisco Catalyst 9136 Series APs:

- Total volatile organic compounds (TVOC) air quality sensor
- Combined Temperature and Humidity sensor

Use Cases

The following are the use cases for the environmental sensors in APs:

- In the healthcare industry, environmental sensors help reduce wastage and spoilage of pharmaceuticals by maintaining a consistent environment.
- In the hospitality industry, environmental sensors help improve customer experience by monitoring the air quality of a room.
- In the retail industry, these sensors prevent spoilage of products.

Configuring Environmental Sensors in an AP Profile (CLI)

To configure the environmental sensor in the Cisco Catalyst 9800 Series Wireless Controllers under an AP profile, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile-name</i> Example: Device(config)# ap profile ap-profile-name	Configures an AP profile.
Step 3	sensor environment air-quality Example: Device(config-ap-profile)# sensor environment air-quality	Configures AP environmental air quality sensor. Enters AP sensor configuration mode.
Step 4	no shutdown Example: Device(config-ap-sensor)# no shutdown	Enables the AP air quality sensor configuration.
Step 5	sensor environment temperature Example: Device(config-ap-profile)# sensor environment temperature	Configures AP environmental temperature sensor. Enters AP sensor configuration mode.
Step 6	no shutdown Example: Device(config-ap-sensor)# no shutdown	Enables the AP temperature sensor configuration.
Step 7	sampling <i>data-sampling-interval</i> Example: Device(config-ap-sensor)# sampling 200	Configures data sampling interval, in seconds. The valid range is between 5 and 3600. The default value is 5. Use the no form of this command to set the data sampling interval to the default time of 5.
Step 8	exit Example: Device(config-ap-sensor)# exit	Exits the sub mode.

Configuring Environment Sensors in Privileged EXEC Mode (CLI)

To disable the sensor on an AP that might be sending invalid data (an AP near an air vent or near a coffee machine), you can disable the sensor by running the corresponding commands in the privileged EXEC mode of the Cisco Catalyst 9800 Series Wireless Controllers.

Note For a sensor to be operational in the **Up** state, both, the AP profile configuration state and the AP administrative state should be enabled. If any of the two is disabled, the sensor operational status will stay **Down**.

To disable and enable the admin state of the sensor, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter the password if prompted.
Step 2	ap name <i>ap-name</i> sensor environment {air-quality temperature} shutdown Example: Device# ap name CiscoAP sensor environment air-quality shutdown	Disables the sensor admin state of the AP.
Step 3	ap name <i>ap-name</i> no sensor environment {air-quality temperature} shutdown Example: Device# ap name CiscoAP no sensor environment air-quality shutdown	Enables the sensor admin state of the AP.

Verifying the AP Sensor Status

To verify the status of the AP sensors, run the following command:

```
Device# show ap sensor status
```

AP Name	Admin-State	Oper-Status	MAC-address	Sampling-Interval	Sensor-type	Config-State
Cisco.1DBC	Enabled	Down	xxxx.xxxx.xxx1	5	Air-quality	Disabled
Cisco.1DBC	Enabled	Down	xxxx.xxxx.xxx2	5	Temperature	Disabled
Cisco.1E24	Enabled	Down	xxxx.xxxx.xxx3	5	Air-quality	Disabled
Cisco.1E24	Enabled	Down	xxxx.xxxx.xxx4	5	Temperature	Disabled

Information About CAPWAP LAG Support

Link aggregation (LAG) simplifies controller configuration because you no longer require to configure primary and secondary ports for each interface. If any of the controller ports fail, traffic is automatically migrated to

one of the other ports. As long as at least one controller port is functioning, the system continues to operate, access points remain connected to the network, and wireless clients continue to send and receive data.

The CAPWAP LAG support feature is applicable for access points that support multiple ethernet ports for CAPWAP.

The 11AC APs with dual ethernet ports require the CAPWAP AP LAG support for data channel.

Cisco Aironet 1850, 2800, and 3800 Series APs' second Ethernet port is used as a link aggregation port, by default. It is possible to use this LAG port as an RLAN port when LAG is disabled.

The following APs use LAG port as an RLAN port:

- 1852E
- 1852I
- 2802E
- 2802I
- 3802E
- 3802I
- 3802P
- 9136I

Restrictions for CAPWAP LAG Support

- APs must be specifically enabled for CAPWAP AP LAG support.
- CAPWAP data does not support IPv6.
- Data DTLS must not be enabled when LAG is enabled.
- APs behind NAT and PAT are not supported.

Enabling CAPWAP LAG Support on Controller (GUI)

Procedure

-
- | | |
|---------------|--|
| Step 1 | Choose Configuration > Wireless > Wireless Global . |
| Step 2 | Check the AP LAG Mode check box. |
| Step 3 | Click Apply . |
-

Enabling CAPWAP LAG Support on Controller

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap lag support Example: Device(config)# <code>ap lag support</code>	Enables CAPWAP LAG support on the controller. Note After executing this command, you get to view the following warning statement: <i>Changing the lag support will cause all the APs to disconnect.</i> Thus, all APs with LAG capability reboots and joins the enabled CAPWAP LAG.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Enabling CAPWAP LAG Globally on Controller

If the CAPWAP LAG is enabled globally on the controller, the following occurs:

- AP joins the controller.
- AP exchanges its CAPWAP support.
- LAG mode starts, if LAG is enabled on AP.

Disabling CAPWAP LAG Globally on Controller

If the CAPWAP LAG is disabled globally on the controller, the following occurs:

- AP joins the controller.
- AP exchanges its CAPWAP support.
- AP LAG config is sent to AP, if LAG is already enabled on AP.
- AP reboots.

- AP joins back with the disabled LAG.

Enabling CAPWAP LAG for an AP Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
- Step 2** Click **Add**.
- Step 3** Under the **General** tab, enter the **Name** of the AP Profile and check the **LAG Mode** check box to set the CAPWAP LAG for the AP profile.
- Step 4** Click **Apply to Device**.
-

Enabling CAPWAP LAG for an AP Profile

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# ap profile xyz-ap-profile	Configures an AP profile and enters AP profile configuration mode. Note When you delete a named profile, the APs associated with that profile will not revert to the default profile.
Step 3	lag Example: Device(config-ap-profile)# lag	Enables CAPWAP LAG for an AP profile.
Step 4	end Example: Device(config-ap-profile)# end	Exits configuration mode and returns to privileged EXEC mode.

Disabling CAPWAP LAG for an AP Profile

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# <code>ap profile xyz-ap-profile</code>	Configures an AP profile and enters AP profile configuration mode. Note When you delete a named profile, the APs associated with that profile will not revert to the default profile.
Step 3	no lag Example: Device(config-ap-profile)# <code>no lag</code>	Disables CAPWAP LAG for an AP profile.
Step 4	end Example: Device(config-ap-profile)# <code>end</code>	Exits configuration mode and returns to privileged EXEC mode.

Disabling CAPWAP LAG Support on Controller

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	no ap lag support Example: Device(config)# <code>no ap lag support</code>	Disables CAPWAP LAG support on the controller . Note All APs with LAG capability reboots and joins the disabled CAPWAP LAG.
Step 3	end Example:	Exits configuration mode and returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config)# end	

Verifying CAPWAP LAG Support Configurations

To verify the global LAG status for all Cisco APs, use the following command:

```
Device# show ap lag-mode
AP Lag-Mode Support Enabled
```

To verify the AP LAG configuration status, use the following command:

```
Device# show ap name <ap-name> config general
Cisco AP Identifier : 0008.3291.6360
Country Code : US
Regulatory Domain Allowed by Country : 802.11bg:-A 802.11a:-AB
AP Country Code : US - United States
::
AP Lag Configuration Status : Enabled/Disabled
Has AP negotiated lag based on AP capability and per AP config.
```

Feature History for CAPWAP Message Aggregation

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 42: Feature History for CAPWAP Message Aggregation

Release	Feature	Feature Information
Cisco IOS XE 17.14.1	CAPWAP Message Aggregation	The CAPWAP Message Aggregation feature aggregates the CAPWAP control messages of the same type waiting in the queue to be transmitted to the AP.

Information About CAPWAP Message Aggregation

The CAPWAP Message Aggregation feature aggregates the CAPWAP control messages to be sent to APs. When APs are busy processing packets, the messages to be sent to the APs are stored in the controller. When you enable the feature, if the last message type in the queue and the current message type are the same, the CAPWAP messages are aggregated and capped at Maximum Transmission Unit (MTU). This improves the performance of the system.

Guidelines

- Applicable to all AP modes.
- The CAPWAP Message Aggregation feature is disabled by default.

Use Case

Flex deployment use case: You can expect a round-trip delay when packets are sent over wide area network (WAN) in Flex deployments. With the CAPWAP message aggregation, the round-trip time reduces significantly. Also, the client join and client roam are faster.

Configuring CAPWAP Message Aggregation (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# ap profile default-ap-profile	Configures an AP profile and enters the AP profile configuration mode.
Step 3	capwap aggregation Example: Device(config-ap-profile)# capwap aggregation	Enables CAPWAP message aggregation. This feature is disabled by default.
Step 4	end Example: Device(config-ap-profile)# end	Exits configuration mode and returns to privileged EXEC mode.

Verifying CAPWAP Message Aggregation

To view the total number of aggregated CAPWAP control packets for the controller, use the following command:

```
Device# show wireless stats ap packet
```

```
Packet stats
```

```
Capwap Control Packets Received* : 11183016
Capwap Data Keep Alive Packets Received : 160399
Capwap Data DOT1X EAP Packets Received: 549
Capwap Data DOT1X Mgmt Packets Received: 6003
Capwap Data DOT1X Key Type Packets Received: 0
Capwap Data DOT1X Control Packets Received: 0
Capwap Data ARP Packets Received: 0
Capwap Data IP Packets Received: 0
Capwap Data IPV6 Packets Received: 0
Capwap Data RRM Packets Received: 0
Capwap Data DHCP Packets Received: 0
```

```
Capwap Data RFID Packets Received: 0
Capwap Data IAPP Packets Received: 2531939
Capwap Dgram Input Errors : 0
Capwap Discovery Packets Received : 22299
Capwap Discovery Dgram Input Errors : 0
Aggregated Capwap Control Packets Sent: 119337
**** Note: Capwap control packets exclude discovery/primary discovery packets ****
```

To verify the status of the CAPWAP message aggregation feature, use the following command:

```
Device# show ap profile name default-ap-profile detailed
AP Profile Name           : default-ap-profile
Description               : default custom profile
Country code              : Not configured
Stats Timer               : 180
Link Latency              : ENABLED
Data Encryption           : DISABLED
LED State                 : ENABLED
NTP server                 : 0.0.0.0
NTP Authentication       : DISABLED
Jumbo MTU                 : ENABLED
24ghz Report Interval    : 90
5ghz Report Interval     : 90
bssid stats status       : ENABLED
bssid stats frqncy interval : 120
bssid neighbor stats status : ENABLED
bssid neighbor stats interval : 120
CAPWAP Control Aggregation : ENABLED
```

Configuring Bulk AP Provisioning

Bulk AP provisioning allows you to configure multiple AP parameters for more than one AP at a time. You can configure AP parameters such as admin status and floor location, geolocation parameters, and high availability parameters.

Procedure

-
- Step 1** Navigate to the **Configuration > Wireless > Bulk AP Provisioning** page.
- You can view the current tasks along with its status.
- Step 2** Click **Start a workflow to create an AP Provisioning task** to start a new bulk AP provisioning task.
- Step 3** In the **Select AP** page, configure the following:
- Change the name of the task.
 - Select the APs you wish to provision.
 - Click **Next**.
- Step 4** In the **Select Parameters** page, configure the following as required:
- Change the admin status by clicking on the drop-down list.
 - Enter the location.
 - Enter the above ground level height in meters. The range is from -100 to 1000.
 - Enter the tolerance as uncertainty height in meters. The range is from 0 to 100.
 - Enter the cable length in meters. The range is from 1 to 100. The default is 10.

We recommend that you keep the default value of 10 meters with the Cisco provided external antenna.

Note This option is available on selected models that support adding an external antenna.

- f) Enter the floor ID.
- g) Enter the name and management IP address of the primary, secondary, and tertiary controller.
- h) Click **Next**.

Step 5 In the **Summary** page, click **Apply** after confirming the changes.

You can view changes in the task status from its provisioning to completion. On clicking the task, you can view the count of the configurations that were applied and not applied on each of the selected APs.

CHAPTER 26

Secure Data Wipe

- [Secure Data Wipe, on page 511](#)

Secure Data Wipe

The Secure Data Wipe feature allows you to securely erase files from the file system of Cisco APs by using the **clear ap config** command. This new command triggers a secure data wipe in an AP. Additionally, this feature also stores basic information about the wipeout along with the wipeout status. The data stored in the AP flash helps to verify the files erased from the AP file system, and troubleshoot issues. Use the **clear ap config** to view the wipeout history details.

The following files are securely erased, without scope of recovery:

- Configuration and backup configuration files
- Crash files
- Log files
- Boot variables
- Package logs

To check the output of the data wipe, run the following AP command:

```
Cisco-AP# show flash wipeout-log
DATA SANITATION LOGS
Filesystem Name      :   Flash
Filesystem size     :   519 M (bytes)
Total Files         :        95
Data Wipe Time      :   Fri Mar  8 09:50:49 UTC 2024
Data Wipe method    :   CLEAR
Files cleared       :        92
Bytes cleared       :   5484544 (bytes)
Total Free byte     :   458846208 (bytes)
Device PID         :   C9130AXI-E
Serial number       :   KWC233202MN
Data Wipe Status    :   SUCCESS
```

**Note**

- Data wipe for APs in Work Group Bridge mode can be done only through the mode button, which needs to be pressed for a duration of 20 to 60 seconds to remove storage content.
- Cisco Wave 1 APs are supported in Cisco IOS XE Amsterdam 17.3 and Cisco IOS XE Cupertino 17.9.3 and its later versions. Cisco Wave 1 APs are not supported in 17.4, 17.5, 17.6, 17.7, 17.8, 17.10 and later releases.
- Cisco Wave 2 APs are supported in Cisco IOS XE Dublin 17.11 and Cisco IOS XE 17.13.
- Cisco Wave 1 APs and Cisco Wave 2 APs are supported in Cisco IOS XE Dublin 17.12.

Table 43: Supported AP models

Cisco IOS APs	Cisco COS APs	Cisco Catalyst APs
3700 (I/E/P)	3800 (I/E/P)	9162I 9164I 9166I 9166D1 9163E
2700 (I/E)	2800 (I/E)	9124AX (I/D/E)
1700I	1815 (I/W)	9136I
702W	1840 (I)	9130AX (I/E)
1532I/E	1850 (I/E)	9120AX (I/E)
1570	1830 (I/W)	9117AXI
—	1810	9115AX (I/E)
—	1800I	9105AX (I/W)
—	1540	—
—	1560	—
—	4800	—

CHAPTER 27

Troubleshooting Lightweight Access Points

- [Overview, on page 513](#)
- [Support Articles, on page 513](#)
- [Feedback Request, on page 514](#)
- [Disclaimer and Caution, on page 514](#)

Overview

This chapter provides links to documents authored by Cisco subject matter experts (SMEs). They aim to help you resolve technical issues without requiring a support ticket. If these documents are unable to resolve your issue, we recommend visiting the applicable [Cisco Community](#). There is a wealth of information and advice available from fellow Cisco customers who may have experienced this issue already and provided a solution. If you are not able to find a resolution on the Community, it may be best that you raise a support ticket at [Cisco Support](#). In cases where a support ticket has to be raised, these documents provide guidance about the data that should be collected and added to the support ticket. Specify the support document you referred, and TAC can create an improvement request with the document owner.

Support Articles

The documents in this section were created using specific software and hardware listed in the Components Used section of each article. However, this does not mean that they are limited to what is listed in Components Used, and generally remain relevant for later versions of software and hardware. Note that there could be some changes in the software or hardware that can cause commands to stop working, the syntax to change, or GUIs and CLIs to look different from one release to another.

The following are the support articles associated with this technology:

Document	Description
Troubleshoot Access Point Disassociation from Controller	This document provides use cases to understand the reason for the Control and Provisioning of Wireless Access Points (CAPWAP)/Lightweight Access Point Protocol (LWAPP) tunnel break between Access Points (APs) and the Wireless Controller.

Feedback Request

Your input helps. A key aspect to improving these support documents is customer feedback. Note that these documents are owned and maintained by multiple teams within Cisco. If you find an issue specific to the document (unclear, confusing, information missing, etc):

- Provide feedback using the **Feedback** button located at the right panel of the corresponding article. The document owner will be notified, and will either update the article, or flag it for removal.
- Include information regarding the section, area, or issue you had with the document and what could be improved. Provide as much detail as possible.

Disclaimer and Caution

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, ensure that you understand the potential impact of any command.

Information About Radio Resource Management

The Radio Resource Management (RRM) software that is embedded in the device acts as a built-in Radio Frequency (RF) engineer to consistently provide real-time RF management of your wireless network. RRM enables devices to continually monitor their associated lightweight access points for the following information:

- **Traffic load**—The total bandwidth used for transmitting and receiving traffic. It enables wireless LAN managers to track and plan network growth ahead of client demand.
- **Interference**—The amount of traffic coming from other 802.11 sources.
- **Noise**—The amount of non-802.11 traffic that is interfering with the currently assigned channel.
- **Coverage**—The Received Signal Strength (RSSI) and signal-to-noise ratio (SNR) for all connected clients.
- **Other** —The number of nearby access points.

RRM performs these functions:

- Radio resource monitoring
- Power control transmission

- Dynamic channel assignment
- Coverage hole detection and correction
- RF grouping

Note RRM grouping does not occur when an AP operates in a static channel that is not in the DCA channel list. The Neighbor Discovery Protocol (NDP) is sent only on DCA channels; therefore, when a radio operates on a non-DCA channel, it does not receive NDP on the channel.

Radio Resource Monitoring

RRM automatically detects and configures new devices and lightweight access points as they are added to the network. It then automatically adjusts the associated and nearby lightweight access points to optimize coverage and capacity.

Lightweight access points can scan all the valid channels for the country of operation as well as for channels available in other locations. The access points in local mode go *offchannel* for a period not greater than 70 ms to monitor these channels for noise and interference. Packets collected during this time are analyzed to detect rogue access points, rogue clients, ad-hoc clients, and interfering access points.

Note In the presence of voice traffic or other critical traffic (in the last 100 ms), access points can defer off-channel measurements. The access points also defer off-channel measurements based on the WLAN scan priority configurations.

Each access point spends only 0.2 percent of its time off channel. This activity is distributed across all the access points so that adjacent access points are not scanning at the same time, which could adversely affect wireless LAN performance.

Information About RF Groups

An RF group is a logical collection of controllers that coordinate to perform RRM in a globally optimized manner to perform network calculations on a per-radio basis. Separate RF groups exist for 2.4-GHz and 5-GHz networks. Clustering Cisco Catalyst 9800 Series Wireless Controller into a single RF group enables the RRM algorithms to scale beyond the capabilities of a single Cisco Catalyst 9800 Series Wireless Controller.

An RF group is created based on the following parameters:

- User-configured RF network name.
- Neighbor discovery performed at the radio level.
- Country list configured on the controller.

RF grouping runs between controllers .

Lightweight access points periodically send out neighbor messages over the air. Access points using the same RF group name validate messages from each other.

When access points on different controllers hear validated neighbor messages at a signal strength of -80 dBm or stronger, the controllers dynamically form an RF neighborhood in auto mode. In static mode, the leader is manually selected and the members are added to the RF Group.

Note RF groups and mobility groups are similar, in that, they both define clusters of controllers, but they are different in terms of their use. An RF group facilitates scalable, system-wide dynamic RF management, while a mobility group facilitates scalable, system-wide mobility and controller redundancy.

RF Group Leader

RF Group Leader can be configured in two ways as follows:

Note RF Group Leader is chosen on the basis of the controller with the greatest AP capacity (platform limit.) If multiple controllers have the same capacity, the leader is the one with the highest management IP address.

- Auto Mode: In this mode, the members of an RF group elect an RF group leader to maintain a *primary* power and channel scheme for the group. The RF grouping algorithm dynamically chooses the RF group leader and ensures that an RF group leader is always present. Group leader assignments can and do change (for instance, if the current RF group leader becomes inoperable or RF group members experience major changes).
- Static Mode: In this mode, a user selects a controller as an RF group leader manually. In this mode, the leader and the members are manually configured and fixed. If the members are unable to join the RF group, the reason is indicated. The leader tries to establish a connection with a member every minute if the member has not joined in the previous attempt.

The RF group leader analyzes real-time radio data collected by the system, calculates the power and channel assignments, and sends them to each of the controllers in the RF group. The RRM algorithms ensure system-wide stability, and restrain channel and power scheme changes to the appropriate local RF neighborhoods.

Note When a controller becomes both leader and member for a specific radio, you get to view the IPv4 and IPv6 address as part of the group leader.

When a Controller A becomes a member and Controller B becomes a leader, the Controller A displays either IPv4 or IPv6 address of Controller B using the address it is connected.

So, if both leader and member are not the same, you get to view only one IPv4 or IPv6 address as a group leader in the member.

If Dynamic Channel Assignment (DCA) needs to use the worst-performing radio as the single criterion for adopting a new channel plan, it can result in pinning or cascading problems.

The main cause of both pinning and cascading is that any potential channel plan changes are controlled by the RF circumstances of the worst-performing radio. The DCA algorithm does not do this; instead, it does the following:

- **Multiple local searches:** The DCA search algorithm performs multiple local searches initiated by different radios in the same DCA run rather than performing a single global search that is driven by a single radio. This change addresses both pinning and cascading, while maintaining the desired flexibility and adaptability of DCA and without jeopardizing stability.
- **Multiple Channel Plan Change Initiators (CPCIs):** Previously, the single worst radio was the sole initiator of a channel plan change. Now each radio in an RF group is evaluated and prioritized as a potential initiator. Intelligent randomization of the resulting list ensures that every radio is eventually evaluated, which eliminates the potential for pinning.
- **Limiting the propagation of channel plan changes (Localization):** For each CPCI radio, the DCA algorithm performs a local search for a better channel plan, but only the CPCI radio itself and its one-hop neighboring access points are actually allowed to change their current transmit channels. The impact of an access point triggering a channel plan change is felt only to within two RF hops from that access point, and the actual channel plan changes are confined to within a one-hop RF neighborhood. Because this limitation applies across all CPCI radios, cascading cannot occur.
- **Non-RSSI-based cumulative cost metric:** A cumulative cost metric measures how well an entire region, neighborhood, or network performs with respect to a given channel plan. The individual cost metrics of all the access points in that area are considered in order to provide an overall understanding of the channel plan's quality. These metrics ensure that the improvement or deterioration of each single radio is factored into any channel plan change. The objective is to prevent channel plan changes in which a single radio improves, but at the expense of multiple other radios experiencing a considerable performance decline.

The RRM algorithms run at a specified updated interval, which is 600 seconds by default. Between update intervals, the RF group leader sends keepalive messages to each of the RF group members and collects real-time RF data.

Note Several monitoring intervals are also available. See the Configuring RRM section for details.

RF Grouping Failure Reason Codes

RF Grouping failure reason codes and their explanations are listed below:

Table 44: RF Grouping Failure Reason Codes

Reason Code	Description
1	Maximum number (20) of controllers are already present in the group.
2	If the following conditions are met: <ul style="list-style-type: none"> • The request is from a similar powered controller and, <ul style="list-style-type: none"> • Controller is the leader for the other band, OR • Requestor group is larger.
3	Group ID do not match.

Reason Code	Description
4	Request does not include source type.
5	Group spilt message to all member while group is being reformed.
6	Auto leader is joining a static leader, during the process deletes all the members.
9	Grouping mode is turned off.
11	Country code does not match.
12	Controller is up in hierarchy compared to sender of join command (static mode). Requestor is up in hierarchy (auto mode).
13	Controller is configured as static leader and receives join request from another static leader.
14	Controller is already a member of static group and receives a join request from another static leader.
15	Controller is a static leader and receives join request from non-static member.
16	Join request is not intended to the controller. Controller name and IP do not match.
18	RF domain do not match.
19	Controller received a Hello packet at incorrect state.
20	Controller has already joined Auto leader, now gets a join request from static leader.
21	Group mode change. Domain name change from CLI. Static member is removed from CLI.
22	Max switch size (350) is reached

Radio Resource Management White Paper: https://www.cisco.com/c/en/us/td/docs/wireless/controller/technotes/8-3/b_RRM_White_Paper/b_RRM_White_Paper_chapter_011.html

RF Group Name

A controller is configured in an RF group name, which is sent to all the access points joined to the controller and used by the access points as the shared secret for generating the hashed MIC in the neighbor messages. To create an RF group, you configure all of the controllers to be included in the group with the same RF group name.

If there is any possibility that an access point joined to a controller might hear RF transmissions from an access point on a different controller, you should configure the controller with the same RF group name. If RF transmissions between access points can be heard, then system-wide RRM is recommended to avoid 802.11 interference and contention as much as possible.

Rogue Access Point Detection in RF Groups

After you have created an RF group of controller, you need to configure the access points connected to the controller to detect rogue access points. The access points will then select the beacon or probe-response frames in neighboring access point messages to see if they contain an authentication information element (IE) that matches that of the RF group. If the selection is successful, the frames are authenticated. Otherwise, the authorized access point reports the neighboring access point as a rogue, records its BSSID in a rogue table, and sends the table to the controller.

Secure RF Groups

Secure RF groups enable to encrypt and secure RF grouping and RRM message exchanges over DTLS tunnel. During the DTLS handshake controllers authenticate each other with wireless management trust-point certificate.

Note If a controller has to be part of secure RF-group, that controller must be part of the same mobility group.

Transmit Power Control

The device dynamically controls access point transmit power based on the real-time wireless LAN conditions.

The Transmit Power Control (TPC) algorithm increases and decreases an access point's power in response to changes in the RF environment. In most instances, TPC seeks to lower an access point's power to reduce interference, but in the case of a sudden change in the RF coverage, for example, if an access point fails or becomes disabled, TPC can also increase power on the surrounding access points. This feature is different from coverage hole detection, which is primarily concerned with clients. TPC provides enough RF power to achieve the required coverage levels while avoiding channel interference between access points. We recommend that you select TPCv1; TPCv2 option is deprecated. With TPCv1, you can select the channel aware mode; we recommend that you select this option for 5 GHz, and leave it unchecked for 2.4 GHz.

Overriding the TPC Algorithm with Minimum and Maximum Transmit Power Settings

The TPC algorithm balances RF power in many diverse RF environments. However, it is possible that automatic power control will not be able to resolve some scenarios in which an adequate RF design was not possible to implement due to architectural restrictions or site restrictions, for example, when all the access points must be mounted in a central hallway, placing the access points close together, but requiring coverage to the edge of the building.

In these scenarios, you can configure maximum and minimum transmit power limits to override TPC recommendations. The maximum and minimum TPC power settings apply to all the access points through RF profiles in a RF network.

To set the Maximum Power Level Assignment and Minimum Power Level Assignment, enter the maximum and minimum transmit power used by RRM in the fields in the **Tx Power Control** window. The range for

these parameters is -10 to 30 dBm. The minimum value cannot be greater than the maximum value; the maximum value cannot be less than the minimum value.

If you configure a maximum transmit power, RRM does not allow any access point attached to the controller, to exceed this transmit power level (whether the power is set by RRM TPC or by coverage hole detection). For example, if you configure a maximum transmit power of 11 dBm, no access point will transmit above 11 dBm, unless the access point is configured manually.

Cisco APs support power level changes in 3 dB granularity. TPC Min and Max power settings allow for values in 1 dB increments. The resulting power level will be rounded to the nearest value supported in the allowed powers entry for the AP model and the current serving channel.

Each AP model has its own set of power levels localized for its regulatory country and region. Moreover, the power levels for the same AP model will vary based on the band and channel it is set to. For more information on Allowed Power Level vs. Actual power(in dBm), use the **show ap name <name> config slot <0|1|2|3>** command to view the specific number of power levels, the range of power levels allowed, and the current power level setting on the AP.

Dynamic Channel Assignment

Two adjacent access points on the same channel can cause either signal contention or signal collision. In a collision, data is not received by the access point. This functionality can become a problem, for example, when someone reading an e-mail in a café affects the performance of the access point in a neighboring business. Even though these are separate networks, someone sending traffic to the café on channel 1 can disrupt communication in an enterprise using the same channel. Devices can dynamically allocate access point channel assignments to avoid conflict and increase capacity and performance. Channels are *reused* to avoid wasting scarce RF resources. In other words, channel 1 is allocated to a different access point far from the café, which is more effective than not using channel 1 altogether.

The device's Dynamic Channel Assignment (DCA) capabilities are also useful in minimizing adjacent channel interference between access points. For example, two overlapping channels in the 802.11b/g band, such as 1 and 2, cannot simultaneously use 11 or 54 Mbps. By effectively reassigning channels, the device keeps adjacent channels that are separated.

Note We recommend that you use only nonoverlapping channels (1, 6, 11, and so on).

Note Channel change does not require you to shut down the radio.

The device examines a variety of real-time RF characteristics to efficiently handle channel assignments as follows:

- Access point received energy: The received signal strength measured between each access point and its nearby neighboring access points. Channels are optimized for the highest network capacity.
- Noise: Noise can limit signal quality at the client and access point. An increase in noise reduces the effective cell size and degrades user experience. By optimizing channels to avoid noise sources, the device can optimize coverage while maintaining system capacity. If a channel is unusable due to excessive noise, that channel can be avoided.

- **802.11 interference:** Interference is any 802.11 traffic that is not a part of your wireless LAN, including rogue access points and neighboring wireless networks. Lightweight access points constantly scan all the channels looking for sources of interference. If the amount of 802.11 interference exceeds a predefined configurable threshold (the default is 10 percent), the access point sends an alert to the device. Using the RRM algorithms, the device may then dynamically rearrange channel assignments to increase system performance in the presence of the interference. Such an adjustment could result in adjacent lightweight access points being on the same channel, but this setup is preferable to having the access points remain on a channel that is unusable due to an interfering foreign access point.

In addition, if other wireless networks are present, the device shifts the usage of channels to complement the other networks. For example, if one network is on channel 6, an adjacent wireless LAN is assigned to channel 1 or 11. This arrangement increases the capacity of the network by limiting the sharing of frequencies. If a channel has virtually no capacity remaining, the device may choose to avoid this channel. In huge deployments in which all nonoverlapping channels are occupied, the device does its best, but you must consider RF density when setting expectations.

- **Load and utilization:** When utilization monitoring is enabled, capacity calculations can consider that some access points are deployed in ways that carry more traffic than other access points, for example, a lobby versus an engineering area. The device can then assign channels to improve the access point that has performed the worst. The load is taken into account when changing the channel structure to minimize the impact on the clients that are currently in the wireless LAN. This metric keeps track of every access point's transmitted and received packet counts to determine how busy the access points are. New clients avoid an overloaded access point and associate to a new access point. This *Load and utilization* parameter is disabled by default.

The device combines this RF characteristic information with RRM algorithms to make system-wide decisions. Conflicting demands are resolved using soft-decision metrics that guarantee the best choice for minimizing network interference. The end result is optimal channel configuration in a three-dimensional space, where access points on the floor above and below play a major factor in an overall wireless LAN configuration.

Note DCA supports only 20-MHz channels in 2.4-GHz band.

Note In a Dynamic Frequency Selection (DFS) enabled AP environment, ensure that you enable the UNII2 channels option under the DCA channel to allow 100-MHz separation for the dual 5-GHz radios.

The RRM startup mode is invoked in the following conditions:

- In a single-device environment, the RRM startup mode is invoked after the device is upgraded and rebooted.
- In a multiple-device environment, the RRM startup mode is invoked after an RF Group leader is elected.
- You can trigger the RRM startup mode from the CLI.

The RRM startup mode runs for 100 minutes (10 iterations at 10-minute intervals). The duration of the RRM startup mode is independent of the DCA interval, sensitivity, and network size. The startup mode consists of 10 DCA runs with high sensitivity (making channel changes easy and sensitive to the environment) to converge to a steady-state channel plan. After the startup mode is finished, DCA continues to run at the specified interval and sensitivity.

Note DCA algorithm interval is set to 1 hour, but DCA algorithm always runs in default interval of 10 min, channel allocation occurs at 10-min intervals for the first 10 cycles, and channel changes occur as per the DCA algorithm every 10 min. After that the DCA algorithm goes back to the configured time interval. This is common for both DCA interval and anchor time because it follows the steady state.

Invoking channel update will not result in any immediate changes until the next DCA interval is triggered.

Note If Dynamic Channel Assignment (DCA)/Transmit Power Control (TPC) is turned off on the RF group member, and auto is set on RF group leader, the channel or TX power on a member gets changed as per the algorithm that is run on the RF group leader.

Dynamic Bandwidth Selection

While upgrading from 11n to 11ac, the Dynamic Bandwidth Selection (DBS) algorithm provides a smooth transition for various configurations.

The following pointers describe the functionalities of DBS:

- It applies an additional layer of bias on top of those applied to the core DCA, for channel assignment in order to maximize the network throughput by dynamically varying the channel width.
- It fine tunes the channel allocations by constantly monitoring the channel and Base Station Subsystem (BSS) statistics.
- It evaluates the transient parameters, such as 11n or 11ac client mix, load, and traffic flow types.
- It reacts to the fast-changing statistics by varying the BSS channel width or adapting to the unique and new channel orientations through 11ac for selection between 40 MHz and 80 MHz bandwidths.

Coverage Hole Detection and Correction

The RRM coverage hole detection algorithm can detect areas of radio coverage in a wireless LAN that are below the level needed for robust radio performance. This feature can alert you to the need for an additional (or relocated) lightweight access point.

If clients on a lightweight access point are detected at threshold levels (RSSI, failed client count, percentage of failed packets, and number of failed packets) lower than those specified in the RRM configuration, the access point sends a “coverage hole” alert to the device. The alert indicates the existence of an area where clients are continually experiencing poor signal coverage, without having a viable access point to which to roam. The device discriminates between coverage holes that can and cannot be corrected. For coverage holes that can be corrected, the device mitigates the coverage hole by increasing the transmit power level for that specific access point. The device does not mitigate coverage holes caused by clients that are unable to increase their transmit power or are statically set to a power level because increasing their downstream transmit power might increase interference in the network.

Cisco AI Enhanced RRM

The AI Enhanced RRM is the next evolution of Cisco's award winning Radio Resource Management (RRM).

The RRM runs as a service in a Cisco Catalyst 9800 Series Wireless Controller. The Cisco RRM manages the RF Group (the components making up the RF Network) based on dynamic measurements between every AP and its neighbors stored in a local database for the entire RF Group. At runtime, the RRM draws the last 10 minutes of the collected data, and gently optimizes based on the current network conditions.

The AI Enhanced RRM integrates the power of Artificial Intelligence and Machine Learning to the reliable and trusted Cisco RRM product family algorithms in the Cloud.

Note The AI enhanced RRM is coordinated through the Cisco Catalyst Center (on-prem appliance) as a service. The current RRM sites are seamlessly transitioned to an intelligent centralized service. AI enhanced RRM along with other Cisco Catalyst Center services brings a host of new features with it.

Cisco AI Enhanced RRM operates as a distributed RRM service. RF telemetry is collected from the Cisco Access Points by the controller, and passed through the Catalyst Center to the Cisco AI Analytics Cloud where the data is stored. The RRM Algorithms run against this telemetry data stored in the cloud. AI analyzes the solutions, and passes any configuration change information back to the Catalyst Center. The Catalyst Center maintains the control connection with the enrolled controller and passes any individual AP configuration changes back to the APs.

The following RRM algorithms run in the cloud while the remaining work in the controller:

- DCA
- TPC
- DBS
- FRA

Note The RRM algorithms run in the cloud against the telemetry data available in the cloud.

If the location of controller, and APs are provisioned previously, assigning a location enrolls the AI Enhanced RRM Services and the profile to be pushed to the controller. Thus, AI Enhanced RRM becomes the RF Group Leader for the subscribed controller.

For more information on the Cisco Catalyst Center, see [Cisco Catalyst Center User Guide](#).

Note The following table covers the controller and Cisco Catalyst Center release versions that support Cisco AI Enhanced RRM support:

Table 45: Controller and Cisco Catalyst Center Releases Supporting Cisco AI Enhanced RRM Support

Controller Release	Cisco Catalyst Center Release	Cisco AI Enhanced RRM Support
Cisco IOS XE Cupertino 17.9.x	<ul style="list-style-type: none"> • Cisco Catalyst Center, Release 2.3.2 or Cisco Catalyst Center, Release 2.3.3 • Cisco Catalyst Center, Release 2.3.4 	<ul style="list-style-type: none"> • 2.4GHz and 5GHz • 2.4GHz, 5GHz, and 6GHz
Cisco IOS XE Cupertino 17.8.x	<ul style="list-style-type: none"> • Cisco Catalyst Center, Release 2.3.2 Cisco Catalyst Center, Release 2.3.3 • Cisco Catalyst Center, Release 2.3.4 	2.4GHz and 5GHz
Cisco IOS XE Cupertino 17.7.x	Cisco Catalyst Center, Release 2.3.2 or Cisco Catalyst Center, Release 2.3.3	2.4GHz and 5GHz

Restrictions for Radio Resource Management

- The number of APs in a RF-group is limited to 3000.
- If an AP tries to join the RF-group that already holds the maximum number of APs it can support, the device rejects the application and throws an error.
- Disabling all data rates for default rf-profile or custom rf-profile, impacts ISSU upgrade and client join process after the software upgrade (ISSU or non-ISSU). To prevent this, you must enable at least one data rate (for example, **ap dot11 24 rate RATE_5_5M enable**) on the default rf-profile or custom rf-profile. We recommend that you enable the lowest data rate if efficiency is of prime concern.
- Keywords such as secure cannot be used a RF group name.

How to Configure RRM

Configuring Neighbor Discovery Type (GUI)

Procedure

- Step 1** Choose **Configuration > Radio Configurations > RRM**.
- Step 2** On the **Radio Resource Management** page, click either the **5 GHz Band**, **2.4 GHz Band** or the **6 GHz Band** tab.
- Step 3** In the **General** tab, under each section enter the corresponding field details:
- a) Under the **Profile Threshold For Traps** section, enter the:
 1. **Interference Percentage**: The foreign interference threshold is between 0 and 100 %. The default is 10 %.
 2. **Clients**: The client threshold between 1 and 75 clients. The default is 12.
 3. **Noise**: The foreign noise threshold between -127 dBm and 0dBm. The default is -70 dBm.
 4. **Utilization Percentage**: The RF utilization threshold between 0 and 100 %. The default is 80 %.
 5. **Throughput**: The average rate of successful messages delivery over a communication channel. Value ranges from 1000 to 1000000 bps.
 - b) Under the **Noise/Interference/Rogue/CleanAir/SI Monitoring Channels** section, choose the:
 1. **Channel List** from the drop-down list:
 - All Channels
 - Country Channels
 - DCA Channels
 2. **RRM Neighbor Discover Type** from the drop-down list:
 - **Transparent**: Packets are sent as is.
 - **Protected**: Packets are protected.
 3. **RRM Neighbor Discovery Mode**:
 - **AUTO**: If the NDP mode configured is AUTO, the controller selects On-Channel as the NDP mode. The default is set as AUTO.
 - **OFF-CHANNEL**: If the NDP mode configured is Off-Channel, the controller selects Off-Channel as the NDP mode.
 - c) Under the **Monitor** section, set:

- **Neighbor Packet Frequency (seconds):** Frequency (in seconds) in which the Neighbor Discovery Packets are sent. The default is 180 seconds.
- **Reporting Interval (seconds):** The default is 180 seconds. Each channel dwell has to be completed within 180 seconds.
- **Neighbor Timeout factor:** Value in seconds used to determine when to prune access points from the neighbor list that have timed out. The default is 20 seconds.

Step 4 Click Apply to save your configuration.

Configuring Neighbor Discovery Type (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} rrm ndp-type {protected transparent} Example: Device(config)# <code>ap dot11 24ghz rrm ndp-type protected</code> Device(config)# <code>ap dot11 24ghz rrm ndp-type transparent</code>	Configures the neighbor discovery type. By default, the mode is set to “transparent”. <ul style="list-style-type: none"> • protected: Sets the neighbor discover type to protected. Packets are encrypted. • transparent: Sets the neighbor discover type to transparent. Packets are sent as is.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring RF Groups

This section describes how to configure RF groups through either the GUI or the CLI.

Note When the multiple-country feature is being used, all controllers intended to join the same RF group must be configured with the same set of countries, configured in the same order.

Configuring RF Group Selection Mode (GUI)

Procedure

-
- Step 1** Choose **Configuration** > **Radio Configurations** > **RRM**.
- Step 2** On the **RRM** page, click the relevant band's tab: either **6 GHz Band**, **5 GHz Band**, or **2.4 GHz Band**.
- Step 3** Click the **RF Grouping** tab.
- Step 4** Choose the appropriate **Group Mode** from these options:

- **Automatic**: Sets the 802.11 RF group selection to automatic update mode
- **Leader**: Sets the 802.11 RF group selection to leader mode
- **Off**: Disables the 802.11 RF group selection

Note When AI Enhanced RRM is enabled on a controller and Cisco Catalyst Center is connected to a wireless network, Cisco Catalyst Center is assigned the group role as a leader. Controllers, managed by Cisco Catalyst Center and enabled with AI Enhanced RRM, are assigned the group role as remote members irrespective of the group mode they were previously assigned. The **Group Role** field will display as **Remote Member** and the **Group leader** field will display the IP address of the Cisco Catalyst Center.

- Step 5** Save the configuration.
-

Configuring RF Group Selection Mode (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} rrm group-mode {auto leader off} Example: Device(config)# <code>ap dot11 24ghz rrm group-mode leader</code>	Configures RF group selection mode for 802.11 bands. <ul style="list-style-type: none"> • auto: Sets the 802.11 RF group selection to automatic update mode. • leader: Sets the 802.11 RF group selection to leader mode. • off: Disables the 802.11 RF group selection.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring an RF Group Name (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless rf-network <i>name</i> Example: Device (config)# <code>wireless rf-network test1</code>	Creates an RF group. The group name should be ASCII String up to 19 characters and is case sensitive. Note Repeat this procedure for each controller that you want to include in the RF group.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring a Secure RF Group (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless rf-network secure Example: Device(config)# <code>wireless rf-network secure</code>	Creates a secure RF group.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.
Step 4	show ap dot11 {24ghz 5ghz 6ghz} group Example: Device# <code>show ap dot11 24ghz group</code>	Displays configuration and statistics of 6-GHz band grouping.

Configuring Members in an 802.11 Static RF Group (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > RRM**.
- Step 2** On the **RRM** page, click either the **6 GHz Band**, **5 GHz Band** or **2.4 GHz Band** tab.
- Step 3** Click the **RF Grouping** tab.
- Step 4** Choose the appropriate **Group Mode** from the following options:
- **Automatic(default)**: Members of an RF group elect an RF group leader to maintain a primary power and channel scheme for the group. The RF grouping algorithm dynamically chooses the RF group leader and ensures that an RF group leader is always present. Group leader assignments can and do change (for instance, if the current RF group leader becomes inoperable or if RF group members experience major changes).
 - **Leader**: A device as an RF group leader, manually. In this mode, the leader and the members are manually configured and are therefore fixed. If the members are unable to join the RF group, the reason is indicated. The members' management IP addresses and system name are used to request the member to join the leader. The leader tries to establish a connection with a member every 1 minute if the member has not joined in the previous attempt.
 - **Off**: No RF group is configured.
- Step 5** Under **Group Members** section, click **Add**.
- Step 6** In the **Add Static Member** window that is displayed, enter the controller name and the IPv4 or IPv6 address of the controller.
- Step 7** Click **Save & Apply to Device**.
-

Configuring Members in an 802.11 Static RF Group (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} rrm group-member group_name ip_addr Example: Device(config)# <code>ap dot11 24ghz rrm group-member Grpmem01 10.1.1.1</code>	Configures members in a 802.11 static RF group. The group mode should be set as leader for the group member to be active.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Transmit Power Control

Configuring Transmit Power (GUI)

Procedure

-
- Step 1** Choose **Configuration** > **Radio Configurations** > **RRM**.
- Step 2** On the **6 GHz Band**, **5 GHz Band**, or **2.4 GHz Band** tab, click the **TPC** tab.
- Step 3** Choose of the following dynamic transmit power assignment modes:
- *Automatic*(default): The transmit power is periodically updated for all APs that permit this operation.
 - *On Demand*: The transmit power is updated on demand. If you choose this option, you get to view the **Invoke Power Update Once**. Click **Invoke Power Update Once** to apply the RRM data successfully.
 - *Fixed*: No dynamic transmit power assignments occur and values are set to their global default.
- Step 4** Enter the maximum and minimum power level assignment on this radio. If you configure maximum transmit power, RRM does not allow any access point attached to the device to exceed this transmit power level (whether the power is set by RRM TPC or by coverage hole detection). For example, if you configure a maximum transmit power of 11 dBm, then no access point would transmit above 11 dBm, unless the access point is configured manually. The range is –10 dBm to 30 dBm.
- Step 5** In the **Power Threshold** field, enter the cutoff signal level used by RRM when determining whether to reduce an access point's power.
- The default value for this parameter varies depending on the TPC version you choose. For TPCv1, the default value is –70 dBm, and for TPCv2, the default value is –67 dBm. The default value can be changed when access points are transmitting at higher (or lower) than desired power levels. The range for this parameter is –80 to –50 dBm.
- Increasing this value (between –65 and –50 dBm) causes the access points to operate at higher transmit power rates. Decreasing the value has the opposite effect. In applications with a dense population of access points, it may be useful to decrease the threshold to –80 or –75 dBm in order to reduce the number of BSSIDs (access points) and beacons seen by the wireless clients. Some wireless clients might have difficulty processing a large number of BSSIDs or a high beacon rate and might exhibit problematic behavior with the default threshold.
- Step 6** Click **Apply**.
-

Configuring the Tx-Power Control Threshold (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	ap dot11 {24ghz 5ghz} rrm tpc-threshold <i>threshold_value</i> Example: Device(config)# ap dot11 24ghz rrm tpc-threshold -60	Configures the Tx-power control threshold used by RRM for auto power assignment. The range is from -80 to -50.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring the Tx-Power Level (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz} rrm txpower {trans_power_level auto max min once} Example: Device (config) # ap dot11 24ghz rrm txpower auto	Configures the 802.11 tx-power level <ul style="list-style-type: none"> • trans_power_level—Sets the transmit power level. • auto—Enables auto-RF. • max—Configures the maximum auto-RF tx-power. • min—Configures the minimum auto-RF tx-power. • once—Enables one-time auto-RF.
Step 3	ap dot11 6ghz rrm txpower trans_power_level auto Example: Device (config) # ap dot11 6ghz rrm txpower auto	Configures the 802.11 6-GHz tx-power level. <ul style="list-style-type: none"> • <i>trans_power_level</i>: Sets the transmit power level. Valid values range from 1 to 5. • auto: Enables auto-RF.

	Command or Action	Purpose
		<p>Note The 6-GHz band uses constant-PSD instead of constant-EIRP, which allows the transmission at higher power as channel width increases. The power levels are derived based on the configured channel width. At the higher power levels between 1-3, these power values exceed the limit for legacy rate frames, like beacons. As a result, there is no change in the beacon power for higher levels, unlike the 2.4-GHz and 5-GHz bands.</p>
Step 4	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.

Configuring 802.11 RRM Parameters

Configuring Advanced 802.11 Channel Assignment Parameters (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > RRM**.
- Step 2** In the **DCA** tab, choose a **Channel Assignment Mode** to specify the DCA mode:
- *Automatic* (default)—Causes the device to periodically evaluate and, if necessary, update the channel assignment for all joined APs.
 - *Freeze*—Causes the device to evaluate and update the channel assignment for all joined APs. If you choose this option, you get to view the Invoke Channel Update Once. Click **Invoke Channel Update Once** to apply the RRM data successfully.
 - *Off*—Turns off DCA and sets all AP radios to the first channel of the band, which is the default value. If you choose this option, you must manually assign channels on all radios.
- Step 3** From the **Interval** drop-down list, choose the interval that tells how often the DCA algorithm is allowed to run. The default interval is 10 minutes.
- Step 4** From the **AnchorTime** drop-down list, choose a number to specify the time of day when the DCA algorithm must start. The options are numbers between 0 and 23 (inclusive) representing the hour of the day from 12:00 a.m. to 11:00 p.m.
- Step 5** Check the **Avoid Foreign AP Interference** check box to cause the device's RRM algorithms to consider 802.11 traffic from foreign APs (those not included in your wireless network) when assigning channels to

lightweight APs, or uncheck it to disable this feature. For example, RRM may adjust the channel assignment to have access points avoid channels close to foreign APs. By default, this feature is in enabled state.

- Step 6** Check the **Avoid Cisco AP Load** check box to cause the device's RRM algorithms to consider 802.11 traffic from Cisco lightweight APs in your wireless network when assigning channels. For example, RRM can assign better reuse patterns to access points that carry a heavier traffic load. By default, this feature is in disabled state.
- Step 7** Check the **Avoid Non-802.11a Noise** check box to cause the device's RRM algorithms to consider noise (non-802.11 traffic) in the channel when assigning channels to lightweight APs. For example, RRM may have APs avoid channels with significant interference from non-AP sources, such as microwave ovens. By default, this feature is in enabled state.
- Step 8** Check the **Avoid Persistent Non-Wi-Fi Interference** check box to enable the device to take into account persistent non-Wi-Fi interference in DCA calculations. A persistent interfering device is any device from the following categories, which has been seen in the past 7 days - Microwave Oven, Video Camera, Canopy, WiMax Mobile, WiMax Fixed, Exalt Bridge. With **Avoid Persistent Non-Wi-Fi Interference** enabled, if a Microwave Oven is detected, that interference from the Microwave Oven is taken into account in the DCA calculations for the next 7 days. After 7 days, if the interfering device is not detected anymore, it is no longer considered in the DCA calculations.
- Step 9** From the **DCA Channel Sensitivity** drop-down list, choose one of the following options to specify how sensitive the DCA algorithm is to environmental changes such as signal, load, noise, and interference when determining whether to change channels:
- *Low*—The DCA algorithm is not particularly sensitive to environmental changes. The DCA threshold is 30 dB.
 - *Medium* (default)—The DCA algorithm is moderately sensitive to environmental changes. The DCA threshold is 15 dB.
 - *High* —The DCA algorithm is highly sensitive to environmental changes. The DCA threshold is 5 dB.
- Step 10** Set the **Channel Width** as required. You can choose the RF channel width as 20 MHz, 40 MHz, 80 MHz, 160 MHz, or Best. This is applicable only for 802.11a/n/ac (5 GHz) radio.
- Step 11** The **Auto-RF Channel List** section shows the channels that are currently selected. To choose a channel, check the corresponding check box.
- Note** If you disable the serving radio channel of the root AP from the **Auto-RF Channel List**, you will not be able to view the neighboring APs in the root APs.
- Step 12** In the **Event Driven RRM** section, check the **EDRRM** check box to run RRM when CleanAir-enabled AP detects a significant level of interference. If enabled, set the sensitivity threshold level at which the RRM is invoked, enter the custom threshold, and check the **Rogue Contribution** check box to enter the rogue duty-cycle.
- Step 13** Click **Apply**.
-

Configuring Advanced 802.11 Channel Assignment Parameters (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz} rrm channel cleanair-event sensitivity {high low medium} Example: Device(config)# <code>ap dot11 24ghz rrm channel cleanair-event sensitivity high</code>	Configures CleanAir event-driven RRM parameters. <ul style="list-style-type: none"> • High—Specifies the most sensitivity to non-Wi-Fi interference as indicated by the air quality (AQ) value. • Low—Specifies the least sensitivity to non-Wi-Fi interference as indicated by the AQ value. • Medium—Specifies medium sensitivity to non-Wi-Fi interference as indicated by the AQ value.
Step 3	ap dot11 6ghz rrm channel dca {anchor-time 0-23 global auto interval 0-24 sensitivity {high low medium}} Example: Device(config)# <code>ap dot11 6ghz rrm channel dca interval 2</code>	Configures 802.11 6GHz dynamic channel assignment algorithm parameters. <ul style="list-style-type: none"> • anchor-time—Configures the anchor time for the DCA. The range is between 0 and 23 hours. • global—Configures the DCA mode for all 802.11 Cisco APs. <ul style="list-style-type: none"> • auto—Enables auto-RF. • interval—Configures the DCA interval value. The values are 1, 2, 3, 4, 6, 8, 12 and 24 hours and the default value 0 denotes 10 minutes. • sensitivity—Configures the DCA sensitivity level to changes in the environment. <ul style="list-style-type: none"> • high—Specifies the most sensitivity. • low—Specifies the least sensitivity. • medium—Specifies medium sensitivity.

	Command or Action	Purpose
Step 4	ap dot11 5ghz rrm channel dca chan-width {20 40 80 best} Example: <pre>Device(config)#ap dot11 5ghz rrm channel dca chan-width best</pre>	Configures the DCA channel bandwidth for all 802.11 radios in the 5-GHz band. Sets the channel bandwidth to 20 MHz, 40 MHz, or 80 MHz; 20 MHz is the default value for channel bandwidth. 80 MHz is the default value for best. Set the channel bandwidth to best before configuring the constraints.
Step 5	ap dot11 5ghz rrm channel dca chan-width width-max {WIDTH_20MHz WIDTH_40MHz WIDTH_80MHz WIDTH_MAX} Example: <pre>Device(config)#ap dot11 5ghz rrm channel dca chan-width width-max WIDTH_80MHz</pre>	Configures the maximum channel bandwidth that can be assigned to a channel. In this example, <i>WIDTH_80MHz</i> assigns the channel bandwidth to 20 MHz, 40 MHz, or 80 MHz but not greater than that.
Step 6	ap dot11 6ghz rrm channel dca chan-width width-max {WIDTH_20MHz WIDTH_40MHz WIDTH_80MHz WIDTH_MAX} Example: <pre>Device(config)#ap dot11 6ghz rrm channel dca chan-width width-max WIDTH_80MHz</pre>	Configures the maximum channel bandwidth that can be assigned to a channel. In this example, <i>WIDTH_80MHz</i> assigns the channel bandwidth to 20 MHz, 40 MHz, or 80 MHz but not greater than that.
Step 7	ap dot11 {24ghz 5ghz} rrm channel device Example: <pre>Device(config)#ap dot11 24ghz rrm channel device</pre>	Configures the persistent non-Wi-Fi device avoidance in the 802.11 channel assignment.
Step 8	ap dot11 {24ghz 5ghz} rrm channel foreign Example: <pre>Device(config)#ap dot11 24ghz rrm channel foreign</pre>	Configures the foreign AP 802.11 interference avoidance in the channel assignment.
Step 9	ap dot11 {24ghz 5ghz} rrm channel load Example: <pre>Device(config)#ap dot11 24ghz rrm channel load</pre>	Configures the Cisco AP 802.11 load avoidance in the channel assignment.

	Command or Action	Purpose
Step 10	ap dot11 {24ghz 5ghz} rrm channel noise Example: Device (config) # ap dot11 24ghz rrm channel noise	Configures the 802.11 noise avoidance in the channel assignment.
Step 11	end Example: Device (config) # end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring 802.11 Coverage Hole Detection (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > RRM** to configure Radio Resource Management parameters for 802.11ax (6-GHz), 802.11a/n/ac (5-GHz) and 802.11b/g/n (2.4-GHz) radios.
 - Step 2** On the **Radio Resource Management** page, click **Coverage** tab.
 - Step 3** To enable coverage hole detection, check the **Enable Coverage Hole Detection** check box.
 - Step 4** In the **Data Packet Count** field, enter the number of data packets.
 - Step 5** In the **Data Packet Percentage** field, enter the percentage of data packets.
 - Step 6** In the **Data RSSI Threshold** field, enter the actual value in dBm. Value ranges from -60 dBm to -90 dBm; the default value is -80 dBm.
 - Step 7** In the **Voice Packet Count** field, enter the number of voice data packets.
 - Step 8** In the **Voice Packet Percentage** field, enter the percentage of voice data packets.
 - Step 9** In the **Voice RSSI Threshold** field, enter the actual value in dBm. Value ranges from -60 dBm to -90 dBm; the default value is -80 dBm.
 - Step 10** In the **Minimum Failed Client per AP** field, enter the minimum number of clients on an AP with a signal-to-noise ratio (SNR) below the coverage threshold. Value ranges from 1 to 75 and the default value is 3.
 - Step 11** In the **Percent Coverage Exception Level per AP** field, enter the maximum desired percentage of clients on an access point's radio operating below the desired coverage threshold and click **Apply**. Value ranges from 0 to 100% and the default value is 25%.
-

Configuring 802.11 Coverage Hole Detection (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	<p>ap dot11 {24ghz 5ghz 6ghz} rrm coverage data {fail-percentage packet-count rssi-threshold}</p> <p>Example:</p> <pre>Device(config)#ap dot11 24ghz rrm coverage data fail-percentage 60</pre>	<p>Configures the 802.11 coverage hole detection for data packets.</p> <ul style="list-style-type: none"> • fail-percentage: Configures the 802.11 coverage failure-rate threshold for uplink data packets as a percentage that ranges from 1 to 100%. • packet-count: Configures the 802.11 coverage minimum failure count threshold for uplink data packets that ranges from 1 to 255. • rssi-threshold: Configures the 802.11 minimum receive coverage level for data packets that range from -90 to -60 dBm.
Step 3	<p>ap dot11 6ghz rrm coverage data {fail-percentage <i>fail-percentage-value</i> packet-count <i>packet-count-value</i>}</p> <p>Example:</p> <pre>Device(config)#ap dot11 6ghz rrm coverage data fail-percentage 60</pre>	<p>Configures the 802.11 6-GHz coverage hole detection for data packets.</p> <ul style="list-style-type: none"> • fail-percentage: Configures the 802.11 6-GHz coverage failure-rate threshold for uplink data packets as a percentage that ranges from 1 to 100%. • packet-count: Configures the 802.11 6-GHz coverage minimum failure count threshold for uplink data packets that ranges from 1 to 255.
Step 4	<p>ap dot11 {24ghz 5ghz} rrm coverage exception global <i>exception level</i></p> <p>Example:</p> <pre>Device(config)#ap dot11 24ghz rrm coverage exception global 50</pre>	<p>Configures the 802.11 Cisco AP coverage exception level as a percentage that ranges from 0 to 100%.</p>
Step 5	<p>ap dot11 {24ghz 5ghz} rrm coverage level global <i>cli_min exception level</i></p> <p>Example:</p> <pre>Device(config)#ap dot11 24ghz rrm coverage level global 10</pre>	<p>Configures the 802.11 Cisco AP client minimum exception level that ranges from 1 to 75 clients.</p>
Step 6	<p>ap dot11 {24ghz 5ghz 6ghz} rrm coverage voice {fail-percentage packet-count rssi-threshold}</p> <p>Example:</p>	<p>Configures the 802.11 coverage hole detection for voice packets.</p> <ul style="list-style-type: none"> • fail-percentage: Configures the 802.11 coverage failure-rate threshold for uplink

	Command or Action	Purpose
	<pre>Device(config)#ap dot11 24ghz rrm coverage voice packet-count 10</pre>	<p>voice packets as a percentage that ranges from 1 to 100%.</p> <ul style="list-style-type: none"> • packet-count: Configures the 802.11 coverage minimum failure count threshold for uplink voice packets that ranges from 1 to 255. • rsi-threshold: Configures the 802.11 minimum receive coverage level for voice packets that range from -90 to -60 dBm.
Step 7	<pre>ap dot11 6ghz rrm coverage voice {fail-percentage fail-percentage-value packet-count packet-count-value} Example: Device(config)#ap dot11 6ghz rrm coverage voice packet-count 10</pre>	<p>Configures the 802.11 6-GHz coverage hole detection for voice packets.</p> <ul style="list-style-type: none"> • fail-percentage: Configures the 802.11 6-GHz coverage failure-rate threshold for uplink voice packets as a percentage that ranges from 1 to 100%. • packet-count: Configures the 802.11 6-GHz coverage minimum failure count threshold for uplink voice packets that ranges from 1 to 255.
Step 8	<pre>end Example: Device(config)# end</pre>	<p>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</p>

Configuring 802.11 Event Logging (CLI)

Procedure

	Command or Action	Purpose
Step 1	<pre>configure terminal Example: Device# configure terminal</pre>	<p>Enters global configuration mode.</p>
Step 2	<pre>ap dot11 24ghz 5ghz 6ghz rrm logging {channel coverage foreign load noise performance txpower} Example: Device(config)#ap dot11 24ghz rrm logging channel Device(config)#ap dot11 24ghz rrm logging coverage</pre>	<p>Configures event-logging for various parameters.</p> <ul style="list-style-type: none"> • channel—Configures the 802.11 channel change logging mode. • coverage—Configures the 802.11 coverage profile logging mode. • foreign—Configures the 802.11 foreign interference profile logging mode.

	Command or Action	Purpose
	<pre>Device(config)#ap dot11 24ghz rrm logging foreign</pre> <pre>Device(config)#ap dot11 24ghz rrm logging load</pre> <pre>Device(config)#ap dot11 24ghz rrm logging noise</pre> <pre>Device(config)#ap dot11 24ghz rrm logging performance</pre> <pre>Device(config)#ap dot11 24ghz rrm logging txpower</pre>	<ul style="list-style-type: none"> • load—Configures the 802.11 load profile logging mode. • noise—Configures the 802.11 noise profile logging mode. • performance—Configures the 802.11 performance profile logging mode. • txpower—Configures the 802.11 transmit power change logging mode.
Step 3	<pre>end</pre> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring 802.11 Statistics Monitoring (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > RRM** to configure Radio Resource Management parameters for 802.11ax (6-GHz), 802.11a/n/ac (5 GHz) and 802.11b/g/n (2.4 GHz) radios.
- Step 2** In the **Monitor Intervals(60 to 3600secs)** section, proceed as follows:
- To configure the 802.11 noise measurement interval (channel scan interval), set the **AP Noise Interval**. The valid range is from 60 to 3600 seconds.
 - To configure the 802.11 signal measurement interval (neighbor packet frequency), set the **AP Signal Strength Interval**. The valid range is from 60 to 3600 seconds.
 - To configure the 802.11 coverage measurement interval, set the **AP Coverage Interval**. The valid range is from 60 to 3600 seconds.
 - To configure the 802.11 load measurement, set the **AP Load Interval**. The valid range is from 60 to 3600 seconds.
- Step 3** Click **Apply**.
-

Configuring 802.11 Statistics Monitoring (CLI)

Procedure

	Command or Action	Purpose
Step 1	<pre>configure terminal</pre> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	ap dot11 {24ghz 5ghz 6ghz} rrm monitor channel-list {all country dca} Example: <pre>Device(config)#ap dot11 24ghz rrm monitor channel-list all</pre>	Sets the 802.11 monitoring channel-list for parameters such as noise/interference/rogue. <ul style="list-style-type: none"> • all: Monitors all channels. • country: Monitor channels used in configured country code. • dca: Monitor channels used by dynamic channel assignment.
Step 3	ap dot11 {24ghz 5ghz 6ghz} rrm monitor coverage interval Example: <pre>Device(config)#ap dot11 24ghz rrm monitor coverage 600</pre>	Configures the 802.11 coverage measurement interval in seconds that ranges from 60 to 3600.
Step 4	ap dot11 {24ghz 5ghz 6ghz} rrm monitor load interval Example: <pre>Device(config)#ap dot11 24ghz rrm monitor load 180</pre>	Configures the 802.11 load measurement interval in seconds that ranges from 60 to 3600.
Step 5	ap dot11 {24ghz 5ghz 6ghz} rrm monitor measurement interval Example: <pre>Device(config)#ap dot11 24ghz rrm monitor measurement 360</pre>	Configures the 802.11 measurement interval in seconds that ranges from 60 to 3600.
Step 6	ap dot11 {24ghz 5ghz 6ghz} rrm monitor neighbor-timeout-factor interval Example: <pre>Device(config)#ap dot11 24ghz rrm monitor neighbor-timeout-factor 50</pre>	Configures the 802.11 neighbor timeout-factor in seconds that ranges from 5 to 60.
Step 7	ap dot11 {24ghz 5ghz 6ghz} rrm monitor reporting interval Example: <pre>Device(config)#ap dot11 24ghz rrm monitor reporting 480</pre>	Configures the 802.11 reporting interval in seconds that ranges from 60 to 3600.
Step 8	ap dot11 {24ghz 5ghz 6ghz} rrm monitor rssi-normalization Example:	Configures the 802.11 RRM Neighbor Discovery RSSI normalization.

	Command or Action	Purpose
	Device (config) #ap dot11 24ghz rrm monitor rssi-normalization	

Configuring the 802.11 Performance Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
- Step 2** On the **AP Join** page, click the name of the profile or click **Add** to create a new one.
- Step 3** In the **Add/Edit RF Profile** window, click the **RRM** tab.
- Step 4** In the **General** tab that is displayed, enter the following parameters:
- In the **Interference (%)** field, enter the threshold value for 802.11 foreign interference that ranges between 0 and 100 percent.
 - In the **Clients** field, enter the threshold value for 802.11 Cisco AP clients that range between 1 and 75 clients.
 - In the **Noise (dBm)** field, enter the threshold value for 802.11 foreign noise ranges between -127 and 0 dBm.
 - In the **Utilization(%)** field, enter the threshold value for 802.11 RF utilization that ranges between 0 to 100 percent.
- Step 5** Click **Update & Apply to Device**.
-

Configuring the 802.11 Performance Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz} rrm profile clients <i>cli_threshold_value</i> Example: Device (config) #ap dot11 24ghz rrm profile clients 20	Sets the threshold value for 802.11 Cisco AP clients that range between 1 and 75 clients.
Step 3	ap dot11 {24ghz 5ghz} rrm profile foreign <i>int_threshold_value</i> Example:	Sets the threshold value for 802.11 foreign interference that ranges between 0 and 100%.

	Command or Action	Purpose
	<code>Device(config)#ap dot11 24ghz rrm profile foreign 50</code>	
Step 4	<p>ap dot11 {24ghz 5ghz} rrm profile noise for_noise_threshold_value</p> <p>Example:</p> <pre>Device(config)#ap dot11 24ghz rrm profile noise -65</pre>	Sets the threshold value for 802.11 foreign noise ranges between -127 and 0 dBm.
Step 5	<p>ap dot11 6ghz rrm profile customize</p> <p>Example:</p> <pre>Device(config)#ap dot11 6ghz rrm profile customize</pre>	Enables performance profiles.
Step 6	<p>ap dot11 {24ghz 5ghz 6ghz} rrm profile throughput throughput_threshold_value</p> <p>Example:</p> <pre>Device(config)#ap dot11 24ghz rrm profile throughput 10000</pre>	Sets the threshold value for 802.11 Cisco AP throughput that ranges between 1000 and 10000000 bytes per second.
Step 7	<p>ap dot11 {24ghz 5ghz} rrm profile utilization rf_util_threshold_value</p> <p>Example:</p> <pre>Device(config)#ap dot11 24ghz rrm profile utilization 75</pre>	Sets the threshold value for 802.11 RF utilization that ranges between 0 to 100%.
Step 8	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.

Configuring Advanced 802.11 RRM

Enabling Channel Assignment (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > RRM**.
 - Step 2** In the **RRM** page, click the relevant band's tab: either **6 GHz Band**, **5 GHz Band** or **2.4 GHz Band**.
 - Step 3** Click the **DCA** tab

Step 4 In the **Dynamic Channel Assignment Algorithm** section, choose the appropriate **Channel Assignment Mode** from these options:

- Automatic: Sets the channel assignment to automatic.
- Freeze: Locks the channel assignment. Click **Invoke Channel Update Once** to refresh the assigned channels.

Step 5 Click **Apply**.

Enabling Channel Assignment (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# <code>enable</code>	Enters privileged EXEC mode.
Step 2	ap dot11 {24ghz 5ghz} rrm channel-update Example: Device# <code>ap dot11 24ghz rrm channel-update</code>	Enables the 802.11 channel selection update for each of the Cisco access points. Note After you enable ap dot11 {24ghz 5ghz} rrm channel-update , a token is assigned for channel assignment in the DCA algorithm.

Restarting DCA Operation

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# <code>enable</code>	Enters privileged EXEC mode.
Step 2	ap dot11 {24ghz 5ghz} rrm dca restart Example: Device# <code>ap dot11 24ghz rrm dca restart</code>	Restarts the DCA cycle for 802.11 radio.

Updating Power Assignment Parameters (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
 - Step 2** On the **Access Points** page, click the AP name from the 5GHz or 2.4 GHz list.
 - Step 3** In the **Edit Radios > Configure > Tx Power Level Assignment** section, choose **Custom** from the **Assignment Method** group-down list.
 - Step 4** Choose the value for **Transmit Power** from the drop-down list.
 - Step 5** Click **Update & Apply to Device**.
-

Updating Power Assignment Parameters (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# <code>enable</code>	Enters privileged EXEC mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} rrm txpower update Example: Device# <code>ap dot11 24ghz rrm txpower update</code>	Initiates the update of the 802.11 6-GHz transmit power for every Cisco AP.

Configuring Rogue Access Point Detection in RF Groups

Configuring Rogue Access Point Detection in RF Groups (CLI)

Before you begin

Ensure that each controller in the RF group has been configured with the same RF group name.

Note The name is used to verify the authentication IE in all beacon frames. If the controller have different names, false alarms will occur.

Procedure

	Command or Action	Purpose
Step 1	<p>ap name <i>Cisco_AP</i> mode{ monitor clear sensor sniffer}</p> <p>Example:</p> <pre>Device# ap name ap1 mode clear</pre>	<p>Perform this step for every access point connected to the controller .</p> <p>Configures the following AP modes of operation:</p> <ul style="list-style-type: none"> • monitor: Sets the AP mode to monitor mode. • clear: Resets AP mode to local or remote based on the site. • sensor: Sets the AP mode to sensor mode. • sniffer: Sets the AP mode to wireless sniffer mode.
Step 2	<p>end</p> <p>Example:</p> <pre>Device (config)# end</pre>	<p>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</p>
Step 3	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	<p>Enters global configuration mode.</p>
Step 4	<p>wireless wps ap-authentication</p> <p>Example:</p> <pre>Device (config)# wireless wps ap-authentication</pre>	<p>Enables rogue access point detection.</p>
Step 5	<p>wireless wps ap-authentication threshold <i>value</i></p> <p>Example:</p> <pre>Device (config)# wireless wps ap-authentication threshold 50</pre>	<p>Specifies when a rogue access point alarm is generated. An alarm occurs when the threshold value (which specifies the number of access point frames with an invalid authentication IE) is met or exceeded within the detection period.</p> <p>The valid threshold range is from 1 to 255, and the default threshold value is 1. To avoid false alarms, you may want to set the threshold to a higher value.</p> <p>Note Enable rogue access point detection and threshold value on every controller in the RF group.</p> <p>Note If rogue access point detection is not enabled on every controller in the RF group, the access points on the controller with this feature disabled are reported as rogues.</p>

Monitoring RRM Parameters and RF Group Status

Monitoring RRM Parameters

Table 46: Commands for monitoring Radio Resource Management

Commands	Description
show ap dot11 24ghz channel	Displays the configuration and statistics of the 802.11b channel assignment.
show ap dot11 24ghz coverage	Displays the configuration and statistics of the 802.11b coverage.
show ap dot11 24ghz group	Displays the configuration and statistics of the 802.11b grouping.
show ap dot11 24ghz logging	Displays the configuration and statistics of the 802.11b event logging.
show ap dot11 24ghz monitor	Displays the configuration and statistics of the 802.11b monitoring.
show ap dot11 24ghz profile	Displays 802.11b profiling information for all Cisco APs.
show ap dot11 24ghz summary	Displays the configuration and statistics of the 802.11b Cisco APs.
show ap dot11 24ghz txpower	Displays the configuration and statistics of the 802.11b transmit power control.
show ap dot11 5ghz channel	Displays the configuration and statistics of the 802.11a channel assignment.
show ap dot11 5ghz coverage	Displays the configuration and statistics of the 802.11a coverage.
show ap dot11 5ghz group	Displays the configuration and statistics of the 802.11a grouping.
show ap dot11 5ghz logging	Displays the configuration and statistics of the 802.11a event logging.
show ap dot11 5ghz monitor	Displays the configuration and statistics of the 802.11a monitoring.
show ap dot11 5ghz profile	Displays 802.11a profiling information for all Cisco APs.
show ap dot11 5ghz summary	Displays the configuration and statistics of the 802.11a Cisco APs.
show ap dot11 5ghz txpower	Displays the configuration and statistics of the 802.11a transmit power control.

Verifying RF Group Status (CLI)

This section describes the new commands for RF group status.

The following commands can be used to verify RF group status on the .

Table 47: Verifying Aggressive Load Balancing Command

Command	Purpose

show ap dot11 5ghz group	Displays the controller name which is the RF group leader for the 802.11a RF network.
show ap dot11 24ghz group	Displays the controller name which is the RF group leader for the 802.11b/g RF network.
show ap dot11 6ghz group	Displays the controller name which is the RF group leader for the 802.11 6-GHz RF network.

To display the controller as a remote member and part of the AI Enhanced RRM, use the following command:

```
Device# show ap dot11 24ghz group
```

```
Radio RF Grouping
```

```
RF Group Name : Open-RRM
RF Protocol Version(MIN) : 100(30)
RF Packet Header Version : 2
802.11b Group Mode : AUTO
802.11b Group Role : Remote-Member
802.11b Group Update Interval : 600 seconds
802.11b Group Leader : 172.19.30.39 (172.19.30.39)
Secure-RRM : Disabled
```

```
RF Group Members
```

```
Controller name Controller IP Controller IPv6 DTLS status
-----
```

Controller name	Controller IP	Controller IPv6	DTLS status
evwlc-188	192.1.0.188	N/A	

Examples: RF Group Configuration

This example shows how to configure RF group name:

```
Device# configure terminal
Device(config)# wireless rf-network test1
Device(config)# ap dot11 24ghz shutdown
Device(config)# end
Device # show network profile 5
```

This example shows how to configure rogue access point detection in RF groups:

```
Device# ap name ap1 mode clear
Device# end
Device# configure terminal
Device(config)# wireless wps ap-authentication
Device(config)# wireless wps ap-authentication threshold 50
Device(config)# end
```

Information About ED-RRM

Spontaneous interference is interference that appears suddenly on a network, perhaps jamming a channel or a range of channels completely. The Cisco CleanAir spectrum event-driven RRM feature allows you to set a

threshold for air quality (AQ) that, if exceeded, triggers an immediate channel change for the affected access point. Once a channel change occurs due to event-driven RRM, the channel is blocked list for three hours to avoid selection. Most RF management systems can avoid interference, but this information takes time to propagate through the system. Cisco CleanAir relies on AQ measurements to continuously evaluate the spectrum and can trigger a move within 30 seconds. For example, if an access point detects interference from a video camera, it can recover by changing channels within 30 seconds of the camera becoming active.

Configuring ED-RRM on the Cisco Wireless Controller (CLI)

Procedure

- Step 1** Trigger spectrum event-driven radio resource management (RRM) to run when a Cisco CleanAir-enabled access point detects a significant level of interference by entering these commands:
- ap dot11 {24ghz | 5ghz} rrm channel cleanair-event**—Configures CleanAir driven RRM parameters for the 802.11 Cisco lightweight access points.
- ap dot11 {24ghz | 5ghz} rrm channel cleanair-event sensitivity {low | medium | high | custom}**—Configures CleanAir driven RRM sensitivity for the 802.11 Cisco lightweight access points. Default selection is Medium.
- ap dot11 {24ghz | 5ghz} rrm channel cleanair-event custom-threshold *custom-threshold-value***—Triggers the ED-RRM event at the set threshold value. The custom threshold values range from 1 to 99.
- ap dot11 {24ghz | 5ghz} rrm channel cleanair-event rogue-contribution**—Enables rogue contribution.
- ap dot11 {24ghz | 5ghz} rrm channel cleanair-event rogue-contribution duty-cycle *thresholdvalue***—Configures threshold value for rogue contribution. The valid range is from 1 to 99, with 80 as the default.
- Step 2** Save your changes by entering this command:
- write memory**
- Step 3** See the CleanAir configuration for the 802.11a/n/ac or 802.11b/g/n network by entering this command:
- show ap dot11 {24ghz | 5ghz} cleanair config**
- Information similar to the following appears:

Information About Rogue PMF Containment

From Cisco IOS XE Dublin 17.12.1, the controller will contain a rogue AP with 802.11w Protected Management Frame (PMF) on centrally switched WLANs if the client-serving radio channel of a rogue-detecting AP matches the channel of the corresponding rogue AP.

PMF Containment is performed in the following scenarios:

- PMF containment is supported only in the local mode.
- PMF containment is done only for rogue clients that have not joined a rogue AP.
- PMF containment is done only if a rogue-detecting AP shares the same primary channel with a rogue client.
- PMF containment is not done on DFS channels even if a DFS channel is being used as a client-serving channel.

- PMF containment is effective only if there is at least one functioning WLAN on the serving radio where the containment is being performed.

The Rogue PMF Containment feature is supported only on the following APs:

- Cisco Catalyst 9130AX
- Cisco Catalyst 9136
- Cisco Catalyst 9162
- Cisco Catalyst 9164
- Cisco Catalyst 9166

Enabling Rogue PMF Containment

Follow this procedure to configure PMF containment on a per site basis.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# ap profile xyz-ap-profile	Configures an AP profile and enters AP profile configuration mode.
Step 3	rogue detection containment pmf-denial Example: Device(config-ap-profile)# rogue detection containment pmf-denial	Enables PMF-denial rogue AP containment.
Step 4	pmf-deauth Example: Device(config-pmf-denial)# pmf-deauth	Enables PMF-denial type deauthentication rogue AP containment.
Step 5	end Example: Device(config-ap-profile)# end	Returns to privileged EXEC mode.

Verifying PMF Containment

To verify PMF containment and the relevant statistics, use the following commands.

To view the containment details summary for all the AP radios, use the following command:

```
Device# show wireless wps rogue containment summary
```

Rogue Containment activities for each managed AP

```
AP: 687d.b45f.2ae0 Slot: 1
  Active Containments   : 3
  Containment Mode      : DEAUTH_PMF
  Rogue AP MAC          : 687d.b45f.2a2d
  Containment Channels  : 40
```

To verify the rogue statistics, use the following command:

```
Device# show wireless wps rogue stats
.
.
.
States
Alert                : 256
Internal             : 0

.
```

Information About Rogue Channel Width

From Cisco IOS XE Dublin 17.12.1, you can specify the channel width and the band for rogue detection. The newly introduced **condition chan-width** command allows you to set the minimum or maximum channel width for rogue detection. Only the rogue APs matching the channel width criteria and band are selected for rogue detection.

Configuring Rogue Channel Width (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless wps rogue rule rule-name priority priority	Creates or enables a rule.

	Command or Action	Purpose
	Example: <pre>Device(config)# wireless wps rogue rule 1 priority 1</pre>	
Step 3	condition chan-width {160MHz 20MHz 40MHz 80MHz} band {2.4GHz 5GHz 6GHz} Example: <pre>Device(config-rule)# condition chan-width 20MHz band 5GHz</pre>	Configures channel width and band for rogue detection. If the classification is Friendly , this is the minimum channel width. If the classification is Custom, Malicious, or Delete , this is the maximum channel width.
Step 4	Use either Step 4 > 5 > 6 > 7	Note Use only one of the Steps: 4, 5, 6 or 7 as required to classify rogue devices. Do not use all of them.
Step 5	classify friendly state {alert external internal } Example: <pre>Device(config-rule)# classify friendly state internal</pre>	(Optional) Classifies devices matching this rule as friendly. <ul style="list-style-type: none"> • alert: Sets the malicious rogue access point to alert mode. • external: Acknowledges the presence of a rogue access point. • internal: Trusts a foreign access point.
Step 6	classify malicious state {alert contained } Example: <pre>Device(config-rule)# classify malicious state alert</pre>	(Optional) Classifies devices matching this rule as malicious. <ul style="list-style-type: none"> • alert: Sets the malicious rogue access point to alert mode. • contained: Contains the rogue access point.
Step 7	classify custom severity-score <i>severity-score</i> [name <i>name</i>] state {alert contained } Example: <pre>Device(config-rule)# classify custom severity-score 12 name rule1 state alert</pre>	(Optional) Classifies devices matching this rule as custom. <ul style="list-style-type: none"> • <i>severity-score</i> : Custom classification severity score. Valid values range from 1 to 100. • <i>name</i>: Defines the name for custom classification. • <i>name</i> : Custom classification name. • <i>state</i>: Defines the final state if rule is matched. • alert: Sets the rogue access point to alert mode.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • contained: Contains the rogue access point.
Step 8	classify delete Example: Device(config-rule)# classify delete	Ignorees the devices matching this rule.
Step 9	end Example: Device(config-rule)# end	Returns to privileged EXEC mode.

Configuring Rogue Classification Rules (GUI)

Procedure

- Step 1** Choose **Configuration > Security > Wireless Protection Policies > Rogue AP Rules** to open the **Rogue Rules** window.
- Rules that have already been created are listed in priority order. The name, type, status, state, match, and hit count of each rule is provided.
- Note** To delete a rule, select the rule and click **Delete**.
- Step 2** Create a new rule as follows:
- Click **Add**.
 - In the **Add Rogue AP Rule** window that is displayed, enter a name for the new rule, in the **Rule Name** field. Ensure that the name does not contain any spaces.
 - From the **Rule Type** drop-down list, choose one of the following options to classify rogue access points matching this rule:
 - **Friendly**
 - **Malicious**
 - **Unclassified**
 - **Custom**
 - Configure the state of the rogue AP from the **State** drop-down list. This is the state when the rule matches the conditions for the rogue APs.
 - **Alert**: A trap is generated when an ad hoc rogue is detected.
 - **Internal**: A foreign ad hoc rogue is trusted.
 - **External**: The presence of an ad hoc rogue is acknowledged.
 - **Contain**: The ad hoc rogue is contained.

- **Delete:** The ad hoc rogue is removed.

Note The **State** field is not displayed if you select **Unclassified** as the **Rule Type**.

- If you chose the **Rule Type** as **Custom**, enter the **Severity Score** and the **Custom Name**.
- Click **Apply to Device** to add this rule to the list of existing rules, or click **Cancel** to discard this new rule.

Step 3

(Optional) Edit a rule as follows:

- Click the name of the rule that you want to edit.
- In the **Edit Rogue AP Rule** page that is displayed, from the **Type** drop-down list, choose one of the following options to classify rogue access points matching this rule:
 - **Friendly**
 - **Malicious**
 - **Custom**
- Configure the notification from the **Notify** drop-down list to **All**, **Global**, **Local**, or **None** after the rule is matched.
- Configure the state of the rogue AP from the **State** drop-down list after the rule is matched.
- From the **Match Operation** field, choose one of the following:
 - **Match All:** The detected rogue access point must meet all of the conditions specified by the rule for the rule to be matched and the rogue access point to adopt the classification type of the rule.
 - **Match Any:** The detected rogue access point must meet any of the conditions specified by the rule for the rule to be matched and the rogue access point to adopt the classification type of the rule. This is the default value.
- To enable this rule, check the **Enable Rule** check box. The default is unchecked.
- If you chose the **Rule Type** as **Custom**, enter the **Severity Score** and the **Classification Name**.
- From the **Add Condition** drop-down list, choose one or more of the following conditions that the rogue access point must meet :
 - **None:** No condition is set for rogue access point detection.
 - **client-count:** Condition requires that a minimum number of clients be associated to the rogue access point. For example, if the number of clients associated to the rogue access point is greater than or equal to the configured value, then the access point can be classified as malicious. If you choose this option, enter the minimum number of clients to be associated with the rogue access point in the **Minimum Number of Rogue Clients** field. The valid range is 1 to 10 (inclusive), and the default value is 0.
 - **duration:** Condition requires that the rogue access point be detected for a minimum period of time. If you choose this option, enter a value for the minimum detection period in the **Time Duration** field. The valid range is 0 to 86400 seconds (inclusive), and the default value is 0 seconds.
 - **encryption:** Condition requires that the advertised WLAN have specified encryption. Requires that the rogue access point's advertised WLAN does not have encryption enabled. If a rogue access point has encryption disabled, it is likely that more clients will try to associate with it. No further configuration is required for this option.

- **infrastructure**: Condition requires that the rogue access point's SSID (the SSID configured for the WLAN) be known to the controller. Select the **Manage SSID** check box to enable this configuration.
- **rss**: Condition requires that the rogue access point have a minimum received signal strength indication (RSSI) value. For example, if the rogue access point has an RSSI that is greater than the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum RSSI value in the **Maximum RSSI** field. The valid range is 0 to -128 dBm (inclusive).
- **channel-width**: Condition requires that the rogue access point use the specified radio spectrum channel width for the specified radio band, as defined below. The valid channel widths are 20, 40, 80, and 160MHz.
 - For APs to be classified as **Malicious**, **Custom** or **Delete**, it must match the value (equal or more) set in the **Minimum Channel Width** drop-down list.
 - For APs to be classified as **Friendly**, it must match the value (equal or less) set using an option from the **Maximum Channel Width** drop-down list.
- **ssid**: Condition requires that the rogue access point have a specific user-configured SSID. If you choose this option, enter the SSID in the **User Configured SSID** text field, and click + to add the SSID.
- **substring-ssid**: Condition requires that the rogue access point have a substring of the specific user-configured SSID. The controller searches the substring in the same occurrence pattern and returns a match if the substring is found in the SSID string.

Step 4 Click **Apply to Device** to save the configuration.

Step 5 Click **OK**.

Verifying Rogue Channel Width

To view channel width and band information of a classification rule, use the following commands.

Note When the same BSSID is beaconing on multiple bands (2.4 GHz, 5 GHz, 6 GHz), the **show wireless wps rogue ap summary** command output displays information for the band with the highest RSSI.

```
Device# show wireless wps rogue rule detailed 1

Priority                : 1
Rule Name              : 1
Status                 : Enabled
Type                   : Friendly
State                  : Alert
Match Operation        : Any
Notification           : Enabled
Hit Count              : 117
Condition :
  type                 : chan-width
  Max value (MHz)     : 40
```

Band (GHz) : 5GHz

Device# wireless wps rogue ap summary

CHAPTER 29

Coverage Hole Detection

- [Coverage Hole Detection and Correction, on page 561](#)

Coverage Hole Detection and Correction

The RRM coverage hole detection algorithm can detect areas of radio coverage in a wireless LAN that are below the level needed for robust radio performance. This feature can alert you to the need for an additional (or relocated) lightweight access point.

If clients on a lightweight access point are detected at threshold levels (RSSI, failed client count, percentage of failed packets, and number of failed packets) lower than those specified in the RRM configuration, the access point sends a “coverage hole” alert to the device. The alert indicates the existence of an area where clients are continually experiencing poor signal coverage, without having a viable access point to which to roam. The device discriminates between coverage holes that can and cannot be corrected. For coverage holes that can be corrected, the device mitigates the coverage hole by increasing the transmit power level for that specific access point. The device does not mitigate coverage holes caused by clients that are unable to increase their transmit power or are statically set to a power level because increasing their downstream transmit power might increase interference in the network.

Configuring Coverage Hole Detection (GUI)

Follow the procedure given below to configure client accounting.

Procedure

- Step 1** Click **Configuration > Radio Configurations > RRM**.
- On this page, you can configure Radio Resource Management parameters for 802.11a/n/ac (5 GHz) and 802.11b/g/n (2.4 GHz) radios, and flexible radio assignment parameters.
- Step 2** Check the **Enable Coverage Hole Detection** check box.
- Enables coverage hole detection.
-

Configuring Coverage Hole Detection (CLI)

Coverage Hole Detection (CHD) is based on upstream RSSI metrics observed by the AP.

Note To revert back radios from 5-GHz to 24-GHz for CHD, ensure that the 5-GHz radio is UP and Client Network Preference value is other than the default.

Follow the procedure given below to configure CHD:

Before you begin

Disable the 802.11 network before applying the configuration.

Procedure

	Command or Action	Purpose
Step 1	ap dot11 {24ghz 5ghz} rrm coverage Example: Device(config)# ap dot11 24ghz rrm coverage	Configures the 802.11 coverage level for data packets. Use the no form of the command to disable CHD.
Step 2	ap dot11 {24ghz 5ghz} rrm coverage data {fail-percentage packet-count rssi-threshold} Example: Device(config)# ap dot11 24ghz rrm coverage data fail-percentage 60	Configures the 802.11 coverage level for data packets. <ul style="list-style-type: none"> • fail-percentage: Configures the 802.11 coverage failure-rate threshold for uplink data packets as a percentage that ranges from 1 to 100%. • packet-count: Configures the 802.11 coverage minimum failure count threshold for uplink data packets that ranges from 1 to 255. • rssi-threshold: Configures the 802.11 minimum receive coverage level for data packets that range from -90 to -60 dBm.
Step 3	ap dot11 6ghz rrm coverage data {fail-percentage fail-percentage-value packet-count packet-count-value} Example: Device(config)# ap dot11 6ghz rrm coverage data fail-percentage 60	Configures the 802.11 6-GHz coverage hole detection for data packets. <ul style="list-style-type: none"> • fail-percentage: Configures the 802.11 6-GHz coverage failure-rate threshold for uplink data packets as a percentage that ranges from 1 to 100%. • packet-count: Configures the 802.11 6-GHz coverage minimum failure count threshold for uplink data packets that ranges from 1 to 255.

	Command or Action	Purpose
Step 4	<p>ap dot11 {24ghz 5ghz} rrm coverage exception global <i>exception level</i></p> <p>Example:</p> <pre>Device(config)# ap dot11 24ghz rrm coverage exception global 50</pre>	Configures the 802.11 Cisco AP coverage exception level as a percentage that ranges from 0 to 100%.
Step 5	<p>ap dot11{24ghz 5ghz}rrm coverage level global <i>cli_min exception level</i></p> <p>Example:</p> <pre>Device(config)# ap dot11 24ghz rrm coverage level global 10</pre>	Configures the 802.11 Cisco AP client minimum exception level that ranges from 1 to 75 clients.
Step 6	<p>ap dot11 {24ghz 5ghz} rrm coverage voice {fail-percentage packet-count rssi-threshold}</p> <p>Example:</p> <pre>Device(config)# ap dot11 24ghz rrm coverage voice packet-count 10</pre>	<p>Configures the 802.11 coverage hole detection for voice packets.</p> <ul style="list-style-type: none"> • fail-percentage: Configures the 802.11 coverage failure-rate threshold for uplink voice packets as a percentage that ranges from 1 to 100%. • packet-count: Configures the 802.11 coverage minimum failure count threshold for uplink voice packets that ranges from 1 to 255. • rssi-threshold: Configures the 802.11 minimum receive coverage level for voice packets that range from -90 to -60 dBm.
Step 7	<p>ap dot11 6ghz rrm coverage voice {fail-percentage <i>fail-percentage-value</i> packet-count <i>packet-count-value</i>}</p> <p>Example:</p> <pre>Device(config)# ap dot11 6ghz rrm coverage voice packet-count 10</pre>	<p>Configures the 802.11 6-GHz coverage hole detection for voice packets.</p> <ul style="list-style-type: none"> • fail-percentage: Configures the 802.11 6-GHz coverage failure-rate threshold for uplink voice packets as a percentage that ranges from 1 to 100%. • packet-count: Configures the 802.11 6-GHz coverage minimum failure count threshold for uplink voice packets that ranges from 1 to 255.
Step 8	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

	Command or Action	Purpose
Step 9	show ap dot11 {24ghz 5ghz 6ghz} coverage Example: Device# show ap dot11 5ghz coverage	Displays the CHD details.

Note If both the number and percentage of failed packets exceed the values entered in the **packet-count** and **fail-rate** commands for a 5-second period, the client is considered to be in a pre-alarm condition. The controller uses this information to distinguish between real and false coverage holes. False positives are generally due to the poor roaming logic implemented on most clients. A coverage hole is detected if both the number and percentage of failed clients meet or exceed the values entered in the **coverage level global** and **coverage exception global** commands over a 90-second period. The controller determines if the coverage hole can be corrected and, if appropriate, mitigates the coverage hole by increasing the transmit power level for that specific access point.

Configuring CHD for RF Tag Profile (GUI)

Procedure

- Step 1** Choose **Configuration > Radio Configurations > RRM**.
- Step 2** On the **Coverage** tab, select the **Enable Coverage Hole Detection** check box.
- Step 3** In the **Data Packet Count** field, enter the number of data packets.
- Step 4** In the **Data Packet Percentage** field, enter the percentage of data packets.
- Step 5** In the **Data RSSI Threshold** field, enter the actual value in dBm. Value ranges from -60 dBm to -90 dBm; the default value is -80 dBm.
- Step 6** In the **Voice Packet Count** field, enter the number of voice data packets.
- Step 7** In the **Voice Packet Percentage** field, enter the percentage of voice data packets.
- Step 8** In the **Voice RSSI Threshold** field, enter the actual value in dBm. Value ranges from -60 dBm to -90 dBm; the default value is -80 dBm.
- Step 9** In the **Minimum Failed Client per AP** field, enter the minimum number of clients on an AP with a signal-to-noise ratio (SNR) below the coverage threshold. Value ranges from 1 to 75 and the default value is 3.
- Step 10** In the **Percent Coverage Exception Level per AP** field, enter the maximum desired percentage of clients on an access point's radio operating below the desired coverage threshold and click **Apply**. Value ranges from 0 to 100% and the default value is 25%.
- Step 11** Click **Apply**.

Configuring CHD for RF Profile (CLI)

Follow the procedure given below to configure Coverage Hole Detection (CHD) for RF profile.

Before you begin

Ensure that the RF profile is already created.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} rf-profile <i>rf-profile-tag</i> Example: Device(config)# <code>ap dot11 24ghz rf-profile</code> <code>alpha-rfprofile-24ghz</code>	Configures the 802.11 coverage hole detection for data packets.
Step 3	coverage data rssi threshold <i>threshold-value</i> Example: Device(config-rf-profile)# <code>coverage data</code> <code>rssi</code> <code>threshold -80</code>	Configures the minimum RSSI value for data packets received by the access point. Valid values range from -90 to -60 in dBm.
Step 4	end Example: Device(config-rf-profile)# <code>end</code>	Returns to privileged EXEC mode.
Step 5	show ap dot11 24ghz rf-profile summary Example: Device# <code>show ap dot11 24ghz</code> <code>rf-profile summary</code>	Displays summary of the available RF profiles.

- [Configuring Optimized Roaming \(CLI\), on page 568](#)

Optimized Roaming

Optimized roaming resolves the problem of sticky clients that remain associated to access points that are far away and outbound clients that attempt to connect to a Wi-Fi network without having a stable connection. This feature disassociates clients based on the RSSI of the client data packets and data rate. The client is disassociated if the RSSI alarm condition is met and the current data rate of the client is lower than the optimized roaming data rate threshold. You can disable the data rate option so that only RSSI is used for disassociating clients.

Optimized roaming also prevents client association when the client's RSSI is low. This feature checks the RSSI of the incoming client against the RSSI threshold. This check prevents the clients from connecting to a Wi-Fi network unless the client has a viable connection. In many scenarios, even though clients can hear beacons and connect to a Wi-Fi network, the signal might not be strong enough to support a stable connection.

You can also configure the client coverage reporting interval for a radio by using optimized roaming. The client coverage statistics include data packet RSSIs, Coverage Hole Detection and Mitigation (CHDM) pre-alarm failures, retransmission requests, and current data rates.

Optimized roaming is useful in the following scenarios:

- Addresses the sticky client challenge by proactively disconnecting clients.
- Actively monitors data RSSI packets.
- Disassociates client when the RSSI is lower than the set threshold.

This section contains the following subsections:

Restrictions for Optimized Roaming

- You cannot configure the optimized roaming interval until you disable the 802.11a/b network.

- When basic service set (BSS) transition is sent to 802.11v-capable clients, and if the clients are not transitioned to other BSS before the disconnect timer expires, the corresponding client is disconnected forcefully. BSS transition is enabled by default for 802.11v-capable clients.
- The Cisco Catalyst 9800 controller increments the 802.11v smart roam failed counter while disconnecting the client due to optimized roaming.
- We recommend that you do not use the optimized roaming feature with RSSI low check.

Configuring Optimized Roaming (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Advanced**.
- Step 2** On the **Advanced** page, click the relevant band's tab: either **5 GHz Band** or **2.4 GHz Band**.
- Step 3** Check the **Optimized Roaming Mode** check box to enable the feature.
- Step 4** Choose the required **Optimized Roaming Data Rate Threshold**. The threshold value options are different for 802.11a and 802.11b networks.
- Optimized roaming disassociates clients based on the RSSI of the client data packet and data rate. The client is disassociated if the current data rate of the client is lower than the Optimized Roaming Data Rate Threshold.
- Step 5** Click **Apply** to save the configuration.
-

Configuring Optimized Roaming (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} rrm optimized-roam Example: Device(config)# ap dot11 24ghz rrm optimized-roam	Configures 802.11a, 802.11b, or 802.11 6-GHz optimized roaming. By default, optimized roaming is disabled.
Step 3	ap dot11 24ghz rrm monitor optimized-roam data-rate-threshold {1M 2M 5_5M 6M 9M 11M 12M 18M 24M 36M 48M 54M disable}	Configure the data rate threshold for 802.11b for optimized roaming.

	Command or Action	Purpose
	Example: Device(config)#ap dot11 24ghz rrm monitor optimized-roam 18M	
Step 4	ap dot11 {5ghz 6ghz} rrm monitor optimized-roam data-rate-threshold {6M 9M 12M 18M 24M 36M 48M 54M disable} Example: Device(config)#ap dot11 6ghz rrm monitor optimized-roam 18M	Configure the data rate threshold for 802.11a or 802.11 6-GHz optimized roaming.
Step 5	show ap dot11 {24ghz 5ghz 6ghz} optimized-roaming statistics Example: Device#show ap dot11 24ghz optimized-roaming statistics	Displays the 802.11a, 802.11b, or 802.11 6-GHz optimized roaming configurations.

CHAPTER 31

Cisco Flexible Radio Assignment

- [Information About Flexible Radio Assignment, on page 571](#)
- [Configuring an FRA Radio \(GUI\), on page 572](#)
- [Enabling FRA \(CLI\), on page 574](#)
- [Configuring Client FRA in RF Profile \(CLI\), on page 576](#)
- [Verifying FRA XOR 5-GHz and 6-GHz Details, on page 576](#)
- [Flexible Radio Assignment \(FRA\) Action, on page 577](#)

Information About Flexible Radio Assignment

Flexible Radio Assignment (FRA) takes advantage of Cisco FRA-capable APs whose radio hardware can operate in multiple roles. The following are the AP models and types of hardware managed by FRA:

Table 48: AP Models and Types of Hardware Managed by FRA

AP Model	FRA Radios	Functions
Cisco Aironet 2800 Series Access Points	2.4/5 XOR	2.4-GHz and 5-GHz or dual 5-GHz operations
Cisco Aironet 3800 Series Access Points	2.4/5 XOR	2.4-GHz and 5-GHz or dual 5-GHz operations
Cisco Aironet 4800 Series Access Points	2.4/5 XOR	2.4-GHz and 5-GHz or dual 5-GHz operations
Cisco Catalyst 9120 Series Access Points	2.4/5 XOR	2.4-GHz and 5-GHz or dual 5-GHz operations
Cisco Catalyst 9130AX Series Access Points	5-GHz Tri-Radio	2.4-GHz 4x4 and single 5-GHz 8x8, or 2.4-GHz 4x4 and dual 5-GHz 4x4
Cisco Catalyst Wireless 9166 Access Points	5/6-GHz XOR	2.4-GHz 4x4 and dual 5-GHz 4x4, or 5-GHz 4x4 and 6-GHz 4x4

FRA performs a number of functions. On the 2.4-GHz and 5-GHz XOR models, FRA establishes the required 2.4-GHz coverage, identifies redundant radios, and converts them to either 5-GHz or a monitor role. For

tri-radio and 5/6-GHz XOR models, FRA determines the 2.4-GHz coverage, and the redundant radios are converted to a monitor role. Additionally, FRA determines the best operating role for the 5-GHz tri-radio (as either a single 8x8 or a dual 4x4), based on connected client capabilities. For the 5/6-GHz XOR radio, the band that the radios should operate on is based on the availability 6-GHz client presence in the regulatory domain.

FRA also manages the resulting configurations of the radios to optimize client experience across flexible roles. Client Steering is responsible for load balancing client connections. For instance, from Cisco Aironet 2800 APs through Cisco Catalyst 9120 Series APs, all the internal antenna AP models perform dual 5-GHz roles as a Macro-Micro cell (a cell within a cell). The antennas on these models are built to support the directionality needed for the micro cell. FRA client steering helps to steer clients to the appropriate radio based on their position within the cell (closer clients are put on the micro cell).

The FRA APs that support external antennas operate as Macro-Macro, which allows full control over power and channels. The CW9166I AP also supports a Macro-Macro model when using the internal antennas.

In Cisco Catalyst 9130 APs and Cisco Catalyst 9136 APs, FRA also manages the operating mode of the band-locked 8x8 5-GHz tri-radio by monitoring client capabilities of connected clients. For instance, if the attached clients are largely Wi-Fi 5-capable clients, then, beam forming should be multi-user MIMO (MU-MIMO), ensuring better capacity with dual 4x4 5-GHz cells. However, if the same cell has a higher number of Wi-Fi 6-capable clients, then 8x8 spatial streams support more MU-MIMO capacity and increase the overall performance of the cell and client experience.

The CW9166 AP is the first AP with a dual-band XOR radio covering the 5-GHz and 6-GHz bands. Criteria for role selection is regulatory domain (that is, if the country's regulatory rules support 6-GHz operations). If yes, 6-GHz is chosen. If not, 5-GHz operations are chosen.

Configuration choices for all FRA radio models include:

- Automatic (Allows FRA to manage role selection automatically)
- Client Serving (Manual role selection of 2.4-GHz, 5-GHz, or 6-GHz, or FRAs are not engaged)
- Monitor (Manual: no FRA)
- Sniffer (Manual: no FRA)

Configuring an FRA Radio (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > RRM > FRA**.
- Step 2** In the **Flexible Radio Assignment** window, in the **5/6 GHz Flexible Radio Assignment** section, perform the following steps:
- a) Click the **FRA Status** toggle button to change the FRA status to **Enabled**. By default, the FRA status is **Disabled**.
 - b) Click the **FRA Freeze** toggle button to enable FRA freeze. Enable **FRA Freeze** to lock the radio's current assigned role. When enabled, the radios continue to operate in their role (monitor, sniffer or client serving) until you manually change it or disable FRA Freeze.
 - c) From the **FRA Interval** drop-down list, choose the FRA run interval. The interval value range is from 1 hour to 24 hours. You can choose the FRA run interval value only after you enable the FRA status.

Step 3

In the **2.4/5 GHz Flexible Radio Assignment** section, perform the following steps:

- a) Click the **FRA Status** toggle button to change the FRA status to **Enabled**. By default, the FRA status is **Disabled**.
- b) Click the **FRA Freeze** toggle button to enable FRA freeze. Enable **FRA Freeze** to lock the radio's current assigned role. When enabled, the radios continue to operate in their role (monitor, sniffer or client serving) until you manually change it or disable FRA Freeze.
- c) From the **FRA Interval** drop-down list, choose the FRA run interval. The interval value range is from 1 hour to 24 hours. You can choose the FRA run interval value only after you enable the FRA status.
- d) From the **FRA Sensitivity** drop-down list, choose the percentage of Coverage Overlap Factor (COF) required to consider a radio as redundant. You can select the supported value only after you enable the FRA status.

The supported values are as follows:

- **Low**: 100 percent
- **Medium** (default): 95 percent
- **High**: 90 percent
- **Higher**: 85 percent
- **Even Higher**: 80 percent
- **Super High**: 50 percent

- e) From the **FRA Action** drop-down list, select the **2.4GHz Monitor** option to globally configure the redundant dual-band (XOR 2.4/5-GHz) radios to operate in monitor role.

By default, dual-band radios operate in the 2.4-GHz/5-GHz/Monitor role. This configuration is helpful especially when there is enough coverage on the 5-GHz band and you want to restrict radios from moving to the 5-GHz band to prevent further interference. Instead, the radios directly move to the monitor mode in the 2.4-GHz band.

- f) Check the **Client Aware** check box to take decisions on redundancy.

When enabled, the **Client Aware** feature monitors the dedicated 5-GHz radio. When the client load passes a preset threshold, the Flexible Radio assignment is automatically changed from a monitor role to a 5-GHz role, effectively doubling the capacity of the cell on demand. After the capacity crisis is over and Wi-Fi load returns to normal, the radios resume their previous roles.

- g) In the **Client Select** field, enter a value for client selection. The valid value range is between 0 and 100 percent. The default value is 50 percent.

This means that if the dedicated 5-GHz interface reaches 50 percent channel utilization, it triggers the monitor role dual-band interface to transition to a 5-GHz client-serving role.

- h) In the **Client Reset** field, enter a reset value for the client. The valid value range is between 0 and 100 percent. The default value is 5 percent.

When the AP is operating as a dual 5-GHz AP, this setting indicates the reduction in the combined radios' overall channel utilization required to reset the dual-band radio to monitor role.

Step 4

Click **Apply** to save the configuration.

Enabling FRA (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	[no] ap fra Example: Device(config)# [no] ap fra	Enables or disables FRA on the AP.
Step 3	[no] ap fra 5-6ghz Example: Device(config)# ap fra 5-6ghz	Enables FRA 5-GHz or 6-GHz on APs that support XOR (5-GHz or 6-GHz). Use the no form of this command to disable this feature.
Step 4	[no] ap fra freeze Example: Device(config)# ap fra freeze	Enables FRA freeze. Use the no form of this command to disable this feature.
Step 5	[no] ap fra 5-6ghz freeze Example: Device(config)# ap fra 5-6ghz freeze	Enables FRA 5-GHz or 6-GHz freeze. Use the no form of this command to disable this feature.
Step 6	ap fra interval Example: Device(config)# ap fra interval 3	Configures the FRA interval, in hours. The range is from 1 to 24 hours. Note The FRA interval must be more than the configured RRM interval.
Step 7	ap fra 5-6ghz interval number-of-hours Example: Device(config)# ap fra 5-6ghz interval 4	Configures the FRA 5-GHz or 6-GHz interval, in hours. The valid range is from 1 to 24 hours.
Step 8	ap fra sensitivity {high medium low} Example: Device(config)# ap fra sensitivity high	Configures FRA sensitivity. <ul style="list-style-type: none"> • high: Sets the FRA Coverage Overlap Sensitivity to high. • medium: Sets the FRA Coverage Overlap Sensitivity to medium. • low: Sets the FRA Coverage Overlap Sensitivity to low.

Configuring Client FRA in RF Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 6ghz rf-profile rf-profile-name Example: Device(config)# ap dot11 6ghz rf-profile rf-profile-name	Configures the RF profile and enters RF profile configuration mode.
Step 3	client-aware-fra client-count-reset client-count Example: Device(config-rf-profile)# client-aware-fra client-count-reset 1	Configures the client count threshold for the radio to switch from 6-GHz to 5-GHz band. The valid range is from 1 to 10 clients.
Step 4	client-aware-fra client-reset-util util-percentage Example: Device(config-rf-profile)# client-aware-fra client-reset-util 5	Configures the utilization threshold for the radio to switch from 6-GHz to 5-GHz band. The valid range is from 0 to 100 percent.

Verifying FRA XOR 5-GHz and 6-GHz Details

To view the FRA 5-GHz and 6-GHz configuration details, run the following command:

```
Device# show ap fra 5-6ghz
```

To view the client utilization threshold and client reset count, run the following command:

```
Device# show ap rf-profile name default-rf-profile-6ghz detail
Description                : default rfprofile for 6GHz radio
RF Profile Name            : default-rf-profile-6ghz
Band                       : 6 GHz
Transmit Power Threshold v1 : -70 dBm
Min Transmit Power        : -10 dBm
Max Transmit Power        : 30 dBm
Operational Rates
 802.11 6GHZ 6M Rate       : Mandatory
 802.11 6GHZ 9M Rate       : Supported
 802.11 6GHZ 12M Rate      : Mandatory
 802.11 6GHZ 18M Rate      : Supported
 802.11 6GHZ 24M Rate      : Mandatory
 802.11 6GHZ 36M Rate      : Supported
 802.11 6GHZ 48M Rate      : Supported
 802.11 6GHZ 54M Rate      : Supported
```

```

Max Clients                : 200
.
.
.
PSC Channel List          : 5,21,37,53,69,85,101,117,133,149,165,181,197,213,229
DCA Bandwidth             : best
DCA Foreign AP Contribution : Enabled
State                     : Up
  Client utilization threshold : 5%
  Client Reset count         : 1
Client Network Preference : default
802.11ax
  OBSS PD                  : Disabled
  Non-SRG OBSS PD Maximum  : -62 dBm
  SRG OBSS PD              : Disabled
  SRG OBSS PD Minimum      : -82 dBm
  SRG OBSS PD Maximum      : -62 dBm
  Broadcast Probe Response : Disabled
  FILS Discovery           : Disabled
  Multi-BSSID Profile Name  : default-multi-bssid-profile
NDP mode                  : Auto
Guard Interval           : none
PSC Enforcement           : Disabled

```

Note The **client utilization threshold** is the utilization threshold for radios to switch from 6-GHz to 5-GHz band. The **client reset count** is the client count threshold for radios to switch from 6-GHz to 5-GHz band.

Flexible Radio Assignment (FRA) Action

Feature History for Flexible Radio Assignment Action

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 49: Feature History for FRA Action

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.10.1	Flexible Radio Assignment (FRA) Action	In Cisco IOS-XE 17.10.1 and earlier releases, the FRA moves the redundant dual-band radios to either 5-GHz client-serving role or monitor role.
Cisco IOS XE Dublin17.11.1	Flexible Radio Assignment (FRA) Action	From Cisco IOS-XE 17.11.1 onwards, you can select the redundant dual-band radios in a network to operate in monitor only mode.

Information About Flexible Radio Assignment Action

Flexible Radio Assignment (FRA) evaluates only 2.4-GHz radio coverage and determines whether there is overlapping coverage that is causing radio interference. If there is an overlapping coverage, the dual-band radio moves to either 5-GHz client serving or monitor role.

In Cisco IOS-XE 17.10.1 and earlier releases, the FRA moves the redundant dual-band radios to either 5-GHz client-serving role or monitor role.

From Cisco IOS-XE 17.11.1 onwards, you can select the redundant dual-band radios in a network to operate in monitor only mode.

Note The FRA action feature is disabled by default.

Configuring FRA Action in Default RF Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	ap dot11 24ghz fra action monitor Example: Device(config)# ap dot11 24ghz fra action monitor	Configures the FRA action as monitor, and moves all redundant dual-band radios to monitor role only.
Step 3	end Example: Device(config)# end	Exits configuration mode and returns to privileged EXEC mode.

Configuring FRA Action in 2.4-GHz RF Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	ap dot11 24ghz rf-profile rf-profile-tag Example:	Configures the RF profile name and enters RF profile configuration mode.

	Command or Action	Purpose
	Device(config)# ap dot11 24ghz rf-profile alpha-rfprofile-24ghz	
Step 3	fra action monitor Example: Device(config-rf-profile)# fra action monitor	Configures the FRA action as monitor, and moves all redundant dual-band radios to monitor role only.
Step 4	end Example: Device(config-rf-profile)# end	Exits configuration mode and returns to privileged EXEC mode.

Verifying FRA Action Configuration

To view the selected FRA action, use the following command:

```
Device# show ap fra
FRA State           : Enabled
FRA Freeze          : Disabled
FRA Operation State : Up
FRA Sensitivity     : higher (85%)
FRA Interval        : 1 Hour(s)
Service Priority    : Coverage
Client Aware FRA   : Enabled
  Client Select     : 25%
  Client Reset      : 5%
FRA Action          : 2.4GHz/Monitor
  Last Run         : 3069 seconds ago
```

To view the FRA action details in an AP RF profile, use the following command:

```
Device# show ap rf-profile name madhu-rf-profile-24 detail | sec FRA
Client Aware FRA      : Disabled
FRA Action            : 2.4GHz/Monitor
```

To view the radio mode and role in an AP, use the following command:

```
Device# show ap name AP7872.5DED.CB74 config slot 0 | sec Attribute
Attributes for Slot 0
Radio Type           : 802.11n - 2.4/5 GHz
Radio Mode           : Monitor
Radio Role           : Monitor
  Assignment Method  : Auto
  Monitor Mode Reason : Automatically Switched by FRA
```

CHAPTER 32

XOR Radio Support

- [Information About Dual-Band Radio Support](#) , on page 581
- [Configuring Default XOR Radio Support](#), on page 582
- [Configuring XOR Radio Support for the Specified Slot Number \(GUI\)](#), on page 584
- [Configuring XOR Radio Support for the Specified Slot Number](#), on page 585

Information About Dual-Band Radio Support

The Dual-Band (XOR) radio in Cisco 2800, 3800, 4800, and the 9120 series AP models offer the ability to serve 2.4-GHz or 5-GHz bands or passively monitor both the bands on the same AP. These APs can be configured to serve clients in 2.4-GHz and 5-GHz bands, or serially scan both 2.4-GHz and 5-GHz bands on the flexible radio while the main 5-GHz radio serves clients.

Cisco Catalyst Wireless 9166 AP (CW9166) now has XOR function for a dual 5-GHz 4x4 or 5-GHz 4x4 and 6-GHz 4x4 radios. These radios can also be configured as client serving, monitor or as a sniffer interface like the earlier XOR radios.

Note For all countries that do not support 6-GHz spectrum for use of Wi-Fi, when the Cisco Catalyst Wireless 9166I AP operates as dual 5-GHz, the 5-GHz channels will be locked on both the radios even if slot 2 is disabled or set up for monitoring.

Cisco APs models up and through the Cisco 9120 APs are designed to support dual 5-GHz band operations with the *i* model supporting a dedicated Macro/Micro architecture and the *e* and *p* models supporting Macro/Macro. The Cisco 9130AXI APs and the Cisco 9136 APs support dual 5-GHz operations as Micro/Messo cell, and the CW9166I supports as Macro/Macro.

When a radio moves between bands (from 2.4-GHz to 5-GHz and vice versa), clients need to be steered to get an optimal distribution across radios. When an AP has two radios in the 5-GHz band, client steering algorithms contained in the Flexible Radio Assignment (FRA) algorithm are used to steer a client between the same band co-resident radios.

The XOR radio support can be steered manually or automatically:

- Manual steering of a band on a radio—The band on the XOR radio can only be changed manually.
- Automatic client and band steering on the radios is managed by the FRA feature that monitors and changes the band configurations as per site requirements.

Note RF measurement will not run when a static channel is configured on slot 1. Due to this, the dual band radio slot 0 will move only with 5-GHz radio and not to the monitor mode.

When slot 1 radio is disabled, RF measurement will not run, and the dual band radio slot 0 will be only on 2.4-GHz radio.

Note Only one of the 5-GHz radios can operate in the UNII band (100 - 144), due to an AP limitation to keep the power budget within the regulatory limit.

Configuring Default XOR Radio Support

Before you begin

Note The default radio points to the XOR radio hosted on slot 0.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap name <i>ap-name</i> dot11 dual-band antenna ext-ant-gain <i>antenna_gain_value</i> Example: Device# ap name <i>ap-name</i> dot11 dual-band antenna ext-ant-gain 2	Configures the 802.11 dual-band antenna on a specific Cisco access point. <i>antenna_gain_value</i> : The valid range is from 0 to 40.
Step 3	ap name <i>ap-name</i> [no] dot11 dual-band shutdown Example: Device# ap name <i>ap-name</i> dot11 dual-band shutdown	Shuts down the default dual-band radio on a specific Cisco access point. Use the no form of the command to enable the radio.
Step 4	ap name <i>ap-name</i> dot11 dual-band role manual client-serving Example: Device# ap name <i>ap-name</i> dot11 dual-band role manual client-serving	Switches to client-serving mode on the Cisco access point.

	Command or Action	Purpose
Step 5	<p>ap name <i>ap-name</i> dot11 dual-band band 24ghz</p> <p>Example:</p> <pre>Device# ap name ap-name dot11 dual-band band 24ghz</pre>	Switches to 2.4-GHz radio band.
Step 6	<p>ap name <i>ap-name</i> dot11 dual-band txpower {<i>transmit_power_level</i> auto}</p> <p>Example:</p> <pre>Device# ap name ap-name dot11 dual-band txpower 2</pre>	<p>Configures the transmit power for the radio on a specific Cisco access point.</p> <p>Note When an FRA-capable radio (slot 0 on 9120 AP[for instance]) is set to Auto, you cannot configure static channel and Txpower on this radio.</p> <p>If you want to configure static channel and Txpower on this radio, you will need to change the radio role to Manual Client-Serving mode.</p> <p>This note is not applicable for Cisco Catalyst Wireless 9166 AP (CW9166).</p>
Step 7	<p>ap name <i>ap-name</i> dot11 dual-band channel <i>channel-number</i></p> <p>Example:</p> <pre>Device# ap name ap-name dot11 dual-band channel 2</pre>	<p>Enters the channel for the dual band.</p> <p><i>channel-number</i>—The valid range is from 1 to 173.</p>
Step 8	<p>ap name <i>ap-name</i> dot11 dual-band channel auto</p> <p>Example:</p> <pre>Device# ap name ap-name dot11 dual-band channel auto</pre>	Enables the auto channel assignment for the dual-band.
Step 9	<p>ap name <i>ap-name</i> dot11 dual-band channel width {20 MHz 40 MHz 80 MHz 160 MHz}</p> <p>Example:</p> <pre>Device# ap name ap-name dot11 dual-band channel width 20 MHz</pre>	Chooses the channel width for the dual band.
Step 10	<p>ap name <i>ap-name</i> dot11 dual-band cleanair</p> <p>Example:</p> <pre>Device# ap name ap-name dot11 dual-band cleanair</pre>	Enables the Cisco CleanAir feature on the dual-band radio.

	Command or Action	Purpose
Step 11	ap name <i>ap-name</i> dot11 dual-band cleanair band {24 GHz 5 GHz} Example: <pre>Device# ap name <i>ap-name</i> dot11 dual-band cleanair band 5 GHz Device# ap name <i>ap-name</i> [no] dot11 dual-band cleanair band 5 GHz</pre>	Selects a band for the Cisco CleanAir feature. Use the no form of this command to disable the Cisco CleanAir feature.
Step 12	ap name <i>ap-name</i> dot11 dual-band dot11n antenna {A B C D} Example: <pre>Device# ap name <i>ap-name</i> dot11 dual-band dot11n antenna A</pre>	Configures the 802.11n dual-band parameters for a specific access point.
Step 13	show ap name <i>ap-name</i> auto-rf dot11 dual-band Example: <pre>Device# show ap name <i>ap-name</i> auto-rf dot11 dual-band</pre>	Displays the auto-RF information for the Cisco access point.
Step 14	show ap name <i>ap-name</i> wlan dot11 dual-band Example: <pre>Device# show ap name <i>ap-name</i> wlan dot11 dual-band</pre>	Displays the list of BSSIDs for the Cisco access point.

Configuring XOR Radio Support for the Specified Slot Number (GUI)

Procedure

-
- Step 1** Click **Configuration > Wireless > Access Points**.
- Step 2** In the **Dual-Band Radios** section, select the AP for which you want to configure dual-band radios.
The AP name, MAC address, CleanAir capability and slot information for the AP are displayed. If the Hyperlocation method is HALO, the antenna PID and antenna design information are also displayed.
- Step 3** Click **Configure**.
- Step 4** In the **General** tab, set the **Admin Status** as required.
- Step 5** Set the **CleanAir Admin Status** field to Enable or Disable.
- Step 6** Click **Update & Apply to Device**.
-

Configuring XOR Radio Support for the Specified Slot Number

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap name <i>ap-name</i> dot11 dual-band slot 0 antenna ext-ant-gain <i>external_antenna_gain_value</i> Example: Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 antenna ext-ant-gain 2	Configures dual-band antenna for the XOR radio hosted on slot 0 for a specific access point. <i>external_antenna_gain_value</i> - Is the external antenna gain value in multiples of .5 dBi unit. The valid range is from 0 to 40. Note <ul style="list-style-type: none"> For APs supporting self-identifying antennas (SIA), the gain depends on the antenna, and not on the AP model. The gain is learned by the AP and there is no need for controller configuration. For APs that do not support SIA, the APs send the antenna gain in the configuration payload, where the default antenna gain depends on the AP model.
Step 3	ap name <i>ap-name</i> dot11 dual-band slot 0 band {24ghz 5ghz} Example: Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 band 24ghz	Configures current band for the XOR radio hosted on slot 0 for a specific access point.
Step 4	ap name <i>ap-name</i> dot11 dual-band slot 0 channel {<i>channel_number</i> auto width [160 20 40 80]} Example: Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 channel 3	Configures dual-band channel for the XOR radio hosted on slot 0 for a specific access point. <i>channel_number</i> - The valid range is from 1 to 165.
Step 5	ap name <i>ap-name</i> dot11 dual-band slot 0 cleanair band {24Ghz 5Ghz} Example:	Enables CleanAir features for dual-band radios hosted on slot 0 for a specific access point.

	Command or Action	Purpose
	Device# <code>ap name AP-SIDD-A06 dot11 dual-band slot 0 cleanair band 24Ghz</code>	
Step 6	<p>ap name <i>ap-name</i> dot11 dual-band slot 0 dot11n antenna {A B C D}</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 dot11n antenna A</pre>	<p>Configures 802.11n dual-band parameters hosted on slot 0 for a specific access point.</p> <p>Here,</p> <p>A- Enables antenna port A.</p> <p>B- Enables antenna port B.</p> <p>C- Enables antenna port C.</p> <p>D- Enables antenna port D.</p>
Step 7	<p>ap name <i>ap-name</i> dot11 dual-band slot 0 role {auto manual [client-serving monitor]}</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 role auto</pre>	<p>Configures dual-band role for the XOR radio hosted on slot 0 for a specific access point.</p> <p>The following are the dual-band roles:</p> <ul style="list-style-type: none"> • auto- Refers to the automatic radio role selection. • manual- Refers to the manual radio role selection.
Step 8	<p>ap name <i>ap-name</i> dot11 dual-band slot 0 shutdown</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 shutdown</pre> <pre>Device# ap name AP-SIDD-A06 [no] dot11 dual-band slot 0 shutdown</pre>	<p>Disables dual-band radio hosted on slot 0 for a specific access point.</p> <p>Use the no form of this command to enable the dual-band radio.</p>
Step 9	<p>ap name <i>ap-name</i> dot11 dual-band slot 0 txpower {tx_power_level auto}</p> <p>Example:</p> <pre>Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 txpower 2</pre>	<p>Configures dual-band transmit power for XOR radio hosted on slot 0 for a specific access point.</p> <ul style="list-style-type: none"> • <i>tx_power_level</i>- Is the transmit power level in dBm. The valid range is from 1 to 8. • auto- Enables auto-RF.

CHAPTER 33

Cisco Receiver Start of Packet

- [Information About Receiver Start of Packet Detection Threshold](#), on page 587
- [Restrictions for Rx SOP](#), on page 587
- [Configuring Rx SOP \(CLI\)](#), on page 588
- [Customizing RF Profile \(CLI\)](#), on page 588

Information About Receiver Start of Packet Detection Threshold

The Receiver Start of Packet (Rx SOP) Detection Threshold feature determines the Wi-Fi signal level in dBm at which an access point's radio demodulates and decodes a packet. As the Wi-Fi level increases, the radio sensitivity decreases and the receiver cell size becomes smaller. Reduction of the cell size affects the distribution of clients in the network.

Rx SOP is used to address clients with weak RF links, sticky clients, and client load balancing across access points. Rx SOP helps to optimize the network performance in high-density deployments, such as stadiums and auditoriums where access points need to optimize the nearest and strongest clients.

Restrictions for Rx SOP

- Rx SOP configuration is not applicable to the third radio module pluggable on Cisco Aironet 3600 Series APs.
- Rx SOP configurations are supported only in Local, FlexConnect, Bridge, and Flex+Bridge modes.
- Rx SOP configurations are not supported in the FlexConnect+PPPoE, FlexConnect+PPPoE-wIPS, and FlexConnect+OEAP submodes.

The following table shows the permitted range for the Rx SOP threshold.

Table 50: Rx SOP Threshold

Radio Band	Threshold High	Threshold Medium	Threshold Low
2.4 GHz	-79 dBm	-82 dBm	-85 dBm
5 GHz	-76 dBm	-78 dBm	-80 dBm

Configuring Rx SOP (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz} rx-sop threshold {auto custom high low medium} Example: Device(config)# <code>ap dot11 5ghz rx-sop threshold high</code>	Configures the 802.11bg/802.11a radio Rx SOP threshold.
Step 3	<code>end</code>	Returns to privileged EXEC mode.
Step 4	show ap dot11 {24ghz 5ghz} high-density Example: Device# <code>show ap dot11 5ghz high-density</code>	Displays the 802.11bg/802.11a high-density parameters.
Step 5	show ap summary Example: Device# <code>show ap summary</code>	Displays a summary of all the connected Cisco APs.

Customizing RF Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	high-density rx-sop threshold {auto custom high low medium} Example: Device(config-rf-profile)# <code>high-density rx-sop threshold high</code>	Configures the 802.11bg, 802.11a or 802.11 6-GHz high-density parameters.

	Command or Action	Purpose
Step 3	show ap summary Example: Device# show ap summary	Displays a summary of all the connected Cisco APs.
Step 4	end	Returns to privileged EXEC mode. Note <ul style="list-style-type: none"> • Irrespective of radio mode, the controller configures the radio with configured RX-SOP value. The AP determines whether to use the configured RX-SOP value. • For the XOR radio (Slot 0), when the AP is in monitor mode the RX-SOP value that gets pushed to AP depends on the band it was operating before moving to monitor mode (basically if radio operating band is 24g then RX-SOP params picked from 24GHz RF profile (or default rf-profile). If it was in 5g then RX-SOP params picked from 5GHz RF profile (or default rf-profile) configured for the AP).

CHAPTER 34

Client Limit

- [Information About Client Limit](#), on page 591
- [Configuring Client Limit Per WLAN \(GUI\)](#), on page 591
- [Configuring Client Limit Per WLAN \(CLI\)](#), on page 592
- [Configuring Client Limit Per AP \(GUI\)](#), on page 593
- [Configuring Client Limit Per AP \(CLI\)](#), on page 593
- [Configuring Client Limit Per Radio \(GUI\)](#), on page 594
- [Configuring Client Limit Per Radio \(CLI\)](#), on page 594
- [Verifying Client Limit](#), on page 595

Information About Client Limit

This feature enforces a limit on the number of clients that can be associated with an AP. Further, you can configure the number of clients that can be associated with each AP radio.

From Cisco IOS XE Cupertino 17.8.x onwards, client limiting is supported per AP, per radio, and per radio per WLAN.

Limitations for Client Limit

- APs other than the Cisco Catalyst 9136 Series APs, support only 200 clients per radio. If you configure more than 200 clients for these APs, the number of clients that can be associated with the AP radios will still be limited to only 200 clients, as per the AP capability value.
- Client limiting is supported on the Cisco Catalyst 9136 Series APs in Flex mode.

Configuring Client Limit Per WLAN (GUI)

Procedure

- Step 1** Choose **Configuration** > **Tags & Profiles** > **WLANs**.
- Step 2** Click a WLAN from the list of WLANs.

- Step 3** Click the **Advanced** tab.
- Step 4** Under the **Max Client Connections** settings, enter the client limit for **Per WLAN**, **Per AP Per WLAN**, and **Per AP Radio Per WLAN**.
- Step 5** Click **Update & Apply to Device**.

Configuring Client Limit Per WLAN (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	wlan wlan-name Example: Device(config)# wlan ramban	Specifies the WLAN name.
Step 4	client association limit <i>maximum-clients-per-WLAN</i> Example: Device(config-wlan)# client association limit 110	Configures the maximum number of clients that can be associated to the given WLAN.
Step 5	client association limit ap <i>max-clients-per-AP-per-WLAN</i> Example: Device(config-wlan)# client association limit ap 120	Configures the maximum number of clients that can be associated to an AP in the WLAN. The valid range is between 0 and 1200 clients. The default value is 0. Note A Cisco Catalyst 9136 Series AP can support a maximum of 1200 clients.
Step 6	client association limit radio <i>maximum-clients-per-AP-radio-per-WLAN(0–400)</i> Example: Device(config-wlan)# client association limit radio 100	Configures the maximum limit of clients that can be associated to an AP radio in the WLAN. The valid range is between 0 to 400 clients. The default value is 200. Note A Cisco Catalyst 9136 Series AP radio can support a maximum of 400 clients.

	Command or Action	Purpose
Step 7	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 8	show wlan id wlan-id Example: Device# show wlan id 2	Displays the current configuration of the WLAN and the corresponding client association limits.

Configuring Client Limit Per AP (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
 - Step 2** Click **Add**.
 - Step 3** In the **General** tab, enter the name and description of the corresponding AP join profile.
 - Step 4** Click the **Client** tab.
 - Step 5** In the **Maximum Client Limit** field, enter the maximum client associations per AP. The valid values are between 0 and 1200. The default value is 0.
 - Step 6** Click **Apply to Device**.
-

Configuring Client Limit Per AP (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile ap-profile-name Example: Device(config)# ap profile ap-profile-name	Configures an AP profile and enters AP profile configuration mode.
Step 3	association-limit max-client-connections Example:	Configures the maximum client connections per AP. The default value is 0.

	Command or Action	Purpose
	Device (config-ap-profile) # association-limit 200	Note A Cisco Catalyst 9136 Series AP can support a maximum of 1200 clients.
Step 4	end Example: Device (config) # end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Client Limit Per Radio (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > RF/Radio**.
 - Step 2** In the **RF** tab, click the required RF profile name from the displayed list of RF profiles.
The **Edit RF Profile** page is displayed.
 - Step 3** Click the **Advanced** tab.
 - Step 4** Under the **High Density Parameters** section, in the **Max Clients** field, enter the maximum number of client connections per AP radio. The valid range is between 0 and 400. The default value is 200 client connections.
 - Step 5** Click **Update & Apply to Device**.
-

Configuring Client Limit Per Radio (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} rf-profile <i>rf-profile-name</i> Example: Device (config) # ap dot11 6ghz rf-profile <i>rf-profile-name</i>	Configures an RF profile and enters RF profile configuration mode.
Step 3	high-density clients count <i>maximum-client-connections <0-400></i>	Configures the maximum number of client connections per AP radio. The valid range is

	Command or Action	Purpose
	Example: Device(config-rf-profile)# high-density clients count 200	between 0 and 400. The default value is 200 client connections. Note A Cisco Catalyst 9136 Series AP radio can support a maximum of 400 clients.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Verifying Client Limit

To verify client limit in local mode, run the following command:

```
Device# show wireless stats client delete reasons | sec Max
Maximum client limit reached on AP           : 0
Maximum client limit reached on AP per wlan  : 0
Maximum client limit reached on AP radio per wlan : 0
Maximum client limit reached on AP radio     : 0
```

To verify client limit in the FlexConnect central authentication mode, run the following command:

```
Device# show wireless stats client delete reasons | sec max
AP limiting maximum client per AP           : 0
AP limiting maximum client per AP radio per wlan : 0
AP limiting maximum client per AP radio     : 0
```

CHAPTER 35

IP Theft

- [Introduction to IP Theft, on page 597](#)
- [Configuring IP Theft \(GUI\), on page 598](#)
- [Configuring IP Theft, on page 598](#)
- [Configuring the IP Theft Exclusion Timer, on page 598](#)
- [Adding Static Entries for Wired Hosts, on page 599](#)
- [Verifying IP Theft Configuration, on page 600](#)

Introduction to IP Theft

The IP Theft feature prevents the usage of an IP address that is already assigned to another device. If the controller finds that two wireless clients are using the same IP address, it declares the client with lesser precedence binding as the IP thief and allows the other client to continue. If blocked list is enabled, the client is put on the exclusion list and thrown out.

The IP Theft feature is enabled by default on the controller. The preference level of the clients (new and existing clients in the database) are also used to report IP theft. The preference level is a learning type or source of learning, such as Dynamic Host Configuration Protocol (DHCP), Address Resolution Protocol (ARP), data glean (looking at the IP data packet that shows what IP address the client is using), and so on. The wired clients always get a higher preference level. If a wireless client tries to steal the wired IP, that client is declared as a thief.

The order of preference for IPv4 clients are:

1. DHCPv4
2. ARP
3. Data packets

The order of preference for IPv6 clients are:

1. DHCPv6
2. NDP
3. Data packets

Note The static wired clients have a higher preference over DHCP.

Configuring IP Theft (GUI)

Procedure

-
- Step 1** Choose **Configuration > Security > Wireless Protection Policies > Client Exclusion Policies**.
 - Step 2** Check the **IP Theft** or **IP Reuse** check box.
 - Step 3** Click **Apply**.
-

Configuring IP Theft

Follow the procedure given below to configure the IP Theft feature:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless wps client-exclusion ip-theft Example: Device(config)# wireless wps client-exclusion ip-theft	Configures the client exclusion policy.

Configuring the IP Theft Exclusion Timer

Follow the procedure given below to configure the IP theft exclusion timer:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy default-policy-profile	Configures a WLAN policy profile and enters wireless policy configuration mode.
Step 3	exclusionlist timeout <i>time-in-seconds</i> Example: Device(config-wireless-policy)# exclusionlist timeout 5	Specifies the timeout, in seconds. The valid range is from 0-2147483647. Enter zero (0) for no timeout.

Adding Static Entries for Wired Hosts

Follow the procedure given below to create static wired bindings:

Note The statically configured wired bindings and locally configured SVI IP addresses have a higher precedence than DHCP.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	Use the first option to configure an IPv4 static entry or the second option to create an IPv6 static entry. <ul style="list-style-type: none"> • device-tracking binding <i>vlan vlan-id</i> <i>ipv4-address interface</i> gigabitEthernet<i>ge-intf-num</i> <i>hardware-or-mac-address</i> • device-tracking binding <i>vlan vlan-id</i> <i>ipv6-address interface</i> gigabitEthernet<i>ge-intf-num</i> <i>hardware-or-mac-address</i> Example: Device(config)# device-tracking binding vlan 20 20.20.20.5 interface gigabitEthernet 1 0000.1111.2222 Example:	Configures IPv4 or IPv6 static entry.

	Command or Action	Purpose
	Device(config)# device-tracking binding vlan 20 2200:20:20::6 interface gigabitEthernet 1 0000.444.3333	

Verifying IP Theft Configuration

Use the following command to check if the IP Theft feature is enabled or not:

```
Device# show wireless wps summary
```

```
Client Exclusion Policy
  Excessive 802.11-association failures : Enabled
  Excessive 802.11-authentication failures: Enabled
  Excessive 802.1x-authentication      : Enabled
  IP-theft                             : Enabled
  Excessive Web authentication failure : Enabled
  Cids Shun failure                    : Enabled
  Misconfiguration failure             : Enabled
  Failed Qos Policy                    : Enabled
  Failed Epm                           : Enabled
```

Use the following commands to view additional details about the IP Theft feature:

```
Device# show wireless client summary
```

```
Number of Local Clients: 1
```

MAC Address	AP Name	WLAN State	Protocol	Method	Role
000b.bbb1.0001	SimAP-1	2 Run	11a	None	Local

```
Number of Excluded Clients: 1
```

MAC Address	AP Name	WLAN State	Protocol	Method
10da.4320.cce9	charlie2	2 Excluded	11ac	None

```
Device# show wireless device-tracking database ip
```

IP	VLAN	STATE	DISCOVERY	MAC
20.20.20.2	20	Reachable	Local	001e.14cc.cbff
20.20.20.6	20	Reachable	IPv4 DHCP	000b.bbb1.0001

```
Device# show wireless exclusionlist
```

```
Excluded Clients
```

MAC Address	Description	Exclusion Reason	Time Remaining
10da.4320.cce9		IP address theft	59

Note Client exclusion timer deletes the entry from exclusion list with a granularity of 10 seconds. The entry is checked to retain or delete after every 10 seconds. There are chances that the running timer value for excluded clients might display negative values upto 10 seconds.

Note When client exclusion is enabled, it adds the client to the exclusion list. It does not block the client from getting deleted.

```
Device# show wireless exclusionlist client mac 12da.4820.cce9 detail
```

```
Client State : Excluded
Client MAC Address : 12da.4820.cce9
Client IPv4 Address: 20.20.20.6
Client IPv6 Address: N/A
Client Username: N/A
Exclusion Reason : IP address theft
Authentication Method : None
Protocol: 802.11ac
AP MAC Address : 58ac.780e.08f0
AP Name: charlie2
AP slot : 1
Wireless LAN Id : 2
Wireless LAN Name: mhe-ewlc
VLAN Id : 20
```

CHAPTER 36

Unscheduled Automatic Power Save Delivery

- [Information About Unscheduled Automatic Power Save Delivery, on page 603](#)
- [Viewing Unscheduled Automatic Power Save Delivery \(CLI\), on page 603](#)

Information About Unscheduled Automatic Power Save Delivery

Unscheduled automatic power save delivery (U-APSD) is a QoS facility that is defined in IEEE 802.11e that extends the battery life of mobile clients. In addition to extending the battery life, this feature reduces the latency of traffic flow that is delivered over the wireless media. Because U-APSD does not require the client to poll each individual packet that is buffered at the access point, it allows delivery of multiple downlink packets by sending a single uplink trigger packet.

U-APSD is enabled automatically when WMM is enabled.

Viewing Unscheduled Automatic Power Save Delivery (CLI)

Procedure

```
show wireless client mac-address client_mac detail
```

Example:

```
Device# show wireless client mac-address 2B:5B:B3:18:56:E9 detail
Output Policy State : Unknown
Output Policy Source : Unknown
WMM Support : Enabled
U-APSD Support : Enabled
  U-APSD value : 15
  APSD ACs      : BK(T/D), BE, VI(T/D), VO(T/D)
Power Save : OFF
Current Rate :

-----
BK : Background
BE : Best Effort
VI : Video
VO : Voice.

T: UAPSD Trigger Enabled
```

```
D: UAPSD Delivery Enabled  
T/D : UAPSD Trigger and Delivery Enabled
```

Show detailed information of a client by MAC address.

CHAPTER 37

Target Wake Time

- [Target Wake Time, on page 605](#)
- [Configuring Target Wake Time at the Radio Level \(CLI\), on page 606](#)
- [Configuring Target Wake Time on WLAN, on page 607](#)
- [Configuring Target Wake Time \(GUI\), on page 609](#)
- [Verifying Target Wakeup Time, on page 609](#)

Target Wake Time

The existing Wi-Fi client power-saving mechanisms have been in use since 802.11b, where the client devices sleep between AP beacons or multiple beacons, waking up only when they have data to transmit (they can transmit at any time, as AP does not sleep), and beacons containing the Delivery Traffic Indication Map (DTIM), a bit-map, indicates that the AP has downlink traffic buffered for transmission to particular clients.

If a client has a DTIM bit set, it can retrieve data from the AP by sending a Power-Save Poll (PS-Poll) frame to the AP. This power-save scheme is effective but only allows clients to doze for a small beacon interval. Clients still need to wake up several times per second to read DTIM from the beacon frame of the AP.

With 802.11e, the new power-saving mechanism was introduced that helps voice-capable Wi-Fi devices, as voice packets are transmitted at short time intervals, typically 20 ms/sec. Unscheduled automatic power-save delivery (U-APSD) allows a power-save client to sleep at intervals within a beacon period. AP buffers the downlink traffic until the client wakes up and requests its delivery.

Note By default Target Wake Time (TWT) is disabled on the controller. To enable TWT, run the **ap dot11 {24ghz | 5ghz| 6ghz} dot11ax twt-broadcast** command.

Extended Power-Savings Using Target Wake Time

Target wake time (TWT) allows an AP to manage activity in the Wi-Fi network, in order to minimize medium contention between Stations (STAs), and to reduce the required amount of time that an STA in the power-save mode needs to be awake. This is achieved by allocating STAs to operate at non-overlapping times, and/or frequencies, and concentrate the frame exchanges in predefined service periods.

TWT capable STA can either negotiate an individual TWT agreement with TWT-scheduling AP, or it can elect to be part or member of Broadcast TWT agreement existing on the AP. An STA does not need to be

aware that a TWT service period (SP) can be used to exchange frames with other STAs. Frames transmitted during a TWT SP can be carried in any PPDU format supported by the pair of STAs that have established the TWT agreement corresponding to that TWT SP, including High Efficiency Multi-User Physical Protocol Data Unit (HE MU PPDU), High Efficiency Trigger-Based Physical Protocol Data Unit (HE TB PPDU), and so on.

Following are the TWT Agreement Types:

Individual TWT

Single TWT session is negotiated between AP and an STA. This ensures a specific service period of DL and UL between AP and STA with expected traffic to be limited within the negotiated SP of 99% accuracy. The service period starts at specific offset from the target beacon transmission time (TBTT) and runs for the SP duration and repeats every SP interval.

TWT Requesting STA communicates the Wake Scheduling information to its TWT responding AP, which then devises a schedule and delivers the TWT values to the TWT requesting STA when a TWT agreement has been established between them.

Solicited TWT

STA initiates the TWT session with the AP.

Unsolicited TWT

AP initiates TWT setup with STA. AP sends TWT response with service period which is accepted by STA.

Broadcast TWT

High-Efficiency AP requests the STA to participate in the broadcast TWT operation, either on-going broadcast SP or new SP.

Configuring Target Wake Time at the Radio Level (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} shutdown Example: Device(config)# <code>ap dot11 24ghz shutdown</code>	Disables the 802.11a, 802.11b, or 802.11 6-GHz network.
Step 3	ap dot11 {24ghz 5ghz 6ghz} dot11ax Example: Device(conf)# <code>ap dot11 24ghz dot11ax</code>	Configures the 802.11ax parameters. 802.11ax cannot be disabled on the 6-GHz band.
Step 4	[no] ap dot11 {24ghz 5ghz 6ghz} dot11ax target-wakeup-time Example:	Configures 802.11 6-GHz dot11ax target wake-up time.

	Command or Action	Purpose
	<code>Device(config)#ap dot11 24ghz dot11ax target-wakeup-time</code>	
Step 5	<p>[no] ap dot11 {24ghz 5ghz 6ghz} dot11ax twt-broadcast</p> <p>Example:</p> <pre>Device(config)#ap dot11 24ghz dot11ax twt-broadcast</pre>	<p>Configures 802.11 6-GHz dot11ax target wake-up time broadcast.</p> <p>Note By default TWT is disabled on the controller. You can enable TWT by running this command.</p>
Step 6	<p>no ap dot11 {24ghz 5ghz 6ghz} shutdown</p> <p>Example:</p> <pre>Device(config)#no ap dot11 24ghz shutdown</pre>	<p>Enables the 802.11a or 802.11b network.</p> <p>Enables the 802.11a, 802.11b, or 802.11 6-GHz network.</p>
Step 7	<p>show ap dot11 {24ghz 5ghz 6ghz} network</p> <p>Example:</p> <pre>Device(config)#show ap dot11 24ghz network</pre>	<p>Displays the 802.11ax network configuration details, which includes information about Target Wakeup Time and Target Wakeup Broadcast.</p>

Configuring Target Wake Time on WLAN

Enabling Target Wake Time on WLAN (CLI)

Procedure

	Command or Action	Purpose
Step 1	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	<p>Enters global configuration mode.</p>
Step 2	<p>wlan wlan-profile</p> <p>Example:</p> <pre>Device(config)# wlan wlan-profile</pre>	<p>Enters WLAN configuration submenu. The <i>wlan-profile</i> is the profile name of the configured WLAN.</p>
Step 3	<p>shutdown</p> <p>Example:</p> <pre>Device(conf-wlan)#shutdown</pre>	<p>Disables the WLAN network</p>
Step 4	<p>dot11ax target-waketime</p> <p>Example:</p> <pre>Device(conf-wlan)#dot11ax target-waketime</pre>	<p>Configures target wake time mode on WLAN.</p>

	Command or Action	Purpose
Step 5	dot11ax twt-broadcast-support Example: Device(conf-wlan)#dot11ax twb-broadcast-support	Configures the TWT broadcast support on WLAN.
Step 6	no shutdown Example: Device(conf-wlan)#no shutdown	Enables WLAN.
Step 7	show wlan {all id name summary} Example: Device# show wlan all Device# show wlan id Device# show wlan name	Displays the details of the configured WLAN, including Target Wakeup Time and Target Wakeup Time Broadcast.

Disabling Target Wakeup Time on WLAN (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan <i>profile-name</i> Example: Device(config)# wlan <i>wlan-profile</i>	Enters WLAN configuration submode. The <i>wlan-profile</i> is the profile name of the configured WLAN.
Step 3	shutdown Example: Device(conf-wlan)#shutdown	Disables the WLAN network
Step 4	no dot11ax target-waketime Example: Device(conf-wlan)#no dot11ax target-waketime	Disables the target wake time mode on WLAN.
Step 5	no dot11ax twt-broadcast-support Example: Device(conf-wlan)#no dot11ax twb-broadcast-support	Disables the TWT broadcast support on WLAN.

	Command or Action	Purpose
Step 6	no shutdown Example: Device(conf-wlan)#no shutdown	Enables WLAN.

Configuring Target Wake Time (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > Parameters**.
- The parameters page is displayed where you can configure global parameters for 5 GHz Band and 2.4 GHz Band radios.
- Step 2** In the **11ax Parameters** section, check the **Target Wakeup Time** check box and the **Target Wakeup Time Broadcast** check box to configure target wakeup time and broadcast target wakeup time.
-

Verifying Target Wakeup Time

To verify Target Wakeup Time and Target Wakeup Time Broadcast, use the following command:

show ap dot11 24ghz network

The following is a sample output:

```
Device#show ap dot11 24ghz network
.
.
.
802.11ax                : Enabled
Target Wakeup Time     : Enabled
Target Wakeup Time Broadcast : Enabled
.
.
.
```

CHAPTER 38

Enabling USB Port on Access Points

- [USB Port as Power Source for Access Points](#), on page 611
- [Configuring an AP Profile \(CLI\)](#), on page 612
- [Configuring USB Settings for an Access Point \(CLI\)](#), on page 613
- [Configuring USB Settings for an Access Point \(GUI\)](#), on page 613
- [Monitoring USB Configurations for Access Points \(CLI\)](#), on page 614

USB Port as Power Source for Access Points

Some Cisco APs have a USB port that can act as a source of power for some USB devices. The power can be up to 2.5W; if a USB device draws more than 2.5W of power, the USB port shuts down automatically. The port is enabled when the power draw is 2.5W and lower. Refer to the datasheet of your AP to check if the AP has a USB port that can act as a source of power.

Note Both IW6300 and ESW6300 APs have a USB port that can act as a source of power up to 4.5W for some USB devices.

Note The controller records the last five power-overdrawn incidents in its logs.

Caution When unsupported USB device is connected to the Cisco AP, the following message is displayed:

The inserted USB module is not a supported device. The behavior of this USB device and the impact to the Access Point is not guaranteed. If Cisco determines that a fault or defect can be isolated due to the use of third-party USB modules installed by a customer or reseller, Cisco may withhold support under warranty or support program under contract. In the course of providing support for Cisco networking products, the end user may be required to install Cisco-supported USB modules in the event Cisco determines that removing third-party parts will assist Cisco in diagnosing root cause for troubleshooting purposes. Cisco also reserves the right to charge the customer per then-current time and material rates for services provided to the customer when Cisco determines, after having provided such services, that an unsupported device caused the root cause of the defective product

Configuring an AP Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# <code>ap profile xyz-ap-profile</code>	Configures an AP profile and enters the AP profile configuration mode. Note When you delete a named profile, the APs associated with that profile will not revert to the default profile.
Step 3	usb-enable Example: Device(config-ap-profile)# <code>usb-enable</code>	Enables USB for each AP profile. Note By default, the USB port on the AP is disabled. Use the no usb-enable command to disable USB for each AP profile.
Step 4	end Example: Device(config-ap-profile)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring USB Settings for an Access Point (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap name <i>ap-name</i> usb-module Example: Device# ap name AP44d3.xy45.69a1 usb-module	Enables the USB port on the AP. Use the ap name <i>ap-name</i> no usb-module command to disable the USB port on the AP. Note If you are using Cisco Catalyst 9105AXW AP and if you enable the USB port (.3at PoE-in), it is not possible to enable the USB PoE-out at the same time.
Step 3	ap name <i>ap-name</i> usb-module override Example: Device# ap name AP44d3.xy45.69a1 usb-module override	Overrides USB status of the AP profile and considers the local AP configuration. Use the ap name <i>ap-name</i> no usb-module override command to override USB status of the AP and consider the AP profile configuration. Note You can configure the USB status for an AP only if you enable USB override for it.

Configuring USB Settings for an Access Point (GUI)

Procedure

- Step 1** Choose **Configuration > Wireless > Access Points**.
- Step 2** In the **Access Points** window, click the name of the AP.
- Step 3** In the **Edit AP** window, click the **Interfaces** tab.
- Step 4** In the **USB Settings** section, configure the **USB Module State** as either of the following:
- **ENABLED:** Enables the USB port on the AP
 - **DISABLED:** Disables the USB port on the AP

Note If you are using Cisco Catalyst 9105AXW AP and if you enable the USB port (.3at PoE-in), it is not possible to enable the USB PoE-out at the same time.

Step 5 Configure **USB Override** as either of the following:

- **ENABLED**: Overrides USB status of the AP profile and considers the local AP configuration
- **DISABLED**: Overrides USB status of the AP and considers the AP profile configuration

Note You can configure the USB status for an AP only if you enable USB override for it.

Step 6 Click **Apply & Update to Device**.

Monitoring USB Configurations for Access Points (CLI)

- To view the inventory details of APs, use the following command:

show ap name *ap-name* inventory

The following is a sample output:

```
Device# show ap name AP500F.8059.1620 inventory
NAME: AP2800 , DESCR: Cisco Aironet 2800 Series (IEEE 802.11ac) Access Point
PID: AIR-AP2802I-D-K9 , VID: 01, SN: XXX1111Y2ZZZZ2800
NAME: SanDisk , DESCR: Cruzer Blade
PID: SanDisk , SN: XXXX1110010, MaxPower: 224
```

- To view the summary of an AP module, use the following command:

show ap module summary

The following is a sample output:

```
Device# show ap module summary
AP Name           External Module   External Module PID   External Module
Description
-----
AP500F.1111.2222   Enable           SanDisk                Cruzer Blade
```

- To view the USB configuration details for each AP, use the following command:

show ap name *ap-name* config general

The following is a sample output:

```
Device# show ap name AP500F.111.2222 config general
.
.
.
USB Module Type..... USB Module
USB Module Status..... Disabled
USB Module Operational State..... Enabled
USB Override ..... Enabled
```

- To view status of the USB module, use the following command:

show ap profile name *xyz* detailed

The following is a sample output:

```
Device# show ap profile name xyz detailed
USB Module           : ENABLED
```

CHAPTER 39

Dynamic Frequency Selection

- [Enabling Zero Wait Dynamic Frequency Selection on a RF Profile \(GUI\), on page 618](#)
- [Verifying Zero Wait Dynamic Frequency Selection Configuration, on page 619](#)

Feature History for Channel Availability Check (CAC)

This table provides release and related information for features explained in this module.

These features are available on all releases subsequent to the one they were introduced in, unless noted otherwise.

Table 51: Feature History for Channel Availability Check (CAC)

Release	Feature	Feature Information
Cisco IOS XE Bengaluru 17.5.1	Channel Availability Check (CAC)	When a DFS channel is selected for an AP radio, the AP radio scans the channel to check for any radar signals before transmitting any frames in the DFS frequency. This process is called Channel Availability Check (CAC).

Information About Dynamic Frequency Selection

Dynamic Frequency Selection (DFS) is the process of detecting radar signals and automatically setting the frequency on a DFS-enabled 5.0-GHz (802.11a/h) radio to avoid interference with the radar signals. Radios configured for use in a regulatory domain must not interfere with radar systems.

In normal DFS, when a radar signal is detected on any of the channels in the 40-MHz or 80-MHz bandwidth, the whole channel is blocked. With Flex DFS, if the radar signals are not detected on the secondary channel, the AP is moved to a secondary channel with a reduction in the bandwidth, usually, by half.

Information About Channel Availability Check (CAC)

When a DFS channel is selected for an AP radio, the AP radio scans the channel to check for any radar signals before transmitting any frames in the DFS frequency. This process is called Channel Availability Check (CAC).

Note CAC is executed before you set a DFS channel for the radio.

If the AP detects that a radar is using a specific DFS channel, the AP marks the channel as non-available and excludes it from the list of available channels. This state lasts for 30 minutes after which the AP checks again to see, if the channel can be used for Wi-Fi transmissions.

Note

- The CAC performed during a boot process takes anywhere between 1 and 10 minutes depending on the country. This is the reason as to why the DFS channels are not available immediately when an AP reboots.
- APs in the ETSI domain scan channels which are not supported by the controller, as the hardware has the ability to scan.

Verifying DFS

Use the following commands to verify the DFS configuration:

To display the 802.11h configuration, use the following command:

```
Device# show wireless dot11h
```

To display the auto-rF information for 802.11h configuration, use the following command:

```
Device# show ap auto-rf dot11 5ghz
```

To display the auto-rF information for a Cisco AP, use the following command:

```
Device# show ap name ap1 auto-rf dot11 5gh
```

To display the channel details for a Cisco AP, use the following command:

```
Device# show ap dot11 5ghz summary
AP Name Mac Address Slot Admin State Oper State Width Txpwr Channel
-----
pnp-ap 04eb.409e.b560 1 Enabled Up 40 *8/8 (3 dBm) (52,56)
BLDG1-9130-RACK-1568 04eb.409f.11a0 1 Disabled Down 40 4/8 (15 dBm) (100,104)#
```

Note In the show command, # is added right next to the channel whenever CAC is running on an AP radio.

Information About Zero Wait Dynamic Frequency Selection

Access points (APs) monitor and perform Channel Availability Check (CAC) on a potential channel for 60 seconds when AP moves to Dynamic Frequency Selection (DFS) channels. Further, the AP ensures that there is no radar operating in the same frequency range before advertising beacons and serving clients. When the AP moves to a DFS, there is a service outage for a minute. This outage can be higher and extend up to 10 minutes. The Zero Wait Dynamic Frequency Selection feature helps to avoid the service outage in regulatory domains. As of now, U.S. and Europe are the only supported domains.

Configuring Zero Wait Dynamic Frequency Selection Globally (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 5ghz rrm channel zero-wait-dfs Example: Device(config)# ap dot11 5ghz rrm channel zero-wait-dfs	Enables the Zero Wait Dynamic Frequency Selection feature. By default, the feature is disabled. Use the no form of this command to disable the feature. Note The Zero Wait Dynamic Frequency Selection feature is only available on a 5-GHz radio.

Configuring Zero Wait Dynamic Frequency Selection Globally (GUI)

Procedure

- Step 1** Choose **Configuration > Radio Configurations > RRM**.
- Step 2** In the **RRM** page, click the **5 GHz Band** tab.

- Step 3** Click the **DCA** tab.
- Step 4** Select the **Zero Wait DFS** check box to allow the AP to change to DFS without a service outage.
- Step 5** Click **Apply**.

Enabling Zero Wait Dynamic Frequency Selection on a RF Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 5ghz rf-profile <i>profile-name</i> Example: Device(config)# ap dot11 5ghz rf-profile test-dfs	Configures a radio frequency (RF) profile and enters RF profile configuration mode.
Step 3	channel zero-wait-dfs Example: Device(config-rf-profile)# channel zero-wait-dfs	Enables the Zero Wait Dynamic Frequency Selection feature for the RF profile. Use the no form of this command to disable the feature.

Enabling Zero Wait Dynamic Frequency Selection on a RF Profile (GUI)

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > RF/Radio**.
- Step 2** In the **RF** tab, click **Add**.
The **Add RF Profile** page is displayed.
- Step 3** Enter the name for the RF profile.
- Step 4** From the **Radio Band** drop-down, choose the **5 GHz** band.
- Step 5** Click the **RRM** tab.
- Step 6** Click the **DCA** tab.
- Step 7** Select the **Zero Wait DFS** check box to allow the AP to change to DFS without a service outage.

Step 8 Click **Apply to Device**.

Verifying Zero Wait Dynamic Frequency Selection Configuration

Use the following commands to verify the DFS configuration.

To display the Zero Wait DFS configuration on an AP, use the following command:

```
Device# show ap name ap1 config slot 1 | inc Zero
```

```
Zero Wait DFS Parameters
Zero Wait DFS Capable      : Yes
CAC Domain                 : None
```

To display the global configuration related to the Zero Wait Dynamic Frequency Selection feature, use the following command:

```
Device# show ap dot11 5ghz channel | inc Zero
```

```
Zero Wait DFS Parameters
Zero Wait DFS Capable      : Yes
CAC Domain                 : None
```

To display the RF profile configuration related to the Zero Wait Dynamic Frequency Selection feature, use the following command:

```
Device# show ap rf-profile name test detail | sec Zero
```

```
Description                :
RF Profile Name             : test
Band                       : 5 GHz
Transmit Power Threshold v1 : -70 dBm
Min Transmit Power         : -10 dBm
Max Transmit Power         : 30 dBm
.
.
Guard Interval             : default
Zero Wait DFS              : Enabled
```

CHAPTER 40

Cisco Access Points with Tri-Radio

- [Cisco Access Points with Tri-Radio, on page 621](#)
- [Guidelines and Restrictions for Tri-Radio Access Points, on page 623](#)
- [Configuring Tri-Radio, on page 623](#)

Cisco Access Points with Tri-Radio

This topic describes the Tri-Radio feature for Cisco Access Points (APs).

Access Points with three radios are designed for high density environments. The APs by default run one dedicated 2.4-GHz 4x4 mode radio and one 5-GHz 8x8 mode radio. In the default mode, the radios are managed by the Flexible Radio Assignment (FRA), and the Dual Radio Mode is in the disabled state indicating that the radios have either been assigned as client serving 8x8 radio or have not yet been evaluated by FRA.

When you enable the dual radio mode setting, the 8x8 radio is split to two independent 5-GHz 4x4 radios. In this mode, slot 1 and slot 2 are active independent 4x4 radio interfaces. They can serve different user groups with different assigned channels.

Note To disable the dual radio mode, you must first disable the admin status of the subordinate radio. Otherwise, a warning message is displayed.

A tri-radio AP has upto two configurable 5-GHz radios. The following table describes the radio role and its deployment benefits:

In Cisco IOS XE Dublin 17.13.1, the **ap tri-radio** command cannot be configured, since the Tri-radio settings are enabled by default, and cannot be disabled.

Table 52: 5-GHz Radio Operational Modes and Criteria

Radio Role		Driving Factors
Radio 1	Radio 2	
8x8 Client-Serving	None	<ul style="list-style-type: none"> Preferred operation: 160 MHz or 80 + 80 MHz Higher MU-MIMO stations Required higher number of Spatial Streams (SS)
4x4 Client-Serving	4x4 Client-Serving	<ul style="list-style-type: none"> Preferred operation: 80 MHz or below High Capacity in low or medium density Directional antenna units (Coverage Slicing)
4x4 Client-Serving	4x4 Monitor	<ul style="list-style-type: none"> Preferred operation: 80 MHz or below Lower MU-MIMO stations Better channel reuse in high density Monitoring application requires 4x4 Rx

The following table lists the different radio modes and roles supported by the AP:

Table 53: Tri-Radio AP Radio Configuration

Setup	Radio Mode	Maximum Radio Capability	Dual Role Mode
1	2.4-GHz + 5-GHz	2.4-GHz, 4 antennas, 4SS, and 20 MHz 5-GHz, 8 antennas, 4SS, and 160 MHz	Disabled
2	2.4-GHz + 5-GHz	2.4-GHz, 4 antennas, 4SS, and 20 MHz 5-GHz, 8 antennas, 8SS, and 80 MHz	Disabled

Setup	Radio Mode	Maximum Radio Capability	Dual Role Mode
3	2.4-GHz + 5-GHz + 5-GHz	2.4-GHz, 4 antennas, 4SS, and 20 MHz 5-GHz, 4 antennas, 4SS, and 80 MHz 5-GHz, 4 antennas, 4SS, and 80 MHz	Enabled

In the Cisco IOS XE 17.2.1 Release, FRA manages the role assignment for each radio independently. You can set the radio mode as automatic or manual, and select either Client-Serving role or Monitor role as the radio role. Based on the dual radio mode configuration, the role selection is available for one or for both interfaces.

Guidelines and Restrictions for Tri-Radio Access Points

- Dual radio mode is set to **Auto** by default. FRA manages the dual radio mode in **Auto** mode.
- The tri-radio support for AP with external antenna is as follows:
 - RP-TNC antenna is supported in Cisco Catalyst 9130AX Series APs.
 - The C-ANT9101, C-ANT9102, and C-ANT9103 antennas on Cisco Catalyst 9130AX Series APs support 2 radios (2.4-GHz (4x4) and 5-GHz (8x8)). This antennas does not support two 5-GHz (4x4) radios due to hardware limitation.
- From Cisco IOS XE Cupertino 17.7.x, the Tri-Radio feature is supported in Cisco Catalyst 9124 Series APs.

Configuring Tri-Radio

Configuring Tri-Radio for AP (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > Network**.
The **Network > 5 GHz Radios** page is displayed.
- Step 2** In the **General** section, the **Tri-Radio Mode** check box is enabled by default.
- Note** You cannot disable the **Tri-Radio Mode** configuration.
- Step 3** Click **Apply**
-

Configuring the Tri-Radio (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	[no] ap tri-radio Example: Device(config)# ap tri-radio	Configures all supporting tri-radio AP's dual radio role in auto mode. Use the [no] form of the command to disable the feature.

Configuring 5-GHz Dual Radio Mode for AP (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Access Points**.
- Step 2** On the **Access Points** page, click the **5 GHz Radios** section and select a Cisco 9130 Series AP from the list. The **Edit Radios 5 GHz Band** window is displayed.
- Step 3** In the **Edit Radios 5-GHz Band > Configure > General** tab, under **Dual Radio Mode**, select one from the following radio button options
- Auto: Permits FRA to decide the mode for this AP.
 - Enabled: Enables Dual Radio mode for this AP.
 - Disabled: Disables Dual Radio mode for this AP.
- Step 4** Click **Update & Apply to Device**.
-

Configuring the Dual Radio Mode and Enabling Slots (CLI)

Procedure

	Command or Action	Purpose
Step 1	ap name <i>ap-name</i> dot11 5ghz slot { 1 2 } shutdown Example: Device# ap name <i>ap-name</i> dot11 5ghz slot 1 shutdown	(Optional) Disables the 802.11a radio on Cisco AP.

	Command or Action	Purpose
Step 2	ap name <i>ap-name</i> dot11 5ghz slot 1 dual-radio mode { disable enable auto } Example: <pre>Device# ap name ap-name dot11 5ghz slot 1 dual-radio mode enable</pre>	Configures the 802.11a dual and tri-radio on the AP. Enable auto to allow RRM to switch the AP between dual radio or tri radio mode based on the channel width configuration. In auto mode, the slot 2 state is managed by the RRM. Use the disable keyword to disable the dual-radio. Note When the AP is set to auto mode, the dual radio mode is disabled by default.
Step 3	ap name <i>ap-name</i> no dot11 5ghz slot { 1 2 } shutdown Example: <pre>Device# ap name ap-name no dot11 5ghz slot 1 shutdown</pre>	Enables the 802.11a radio on Cisco AP.

Setting Radio Roles for Slots (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	ap name <i>ap-name</i> dot11 { 24ghz 5ghz 6ghz } slot <slot ID> radio role { auto manual { monitor client-serving } } Example: <pre>Device# ap name ap-name dot11 5ghz slot 2 radio role manual monitor</pre>	Sets the radio role manual to either client serving or monitor.

Configuring the Tri-Radio Dual Radio Role (CLI)

Procedure

	Command or Action	Purpose
Step 1	ap name <i>ap-name</i> dot11 5ghz slot { 1 2 } radio role { auto manual { client-serving monitor } } Example:	Configures the 802.11a radio role independently for each supporting AP's radio. The channel and the Tx power values can be configured when the radio role is set to manual mode.

	Command or Action	Purpose
	Device# ap name 9130axtrial dot11 5ghz slot 1 radio role manual monitor	
Step 2	ap name <i>ap-name</i> dot11 24ghz slot 0 radio role {auto manual {client-serving monitor}} Example: Device# ap name 9130axtrial dot11 24ghz slot 0 radio role manual client-serving	Configures the 802.11b radio role independently for the supporting AP's radio.

Verifying Tri-Radio Configuration on the Controller

To verify that the dual radio mode is enabled, use the following **show** command:

- Device# show ap name APXXXX.4XXX.04XX config slot 1 | inc Dual

```
Dual Radio Capable           : True
Dual Radio Mode               : Enabled
Dual Radio Operation mode     : Auto
```

To verify the tri-radio status, use the following **show** command:

- Device# show ap triradio status

```
Tri-Radio Status : Enabled
```

To verify that the radio role is set, use the following **show** command:

- show ap name *ap-name* config slot <slot_number> | i Radio

```
Radio Type                   : 802.11ax - 5 GHz
Radio Subband                 : All
Radio Role                    : Auto
Radio Mode                    : Local
Radio SubType                 : Main
```

CHAPTER 41

Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard

- [Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard, on page 627](#)
- [Configuring Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard Parameters \(CLI\), on page 628](#)
- [Verifying AP DFS Counters \(CLI\), on page 629](#)
- [Verifying Wi-Fi 6 Access Point Parameters, on page 630](#)

Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard

Note We recommend you manage this feature using the Cisco Catalyst Center UI. The procedures are to be executed with for debugging purposes only.

The Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard provides a visual representation of your wireless network. The dashboard contains various dashlets which show you the Wi-Fi 6 Readiness, and the efficiency of the Wi-Fi 6 networks compared to non-Wi-Fi 6 networks. For more information, see the **Monitor Wi-Fi 6 Readiness** section in the [Cisco DNA Assurance User Guide](#).

- **Client Distribution by Capability:** This dashlet shows all the clients associated and their capability in the wireless network. The inner circle shows the wireless protocol capabilities of all the different clients in the network. Capability here is the ability of wireless clients to associate with Wi-Fi 6 APs or non-Wi-Fi 6 APs. The outer arc segment shows how many 802.11ax capable clients are joined to a Wi-Fi 6 network as well as how many of them are not.
- **Wi-Fi 6 Network Readiness:** This dashlet shows all the APs in the network. The inner circle shows the APs which are Wi-Fi 6 APs and non Wi-Fi 6 APs. The outer arc segment shows the number of Wi-Fi 6 enabled AP in the network.
- **AP Distribution by Protocol:** This dashlet shows the protocols enabled on your APs in real time.
- **Wireless Airtime Efficiency:** This dashlet compares and displays the Airtime Efficiency between your Wi-Fi 6 network and Non-Wi-Fi 6 network for each of the access categories (voice, video, best effort, background).

The spectrum is efficiently utilized if the AP's radios can send more traffic (successful bytes transmitted to the client) in less airtime (microseconds) than other networks under similar RF conditions.

- **Wireless Latency by Client Count:** This Dashlet compares the Wireless Latency between your Wi-Fi 6 and Non-Wi-Fi 6 Network for each of the access categories (voice, video, best effort, background).

Wireless latency is measured by the time (microseconds) it takes for a packet to be successfully transmitted from an AP to the client. Hence, AP radios with a higher client count generally have higher latency than compared to those with a lower client count under similar RF conditions.

Note **Client count** in this dashlet refers to the clients that are actively sending traffic for a given Access Category and are not just associated clients.

Configuring Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard Parameters (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap profile <i>profile-name</i> Example: Device(config)# <code>ap profile pp-1</code>	Enables configuration for all the APs that are associated with the specified AP profile name.
Step 3	statistics traffic-distribution Example: Device(config-ap-profile)# <code>statistics traffic-distribution</code>	Enables traffic distribution feature with the specified AP profile.
Step 4	statistics traffic-distribution interval <i>interval-secs</i> Example: Device(config-ap-profile)# <code>statistics traffic-distribution interval 300</code>	Configures the interval at which the AP sends the traffic distribution statistics. Default value is 300 seconds. Valid range is between 30 and 3600 seconds. Note Execute this command only with the assistance from Cisco Technical Assistance Center (TAC) support engineer.
Step 5	end Example: Device(config-ap-profile)# <code>exit</code>	Returns to privileged EXEC mode.

	Command or Action	Purpose
Step 6	<pre>show wireless stats ap name <i>ap-name</i> traffic-distribution slot <i>slot-id</i> packet-count signal { average good poor } [last-received]</pre> <p>Example:</p> <pre>Device#show wireless stats ap name ff123a traffic-distribution slot 1 packet-count signal good</pre>	Displays traffic distribution data by signal strength, if received from the AP in the latest statistics update interval. Use last-received keyword to view the statistics received in any statistics update interval from the AP.
Step 7	<pre>show wireless stats ap name <i>ap-name</i> traffic-distribution slot <i>slot-id</i> airtime access-category { background best-effort video voice } [last-received]</pre> <p>Example:</p> <pre>Device#show wireless stats ap name ff123a traffic-distribution slot 1 airtime access-category best-effort</pre>	Displays the Airtime efficiency data based on access category, if received from the AP in the latest statistics update interval. Use last-received keyword to view the statistics received in any statistics update interval from the AP.
Step 8	<pre>show wireless stats ap name <i>ap-name</i> traffic-distribution slot <i>slot-id</i> airtime traffic-type { legacy mu ofdma su } [last-received]</pre> <p>Example:</p> <pre>Device#show wireless stats ap name ff123a traffic-distribution slot 1 traffic-type ofdma</pre>	Displays the Airtime efficiency data based on traffic type, if received from the AP in the latest statistics update interval. Use last-received keyword to view the statistics received in any statistics update interval from the AP.
Step 9	<pre>show wireless stats ap name <i>ap-name</i> traffic-distribution slot <i>slot-id</i> latency access-category { background best-effort video voice } [last-received]</pre> <p>Example:</p> <pre>Device#show wireless stats ap name ff123a traffic-distribution slot 1 latency access-category best-effort</pre>	Displays wireless latency data based on access category, if received from the AP in the latest statistics update interval. Use last-received keyword to view the statistics received in any statistics update interval from the AP.

Verifying AP DFS Counters (CLI)

Procedure

- To verify the DFS counter for the selected radio band, use the following command:

```
show ap auto-rf dot11 { 24ghz | 5ghz | dual-band } ]
```

Example:

```
Device#show ap auto-rf dot11 dual-band
```

- To verify the DFS counter for the selected radio band of a specific AP, use the following command:

```
show ap name ap-name auto-rf dot11 { 24ghz | dual-band }
```

Example:

```
Device#show ap name ff32a auto-rf dot11 dual-band
```

- To verify the DFS counter for the selected 5-GHz slot of a specific AP, use the following command:

```
show ap name ap-name auto-rf dot11 5ghz slot slot-id
```

Example:

```
Device#show ap name ff32a auto-rf dot11 5ghz slot 1
```

Verifying Wi-Fi 6 Access Point Parameters

Enter these commands in the AP console.

- To verify the traffic distribution statistics configuration, use the following command: **show ap traffic distribution configuration**
- To verify the exported data from the AP to the controller, use the following command: **show interfaces dot11Radio *slot-id* traffic distribution {cumulative | instantaneous | periodic} database**
- To verify Access Point DFS counters, use the following command: **show interfaces dot11radio *slot-id*dfs**
- To debug the traffic distribution statistics, use the following command: **{no} debug traffic wireless distribution dump {periodic | aggregated}**
- To clear the traffic distribution dump, use the following command: **clear traffic distribution dump**

CHAPTER 42

Antenna Disconnection Detection

- [Detecting Broken Antenna Using SNMP Trap \(GUI\)](#), on page 634
- [Verifying Antenna Disconnection Detection](#), on page 635
- [Verifying Antenna Disconnection Detection \(GUI\)](#), on page 636

Feature History for Antenna Disconnection Detection

This table provides release and related information for the features explained in this module.

These features are available in all releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Bengaluru 17.4.1	Antenna Disconnection Detection	This feature detects the signal strength delta across the antennas on the receiver. If the delta is more than the defined limit for a specific duration, the corresponding antenna is considered to have issues.

Information About Antenna Disconnection Detection

Having multiple antennas on the transmitter and receiver of an access point (AP) results in better performance and reliability. Multiple antennas improve reception through the selection of the stronger signal or a combination of individual signals at the receiver. Therefore, detection of an impaired antenna or physical breakage of an antenna is critical to the reliability of APs.

The Antenna Disconnection Detection feature is based on the signal strength delta across the antennas on the receiver. If the delta is more than the defined limit for a specific duration, the antenna is considered to have issues.

For every detection time period that you configure, the AP sends an Inter-Access Point Protocol (IAPP) message that carries the antenna condition. This message is sent only once when the issue is detected and is displayed in the controller trap messages, SNMP traps, and controller debug logs.

Configuration Workflow

1. Configure APs.
2. Configure an AP profile.
3. Enable the feature in AP profile.
4. Configure feature parameters.
5. Verify the configuration.

Recommendations and Limitations

- The feature is supported only on the following APs:
 - Cisco Catalyst 9120AX Series Access Points
 - Cisco Catalyst 9130AX Series Access Points
 - Cisco Aironet 2800e Access Points
 - Cisco Aironet 3800e Access Points
- The SNMP trap is not supported on the Cisco Embedded Wireless Controller.
- The IAPP message is sent only when there is a change in the error condition.

Configuring Antenna Disconnection Detection (CLI)

Antenna disconnection detection works by comparing the received signal strength intensity (RSSI) of each antenna with the antenna receiving the higher RSSI. If the delta is higher than the RSSI failure threshold, the corresponding antenna is declared as broken.

The *weak-rssi* is an absolute RSSI threshold value, expressed in dBm. If the antennas detect a lower RSSI value than the one configured in *weak-rssi*, all the antennas are reported as malfunctioning. The RSSI failure threshold is evaluated only if an antenna detects a signal over the *weak-rssi* value.

Follow the procedure given below to configure antenna disconnection detection:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# ap profile xyz-ap-profile	Configures an AP profile and enters AP profile configuration mode.
Step 3	antenna monitoring Example: Device(config-ap-profile)# antenna monitoring	Enables antenna disconnection detection. To disable antenna disconnection detection, use the no antenna monitoring command.
Step 4	antenna monitoring rssi-failure-threshold <i>threshold-value</i> Example: Device(config-ap-profile)# antenna monitoring rssi-failure-threshold 20	Configures RSSI failure threshold value, in dB. Valid values range from 10 to 90, with a default of 40.
Step 5	antenna monitoring weak-rssi <i>weak-rssi-value</i> Example: Device(config-ap-profile)# antenna monitoring weak-rssi -90	Configures weak RSSI value, in dBm. Valid values range from -90 to -10, with a default of 60.
Step 6	antenna monitoring detection-time <i>detect-time-in-mins</i> Example: Device(config-ap-profile)# antenna monitoring detection-time 20	Configures the antenna disconnection detection time, in minutes. Valid values range from 9 to 180, with a default of 120.
Step 7	end Example: Device(config-ap-profile)# end	Saves the configuration and returns to privileged EXEC mode.

Configuring Antenna Disconnection Detection (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
 - Step 2** In the **AP Join Profile** window, click the **General** tab.
 - Step 3** In the **Antenna Monitoring** check box to enable antenna monitoring.
 - Step 4** In the **RSSI Fail Threshold(dB)** field, enter a value, in dB. Valid values range from 10 to 90, with a default of 40.
 - Step 5** In the **Weak RSSI(dBm)** field, enter a value, in dBm. Valid values range from -90 to -10, with a default of 60.

- Step 6** In the **Detection Time(min)** field, enter the antenna disconnection detection time, in minutes. Valid values range from 9 to 180, with a default of 120.
- Step 7** Click **Update & Apply to Device**.

Detecting Broken Antenna Using SNMP Trap (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	snmp-server enable traps Example: Device(config)# snmp-server enable traps	Enables all the SNMP notification types that are available on the system.
Step 3	trapflags ap broken-antenna Example: Device(config)# trapflags ap broken-antenna	Enables an SNMP trap, which will be sent when an antenna fails in any Cisco AP.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode.

Detecting Broken Antenna Using SNMP Trap (GUI)

Procedure

- Step 1** Choose **Administration > Management > SNMP**.
- Step 2** Click the **Wireless Traps** tab.
- Step 3** Set the **Access Point** status as **Enabled**, if not done already.
- Step 4** Check the **Broken Antenna** check box to enable the trap.
- Step 5** Click **Apply**.

Verifying Antenna Disconnection Detection

To verify the Antenna Disconnection Detection feature configuration on an AP, use the following command:

```
Device# show ap name 3800-AP config general
```

```
Cisco AP Name: 3800-AP
```

```
=====
Cisco AP Identifier           : f4db.e632.df40
Country Code                 : Multiple Countries : US,IN,CN,CU
Regulatory Domain Allowed by Country : 802.11bg:-ACE 802.11a:-ABCDHN
AP Country Code              : CN - China

Weak RSSI                     : -80
Detection Time                : 120

.
.
.
```

To verify the Antenna Disconnection Detection feature configuration on an AP profile, use the following command:

```
Device# show ap profile name rf-profile-24g detailed
```

```
AP Profile Name: rf-profile-24g
```

```
.
.
.
AP broken antenna detection:
  Status                       : ENABLED
  RSSI threshold                : 40
  Weak RSSI                     : -80
  Detection Time                : 120
```

Verifying Antenna Disconnection Detection (GUI)

Procedure

Step 1 Choose **Monitoring > Wireless > AP Statistics**.

Step 2 Click an AP name or anywhere on the row corresponding to an AP in order to activate **General** window.

Step 3 Click the **360 View** tab.

The 360 View tab is the default selection. The **Antenna Monitoring** field indicates whether the AP supports monitoring or not.

CHAPTER 43

Neighbor Discovery Protocol Mode on Access Points

- [Information About Neighbor Discovery Protocol Mode](#), on page 637
- [Configuring RRM Neighbor Discovery Mode \(GUI\)](#), on page 638
- [Configuring the Neighbor Discovery Protocol Mode \(CLI\)](#), on page 638
- [Configuring the Neighbor Discovery Protocol Type \(CLI\)](#), on page 638
- [Configuring Neighbor Discovery Protocol Mode in the RF Profile \(GUI\)](#), on page 639
- [Configuring Neighbor Discovery Protocol Mode in the RF Profile \(CLI\)](#), on page 639
- [Monitoring Radio Statistics-NDP Capability and NDP Mode \(GUI\)](#), on page 640
- [Verifying Neighbor Discovery Protocol Mode](#), on page 641

Information About Neighbor Discovery Protocol Mode

In Cisco Catalyst 9124AX outdoor Access Points, the Neighbor Discovery Protocol (NDP) packets are transmitted either ON-channel on the serving radio, or OFF-channel on the RF ASIC conventional radio. The controller has a knob to select the NDP mode for Cisco Catalyst 9124AX outdoor APs based on the deployment requirements. In Cisco IOS XE Bengaluru 17.5.1, Cisco Catalyst 9124AX outdoor APs support both ON-Channel and OFF-Channel NDP mode.

The Cisco Catalyst 9124AX outdoor AP advertises the following NDP mode capabilities while joining the controller:

- ON-Channel (Serving channel)
- OFF-Channel (RF ASIC radio)
- Both (Serving channel and RF ASIC radio)

The supported values for NDP mode are AUTO and OFF-Channel. By default, the NDP mode is set to AUTO.

If the configured NDP mode is AUTO, the AP determines which NDP mode is to be used. The Cisco Catalyst 9124AX outdoor AP uses ON-Channel when the controller is configured for AUTO NDP mode. If the NDP mode that is configured is OFF-Channel, the AP uses OFF-Channel for NDP mode.

Use Cases

You must configure the controller NDP mode to OFF-channel in order to support brownfield deployment. A brownfield deployment refers to the mixed deployment of Cisco Catalyst 9124AX with other APs that do not

support RF ASIC conventional radio. APs that support RF ASIC conventional radio are Cisco Catalyst 9120 Series Access Points, Cisco Catalyst 9130 Series Access Points, and Cisco Catalyst 9124 Series Access Points.

Configuring RRM Neighbor Discovery Mode (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > RRM**.
- Step 2** In the **Radio Resource Management** window, click either the **5 GHz Band** or the **2.4 GHz Band** tab.
- Step 3** In the **General** tab, under the **Noise/Interference/Rogue/CleanAir/SI Monitoring Channels** section, click the **RRM Neighbor Discovery Mode** toggle button to configure either of the following modes:
- **AUTO**: If the NDP mode that is configured is **AUTO**, the controller selects ON-Channel as the NDP mode. (The default is set as AUTO).
 - **OFF-CHANNEL**: If the NDP mode configured is **OFF-CHANNEL**, the controller selects **OFF-CHANNEL** as the NDP mode.
- Step 4** Click **Apply**.
-

Configuring the Neighbor Discovery Protocol Mode (CLI)

To configure the NDP mode for an AP, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz} rrm ndp-mode {auto off-channel} Example: Device(config)# ap dot11 24ghz rrm ndp-mode off-channel	Configures the operating mode for 802.11a neighbor discovery. The Off-channel command enables NDP packets on the RF ASIC radio and the auto command enables the auto mode.

Configuring the Neighbor Discovery Protocol Type (CLI)

To configure the NDP type for an AP, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} rrm ndp-type {protected transparent} Example: Device(config)# ap dot11 6ghz rrm ndp-type	Configures the NDP type for 802.11a, 802.11b, or 802.11 6-GHz neighbor discovery. The two types are protected and transparent.

Configuring Neighbor Discovery Protocol Mode in the RF Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > RF**.
 - Step 2** Click **Add**.
The **Add RF Profile** window is displayed.
 - Step 3** Click the **General** tab.
 - Step 4** Click the **NDP Mode** toggle button to select the NDP mode as **AUTO** or as **OFF-CHANNEL**.
 - Step 5** Click **Apply to Device**.
-

Configuring Neighbor Discovery Protocol Mode in the RF Profile (CLI)

To configure the NDP mode for an AP under the RF profile, follow these steps:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} rf-profile rf-profile-name	Enters the RF profile configuration.

	Command or Action	Purpose
	Example: Device(config)# ap dot11 24ghz rf-profile rf-profile-name	
Step 3	ndp-mode {auto off-channel} Example: Device(config-rf-profile)# ndp-mode off-channel	Configures the operating mode for neighbor discovery. Off-channel enables NDP packets on the RF ASIC radio and auto enables the auto mode.

Monitoring Radio Statistics-NDP Capability and NDP Mode (GUI)

Procedure

-
- Step 1** Choose **Monitoring > Wireless > Radio Statistics**.
- Step 2** Click either **5 GHz Radios**, **2.4 GHz Radios**, or **Dual-Band Radios** tab. The corresponding radio band window displays the list of configured APs.
- Step 3** To view the general attributes of an AP, click the corresponding AP to display the **General** tab. The following information is displayed:
- **AP Name:** Displays the assigned identifier for the AP, which is unique within the network. The AP name can be ASCII characters from 32 to 126, without leading and trailing spaces.
 - **IP Address:** Displays the IP address assigned to the AP in dotted-decimal format.
 - **AP Mode:** Displays the configured AP mode. The supported modes are:
 - **Local:** It is the default mode, and it offers a basic service set (BSS) on a specific channel. When the AP does not transmit wireless client frame, it scans other channels to measure noise interference, discover rogue devices, and check for matches against Intrusion Detection System (IDS) events.
 - **Monitor:** An AP in monitor mode does not transmit. It is a dedicated sensor that checks IDS events, detects rogue APs, and determines the position of wireless stations.
 - **Sniffer:** The controller enables you to configure an AP as a network *sniffer*, which captures and forwards all the packets on a particular channel to a remote machine that runs packet analyzer software. These packets contain information on time stamps, signal strength, packet sizes, and so on. Sniffers allow you to monitor and record network activity and detect problems.
 - **Bridge:** The AP becomes a dedicated point-to-point or point-to multipoint bridge. Two APs in bridge mode can connect two remote sites. Multiple APs can also form an indoor or outdoor mesh. Note that you cannot connect to the bridge with clients.
 - **Clear:** Returns the AP back to client-serving mode depending on the remote site tag configuration.
 - **MAC Address:** Displays the registered MAC address on the controller.
 - **Number of Slots :** Displays the number of slots supported by the AP.

- **Radio Type:** Displays the radio band configured on the controller. By default, both, 802.11b/g/n (2.4-GHz) and 802.11a/n/ac (5-GHz) bands are enabled.
- **Slot ID:** Displays the slot on which radio is installed.
- **Sub band Type:** Displays the configured radio sub-band.
- **NDP Capability:** Displays the supported Neighbor Discovery Protocol (NDP) capability. The AP advertises the following NDP mode capabilities while joining the controller:
 - ON-Channel (Serving channel)
 - OFF-Channel (RHL radio)
 - Both (Serving channel and RHL radio)

Note Only Cisco Catalyst 9124AX outdoor Access Points support both ON-channel and OFF-channel NDP capability from Cisco IOS XE Bengaluru 17.5.1.
- **NDP Mode:** Displays the configured NDP mode. If the NDP mode that is configured is AUTO, the controller selects ON-Channel as the NDP mode. If the NDP-mode that is configured is OFF-Channel, the controller selects OFF-Channel as the NDP mode.

Verifying Neighbor Discovery Protocol Mode

To verify the NDP mode, run the following commands:

```

Device# show ap rf-profile name test-24g
Description                : test
RF Profile Name            : test-24g
Band                      : 2.4 GHz
Transmit Power Threshold v1 : -70 dBm
Min Transmit Power        : -10 dBm
Max Transmit Power        : 30 dBm
.
.
.
NDP mode                   : Auto
.
.
.

Device# show ap rf-profile name test-5g detail
Description                : Test
RF Profile Name            : test-5g
Band                      : 5 GHz
Transmit Power Threshold v1 : -70 dBm
Min Transmit Power        : -10 dBm
Max Transmit Power        : 30 dBm
.
.
.
NDP mode                   : Off-channel
.

CHAPTER 44

6-GHz Band Operations

The following topics describe the features that are specific to 6-GHz band radio:

- [Configuring Preferred Scanning Channels in the RF Profile \(GUI\), on page 643](#)
- [Configuring Preferred Scanning Channels in the RF Profile \(CLI\), on page 644](#)
- [Configuring Broadcast Probe Response in RF Profile \(GUI\), on page 644](#)
- [Configuring Broadcast Probe Response in RF Profile \(CLI\), on page 644](#)
- [Configuring FILS Discovery Frames in the RF Profile \(GUI\), on page 645](#)
- [Configuring FILS Discovery Frames in the RF Profile \(CLI\), on page 646](#)
- [Configuring Multi BSSID Profile \(GUI\), on page 646](#)
- [Configuring Multi BSSID Profile, on page 647](#)
- [Configuring Multi-BSSID in the RF Profile \(GUI\), on page 647](#)
- [Configuring Multi-BSSID in the RF Profile \(CLI\), on page 648](#)
- [Configuring Dynamic Channel Assignment Freeze \(CLI\), on page 648](#)
- [Information About 6-GHz Client Steering, on page 649](#)

Configuring Preferred Scanning Channels in the RF Profile (GUI)

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > RF/Radio**.
 - Step 2** In the **RF** tab, click **Add**.
The **Add RF Profile** page is displayed.
 - Step 3** Choose the **RRM** tab.
 - Step 4** Choose the **DCA** tab.
 - Step 5** In the **Dynamic Channel Assignment** section, select the required channels in **DCA Channels** section.
 - Step 6** In the **PSC Bias** field, click the toggle button to enable the preferred scanning channel bias for DCA.
 - Step 7** Click **Apply to Device**.
-

Configuring Preferred Scanning Channels in the RF Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 6ghz rf-profile <i>rf-profile-name</i> Example: Device(config)# <code>ap dot11 6ghz rf-profile rf-profile-name</code>	Configures an RF profile and enters RF profile configuration mode.
Step 3	channel psc Example: Device(config-rf-profile)# <code>channel psc</code>	Configures the RF Profile DCA settings and enables the preferred scanning channel bias for DCA.

Configuring Broadcast Probe Response in RF Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > RF/Radio**.
 - Step 2** In the **RF** tab, click **Add**.
The **Add RF Profile** page is displayed.
 - Step 3** Choose the **802.11ax** tab.
 - Step 4** In the **6 GHz Discovery Frames** section, click the **Broadcast Probe Response** option.
 - Step 5** In the **Broadcast Probe Response Interval** field, enter the broadcast probe response time interval in milli-seconds (ms). The value range is between 5 ms and 25 ms. The default value is 20 ms.
 - Step 6** Click **Apply to Device**.
-

Configuring Broadcast Probe Response in RF Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Device# <code>configure terminal</code>	
Step 2	ap dot11 6ghz rf-profile <i>rf-profile-name</i> Example: Device(config)# ap dot11 6ghz rf-profile <i>rf-profile-name</i>	Configures an RF profile and enters RF profile configuration mode.
Step 3	dot11ax bcast-probe-response Example: Device(config-rf-profile)# dot11ax bcast-probe-response	Configures broadcast probe response.
Step 4	dot11ax bcast-probe-response time-interval <i>time-interval</i> Example: Device(config-rf-profile)# dot11ax bcast-probe-response time-interval 20	Configures broadcast probe response interval.

Configuring FILS Discovery Frames in the RF Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > RF/Radio**.
- Step 2** In the **RF** tab, click **Add**.
The **Add RF Profile** page is displayed.
- Step 3** Choose the **802.11ax** tab.
- Step 4** In the **6 GHz Discovery Frames** section, click the **FILS Discovery** option.
- Note** To prevent the transmission of discovery FILS frames when the discovery frames are set to **None** in the RF profile, ensure that you disable FILS discovery frames by either switching to the 5-GHz or the 2.4-GHz bands on the AP or by selecting the Broadcast Probe Response option.
- Step 5** Click **Apply to Device**.
-

Configuring FILS Discovery Frames in the RF Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 6ghz rf-profile rf-profile-name Example: Device(config)# ap dot11 6ghz rf-profile rf-profile-name	Configures an RF profile and enters RF profile configuration mode.
Step 3	dot11ax fils-discovery Example: Device(config-rf-profile)# dot11ax fils-discovery	Configures the 802.11ax FILS discovery. Note To prevent the transmission of discovery FILS frames when the discovery frames are set to None in the RF profile, ensure that you disable FILS discovery frames by either switching to the 5-GHz or the 2.4-GHz bands on the AP or by changing to Broadcast Probe Response.

Configuring Multi BSSID Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Multi BSSID**.
- Step 2** Click **Add**.
The **Add Multi BSSID Profile** page is displayed.
- Step 3** Enter the name and the description of the BSSID profile.
- Step 4** Enter the following 802.11ax parameters:
- Downlink OFDMA**
 - Uplink OFDMA**
 - Downlink MU-MIMO**
 - Uplink MU-MIMO**
 - Target Waketime**
 - TWT Broadcast Support**

Step 5 Click **Apply to Device**.

Configuring Multi BSSID Profile

To configure the multi BSSID profile for 6-GHz band radio, follow the steps given below:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless profile multi-bssid <i>multi-bssid-profile-name</i> Example: Device (config)# <code>wireless profile multi-bssid multi-bssid-profile-name</code>	Configures the multi BSSID profile. Enters the multi BSSID profile configuration.
Step 3	dot11ax {downlink-mumimo downlink-ofdma target-waketime twt-broadcast uplink-mumimo uplink-ofdma} Example: Device (config-wireless-multi-bssid-profile)# <code>dot11ax downlink-mumimo</code>	Configures the 802.11ax parameters.

Configuring Multi-BSSID in the RF Profile (GUI)

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > RF/Radio**.
- Step 2** In the **RF** tab, click **Add**.
The **Add RF Profile** page is displayed.
- Step 3** Choose the **802.11ax** tab.
- Step 4** In the **Multi BSSID Profile** field, choose the profile from the drop-down list.
- Step 5** Click **Apply to Device**.

Configuring Multi-BSSID in the RF Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 6ghz rf-profile rf-profile-name Example: Device(config)# <code>ap dot11 6ghz rf-profile rf-profile-name</code>	Configures an RF profile and enters RF profile configuration mode.
Step 3	dot11ax multi-bssid-profile multi-bssid-profile-name Example: Device(config-rf-profile)# <code>dot11ax multi-bssid-profile multi-bssid-profile-name</code>	Configures 802.11ax multi BSSID profile name, in the RF profile configuration mode.

Configuring Dynamic Channel Assignment Freeze (CLI)

When the 6-GHz radios receive the right channels, disable DCA for 6-GHz by issuing the following command:

Before you begin

Ensure that Dynamic Channel Assignment (DCA) for 6-GHz is enabled. Wait for the 6-GHz radios to get stabilized with the right set of channel assignments.

Procedure

	Command or Action	Purpose
Step 1	no ap dot11 6ghz rrm channel dca global auto Example: Device# <code>no ap dot11 6ghz rrm channel dca global auto</code>	Disables DCA for 6-GHz bands.

Information About 6-GHz Client Steering

The 6-GHz band provides more channels, more bandwidth, and has less network congestion when compared to the existing 2.4-GHz and 5-GHz bands. As a result, wireless clients that are 6-GHz capable connect to the 6-GHz radio to take advantage of these benefits.

This topic provides details about 6-GHz client steering for APs supporting 6-GHz band.

The 6-GHz client steering takes place when the controller receives a periodic client statistics report from the 2.4-GHz band or the 5-GHz band. The client steering configuration is enabled under WLAN, and is configured only for clients that are 6-GHz capable. If a client in the report is 6-GHz capable, then client steering is triggered, and the client is steered to the 6-GHz band.

Configuring 6-GHz Client Steering in the Global Configuration Mode (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Advanced**.
 - Step 2** Click the **6 GHz Client Steering** tab. Client steering is configurable per WLAN.
 - Step 3** In the **6 GHz Transition Minimum Client Count** field, enter a value to set the minimum number of clients for client steering. The default value is three clients. The value range is between 0 and 200 clients.
 - Step 4** In the **6 GHz Transition Minimum Window Size** field, enter a value to set the minimum window size of client steering. The default value is three clients. The value range is between 0 and 200 clients.
 - Step 5** In the **6 GHz Transition Maximum Utilization Difference** field, enter a value to set the maximum utilization difference for steering. The value range is between 0 percent to 100 percent. The default value is 20.
 - Step 6** In the **6 GHz Transition Minimum 2.4 GHz RSSI Threshold** field, enter a value to set the minimum value for client steering 2.4-GHz RSSI threshold.
 - Step 7** In the **6 GHz Transition Minimum 5 GHz RSSI Threshold** field, enter a value to set the minimum value for client steering 5-GHz RSSI threshold.
 - Step 8** Click **Apply**.
-

Configuring 6-GHz Client Steering in the Global Configuration Mode

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	wireless client client-steering client-count <i>min-num-clients</i> Example: Device(config)# client-steering client-count 3	Sets the minimum number of clients for client steering. The value range is between 0 and 200.
Step 3	wireless client client-steering window-size <i>window-size</i> Example: Device(config)# client-steering window-size 5	Sets the minimum window size of client steering. The value range is between 0 and 200.
Step 4	wireless client client-steering util-threshold <i>threshold</i> Example: Device(config)# wireless client client-steering util-threshold 25	Sets the maximum channel utilization difference (2.4-GHz or 5-GHz to 6-GHz) for steering. The value range is between 0 to 100 percent.
Step 5	wireless client client-steering min-rssi-24ghz -70 Example: Device(config)# wireless client client-steering min-rssi-24ghz -70	Sets the minimum value for client steering the 2.4-GHz RSSI threshold.
Step 6	wireless client client-steering min-rssi-5ghz -75 Example: Device(config)# wireless client client-steering min-rssi-5ghz -75	Sets the minimum value for client steering the 5-GHz RSSI threshold.

Configuring 6-GHz Client Steering on the WLAN (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > WLANs**.
 - Step 2** Click **Add**.
The **Add WLAN** page is displayed.
 - Step 3** Click the **Advanced** tab.
 - Step 4** Check the **6 GHz Client Steering** check box to enable client steering on the WLAN.
 - Step 5** Click **Apply to Device**.
-

Configuring 6-GHz Client Steering on the WLAN

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan wlan-name wlan-id SSID-name Example: Device(config)# wlan wlan-name 18 ssid-name	Enters WLAN configuration submode.
Step 3	client-steering Example: Device(config-wlan)# client-steering	Configures 6-GHz client steering on the WLAN.

Verifying 6-GHz Client Steering

To verify client steering, run the following commands:

```
Device# show wlan wlan-id
WLAN Profile Name      : wlan1
=====
Identifier              : 1
Description             :
Network Name (SSID)    : ssid-demo
Status                  : Disabled
Broadcast SSID         : Enabled
.
.
.
6Ghz Client Steering   : Enabled
.
.
.

Device# show wireless client steering
Client Steering Configuration Information
Macro to micro transition threshold      : -55 dBm
Macro to Macro transition threshold     : -65 dBm
Micro-Macro transition minimum client count : 3
Micro-Macro transition client balancing window : 3
Probe suppression mode                   : Disabled
Probe suppression transition aggressiveness : 3
Probe suppression hysteresis             : -6 dB
6Ghz transition minimum client count     : 3
6Ghz transition minimum window size      : 3
6Ghz transition maximum channel util difference : 20%
6Ghz transition minimum 2.4Ghz RSSI threshold : -60 dBm
6Ghz transition minimum 5Ghz RSSI threshold : -65 dBm

WLAN Configuration Information
```

WLAN Profile Name	11k Neighbor Report	11v BSS Transition
12 test1	Enabled	Enabled
8 test	Enabled	Enabled

CHAPTER 45

AP Packet Capture

- [Introduction to AP Client Packet Capture, on page 655](#)
- [Enabling Packet Capture \(GUI\), on page 655](#)
- [Enabling Packet Capture \(CLI\), on page 656](#)
- [Create AP Packet Capture Profile and Map to an AP Join Profile \(GUI\), on page 656](#)
- [Create AP Packet Capture Profile and Map to an AP Join Profile, on page 657](#)
- [Start or Stop Packet Capture, on page 657](#)

Introduction to AP Client Packet Capture

The AP Client Packet Capture feature allows the packets on an AP to be captured for wireless client troubleshooting. The packet capture operation is performed on the AP by the radio drivers on the current channel on which it is operational, based on the specified packet capture filter. All the packets that are captured for a specific client are uploaded to a file in the FTP server. This file can be opened in Wireshark for packet inspection.

Limitations for AP Client Packet Capture

- The packet capture task can be performed for only one client at a time per site.
- Packet capture can be started on a specific AP or a set of APs using static mode. It can be started or stopped for the same client on different APs, when the capture is in progress.

When packet capture is started in auto mode, system automatically selects the set of nearby APs to start packet capture for a specific client. In this mode, you cannot start or stop packet capture on individual APs. Use the **stop all** command to stop the packet capture when it is started in auto-mode.

- After the SSO is complete, the packet capture action will not continue after a switchover.

Enabling Packet Capture (GUI)

Procedure

- Step 1** Choose **Troubleshooting > AP Packet Capture**.

- Step 2** On the **Troubleshooting** page, in the **Start Packet Capture** section, in the **Client MAC Address** field, enter the client's MAC address. Enter the MAC address either in *xx:xx:xx:xx:xx:xx*, *xx-xx-xx-xx-xx-xx*, or *xxxx.xxxx.xxxx* format.
- Step 3** From the **Capture Mode** options, choose **Auto**.
- Step 4** Click **Start**.

Enabling Packet Capture (CLI)

Follow the procedure given below to enable packet capture:

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	ap packet-capture start <i>client-mac-address</i> auto Example: Device# ap packet-capture start 0011.0011.0011 auto	Enables packet capture for the specified client on a set of nearby access points.

Create AP Packet Capture Profile and Map to an AP Join Profile (GUI)

Procedure

- Step 1** Click **Configuration > Tags & Profiles > AP Join Profile**.
- Step 2** Click **Add** to create a new AP Join Profile and enter the requisite details.
- Step 3** In the **Add AP Join Profile** area, click **AP > Packet Capture**.
- Step 4** Click the **Plus** icon to create a new Packet Capture profile or select one from the drop-down menu.
- Step 5** Click **Save**.

Create AP Packet Capture Profile and Map to an AP Join Profile

While packet capture profile configurations are used for an AP, the packet capture profile is mapped to an AP profile. The AP profile is in turn mapped to site tag.

While starting packet capture, APs use the packet capture profile configurations based on the site and AP join profile they belong to.

Follow the procedure given below to create an AP packet capture profile and map it to an AP join profile:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode..
Step 2	wireless profile ap packet-capture <i>packet-capture-profile-name</i> Example: Device(config)# wireless profile ap packet-capture test1	Configures an AP profile.
Step 3	ap profile <i>profile-name</i> Example: Device(config)# ap profile default-ap-profile	Configures an AP packet capture profile.
Step 4	packet-capture <i>profile-name</i> Example: Device(config-ap-profile)# packet-capture capture-test	Enables packet capture on the AP profile.
Step 5	end Example: Device(config-ap-profile)# end	Exits the AP profile configuration mode.
Step 6	show wireless profile ap packet-capture detailed <i>profile-name</i> Example: Device# show wireless profile ap packet-capture detailed test1	Displays detailed information of the selected AP packet capture profile.

Start or Stop Packet Capture

Perform either of these tasks to start or stop a packet capture procedure.

Procedure

	Command or Action	Purpose
Step 1	ap packet-capture start <i>client-mac-address</i> { auto static <i>ap-name</i> } Example: Device# ap packet-capture start 0011.0011.0011 auto	Enables packet capture for a client.
Step 2	ap packet-capture stop <i>client-mac-address</i> { all static <i>ap-name</i> } Example: Device# ap packet-capture stop 0011.0011.0011 all	Disables packet capture for a client.

CHAPTER 46

DHCP Option82

- [Information About DHCP Option 82, on page 659](#)
- [Configuring DHCP Option 82 Global Interface, on page 661](#)
- [Configuring DHCP Option 82 Format, on page 663](#)
- [Configuring DHCP Option82 Through a VLAN Interface, on page 664](#)
- [Information About AP DHCP Option 82 Support on FlexConnect Local Switching Mode, on page 669](#)
- [Configuring AP DHCP Option82 Support, on page 669](#)
- [Verifying AP DHCP Option82 Support, on page 670](#)

Information About DHCP Option 82

DHCP Option 82 is organized as a single DHCP option that contains information known by the relay agent. This feature provides additional security when DHCP is used to allocate network addresses, and enables the Cisco controller to act as a DHCP relay agent to prevent DHCP client requests from untrusted sources.

The controller can be configured to add Option 82 information to DHCP requests from clients before forwarding the requests to a DHCP server. The DHCP server can then be configured to allocate IP addresses to the wireless client based on the information present in DHCP Option 82.

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. Configuration parameters and other control information are carried in tagged data items that are stored in the Options field of the DHCP message. The data items themselves are also called options. Option 82 contains information known by the relay agent.

The Relay Agent Information option is organized as a single DHCP option that contains one or more suboptions that convey information known by the relay agent. Option 82 was designed to allow a DHCP Relay Agent to insert circuit-specific information into a request that is being forwarded to a DHCP server. This option works by setting two suboptions:

- Circuit ID
- Remote ID

The Circuit ID suboption includes information that is specific to the circuit the request came in on. This suboption is an identifier that is specific to the relay agent. Thus, the circuit that is described will vary depending on the relay agent.

The Remote ID suboption includes information on the remote host–end of the circuit. This suboption usually contains information that identifies the relay agent. In a wireless network, this would likely be a unique identifier of the wireless access point.

Note All valid Remote ID combinations are separated with a colon (:) as the delimiter.

You can configure the following DHCP Option 82 options in a controller :

- DHCP Enable
- DHCP Opt82 Enable
- DHCP Opt82 Ascii
- DHCP Opt82 RID
- DHCP Opt Format
- DHCP AP MAC
- DHCP SSID
- DHCP AP ETH MAC
- DHCP AP NAME
- DHCP Site Tag
- DHCP AP Location
- DHCP VLAN ID

Note The controller includes the SSID in ASCII and the VLAN-ID in hexadecimal format within the remote-ID sub-option of option 82 in the outgoing DHCP packets to the server for the following configurations:

```
ipv4 dhcp opt82 format ssid  
ipv4 dhcp opt82 format vlan-id
```

However, if *ipv4 dhcp opt82 ascii* configuration is also present, the controller adds VLAN-ID and SSID in ASCII format.

For Cisco Catalyst 9800 Series Configuration Best Practices, see the following link: <https://www.cisco.com/c/en/us/products/collateral/wireless/catalyst-9800-series-wireless-controllers/guide-c07-743627.html>

Configuring DHCP Option 82 Global Interface

Configuring DHCP Option 82 Globally Through Server Override (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ip dhcp-relay information option server-override Example: Device(config)# <code>ip dhcp-relay information option server-override</code>	Inserts global server override and link selection suboptions.

Configuring DHCP Option 82 Through Server Override (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ip dhcp compatibility suboption server-override [cisco standard] Example: Device(config)# <code>ip dhcp compatibility suboption server-override cisco</code>	Configures the server override suboption to an RFC or Cisco specific value.
Step 3	ip dhcp compatibility suboption link-selection [cisco standard] Example: Device(config)# <code>ip dhcp compatibility suboption link-selection cisco</code>	Configures the link-selection suboption to an RFC or Cisco specific value.

Configuring DHCP Option 82 Globally Through Different SVIs (GUI)

Procedure

-
- Step 1** Choose **Configuration > VLAN**.
- Step 2** Choose a VLAN from the drop-down list.
The **Edit SVI** window appears.
- Step 3** Click the **Advanced** tab.
- Step 4** Choose an option from the **IPv4 Inbound ACL** drop-down list.
- Step 5** Choose an option from the **IPv4 Outbound ACL** drop-down list.
- Step 6** Choose an option from the **IPv6 Inbound ACL** drop-down list.
- Step 7** Choose an option from the **IPv6 Outbound ACL** drop-down list.
- Step 8** Enter an IP address in the **IPv4 Helper Address** field.
- Step 9** Set the status to **Enabled** if you want to enable the **Relay Information Option** setting.
- Step 10** Enter the **Subscriber ID**.
- Step 11** Set the status to **Enabled** if you want to enable the **Server ID Override** setting.
- Step 12** Set the status to **Enabled** if you want to enable the **Option Insert** setting.
- Step 13** Choose an option from the **Source-Interface Vlan** drop-down list.
- Step 14** Click **Update & Apply to Device**.
-

Configuring DHCP Option 82 Globally Through Different SVIs (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ip dhcp-relay source-interface vlan <i>vlan-id</i> Example: Device(config)# <code>ip dhcp-relay source-interface vlan 74</code>	Sets global source interface for relayed messages.

Configuring DHCP Option 82 Format

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>policy-name</i> Example: Device (config) # wireless profile policy pp3	Enables configuration for the specified profile policy.
Step 3	shutdown Example: Device (config-wireless-policy) # shutdown	Shuts down the profile policy.
Step 4	vlan <i>vlan-name</i> Example: Device (config-wireless-policy) # vlan 72	Assigns the profile policy to a VLAN.
Step 5	session-timeout <i>value-btwn-20-86400</i> Example: Device (config-wireless-policy) # session-timeout 300	(Optional) Sets the session timeout value in seconds. The range is between 20-86400.
Step 6	idle-timeout <i>value-btwn-15-100000</i> Example: Device (config-wireless-policy) # idle-timeout 15	(Optional) Sets the idle timeout value in seconds. The range is between 15-100000.
Step 7	central switching Example: Device (config-wireless-policy) # central switching	Enables central switching.
Step 8	ipv4 dhcp opt82 Example: Device (config-wireless-policy) # ipv4 dhcp opt82	Enables DHCP Option 82 for the wireless clients.
Step 9	ipv4 dhcp opt82 ascii Example:	(Optional) Enables ASCII on the DHCP Option 82 feature.

	Command or Action	Purpose
	Device(config-wireless-policy)# ipv4 dhcp opt82 ascii	
Step 10	ipv4 dhcp opt82 rid Example: Device(config-wireless-policy)# ipv4 dhcp opt82 rid	(Optional) Supports the addition of Cisco 2 byte Remote ID (RID) for the DHCP Option 82 feature.
Step 11	ipv4 dhcp opt82 format {ap-dmac ap-hcafn apmac apname policy eg sid vlan-id} Example: Device(config-wireless-policy)# ipv4 dhcp opt82 format apmac	Enables DHCP Option 82 on the corresponding AP. For information on the various options available with the command, see Cisco Catalyst 9800 Series Wireless Controller Command Reference .
Step 12	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables the profile policy.

Configuring DHCP Option82 Through a VLAN Interface

Configuring DHCP Option 82 Through Option-Insert Command (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface vlan <i>vlan-id</i> Example: Device(config)# interface vlan 72	Configures a VLAN ID.
Step 3	ip dhcp relay information option-insert Example: Device(config-if)# ip dhcp relay information option-insert	Inserts relay information in BOOTREQUEST.
Step 4	ip address <i>ip-address</i> Example:	Configures the IP address for the interface.

	Command or Action	Purpose
	Device(config-if)# ip address 9.3.72.38 255.255.255.0	
Step 5	ip helper-address <i>ip-address</i> Example: Device(config-if)# ip helper-address 9.3.72.1	Configures the destination address for UDP broadcasts.
Step 6	[no] mop enabled Example: Device(config-if)# no mop enabled	Disables the MOP for an interface.
Step 7	[no] mop sysid Example: Device(config-apgroup)# [no] mop sysid	Disables the task of sending MOP periodic system ID messages.

Configuring DHCP Option 82 Through the server-ID-override Command (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ip dhcp compatibility suboption server-override cisco Example: Device(config)# ip dhcp compatibility suboption server-override cisco	Configures the server-id override suboption to an RFC or Cisco specific value.
Step 3	ip dhcp compatibility suboption link-selection cisco Example: Device(config)# ip dhcp compatibility suboption link-selection cisco	Configures the link-selection suboption to an RFC or Cisco specific value.
Step 4	interface vlan <i>vlan-id</i> Example: Device(config)# interface vlan 72	Configures a VLAN ID.
Step 5	ip dhcp relay information option server-id-override Example:	Inserts the server id override and link selection suboptions.

	Command or Action	Purpose
	Device(config-if)# ip dhcp relay information option server-id-override	
Step 6	ip address <i>ip-address</i> Example: Device(config-if)# ip address 9.3.72.38 255.255.255.0	Configures the IP address for the interface.
Step 7	ip helper-address <i>ip-address</i> Example: Device(config-if)# ip helper-address 9.3.72.1	Configures the destination address for UDP broadcasts.
Step 8	[no] mop enabled Example: Device(config-if)# no mop enabled	Disables MOP for an interface.
Step 9	[no] mop sysid Example: Device(config-if)# [no] mop sysid	Disables the task of sending MOP periodic system ID messages.

Configuring DHCP Option 82 Through a Subscriber-ID (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface vlan <i>vlan-id</i> Example: Device(config)# interface vlan 72	Configures a VLAN ID.
Step 3	ip dhcp relay information option subscriber-id <i>subscriber-id</i> Example: Device(config-if)# ip dhcp relay information option subscriber-id test10	Inserts the subscriber identifier suboption.
Step 4	ip address <i>ip-address</i> Example:	Configures the IP address for the interface.

	Command or Action	Purpose
	Device(config-if)# ip address 9.3.72.38 255.255.255.0	
Step 5	ip helper-address <i>ip-address</i> Example: Device(config-if)# ip helper-address 9.3.72.1	Configures the destination address for UDP broadcasts.
Step 6	[no] mop enabled Example: Device(config-if)# no mop enabled	Disables MOP for an interface.
Step 7	[no] mop sysid Example: Device(config-apgroup)# [no] mop sysid	Disables the task of sending MOP periodic system ID messages.

Configuring DHCP Option 82 Through server-ID-override and subscriber-ID Commands (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface vlan <i>vlan-id</i> Example: Device(config)# interface vlan 72	Configures a VLAN ID.
Step 3	ip dhcp relay information option server-id-override Example: Device(config-if)# ip dhcp relay information option server-id-override	Inserts server ID override and link selection suboptions.
Step 4	ip dhcp relay information option subscriber-id <i>subscriber-id</i> Example: Device(config-if)# ip dhcp relay information option subscriber-id test10	Inserts the subscriber identifier suboption.

	Command or Action	Purpose
Step 5	ip address <i>ip-address</i> Example: Device(config-if)# ip address 9.3.72.38 255.255.255.0	Configures the IP address for the interface.
Step 6	ip helper-address <i>ip-address</i> Example: Device(config-if)# ip helper-address 9.3.72.1	Configures the destination address for UDP broadcasts.
Step 7	[no] mop enabled Example: Device(config-if)# no mop enabled	Disables the MOP for an interface.
Step 8	[no] mop sysid Example: Device(config-apgroup)# [no] mop sysid	Disables the task of sending MOP periodic system ID messages.

Configuring DHCP Option 82 Through Different SVIs (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	interface vlan <i>vlan-id</i> Example: Device(config)# interface vlan 72	Configures a VLAN ID.
Step 3	ip dhcp relay source-interface vlan <i>vlan-id</i> Example: Device(config-if)# ip dhcp relay source-interface vlan 74	Configures a source interface for relayed messages on a VLAN ID.
Step 4	ip address <i>ip-address</i> Example: Device(config-if)# ip address 9.3.72.38 255.255.255.0	Configures the IP address for the interface.

	Command or Action	Purpose
Step 5	ip helper-address <i>ip-address</i> Example: Device(config-if)# ip helper-address 9.3.72.1	Configure the destination address for UDP broadcasts.
Step 6	[no] mop enabled Example: Device(config-if)# no mop enabled	Disables the MOP for an interface.
Step 7	[no] mop sysid Example: Device(config-apgroup)# [no] mop sysid	Disables the task of sending MOP periodic system ID messages.

Information About AP DHCP Option 82 Support on FlexConnect Local Switching Mode

The DHCP Option 82 provides additional information on the physical attachment of the client. It enhances security while using DHCP for network address allocation.

The AP DHCP Option82 Support on FlexConnect Local Switching Mode feature enables the AP to act as a DHCP relay agent to prevent DHCP client requests from unreliable sources. As a DHCP relay agent, the AP can add DHCP Option 82 information such as AP MAC, AP Name, and SSID to DHCP requests from clients before forwarding the requests to the DHCP server. Afterward, the DHCP servers can allocate IP addresses to wireless clients based on the data contained within DHCP Option 82.

This feature is supported only in FlexConnect Local Switching mode.

Configuring AP DHCP Option82 Support

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless profile policy <i>policy-name</i> Example: Device(config)# <code>wireless profile policy</code> <code>policy-ap</code>	Enables configuration for the specified profile policy.

	Command or Action	Purpose
Step 3	shutdown Example: Device(config-wireless-policy)# shutdown	Shuts down the profile policy.
Step 4	ipv4 dhcp opt82 format { apmac apname } Example: Device(config-wireless-policy)# ipv4 dhcp opt82 format apmac	Configures the AP MAC address or the AP name format to be added to DHCP requests from clients before forwarding them to the DHCP server. You can use either apmac or apname , but not both.
Step 5	ipv4 dhcp opt82 format ssid Example: Device(config-wireless-policy)# ipv4 dhcp opt82 format ssid	Configures the unique SSID format to be added to DHCP requests from clients before forwarding them to the DHCP server.
Step 6	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables the profile policy.

Verifying AP DHCP Option82 Support

To verify the configured parameters for DHCP Option82, use the following command on the AP console:

Note You can fetch information about the WLAN and WLAN ID using the **show flexconnect wlan** command.

```
Device# show flexconnect dhcp option-82 wlan 1
```

```
DHCP OPTION 82 CONFIG FOR WLAN:
VAP ID      :0
Format      :Binary
Delimiter   :":"
Circuit-ID  :
Remote-ID   :
  AP Name
  SSID-Name
```

To verify whether DHCP Option82 is enabled on the controller, use the following command:

```
Device# show wireless profile policy detailed
```

```
Opt82
  SSID                : ENABLED
  AP_ETHMAC           : DISABLED
  APNAME              : ENABLED
```

CHAPTER 47

RADIUS Realm

- [Information About RADIUS Realm, on page 671](#)
- [Enabling RADIUS Realm, on page 672](#)
- [Configuring Realm to Match the RADIUS Server for Authentication and Accounting, on page 672](#)
- [Configuring the AAA Policy for a WLAN, on page 673](#)
- [Verifying the RADIUS-Realm Configuration, on page 675](#)

Information About RADIUS Realm

The RADIUS Realm feature is associated with the domain of the user. Using this feature, a client can choose the RADIUS server through which authentication and accounting is to be processed.

When mobile clients are associated with a WLAN, RADIUS realm is received as a part of Extensible Authentication Protocol Method for UMTS Authentication and Key Agreement (EAP-AKA) identity response request in the authentication request packet. The Network Access Identifier (NAI) format (EAP-AKA) for WLAN can be specified as *username@domain.com*. The realm in the NAI format is represented after the @ symbol, which is specified as domain.com. If vendor-specific attributes are added as *test*, the NAI format is represented as *test@domain.com*.

The RADIUS Realm feature can be enabled and disabled on a WLAN. If Realm is enabled on a WLAN, the corresponding user should send the username in the NAI format. The controller sends the authentication request to the AAA server only when the realm, which is in the NAI format and is received from the client, is compiled as per the given standards. Apart from authentication, accounting requests are also required to be sent to the AAA server based on realm filtering.

Realm Support on a WLAN

Each WLAN is configured to support NAI realms. After the realm is enabled on a particular SSID, the lookup is done to match the realms received in the EAP identity response against the configured realms on the RADIUS server. If the client does not send a username with the realm, the default RADIUS server that is configured on the WLAN is used for authentication. If the realm that is received from the client does not match the configured realms on the WLAN, the client is deauthenticated and dropped.

If the RADIUS Realm feature is not enabled on a WLAN, the username that is received as part of the EAP identity request is directly used as the username and the configured RADIUS server is used for authentication and accounting. By default, the RADIUS Realm feature is disabled on WLANs.

- **Realm Match for Authentication:** In dot1x with EAP methods (similar to EAP AKA), the username is received as part of an EAP identity response. A realm is derived from the username and are matched

with the realms that are already configured in the corresponding RADIUS authentication server. If there is a match, the authentication requests are forwarded to the RADIUS server. If there is a mismatch, the client is deauthenticated.

- **Realm Match for Accounting:** A client's username is received through an access-accept message. When accounting messages are triggered, the realm is derived from the corresponding client's username and compared with the accounting realms configured on the RADIUS accounting server. If there is a match, accounting requests are forwarded to the RADIUS server. If there is a mismatch, accounting requests are dropped.

Enabling RADIUS Realm

Follow the procedure given below to enable RADIUS realm:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless aaa policy <i>aaa-policy</i> Example: Device(config)# wireless aaa policy policy-1	Creates a new AAA policy.
Step 3	aaa-realm enable Example: Device(config-aaa-policy)# aaa-realm enable	Enables AAA RADIUS realm selection. Note Use the no aaa-realm enable or the default aaa-realm enable command to disable the RADIUS realm.

Configuring Realm to Match the RADIUS Server for Authentication and Accounting

Follow the procedure given below to configure the realm to match the RADIUS server for authentication and accounting:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Device# configure terminal	
Step 2	aaa new-model Example: Device(config)# aaa new-model	Creates a AAA authentication model.
Step 3	aaa authorization network default group <i>radius-server-group</i> Example: Device(config)# aaa authorization network default group aaa_group_name	Sets the authorization method.
Step 4	aaa authentication dot1x realm group <i>radius-server-group</i> Example: Device(config)# aaa authentication dot1x cisco.com group cisco1	Indicates that dot1x must use the realm group RADIUS server.
Step 5	aaa authentication login realm group <i>radius-server-group</i> Example: Device(config)# aaa authentication login cisco.com group cisco1	Defines the authentication method at login.
Step 6	aaa accounting identity realm start-stop group <i>radius-server-group</i> Example: Device(config)# aaa accounting identity cisco.com start-stop group cisco1	Enables accounting to send a start-record accounting notice when a client is authorized, and a stop-record at the end.

Configuring the AAA Policy for a WLAN

Follow the procedure given below to configure the AAA policy for a WLAN:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless aaa policy <i>aaa-policy-name</i> Example: Device(config)# wireless aaa policy aaa-policy-1	Creates a new AAA policy for wireless.

	Command or Action	Purpose
Step 3	aaa-realm enable Example: Device(config-aaa-policy)# aaa-realm enable	Enables AAA RADIUS server selection by realm.
Step 4	exit Example: Device(config-aaa-policy)# exit	Returns to global configuration mode.
Step 5	wireless profile policy wlan-policy-profile Example: Device(config)# wireless profile policy wlan-policy-a	Configures a WLAN policy profile.
Step 6	aaa-policy aaa-policy Example: Device(config-wireless-policy)# aaa-policy aaa-policy-1	Maps the AAA policy.
Step 7	accounting-list acct-config-realm Example: Device(config-wireless-policy)# accounting-list cisco.com	Sets the accounting list.
Step 8	exit Example: Device(config-wireless-policy)# exit	Returns to global configuration mode.
Step 9	wlan wlan-name wlan-id ssid Example: Device(config)# wlan wlan2 14 wlan-aaa	Configures a WLAN.
Step 10	security dot1x authentication-list auth-list-realm Example: Device(config-wlan)# security dot1x authentication-list cisco.com	Enables the security authentication list for IEEE 802.1x.
Step 11	exit Example: Device(config-wireless-policy)# exit	Returns to global configuration mode.
Step 12	wireless tag policy policy Example: Device(config)# wireless tag policy tag-policy-1	Configures a policy tag.

	Command or Action	Purpose
Step 13	wlan wlan-name policy policy-profile Example: Device(config-policy-tag)# wlan Abc-wlan policy wlan-policy-a	Maps a policy profile to the WLAN.
Step 14	exit Example: Device(config-policy-tag)# exit	Returns to global configuration mode.

Verifying the RADIUS-Realm Configuration

Use the following command to verify the RADIUS-realm configuration:

```
Device# show wireless client mac-address 14bd.61f3.6a24 detail
```

```
Client MAC Address : 14bd.61f3.6a24
Client IPv4 Address : 9.4.113.103
Client IPv6 Addresses : fe80::286e:9fe0:7fa6:8f4
Client Username : sacthoma@cisco.com
AP MAC Address : 4c77.6d79.5a00
AP Name: AP4c77.6d53.20ec

CHAPTER 48

RADIUS Accounting

- [Information About RADIUS Accounting of AP Events, on page 677](#)
- [Configuring Accounting Method-List for an AP Profile, on page 677](#)
- [Verifying the AP Accounting Information, on page 678](#)
- [AAA Accounting, on page 678](#)
- [Feature History for Device Ecosystem Data, on page 679](#)
- [Information About Device Ecosystem Data, on page 680](#)
- [Enable Device Ecosystem Data, on page 680](#)
- [Verify Device Ecosystem Data, on page 681](#)

Information About RADIUS Accounting of AP Events

This topic describes the configuration of a RADIUS server to monitor a network with regards to Access Points (APs). Prior to Cisco IOS XE Amsterdam 17.1.1 release, during times of network issues, the controller would not send accounting messages when APs join and disjoin from the controller. From Cisco IOS XE Amsterdam 17.1.1 release onwards, the RADIUS server keeps a record of all the APs that were down and have come up.

Configuring Accounting Method-List for an AP Profile

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device#configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile-name</i> Example: Device(config)# ap profile <i>ap-profile-name</i>	Configures the AP profile. The default AP join profile name is <i>default-ap-profile</i> .
Step 3	[no] accounting method-list <i>method-list-name</i> Example:	Configures the accounting method list for the AP profile.

	Command or Action	Purpose
	Device(config-ap-profile)# [no] accounting method-list <i>method-list-name</i>	Use the no form of this command to disable the command.

Verifying the AP Accounting Information

To verify the AP accounting information, use the following command:

```
Device#show wireless stats ap accounting
Base MAC          Total packet Send   Total packet Received Methodlist
-----
00b0.e192.0f20    4           3           abc
38ed.18cc.5788    8           8           ML_M
70ea.1ae0.af08    0           0           ML_A
```

To view the details of a method list that is configured for an AP profile, use the following command:

```
Device#show ap profile name Method-list detailed
AP Profile Name      : test-profile
Description          :
.
.
.
Method-list name     : Method-list
Packet Sequence Jump DELBA : ENABLED
Lag status           : DISABLED
.
Client RSSI Statistics
  Reporting           : ENABLED
  Reporting Interval  : 30 seconds
```

AAA Accounting

Configuring AAA Accounting Using Default Method List (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	aaa accounting commands <i>privilege_level</i> default start-stop group <i>group-name</i> Example: Device(config)# aaa accounting commands 15 default start-stop group group-name	Creates an accounting method list and enables accounting. <ul style="list-style-type: none"> • <i>privilege_level</i>: AAA accounting level. The valid range is from 0 to 15. • <i>group-name</i>: AAA accounting group that supports only TACACS+ group.

	Command or Action	Purpose
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.

Configuring HTTP Command Accounting Using Named Method List (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ip http accounting commands level <i>named-accounting-method-list</i> Example: Device(config)# ip http accounting commands 1 oneacct	Configures HTTP command accounting using the named method list. <ul style="list-style-type: none"> • <i>level</i>: Privilege value from 0 to 15. By default, the following command privilege levels are available on the controller: <ul style="list-style-type: none"> • 0: Includes the disable, enable, exit, help, and logout commands. • 1: Includes all the user-level commands at the controller prompt (>). • 15: Includes all the enable-level commands at the controller prompt (>). • <i>named-accounting-method-list</i>: Name of the predefined command accounting method list.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.

Feature History for Device Ecosystem Data

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 54: Feature History for Device Ecosystem Data

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.10.1	Device Ecosystem Data	This feature sends device analytics data in the RADIUS accounting request to Cisco ISE to profile the endpoints.

Information About Device Ecosystem Data

Edge analytics is the process of collecting, processing, and analyzing data from devices in a network. The controller learns about endpoint attributes, such as model number, operating system version, and other information from a set of endpoints using device analytics. The device analytics data is further shared with Cisco Identity Services Engine (ISE) to profile the endpoints. This information sharing is in addition to the DHCP and HTTP attributes already being shared with Cisco ISE using RADIUS accounting messages.

Enable Device Ecosystem Data

Note Before proceeding with the configuration, ensure that device classifier and accounting features are enabled.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>policy-profile-name</i> Example: Device(config)# wireless profile policy default-policy-profile	Configures a wireless policy profile.
Step 3	shutdown Example: Device(config-wireless-policy)# shutdown	Disables the wireless policy profile.
Step 4	radius-profiling Example: Device(config-wireless-policy)# radius-profiling	Configures client radius profiling.
Step 5	dot11-tlv-accounting Example:	Configures the controller to send device analytics data that is found in the RADIUS

	Command or Action	Purpose
	Device(config-wireless-policy) # dot11-tlv-accounting	accounting request to Cisco ISE in order to profile the endpoints. The no form of this command disables the feature.
Step 6	no shutdown Example: Device(config-wireless-policy) # no shutdown	Enables the wireless policy profile.
Step 7	end Example: Device(config-wireless-policy) # end	Returns to privileged EXEC mode.

Verify Device Ecosystem Data

Use the following command to verify device ecosystem data in RADIUS accounting configuration:

```
Device# show wireless profile policy detailed <name>
```

```
.
.
.
WLAN Local Profiling
  Subscriber Policy Name      : Not Configured
  RADIUS Profiling           : ENABLED
  HTTP TLV caching           : DISABLED
  DHCP TLV caching           : DISABLED
  DOT11 TLV accounting        : ENABLED
.
.
.
```

CHAPTER 49

RADIUS Call Station Identifier

- [RADIUS Call Station Identifier, on page 683](#)
- [Configuring a RADIUS Call Station Identifier, on page 684](#)

RADIUS Call Station Identifier

The RADIUS called station identifier attribute allows a Network Access Server (NAS) to capture the Access-Request packet used by a phone number by means of Dialed Number Identification (DNIS) or similar technology. The IEEE 802.1X authenticators can use this attribute to store the bridge or Access Point MAC address in ASCII format.

The called station identifier allows a RADIUS server to specify the MAC addresses or networks that a client can connect. One such attribute can be added in the Access-Request packet. The called station identifier is useful in scenarios where preauthentication is supported. In such instances, the called station identifier enables the RADIUS server to restrict the networks and attachment points the client can connect.

Note The called station identifier attribute is applicable only for Access-Request and not for Access-Accept or CoA-Request.

In Cisco IOS XE Bengaluru 17.4.1, the RADIUS called station identifier configuration is enhanced to include more attributes. The newly added options for authentication and accounting are listed below:

- policy-tag-name
- flex-profile-name
- ap-macaddress-ssid-flexprofilename
- ap-macaddress-ssid-policytagname
- ap-macaddress-ssid-sitetagname
- ap-ethmac-ssid-flexprofilename
- ap-ethmac-ssid-policytagname
- ap-ethmac-ssid-sitetagname

For more information on the attributes listed above, see the following commands:

- radius-server attribute wireless accounting call-station-id
- radius-server attribute wireless authentication call-station-id

Configuring a RADIUS Call Station Identifier

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	radius-server attribute wireless authentication call-station-id policy-tag-name Example: Device(config)# radius-server attribute wireless authentication call-station-id policy-tag-name	Configures a call station identifier sent in the RADIUS authentication messages.
Step 3	radius-server attribute wireless accounting call-station-id policy-tag-name Example: Device(config)# radius-server attribute wireless accounting call-station-id policy-tag-name	Configures a call station identifier sent in the RADIUS accounting messages.

CHAPTER 50

RADIUS VSA

- [Information About RADIUS VSA, on page 685](#)
- [Create an Attribute List, on page 686](#)
- [Create a AAA Policy and Map it to Attribute List, on page 687](#)
- [Map a AAA Policy to the WLAN Policy Profile, on page 688](#)
- [Map the WLAN Policy Profile to a WLAN, on page 689](#)

Information About RADIUS VSA

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the network access server and the RADIUS server by using vendor specific attributes (VSA). VSA allow vendors to support their own extended attributes otherwise not suitable for general use. The controller uses these attributes value in authentication or accounting packets, or both based on specified usage format.

VSA contains these three elements:

- Type
- Length
- String (also known as data)
 - Vendor-ID
 - Vendor-Type
 - Vendor-Length
 - Vendor-Data

This feature is supported only in FlexConnect central authentication mode with local switching. FlexConnect local authentication mode is not supported.

This feature is supported only for wireless sessions.

This feature supports the following set of VSAs per WLAN for authentication and accounting requests, in addition to the existing AAA attributes.

Table 55: Newly Supported Attributes

Attribute Name	Well-known Attribute	VSA Sub-attribute	Vendor ID
SVR-Zip-Code	26	14	14369
SVR-Device-Type	26	17	14369
SVR-Device-Model-Number	26	18	14369
SVR-Lat-Long	26	19	14369
SVR-Venue-Category	26	20	14369
SVR-Network-Type	26	21	14369
Aggregation-AAA	26	22	14369
BW-Venue-Id	26	7	22472
BW-Venue-TZ	26	8	22472
BW-Class	26	10	22472
BW-Venue-Description	26	11	22472
BW-ISO-Country-Code	26	14	22472
BW-E164-Country-Code	26	15	22472
BW-State-Name	26	16	22472
BW-City-Name	26	17	22472
BW-Area-Code	26	18	22472
BW-User-Group	26	27	22472
BW-Venue-Name	26	29	22472
BW-Operator-Name	26	37	22472

Create an Attribute List

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	aaa attribute list <i>list</i> Example: Device(config)# aaa attribute list TEST	Creates a AAA attribute list.
Step 3	attribute type <i>attribute-type</i> Example: Device(config-attr-list)# attribute type BW-City-Name "MUMBAI"	Specifies a AAA attribute type.
Step 4	attribute type <i>attribute-type</i> Example: Device(config-attr-list)# attribute type BW-State-Name "MAHARASHTRA"	(Optional) Specifies a AAA attribute type.
Step 5	attribute type <i>attribute-type</i> Example: Device(config-attr-list)#attribute type BW-Venue-Name "WANKHEDE"	(Optional) Specifies a AAA attribute type.
Step 6	end Example: Device(config-attr-list)# end	Returns to Privileged EXEC mode.

What to do next

Create a AAA policy and map the attribute list.

Create a AAA Policy and Map it to Attribute List

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless aaa policy <i>aaa-policy</i> Example: Device(config)# wireless aaa policy policy-1	Creates a new AAA policy.
Step 3	attrlist authentication <i>authentication-attr-list</i> Example:	Configures VSA authentication attribute list.

	Command or Action	Purpose
	Device(config-aaa-policy)# attrlist authentication auth-attr-list	
Step 4	attrlist accounting <i>accounting-attr-list</i> Example: Device(config-aaa-policy)# attrlist accounting acct-attr-list	Configures VSA accounting attribute list.
Step 5	end Example: Device(config-aaa-policy)# end	Returns to Privileged EXEC mode.

What to do next

Map the AAA policy to the WLAN policy profile.

Map a AAA Policy to the WLAN Policy Profile

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy EAP-AKA	Creates a new wireless policy profile.
Step 3	aaa-policy <i>aaa-policy</i> Example: Device(config-wireless-policy)# aaa-policy Verizon-aaa-policy	Creates a new AAA policy.
Step 4	end Example: Device(config-wireless-policy)# end	Returns to Privileged EXEC mode.

What to do next

Map the WLAN policy profile to a WLAN.

Map the WLAN Policy Profile to a WLAN

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag policy <i>policy-name</i> Example: Device(config)# wireless tag policy EAP-AKA	Creates a new policy tag.
Step 3	wlan <i>wlan-profile-name</i> policy <i>aaa-policy</i> Example: Device(config-policy-tag)# wlan EAP-AKA policy EAP-AKA	Maps the policy profile to a WLAN.
Step 4	end Example: Device(config-policy-tag)# end	Returns to Privileged EXEC mode.

CHAPTER 51

Cisco StadiumVision

- [Cisco StadiumVision Overview](#), on page 691
- [Configure Parameters for Cisco StadiumVision \(GUI\)](#), on page 692
- [Configure Parameters for Cisco StadiumVision \(CLI\)](#), on page 692
- [Verify StadiumVision Configurations](#), on page 693

Cisco StadiumVision Overview

Cisco StadiumVision solution is a proven, end-to-end, high-definition IPTV solution that provides advanced digital content management and delivery that can transform the look and feel of venues. It is built on top of the Cisco Connected Stadium solution and centrally-managed through the StadiumVision Director. Cisco StadiumVision solution enables the integration and automated delivery of customized and dynamic content from multiple sources to different areas of the stadium in high definition quality.

This technology allows you to replay certain exciting and critical moments of a game on Wi-Fi capable devices.

To enable Cisco StadiumVision solution on the controller , you need to configure these parameters:

1. On Wireless Controller :
 - Multicast Data Rate
 - RX Sensitivity SOP
 - Multicast Buffer
2. CAPWAP
3. AP Radio Driver and Firmware:
 - Multicast Data Rate
 - RX Sensitivity SOP
 - Multicast Buffer

Configure Parameters for Cisco StadiumVision (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Advanced**.
 - Step 2** Click the **High Density** tab.
 - Step 3** In the **Multicast Data Rate** section, set the data rate for 5 GHz radio or 2.4 GHz radio using the drop-down lists.
 - Step 4** Click **Apply** .
-

Configure Parameters for Cisco StadiumVision (CLI)

Note Multicast buffer and data rate configurations are supported for all AP models.

Procedure

	Command or Action	Purpose
Step 1	wlan <i>wlan-name wlan-id</i> Example: Device(config)# wlan wlan1 10	Configures a WLAN.
Step 2	multicast buffer <i>multicast-buffer-number</i> Example: Device(config-wlan)# multicast buffer 45	Configures enhanced multicast buffer size between 30 (default) and 60 on a WLAN. Note You can enable only two out of the possible 512 WLANs configured on Controller embedded wireless controller for enhanced multicast buffers.
Step 3	ap dot11 [5ghz 24ghz] multicast data-rate rate Example: Device(config)# ap dot11 [5ghz 24ghz] rx-sop threshold custom -70	Configures the radio receive sensitivity SOP threshold between -60 to -85 dB, which can also be configured as predefined auto, low, high, medium values specific to 5ghz or 24ghz bands. By default, the configuration is disabled and it's value is set to <i>auto</i> . If the RxSOP value of <i>auto</i> (0) is pushed, then the AP considers the value burnt-in during manufacturing.

Verify StadiumVision Configurations

- **show ap rf-profile name *rf-name* detail**
- **show ap dot11 5ghz high-density**

Rx SOP

```
Device#show ap rf-profile name Typical_Client_Density_rf_5gh detail | i SOP
Rx SOP Threshold           : auto
```

Multicast Buffer

```
Device#show wlan id 1 | sec Buffer
Multicast Buffer           : Enabled
Multicast Buffer Size      : 45
```

CHAPTER 52

Persistent SSID Broadcast

- [Persistent SSID Broadcast, on page 695](#)
- [Configuring Persistent SSID Broadcast, on page 695](#)
- [Verifying Persistent SSID Broadcast, on page 696](#)

Persistent SSID Broadcast

Access Points within a mesh network work as Root Access Points (RAP) or Mesh Access Points (MAP). RAPs have wired connection to the controller and MAPs have wireless connection to the controller. This feature is applicable only to the Cisco Aironet 1542 Access Points in the Flex+Bridge mode.

This feature is about the Root Access Points (RAPs) and Mesh Access Points (MAPs) broadcasting the SSID even when the WAN connectivity is down. This is required in order to isolate the responsibility; whether the fault is with backhaul or with the access wireless network, since there can be different operators owning each part of the network.

RAPs and MAPs broadcast SSID while in standalone mode, as long as the default gateway is reachable.

Also refer [Mesh Deployment Guide for Cisco Catalyst 9800 Series Wireless Controllers](#).

Configuring Persistent SSID Broadcast

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile-name</i> Example: Device(config)# ap profile ap-profile-name	Configures the AP profile.

	Command or Action	Purpose
Step 3	<p>[no]ssid broadcast persistent</p> <p>Example:</p> <pre>Device(config-ap-profile)# [no] ssid broadcast persistent</pre>	<p>The ssid broadcast command configures the SSID broadcast mode. The persistent keyword enables a persistent SSID broadcast, where the associated APs will re-join. Use the [no] form of the command to disable the feature.</p> <p>Note Enabling or disabling this feature causes the AP to re-join.</p>

Verifying Persistent SSID Broadcast

To view the configuration of all Cisco APs, use the following **show** command:

```
Device#show ap config general
Cisco AP Name   : AP4C77.6DF2.D598
=====
Office Extend Mode           : Disabled
Persistent SSID Broadcast   : Enabled
Remote AP Debug              : Disabled
```

CHAPTER 53

Network Monitoring

- [Network Monitoring](#) , on page 697
- [Status Information Received Synchronously - Configuration Examples](#), on page 697
- [Alarm and Event Information Received Asynchronously - Configuration Examples](#), on page 699

Network Monitoring

The mechanism that is used to transfer data to the third-party system is NETCONF/YANG. YANG can be used with the Network Configuration Protocol (NETCONF) to provide the desired solution of automated and programmable network operations.

You can contact the API or Developer Support for NETCONF/YANG features using the following link:

<https://developer.cisco.com/site/support/#>

The two types of information provided are:

- Status information received synchronously - NETCONF is the management interface used for status information, which allows to publish the operational state of the device, including the controller .
- Alarm and event information sent asynchronously - NETCONF/YANG push is the solution used for alarm and event information, which provides the mechanism to send NETCONF notifications subscribed for.

Status Information Received Synchronously - Configuration Examples

NETCONF/YANG interface is used to accomplish customer requests.

The prerequisite configuration for Status Information and Alarm and Event Information is to enable NETCONF server on the controller by using the following command:

netconf-yang

The above command not only enables notifications, but also allows for configuration and operation access (OAM) via Netconf/Yang. For more information on Netconf/Yang, see the *NETCONF Protocol* chapter of the Programmability Configuration Guide at: <https://www.cisco.com/c/en/us/support/ios-nx-os-software/ios-xe-17/products-installation-and-configuration-guides-list.html>

In the Status Information Received Synchronously type, the following information is exported through NETCONF:

- Name of the village
- APs in each village
- Status of each AP
- Number of clients currently connected and logged on in each village and each AP

All the data for the items listed above is already available as the controller operational data exported through NETCONF. The examples below explain where the data items listed are available.

The following command is used in the controller :

```
wireless tag site village_name_1
```

The site tags can be retrieved by NETCONF using the **get-config** operation.

Example output for **Name of the Village**:

```
<site-cfg-data xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-site-cfg">
[...]
```

```
<site-tag-configs>
  <site-tag-config>
    <site-tag-name>village_name_1</site-tag-name>
    <description>custom user site tag for a village</description>
  </site-tag-config>
[...]
```

```
</site-tag-configs>
```

The controller's operational data contains all the connected (joined) APs and lists their site tags. The example output displays the detailed information about the APs and the site tags. The following example displays the relevant fields and the corresponding controller show commands:

Example output of **Access Point per Village**:

```
<data>
  <access-point-oper-data
xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-access-point-oper">
  [...]
    <radio-oper-data>
      <wtp-mac>00:1b:0c:00:02:00</wtp-mac> #show ap dot11 {24ghz|5ghz} summary "MAC
Address"
      <radio-slot-id>0</radio-slot-id> #show ap dot11 {24ghz|5ghz} summary "Slot"
      <ap-mac>00:1b:0c:00:02:00</ap-mac>
      <slot-id>0</slot-id>
      <radio-type>1</radio-type> # 1 - 2.4GHz, 2 - 5GHz
      <admin-state>enabled</admin-state> #show ap dot11 {24ghz|5ghz} summary "Admin
State"
      <oper-state>radio-up</oper-state> #show ap dot11 {24ghz|5ghz} summary "Oper
State"
    [...]
  [...]
    <capwap-data>
      <wtp-mac>00:1b:0c:00:02:00</wtp-mac> #show ap summary "Radio MAC"
      <ap-operation-state>registered</ap-operation-state> #show ap summary "State"
      <ip-addr>10.102.140.10</ip-addr> #show ap summary "IP Address"
    [...]
      <admin-state>1</admin-state> #show ap status "Status", 1 - Enabled,
2 - Disabled
      <location>default-location </location> #show ap summary "Location"
      <country-code>CH </country-code>
```

```

        <name>AP_A-1</name>                                #show ap summary "AP Name"
[... ]
    <tag-info>
        [...]
        <site-tag>
            <site-tag-name>village_name_1</site-tag-name> #show ap name AP_A-1 config general
"Site Tag Name"
            [...]
        </site-tag>
[... ]

```

The operational data of the controller contains all the connected wireless clients information, which includes detailed client device information, such as the MAC address, IP address, State and the AP name.

Example output of the **Number of clients currently online and logged in each village and each AP:**

```

<data>
  <client-oper-data xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-client-oper">
    <common-oper-data>
      <client-mac>00:00:1a:04:00:02</client-mac>      #show wireless client summary "MAC
Address"
      <ap-name>AP_A-1</ap-name>                      #show wireless client summary "AP
Name"
      [...]
      <co-state>client-status-run</co-state>          #show wireless client summary "State"

```

Alarm and Event Information Received Asynchronously - Configuration Examples

The push functionality for the alarm and event information is fulfilled with on-change notifications through NETCONF dynamic subscriptions, with XML encoding.

Example output of **AP Up/Down Events - Subscription**

Request:

```

<?xml version="1.0" encoding="UTF-8"?>

CHAPTER 54

Creating a Lobby Ambassador Account

- [Information About Lobby Ambassador Account, on page 701](#)
- [Creating a Lobby Ambassador User Account \(GUI\), on page 701](#)
- [Creating a Lobby Ambassador Account \(CLI\), on page 703](#)

Information About Lobby Ambassador Account

A global administrator can create a lobby ambassador (lobby admin) user for creating guest users.

While creating a guest user, a lobby ambassador can create and delete a guest user, besides setting the following parameters for a guest user:

- Password
- Lifetime of the guest user
- Guest role profiles (Quality-of-Service profiles that should be applied on a guest using the AAA attribute list.

You must ensure that the RADIUS server must be configured with Cisco-AV-pair privilege level with a value greater than zero.

Note You can create a lobby admin from a RADIUS or TACACS server, instead of creating one locally.

Only the admin can create WLAN and web authentication policies. The admin can also create an AAA attribute list, which the lobby admin can use to map to the corresponding guest user.

After an upgrade to Cisco Catalyst 9800 Controller Software release 17.2.x , you must clear the browser cache data to view the lobby admin GUI correctly.

Creating a Lobby Ambassador User Account (GUI)

You can configure administrator or lobby ambassador usernames and passwords to prevent unauthorized users from reconfiguring the controller and viewing configuration information.

Creating a User Account

Procedure

- Step 1** From the home page, choose **Administration > User Administration**.
- Step 2** Click **Add**.
- Step 3** In the **User Name** field, enter a user name for the new account.
- Step 4** From the **Policy** drop-down list, choose the policy that you want to associate with the user.
- Step 5** From the **Privilege** drop-down list, choose the privilege level that you want to associate with the user by clicking the user privilege icon. The following are the options:

- **Go to Basic Mode**
- **Go to Advanced Mode**

Go to Basic Mode: This privilege level defines the commands that users can enter using the CLI after they have logged into the device. Privilege 1 allows access in user EXEC mode and privilege 15 allows access in Privileged EXEC mode.

Go to Advanced Mode:

Admin: Users with Privilege 15 can execute all the **show**, **config**, and **exec** commands on the device. These users will have access to all the sections of the GUI.

Read Only: Users with Privileges 1 to 14 are considered read-only users. The default privilege is 1 if a user is created using the GUI. These users will have access only to the Dashboard and the Monitoring sections.

No Access: Users with Privilege 0 can log in to the device through Telnet or SSH and access the CLI. However, they cannot access the GUI.

Lobby Admin: Users who can create only guest user accounts. While creating a guest user, a lobby ambassador can create and delete a guest user, besides setting the following parameters for a guest user:

- Password
- Lifetime of the guest user
- Guest role profiles (quality-of-service) profiles that should be applied on a guest using the AAA attribute list.

- Step 6** In the **Password** field, enter a password for the new account.
- Step 7** In the **Confirm Password** field, enter the same password again to reconfirm.
- Step 8** Click **Apply to Device**.
-

Logging In Using the Lobby Account

Note Execute the following commands before logging in using the lobby credentials:

```
aaa new-model
aaa authorization exec default local
ip http authentication aaa
```

Logout from the Administrator account and login using the lobby credentials.

You get to view the **Guest User** page.

Creating a Lobby Ambassador Account (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	user-name <i>user-name</i> Example: Device(config)# user-name example-user	Creates a user account.
Step 3	type lobby-admin Example: Device(config-user-name)# type lobby-admin	Specifies the account type as lobby admin.
Step 4	password 0 <i>password</i> Example: Device(config-user-name)# password 0 example-password	Creates a password for the lobby administrator account.
Step 5	aaa attribute list <i>user-name</i> Example: Device(config-user-name)# aaa attribute list example-user	Creates attribute list for lobby admin access.
Step 6	attribute type <i>wlan-profile-name</i> Example: Device(config-user-name)# attribute type wlan_wl_mab	Creates attribute type for lobby admin access.

	Command or Action	Purpose
Step 7	exit Example: <code>Device(config-user-name)# exit</code>	Returns to global configuration mode.

CHAPTER 55

Lobby Ambassador Account

Information About Lobby Ambassador Account

A global administrator can create a lobby ambassador (lobby admin) user for creating guest users.

While creating a guest user, a lobby ambassador can create and delete a guest user, besides setting the following parameters for a guest user:

- Password
- Lifetime of the guest user
- Guest role profiles (Quality-of-Service profiles that should be applied on a guest using the AAA attribute list).

You must ensure that the RADIUS server must be configured with Cisco-AV-pair privilege level with a value greater than zero.

Note You can create a lobby admin from a RADIUS or TACACS server, instead of creating one locally.

Only the admin can create WLAN and web authentication policies. The admin can also create an AAA attribute list, which the lobby admin can use to map to the corresponding guest user.

After an upgrade to Cisco Catalyst 9800 Controller Software release 17.2.x , you must clear the browser cache data to view the lobby admin GUI correctly.

Creating a Lobby Ambassador User Account (GUI)

You can configure administrator or lobby ambassador usernames and passwords to prevent unauthorized users from reconfiguring the controller and viewing configuration information.

Creating a User Account

Procedure

- Step 1** From the home page, choose **Administration > User Administration**.
- Step 2** Click **Add**.
- Step 3** In the **User Name** field, enter a user name for the new account.
- Step 4** From the **Policy** drop-down list, choose the policy that you want to associate with the user.
- Step 5** From the **Privilege** drop-down list, choose the privilege level that you want to associate with the user by clicking the user privilege icon. The following are the options:

- **Go to Basic Mode**
- **Go to Advanced Mode**

Go to Basic Mode: This privilege level defines the commands that users can enter using the CLI after they have logged into the device. Privilege 1 allows access in user EXEC mode and privilege 15 allows access in Privileged EXEC mode.

Go to Advanced Mode:

Admin: Users with Privilege 15 can execute all the **show**, **config**, and **exec** commands on the device. These users will have access to all the sections of the GUI.

Read Only: Users with Privileges 1 to 14 are considered read-only users. The default privilege is 1 if a user is created using the GUI. These users will have access only to the Dashboard and the Monitoring sections.

No Access: Users with Privilege 0 can log in to the device through Telnet or SSH and access the CLI. However, they cannot access the GUI.

Lobby Admin: Users who can create only guest user accounts. While creating a guest user, a lobby ambassador can create and delete a guest user, besides setting the following parameters for a guest user:

- Password
- Lifetime of the guest user
- Guest role profiles (quality-of-service) profiles that should be applied on a guest using the AAA attribute list.

- Step 6** In the **Password** field, enter a password for the new account.
- Step 7** In the **Confirm Password** field, enter the same password again to reconfirm.
- Step 8** Click **Apply to Device**.
-

Logging In Using the Lobby Account

Note Execute the following commands before logging in using the lobby credentials:

```
aaa new-model
aaa authorization exec default local
ip http authentication aaa
```

Logout from the Administrator account and login using the lobby credentials.

You get to view the **Guest User** page.

Creating a Lobby Ambassador Account (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	user-name <i>user-name</i> Example: Device(config)# user-name example-user	Creates a user account.
Step 3	type lobby-admin Example: Device(config-user-name)# type lobby-admin	Specifies the account type as lobby admin.
Step 4	password 0 <i>password</i> Example: Device(config-user-name)# password 0 example-password	Creates a password for the lobby administrator account.
Step 5	aaa attribute list <i>user-name</i> Example: Device(config-user-name)# aaa attribute list example-user	Creates attribute list for lobby admin access.
Step 6	attribute type <i>wlan-profile-name</i> Example: Device(config-user-name)# attribute type wlan_wl_mab	Creates attribute type for lobby admin access.

	Command or Action	Purpose
Step 7	exit Example: Device(config-user-name)# exit	Returns to global configuration mode.

Configuring WLAN (GUI)

Before you begin

You need to enable MAC filtering for Layer 2 authentication to download the redirect URL and ACL.

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > WLANs**.
- Step 2** In the **WLANs** window, click the name of the **WLAN** or click **Add** to create a new one.
- Step 3** In the **Add/Edit WLAN** window that is displayed, click the **General** tab to configure the following parameters.
- In the **Profile Name** field, enter or edit the name of the profile.
 - In the **SSID** field, enter or edit the SSID name.
The SSID name can be alphanumeric, and up to 32 characters in length.
 - In the **WLAN ID** field, enter or edit the ID number. The valid range is between 1 and 512.
 - From the **Radio Policy** drop-down list, choose the **802.11** radio band.
 - Using the **Broadcast SSID** toggle button, change the status to either **Enabled** or **Disabled**.
 - Using the **Status** toggle button, change the status to either **Enabled** or **Disabled**.
- Step 4** Click the **Security** tab, and then **Layer 2** tab to configure the following parameters:
- From the **Layer 2 Security Mode** drop-down list, choose **None**. This setting disables Layer 2 security.
 - Enter the **Reassociation Timeout** value, in seconds. This is the time after which a fast transition reassociation times out.
 - Check the **Over the DS** check box to enable Fast Transition over a distributed system.
 - Choose OWE, Opportunistic Wireless Encryption (OWE) provides data confidentiality with encryption over the air between an AP radio and a wireless client. OWE Transition Mode is meant to provide a sort of backwards compatibility.
 - Choose Fast Transition, 802.11r which is the IEEE standard for fast roaming, introduces a new concept of roaming where the initial handshake with a new AP is done even before the corresponding client roams to the target access point. This concept is called Fast Transition.
 - Check the check box to enable MAC filtering in the WLAN.
 - Check the **Lobby Admin Access** check box to enable Lobby Admin access.

Step 5 Click **Save & Apply to Device**.

Client Allowed List

Clients in universities and hotels need access to networks for a limited period of time. These locations also receive many guests with multiple devices. Therefore it becomes important to protect the networks from misuse or unauthorized access, and allow legitimate clients to connect to the corresponding network.

The client listing feature addresses the need of creating an allowed list for clients on a particular WLAN or SSID- based MAC address.

When you create a new client MAC address as an allowed list user with an invalid WLAN profile name, you must be careful while you map the client MAC to the WLAN profile.

Client allowed list is supported only with MAC addresses that are without a delimiter format.

Two types of administrator roles defined are:

- **Global Administrator:** Creates a lobby admin user on the controller and enables the lobby administrators access each to the WLAN.
- **Lobby Administrator:** Adds or deletes a client from the allowed list to manage the association to a WLAN or SSID through the GUI only. Existing lobby administrators can also be used to configure the allowed list.

Restrictions for Client Allowed List

A lobby admin can add clients to allowed list only through the graphical user interface (GUI) and not through the command-line interface (CLI).

Creating a Client Allowed List (GUI)

This section provides multiple methods that you can use as a lobby administrator to create an allowed list for valid users for a WLAN.

Adding Single MAC Address to Allowed List

Procedure

- Step 1** Log into Lobby Admin portal.
- Step 2** Click **Whitelist Users**.
- Step 3** From the drop-down list, choose **WLAN**.
- Step 4** Click **Add New Whitelist User**.
- Step 5** Select **By MAC Address** radio button.

- Step 6** Enter the **MAC address** and **Description**.
- Step 7** Click **Apply to Device**.
-

Adding Bulk MAC Address to Allowed List

Procedure

- Step 1** Log into Lobby Admin portal.
- Step 2** Click **Whitelist Users**.
- Step 3** From the drop-down list, choose the WLAN.
- Step 4** Click **Add New Whitelist User**.
- Step 5** Select **Bulk Import** radio button.
- Step 6** Select the CSV file that lists the clients in MAC Address, Description format.
- Step 7** Click **Apply to Device**.
-

Managing Guest Users

Procedure

- Step 1** Log in to Lobby Admin portal using the lobby admin credentials.
- Step 2** Click **Whitelist Users**.
- Step 3** From the **WLAN** drop-down list, choose the corresponding **WLAN**.
- Step 4** From the **WLAN Mode**, select **Onboarding** to enable clients to access the network.
- Step 5** Click **Apply**.
- Step 6** From the **Connected/Not Whitelisted** in the Whitelist window, select a MAC address . Once the clients join the controller, the MAC addresses are listed in the **Connected/Not Whitelisted**. In the Onboarding mode, MAC filtering in the selected WLAN is disabled. In such a scenario you can change the mode using **Secure** mode.
- Step 7** Select **Secure** to automatically add the clients that are connected to the allowed list. In the secure mode, MAC filtering in the selected WLAN is enabled.
- Step 8** Click **Apply to Device**.
- The clients are listed in the **Connected/Whitelisted**.
-

Viewing a Client Allowed List

Procedure

- Step 1** Log in to the Lobby Admin portal.
- Step 2** Click **Whitelist Users**.
- Step 3** From the **WLAN** drop-down list, choose the corresponding **WLAN**.

The window lists the following information:

- **Connected/Whitelisted:** Lists the clients that are connected and added to the allowed list by the Lobby admin.
 - **Connected/Not Whitelisted:** Lists the clients that are connected, but not added to the allowed list by the Lobby admin.
 - **Not Connected/Whitelisted:** Lists the clients that are not connected but added to the allowed list.
-

CHAPTER 56

Guest User Accounts

- [Information About Creating Guest User Accounts, on page 713](#)
- [Creating a Guest User Account \(GUI\), on page 713](#)
- [Creating a Guest User Account \(CLI\), on page 714](#)
- [Verifying Guest User Account, on page 715](#)
- [Assigning Username to Guest Users in a WLAN \(CLI\), on page 716](#)

Information About Creating Guest User Accounts

The controller can provide guest user access on WLANs for which you must create guest user accounts. Guest user accounts can be created by network administrators, or, if you would like a non-administrator to be able to create guest user accounts on demand, you can do so through a lobby administrator account. The lobby ambassador has limited configuration privileges and access only to the web pages used to manage the guest user accounts.

The lobby ambassador can specify the amount of time that the guest user accounts remain active. After the specified time elapses, the guest user accounts expire automatically.

You can associate user name with WLAN profile name to restrict guest users in a specific WLAN.

Prerequisites for Guest Users

- Guest users are created by administrator or lobby ambassador.
- Guest user should not have device access either through telnet/ssh or WebUI.
- Guest user should be role-based.
- Guest user should be able to connect to the network and access internet.

Creating a Guest User Account (GUI)

Procedure

- Step 1** Choose **Configuration > Security > Guest User**.

- Step 2** On the **Guest User** page, click **Add**.
- Step 3** Enter a user name, password, and description for the new account. Check the **Generate password** check box to automatically generate a password.
- Step 4** Enter the number of simultaneous user logins. Valid values range between 0 to 64.
Enter 0 for unlimited users.
- Step 5** In the **Lifetime** section, choose the number of years, months, days, hours, and minutes.
- Step 6** Click **Save & Apply to Device**.

Creating a Guest User Account (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	user-name <i>guest-user-name</i> Example: Device(config)# user-name guest	Creates a guest user account.
Step 3	type network-user description <i>description</i> guest-user max-login-limit <i>number of simultaneous logins</i> lifetime year yy month mm day day hour hour minute minute second second Example: Device(config-user-name)# type network-user description sample-description guest-user max-login-limit 3 lifetime 1 years 0 months 0 days 0 hours 0 mins 0 secs	Specifies the account type as guest user account.
Step 4	password 0 <i>password</i> Example: Device(config-user-name)# password 0 guest	Creates a password for the guest user account.
Step 5	aaa attribute list <i>aaa-attribute-list-name</i> Example: Device(config-user-name)# aaa attribute list aaa-attribute-list-name	Creates a AAA attribute list to apply QoS profiles on the guest user account.

	Command or Action	Purpose
Step 6	exit Example: Device(config-user-name)# exit	Returns to global configuration mode. Note If the lobby admin is local, enter the following command: <pre>aaa authentication login default local</pre> If the lobby admin is a remote user, enter the following commands: <pre>aaa authentication login default group radius/tacacs aaa remote username <remote-lobby-admin-name></pre> In case of local or remote lobby, enter the following command to map the authorization policies: <pre>aaa authorization exec default local</pre>

Verifying Guest User Account

Verify Guest User Account.

```
Device# show aaa local guest_user all
User-Name          : new4
  Type              : GUEST USER
  Password          : *
  Is_passwd_encrypted : No
  Attribute-List    : Not-Configured
  Viewname          : Not-Configured
  Lobby Admin Name  : NEW_LOBBY_ADMIN
  Max Login Limit   : 0
  Description       : guest
  Start-Time        : 07:56:39 IST Jan 25 2019
  Lifetime          : 1 years 0 months 0 days 0 hours 0 mins 0 secs
  Expiry-Time       : 07:56:39 IST Jan 20 2020 Remaining Lifetime : 0 years 11 months
  29 days 22 hours 52 mins 49 secs
```

To verify a specific guest user account, use the following command:

```
Device# show aaa local guest_user new_guest3
User-Name          : new_guest3
  Type              : GUEST USER
  Password          : *
  Is_passwd_encrypted : No
  Attribute-List    : Not-Configured
  Viewname          : Not-Configured
  Lobby Admin Name  : INVALID_ADMIN
  Max Login Limit   : 9
  Description       : new
  Start-Time        : 04:39:01 IST Feb 4 2019
  Lifetime          : 1 years 0 months 0 days 0 hours 0 mins 0 secs
```

Expiry-Time : 04:39:01 IST Jan 30 2020
 Remaining Lifetime : 0 years 11 months 11 days 21 hours 16 mins 34 secs

Assigning Username to Guest Users in a WLAN (CLI)

Before you begin

- If wlan-profile-name is configured for a user, guest user authentication is allowed only from that WLAN.
- If wlan-profile-name is not configured for a user, guest user authentication is allowed on any WLAN.
- To work in a connected mode, you need to configure AAA policy override under both SSID policies before assigning a username to a guest user on a WLAN.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters configuration mode.
Step 2	username user_name mac wlan-profile-name profile_name Example: Device(config)# username user_name mac wlan-profile-name profile_name	Assigns a username to the WLAN profile. Note The wlan-profile-name per user is applicable for MAC type users.
Step 3	show aaa local guest_user new_guest3 Example: Device# show aaa local guest_user new_guest3	(Optional) Displays the values of the WLAN profile.
Step 4	end Example: Device# end	Returns to privileged EXEC mode.

CHAPTER 57

Link Local Bridging

- [Feature History for Link Local Bridging](#), on page 717
- [Information About Link Local Bridging](#), on page 717
- [Use Case for Link Local Bridging](#), on page 718
- [Guidelines and Restrictions for Link Local Bridging](#), on page 718
- [Enabling Link Local Bridging Per Policy Profile \(GUI\)](#), on page 718
- [Enabling Link Local Bridging Per Policy Profile \(CLI\)](#), on page 719
- [Verifying Link Local Bridging](#), on page 719

Feature History for Link Local Bridging

This table provides release and related information for the feature explained in this module.

This feature is available in all the releases subsequent to the one in which it is introduced in, unless noted otherwise.

Table 56: Feature History for Link Local Bridging

Release	Feature	Feature Information
Cisco IOS XE Bengaluru 17.6.1	Link Local Bridging	The Link Local Bridging feature allows you to manage link-local traffic in intercontroller and intracontroller roaming scenarios.

Information About Link Local Bridging

In Cisco IOS XE Bengaluru 17.5.1 and earlier releases, client packets were forwarded through the access VLAN of a client. The client also received all the IPv4 or IPv6 packets from its assigned access VLAN.

When an L3 client roamed from one controller to another controller, the point-of-presence (PoP) remained with the first controller, also known as the anchor controller or the home controller, and the point-of-attachment (PoA) moved to the second controller, also known as the foreign controller or the visited controller. In this anchor-foreign scenario, the client packets were tunneled back to the anchor controller to be forwarded on the access VLAN of the client.

Similarly, in case of L3 intracontroller roaming, when the feature Roaming Across Policy Profile is enabled, the client access VLAN is maintained, regardless of the policy profile VLAN. In such a scenario, the PoA becomes the destination policy profile VLAN.

A roaming wireless client is served better by the local services present near its PoA rather than discovering services present at its PoP. Therefore, from Cisco IOS XE Bengaluru 17.6.1 onwards, the intracontroller and intercontroller roaming scenarios described above, can now be managed with the help of the Link Local Bridging feature. Link Local Bridging is disabled by default.

Use Case for Link Local Bridging

If you have a local mode deployment, and L3 roaming is used to manage roaming clients across physical locations, the Link Local Bridging feature helps you to discover services, for example, using mDNS, which are physically close to the wireless client.

Guidelines and Restrictions for Link Local Bridging

- The Link Local Bridging feature is supported in local-mode or FlexConnect central switching.
- Only mDNS bridge mode is supported with Link Local Bridging.
- Guest profiles are not supported.
- Wired Guest LAN, Remote LAN (RLAN), and Inter-Release Controller Mobility (IRCM) are not supported.
- Mesh and IP Source Guard (IPSG) is not supported when the Link Local Bridging feature is enabled.
- Enabling Link Local Bridging on the anchor controller and disabling it on the foreign controller is not supported, even if roaming is successful.
- Access VLAN and bridge VLAN should be operational, for the Link Local Bridging feature to work.
- Link Local Bridging must be enabled across policy profiles for the same SSID.
- Wireless multicast-over-multicast (**wireless multicast** *multicast IP address*) must be configured, before enabling the Link Local Bridging feature. Therefore, the **wireless multicast link-local** command is enabled by default when wireless multicast is enabled.

Enabling Link Local Bridging Per Policy Profile (GUI)

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > Policy**.
- Step 2** Click **Add**.
The **Add Policy Profile** window is displayed.
- Step 3** In the **Add Policy Profile** page, in the **General** tab, enter the name of the policy profile.

Step 4 In the **Advanced** tab, check the **Link-Local Bridging** check box to enable link-local bridging on the policy profile.

Note When link-local bridging is enabled, Export Anchor will be disabled and Central Switching will be enabled automatically.

Step 5 Click **Apply to Device**.

Enabling Link Local Bridging Per Policy Profile (CLI)

To enable link local bridging per policy profile, follow these steps.

Before you begin

Ensure that wireless multicast-over-multicast and wireless multicast link-local are enabled.

Note From Cisco IOS XE Bengaluru 17.6.1, the wireless multicast link-local setting is enabled by default as soon as multicast is enabled. This means that all the downstream multicast link-local frames will be forwarded to wireless clients. In the Cisco IOS XE Bengaluru 17.5.x and the earlier releases, only mDNS multicast link-local frames were forwarded.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-name</i> Example: Device(config)# wireless profile policy <i>wireless-profile1</i>	Creates policy profile for the WLAN.
Step 3	link-local-bridging Example: Device(config-wireless-policy)# link-local-bridging	Enables link local bridging per policy profile.

Verifying Link Local Bridging

To verify the configuration status of Link Local Bridging, use the following command:

```
Device# show wireless profile policy detailed policy1
Policy Profile Name          : policy1
```

```

Description                               :
Status                                    : ENABLED
VLAN                                       : 81
Multicast VLAN                            : 0
OSEN client VLAN                          :
Multicast Filter                          : DISABLED
QBSS Load                                  : ENABLED
Passive Client                            : DISABLED
ET-Analytics                              : DISABLED
StaticIP Mobility                          : DISABLED
WLAN Switching Policy
  Flex Central Switching                   : ENABLED
  Flex Central Authentication               : ENABLED
  Flex Central DHCP                        : ENABLED
  Flex NAT PAT                             : DISABLED
.
.
.
-----
mDNS Gateway
  mDNS Service Policy name                 : default-mdns-service-policy
  User Defined (Private) Network           : Disabled
  User Defined (Private) Network Unicast Drop : Disabled
  Policy Proxy Settings
    ARP Proxy State                        : DISABLED
    IPv6 Proxy State                       : None
  Airtime-fairness Profile
    2.4Ghz ATF Policy                      : default-atf-policy
    5Ghz ATF Policy                       : default-atf-policy
  Link-local bridging                      : ENABLED

```

To verify if Link Local Bridging VLAN is included, use the following command:

```

Device# show wireless client mac 7xxx.3xxx.3xxx detail
Client MAC Address : 7xxx.3xxx.3xxx
.
.
.
Link-local bridging VLAN: 3
.
.
.
WiFi Direct Capabilities:
  WiFi Direct Capable                    : No

```

To verify if link local multicast traffic is enabled, use the following command:

```

Device# show wireless multicast
Multicast                                : Disabled
AP Capwap Multicast                      : Unicast
Wireless Broadcast                       : Disabled
Wireless Multicast non-ip-mcast          : Disabled
Wireless Multicast link-local            : Enabled

```

CHAPTER 58

Web Admin Settings

- [Information About Web Admin Settings, on page 721](#)
- [Configuring HTTP/HTTPS Access , on page 721](#)
- [Configuring HTTP Trust Point, on page 722](#)
- [Configuring Netconf Yang, on page 723](#)
- [Configuring Timeout Policy , on page 723](#)
- [Configuring VTY, on page 724](#)

Information About Web Admin Settings

This chapter outlines the various settings to access the controller's web interface. These include setting up the controller for communication with others in the network, configuring the management interface to connect over IP, setting up the number of users and protocols to access the controller remotely and configure the source interface for file transfers depending upon the preferred file transfer protocols.

Use the **Administration > Management > HTTP/HTTPS/Netconf/VTY** page to configure system-wide settings.

Configuring HTTP/HTTPS Access

HTTP/HTTPS access allows users to access the controller's WebUI using its IP address. You can either allow users to connect securely over HTTPS or over HTTP, which is not a secure connection.

Use the **Administration > Management > HTTP/HTTPS/Netconf/VTY** page to configure secure access to the controller.

Procedure

- Step 1** Enable **HTTP Access** and enter the port that will listen for HTTP requests. The default port is 80. Valid values are 80, and ports between 1025 and 65535.
- Step 2** Enable **HTTPS Access** on the device and enter the designated port to listen for HTTPS requests. The default port is 1025. Valid values are 443, and ports between 1025 and 65535.

Enabling HTTPs access allows users to access the controller's GUI using 'https://ip-address' . On a secure HTTP connection, data to and from an HTTP server is encrypted before being sent over the Internet. HTTP

with SSL encryption provides a secure connection to allow such functions as configuring a switch from a Web browser.

Step 3 Enable Personal Identity Verification (PIV) for two factor authentication.

This method of authentication allows users to access the WebUI using Personal Identity Verification (PIV) compatible smart cards, enabling login without password. For this to work, ensure that you have configured the trustpoint, CA server certificate on the device and the client certificate signed by the CA server on the browser. Failure to provide the client certificate would deny access to the UI.

Step 4 Set the **Personal Identity Verification Authorization only** option to *Enabled* for authorizing a user's permissions and restrictions based on a remote TACACS+/RADIUS security server.

Step 5 Click **Apply** to save the configuration.

Note In order to use Personal Identity Verification (PIV) for two factor authentication on Safari, perform the following steps.

a. Open Safari browser and go to **Settings > Advanced**

1. Check the **Show Develop in menu bar** check box. This enables the Develop option in the top menu bar.
2. Click **Develop**, and from the dropdown, select **Empty Caches**.

b. Open the web url to login.

Configuring HTTP Trust Point

Certificate authorities (CAs) manage certificate requests and issue certificates to participating network devices. These services provide centralized security key and certificate management for the participating devices. Specific CA servers are referred to as trustpoints. When a connection attempt is made, the HTTPS server provides a secure connection by issuing a certified X.509v3 certificate, obtained from a specified CA trustpoint, to the client. The client (usually a Web browser), in turn, has a public key that allows it to authenticate the certificate. For secure HTTP connections, we highly recommend that you configure a CA trustpoint. If a CA trustpoint is not configured for the device running the HTTPS server, the server certifies itself and generates the needed RSA key pair. Because a self-certified (self-signed) certificate does not provide adequate security, the connecting client generates a notification that the certificate is self-certified, and the user has the opportunity to accept or reject the connection. This option is useful for internal network topologies (such as testing). If you do not configure a CA trustpoint, when you enable a secure HTTP connection, either a temporary or a persistent self-signed certificate for the secure HTTP server (or client) is automatically generated. If the device is not configured with a hostname and a domain name, a temporary self-signed certificate is generated. If the switch reboots, any temporary self-signed certificate is lost, and a new temporary new self-signed certificate is assigned. If the device has been configured with a host and domain name, a persistent self-signed certificate is generated. This certificate remains active if you reboot the device or if you disable the secure HTTP server so that it will be there the next time you re-enable a secure HTTP connection.

Use the **Trust Point Configuration** section of the **Administration > Management > HTTP/HTTPS/Netconf/VTY** page to make these changes.

Before you begin

You must have configured a trustpoint for web administration purposes.

Procedure

- Step 1** Tap to enable the Trust Point.
- Step 2** Select the appropriate Trust Point from the drop-down list to be used for web admin purpose.
- If you have not configured a trust point earlier, you can navigate to the appropriate page and first configure it.
- Step 3** Click **Apply** to save the configuration.
-

Configuring Netconf Yang

NETCONF provides a mechanism to install, manipulate, and delete the configuration of network devices.

If the NETCONF connection is configured to use AAA for authentication purposes, it uses only the default Method List and cannot be pointed to use any other named Method List.

Use the **Netconf Yang Configuration** section of the **Administration > Management > HTTP/HTTPS/Netconf/VTY** page to make these changes.

Procedure

- Step 1** Enable NETCONF.
- Step 2** Enter the SSH port number that will be used to facilitate communication between a client and a server. The default port is 830.
- Step 3** Click **Apply** to save the configuration.
-

Configuring Timeout Policy

The Timeout Policy Configuration allows you to configure the details of the interval that the management sessions can remain idle before they timeout. Once the time value is reached, you must log in again to be able to reestablish the connection.

Use the **Timeout Policy Configuration** section of the **Administration > Management > HTTP/HTTPS/Netconf/VTY** page to make these changes.

Procedure

- Step 1** Enter the maximum number of seconds a connection to the HTTP server should remain open before they timeout in the **HTTP Timeout-policy** field. Once the time value is reached, you must log in again to be able to reestablish connection.
- Step 2** Enter the maximum number of seconds the connection will be kept open if no data is received or if response data cannot be sent out on the connection in the **Session Idle Timeout** field.
- Note that a new value may not take effect on any already existing connections. If the server is too busy or the limit on the life time or the number of requests is reached, the connection may be closed sooner. The default value is 180 seconds (3 minutes).
- Step 3** Enter the maximum number of seconds the connection will be kept open, from the time the connection is established in the **Server Life Time** field.
- Note that the new value may not take effect on any already existing connections. If the server is too busy or the limit on the idle time or the number of requests is reached, it may close the connection sooner. Also, since the server will not close the connection while actively processing a request, the connection may remain open longer than the specified life time if processing is occurring when the life maximum is reached. In this case, the connection will be closed when processing finishes. The default value is 180 seconds (3 minutes). The maximum value is 86400 seconds (24 hours).
- Step 4** Enter a value for the maximum limit on the number of requests processed on a persistent connection before it is closed in the **Max Number of Requests** field.
- Note that the new value may not take effect on already existing connections. If the server is too busy or the limit on the idle time or the life time is reached, the connection may be closed before the maximum number of requests are processed. The default value is 1. The maximum value is 86400.
- Step 5** Click **Apply** to save the configuration.
-

Configuring VTY

VTY is a virtual port used for Telnet or SSH access to the device. VTY is solely used for inbound connections to the device. You can configure the number of simultaneous connections to your device and add security to validate these connections.

Use the **VTY** section of the **Administration > Management > HTTP/HTTPs/Netconf/VTY** page to make these changes.

Procedure

- Step 1** Set the number of vty lines to allow the number of simultaneous access to the device remotely.
- Virtual Terminal Lines or Virtual TeleType (VTY) is a virtual way of accessing the controller's CLI remotely, unlike physically connecting a laptop to the controller through a console. The number of VTY lines is the maximum number of simultaneous connections possible. 0-50 allows up to fifty simultaneous telnet or ssh sessions to the controller. Although the default is set at 15, we recommend that you to increase the number of VTY lines to 50 to avoid a disruption in connectivity when there are multiple connections to the device.

- Step 2** Select the protocol for the remote connection from the **VTY Transport Mode** drop-down list. You can split the connections based on protocol. For e.g. 0-5 might allow for SSH and 10-20 might allow Telnet.
- Step 3** (Optional) You can add security in the WebUI to validate login requests. To configure AAA authentication and authorization for inbound sessions to vty lines on your system you must first configure a Radius or a TACACS+ authentication server and select the authentication and authorization list from the corresponding drop-downs.
- Step 4** Click **Apply** to save the configuration.
-

CHAPTER 59

Web UI Configuration Command Accounting in TACACS Server

- [Feature History for Web UI Configuration Command Accounting in TACACS+ Server, on page 727](#)
- [Information About Web UI Configuration Command Accounting in TACACS+ Server, on page 727](#)
- [Guidelines for Web UI Configuration Command Accounting in TACACS+ Server, on page 728](#)
- [Configuring AAA Accounting Using Default Method List \(CLI\), on page 728](#)
- [Configuring HTTP Command Accounting Using Named Method List \(CLI\), on page 729](#)

Feature History for Web UI Configuration Command Accounting in TACACS+ Server

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 57: Feature History for Web UI Configuration Command Accounting in TACACS+ Server

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.9.1	Logging Web UI-Based Configuration Changes in TACACS+ Server	This feature logs all configuration changes made in controller web UI. Support for logging configurations done in IOS console in TACACS+ server is already available.

Information About Web UI Configuration Command Accounting in TACACS+ Server

The Cisco Catalyst 9800 Series Wireless Controller configuration is stored in databases. Prior to Cisco IOS XE Cupertino 17.9.1 release, audit log or traceability were not available for the configuration changes stored in databases that were made from the controller GUI. With the Cisco IOS XE Cupertino 17.9.1 release, along with the existing configuration logging of commands executed from Cisco IOS console to TACACS+ server,

support is also added to log the configuration changes done from the controller GUI to TACACS+ server. The logging information includes the command, user, and other session related parameters.

Guidelines for Web UI Configuration Command Accounting in TACACS+ Server

- By default, the configuration commands are not logged to TACACS+ server without configuring command accounting.
- All commands are accounted when AAA default command accounting is configured only for privilege 15.
- When AAA default command accounting is not configured and commands need to be logged in the TACACS+ server, do the following:
 1. The HTTP named method list command accounting.
 2. The AAA named method list (same as the one configured in **Step 1**) command accounting.

Configuring AAA Accounting Using Default Method List (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	aaa accounting commands <i>privilege_level</i> default start-stop group <i>group-name</i> Example: Device(config)# aaa accounting commands 15 default start-stop group group-name	Creates an accounting method list and enables accounting. <ul style="list-style-type: none"> • <i>privilege_level</i>: AAA accounting level. The valid range is from 0 to 15. • <i>group-name</i>: AAA accounting group that supports only TACACS+ group.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.

Configuring HTTP Command Accounting Using Named Method List (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ip http accounting commands level <i>named-accounting-method-list</i> Example: Device(config)# ip http accounting commands 1 oneacct	Configures HTTP command accounting using the named method list. <ul style="list-style-type: none"> • <i>level</i>: Privilege value from 0 to 15. By default, the following command privilege levels are available on the controller: <ul style="list-style-type: none"> • <i>0</i>: Includes the disable, enable, exit, help, and logout commands. • <i>1</i>: Includes all the user-level commands at the controller prompt (>). • <i>15</i>: Includes all the enable-level commands at the controller prompt (>). • <i>named-accounting-method-list</i>: Name of the predefined command accounting method list.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.

Embedded Packet Capture

- [Feature History for Embedded Packet Capture](#), on page 731
- [Information About Embedded Packet Capture](#), on page 731
- [Configuring Embedded Packet Capture \(CLI\)](#), on page 732
- [Verifying Embedded Packet Capture](#), on page 734

Feature History for Embedded Packet Capture

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 58: Feature History for Embedded Packet Capture

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.12.1	Embedded Packet Capture	The Embedded Packet Capture feature is enhanced to support increased buffer size, continuous capture, and filtering of multiple MAC addresses in one Embedded Packet Capture (EPC) session.

Information About Embedded Packet Capture

The Embedded Packet Capture feature helps in tracing and troubleshooting packets. The Embedded Packet Capture on the controller is used for troubleshooting multiple issues, such as, authentication issues with RADIUS, AP join or disconnection, client forwarding, disconnection, and roaming, and other specific features such as multicast, mDNS, umbrella, mobility, and so on. This feature allows network administrators to capture data packets flowing through, to, and from a Cisco device. When troubleshooting an AP join or a client onboarding issue, if you are unable to stop capture as soon as an issue occurs, important information might be lost. In most cases, a buffer of 100 MB is not sufficient for data capture. Moreover, the existing Embedded Packet Capture feature supports only the filtering of one inner MAC address, which captures the traffic of a specific client. At times, it is difficult to pin-point which wireless client is facing an issue.

From Cisco IOS XE Dublin 17.12.1, the Embedded Packet Capture feature supports increased buffer size, continuous capture, and filtering of multiple MAC addresses in one Embedded Packet Capture session. There are no GUI steps to configure the Embedded Packet Capture enhancement.

Configuring Embedded Packet Capture (CLI)

With the Embedded Packet Capture feature enhancement, the buffer size is increased from 100 MB to 500 MB.

Note Buffer is of memory type. You can either maintain a memory buffer or copy the memory buffer that is present in a file to store more information.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	monitor capture <i>epc-session-name</i> interface GigabitEthernet <i>interface-number</i> {both in out} Example: Device# monitor capture <i>epc-session1</i> interface GigabitEthernet <i>0/0/1</i> both	Configures the Gigabit Ethernet interface for inbound, outbound, or both inbound and outbound packets. Gigabit is for Cisco 9800-CL controllers, for example, Gi1, Gi2, or Gi3. For physical controllers, you must specify the port channel, if configured. Examples for physical interfaces are Te or Tw. Note You can also run the control-plane command to capture the packet punt to the CPU.
Step 3	(Optional) monitor capture <i>epc-session-name</i> limit duration <i>limit-duration</i> Example: Device# monitor capture <i>epc-session1</i> limit duration <i>3600</i>	Configures monitor capture limit, in seconds.
Step 4	(Optional) monitor capture <i>epc-session-name</i> buffer circular file <i>no-of-files</i> file-size <i>per-file-size</i> Example: Device# monitor capture <i>epc-session1</i> buffer circular file <i>4</i> file-size <i>20</i>	Configures the file in circular buffer. (Buffer can be circular or linear). When circular is configured, the files work as a ring buffer. The value range of the number of files to be configured is from 2 to 5. The value range of the file size is from 1 MB to 500 MB.

	Command or Action	Purpose
		<p>There are various keywords available for the buffer command, such as, circular, file, and size. Here, the circular command is optional.</p> <p>Note Circular buffer is needed for continuous capture.</p> <p>This step generates swap files in the controller. Swap files are not packet capture (PCAP) files, and therefore, cannot be analyzed. When the export command is run, the swap files are combined and exported as one PCAP file.</p>
Step 5	<p>monitor capture <i>epc-session-name</i> match {any ipv4 ipv6 mac pklen-range}</p> <p>Example:</p> <pre>Device# monitor capture epc-session1 match any</pre>	<p>Configures inline filters.</p> <p>Note You can configure filters and ACLs.</p>
Step 6	<p>(Optional) monitor capture <i>epc-session-name</i> access-list <i>access-list-name</i></p> <p>Example:</p> <pre>Device# monitor capture epc-session1 access-list access-list1</pre>	<p>Configures a monitor capture specifying an access list as the filter for the packet capture.</p>
Step 7	<p>(Optional) monitor capture <i>epc-session-name</i> continuous-capture http:<i>location/filename</i></p> <p>Example:</p> <pre>Device# monitor capture epc-session1 continuous-capture https://www.cisco.com/epcl.pcap</pre>	<p>Configures continuous packet capture. Enables the automatic export of files to a specific location before the buffer is overwritten.</p> <p>Note</p> <ul style="list-style-type: none"> • Circular buffer is needed for continuous capture. • Configure the filename with a .pcap extension. • An example of the filename and nomenclature used to generate the filename is as follows: CONTINUOUS_CAP_20230601130203.p CONTINUOUS_CAP_20230601130240.p • After the packets are exported automatically, the buffer is not cleared until it is overwritten by the new incoming capture packets, or cleared, or deleted commands.

	Command or Action	Purpose
Step 8	<p>(Optional) [no] monitor capture <i>epc-session-name</i> inner mac <i>MAC1</i> [<i>MAC2...</i> <i>MAC10</i>]</p> <p>Example:</p> <pre>Device# monitor capture epc-session1 inner mac 1.1.1 2.2.2 3.3.3 4.4.4</pre>	<p>Configures up to 10 MAC addresses as inner MAC filter.</p> <p>Note</p> <ul style="list-style-type: none"> You can not modify the inner MACs while the capture is in progress. You can enter the MAC addresses in a single command or by using multiple command lines. Because of the character string limitation, you can enter only five MAC addresses in a single command line. You can enter the rest of the MAC addresses in the next command line. If the number of configured inner MAC addresses is 10, a new MAC address cannot be configured until you delete an old configured inner MAC address.
Step 9	<p>monitor capture <i>epc-session-name</i> start</p> <p>Example:</p> <pre>Device# no monitor capture epc-session1 start</pre>	Starts capture of packet data.
Step 10	<p>monitor capture <i>epc-session-name</i> stop</p> <p>Example:</p> <pre>Device# no monitor capture epc-session1 stop</pre>	Stops capture of packet data.
Step 11	<p>monitor capture <i>epc-session-name</i> export <i>filelocation/filename</i></p> <p>Example:</p> <pre>Device# monitor capture epc-session1 export https://www.cisco.com/ecap-file.pcap</pre>	Exports captured data for analysis when continuous capture is not configured.

Verifying Embedded Packet Capture

To view the configured file number and per file size, run the following command:

Note The following command is displayed irrespective of whether continuous capture is enabled or not. The configured inner MAC addresses are also displayed using this command.

```
Device# show monitor capture epc-session1
Status Information for Capture epc-session1
Target Type:
Interface: TwoGigabitEthernet0/0/0, Direction: BOTH
Status : Inactive
Filter Details:
  Capture all packets
Inner Filter Details:
Continuous capture: enabled
Continuous capture path: ftp://mgcusr:mgcusr@10.124.19.169//home/mgcusr/xij/repo.pcap
Buffer Details:
Buffer Type: CIRCULAR
No of files: 5
File Size (in MB): 21
Limit Details:
  Number of Packets to capture: 0 (no limit)
  Packet Capture duration: 3600
  Packet Size to capture: 0 (no limit)
  Maximum number of packets to capture per second: 1000
  Packet sampling rate: 0 (no sampling)
```

To view the configured Embedded Packet Capture buffer files, run the following commands:

```
Device# show monitor capture epc-session1 buffer brief
-----
#   size  timestamp      source          destination      dscp   protocol
-----
0 1386    0.000000    192.168.10.117 -> 192.168.10.100  0 BE   UDP
1 1378    0.000000    192.168.10.100 -> 192.168.10.117  0 BE   UDP
2 1386    0.001007    192.168.10.117 -> 192.168.10.100  0 BE   UDP

Information About Layer 3 Access

Starting from Cisco IOS XE 17.13.1, the Cisco Catalyst 9800 Series Wireless Controller platforms can be deployed as Layer 3 (L3) network to perform routing functions.

In Cisco IOS XE 17.12.x and earlier releases, the Cisco Catalyst 9800 Series Wireless Controller platforms are deployed as Layer 2 network element. In such deployments, the wireless client subnets are terminated at an upstream network element. Upstream refers to the direction in which the data can be transferred from clients to a server. The controller forwards the traffic based on the MAC address of the clients.

The L3 access feature terminates the wireless client subnets in the controller and supports L3 forwarding for wireless client traffic. When L3 is enabled on a given SSID, the client VLAN of that SSID is terminated at the controller. In this scenario, wireless controller forwards traffic based on the network layer (IP) address.

The L3 access feature brings in support for unicast (OSPFv2) and multicast routing (PIM-SM) on the controller.

This enables the following:

- Segmentation and client overlapping IP address support using VRF.
- Flexible network design and faster convergence.
- Consistency in network design.
- Addresses scale limitations of the upstream switches or routers.

The core focus is the seamless integration of OSPF and multicast routing. This transition empowers your wireless networks to dynamically respond to shifting business requirements, ensuring optimal performance and agility in dynamic networking environment.

Information About OSPF

The OSPF is a link-state routing protocol for Internet Protocol (IP) networks. It uses the shortest path first technique to calculate the best path through a network. OSPF is a widely used Interior Gateway Protocol (IGP).

One of the key features of OSPF is that it supports authentication. This means each device can verify the identity of the other devices it communicates with.

The following types of authentication can be used with OSPF:

- Simple password authentication: The most basic method of authentication in which each device has a clear-text password configured that it uses to authenticate with other devices. The issue with this authentication method is that the password is displayed in the configuration and OSPF messages. This is not a secure way to configure devices.
- MD5 authentication: The most secure form of authentication in which a hash value from the contents of an OSPF packet and a password using the MD5 algorithm (key) are computed.

Note From Cisco IOS XE 17.13.1 release onwards, the OSPFv2 is supported along with ECMP.

Information About PIM Sparse Mode

The Protocol Independent Multicast (PIM) is a collection of multicast routing protocols optimized for different environments.

For information about PIM-SM, see

https://www.cisco.com/c/en/us/td/docs/ios-xml/ios/ipmulti_pim/configuration/15-sy/imc-pim-15-sy-book/ip6-mcast-pim-sm.html

PIM-SM

The PIM-SM is a multicast routing protocol designed on the assumption that recipients for any particular multicast group sparsely distributed throughout the network. In other words, most of the subnets in the network do not want any given multicast packet. To receive multicast data, routers must explicitly convey the upstream neighbors about their interest in particular groups and sources.

By default, the PIM-SM uses multicast distribution trees rooted at some selected node (This router is called the Rendezvous Point or RP) and used by all sources sending multicast group.

One of the important requirements of the PIM-SM mode is the ability to discover the address of an RP for a multicast group using a shared tree.

Information About Network Address Translation

The Network Address Translation (NAT) is a mechanism to map multiple local IP addresses within a private network to a public IP address to access external network (Internet or Cloud). The Port Address Translation (PAT) enables a single IP address to be shared by multiple hosts using IP and port translations.

The L3 access on the controller supports only the following NAT use cases:

- Translating client traffic in the guest network to reach corporate services (such as, Cisco ISE).
- Hiding the private IP addresses of clients from outside networks.

The following types of NAT are supported:

- Static address translation (static NAT): It allows a one-to-one mapping between local and global addresses. The static translation is useful when a host from the inside is accessible from a fixed address from the outside.
- Dynamic address translation (dynamic NAT/PAT): It maps between client subnet and public global IP address or source port pool.

This can be achieved using the following:

- Dynamic NAT without VRF
- Dynamic NAT with VRF

Note The following NAT CLIs are not supported in Cisco IOS XE 17.13.1:

- `show ip nat aggregation`
- `show ip nat bpa`
- `show ip nat ha`
- `show ip nat limits`
- `show ip nat map`
- `show ip nat platform`
- `show ip nat pool`
- `show ip nat portblock`
- `show ip nat redundancy`
- `show ip nat route-dia`
- `show ip nat translations`
- `clear ip nat translations`

Restrictions for Layer 3 Access

- By default, the L3 access is disabled on a WLAN.
- Only N+1 redundancy is supported with L3 access.
- Configuring multiple IP addresses in an SVI is not supported.
- High Availability SSO is not supported in L3 WLANs.
- In mixed mode (L2 and L3 WLANs), HA SSO with Loopback as WMI is not supported.
- The `ip radius source-interface vrf` global command is not supported.
- Few NAT CLIs are not supported in Cisco IOS XE 17.13.1. For more information, see [Information About Network Address Translation](#).
- Multicast stream is not supported with VRF.

Use Cases for Layer 3 Access

Layer 3 Access Support

- Segmentation and client overlapping IP address support.
- Flexible and optimized network design using L3 access.

Network Address Translation (NAT) Support

- Translating client traffic in the guest network to reach the corporate services (For instance, Cisco ISE).
- Hiding the private IP addresses of clients from outside networks.

Note Only NAT with IPv4 to IPv4 translation is supported in Cisco IOS XE 17.13.1.

Configuring a Client Gateway (GUI)

Procedure

-
- Step 1** Choose **Configuration > Layer2 > VLAN** and select the **SVI** tab.
 - Step 2** Click an SVI interface. On the **General** tab of the **Edit SVI** window, select a VRF from the drop-down list to associate it with the SVI interface.
 - Step 3** Enable the **Autostate Disable** to keep the SVI UP even if any port on that VLAN is not UP.
 - Step 4** Click **Save & Apply to Device**.
-

Configuring a Client Gateway (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	interface <i>type number</i> Example: Device(config)# interface Vlan 55	Specifies an interface and enters interface configuration mode.
Step 3	vrf forwarding <i>vrf-name</i> Example: Device(config-if)# vrf forwarding corporate	Activates multiprotocol VRF in an interface.
Step 4	ip address <i>ip-address mask-address</i> Example: Device(config-if)# ip address 10.10.10.55 255.255.255.0	Defines the IP address for the VRF.
Step 5	no autostate Example: Device(config-if)# no autostate	Configures SVI to ensure that SVI is up even if the VLAN is not switched out.

	Command or Action	Purpose
Step 6	end Example: Device(config-if)# end	Exits the interface configuration mode and enters global configuration mode.

Configuring OSPF Interfaces (GUI)

Procedure

-
- Step 1** Choose **Configuration > Interface > Ethernet** and select an interface to configure it with OSPF settings.
 - Step 2** In the **Configure Interface** window, ensure that you have configured an IP address, subnet mask and optionally a secondary IP address.
 - Step 3** In the **OSPF** section, enter the **Process ID** to enable OSPF on the interface.
 - Step 4** Enable the **BFD** to create a Bidirectional Forwarding Detection session between two systems. BFD provides a short-duration method of detecting failures in the forwarding path between two adjacent peers.
 - Step 5** Select the **Dead Interval Minimal** and enter the number of seconds in the **Hello Multiplier** field to set the interval at which at least one hello packet must be received, or else the neighbor is considered down.
 - Step 6** Select **Message Digest Authentication** to configure the authentication supported by OSPF.
 - Step 7** Under the **Message Digest Authentication- Key Map** association box enter the Key, Type and Password.
 - Step 8** Click **Save & Apply to Device**.

Note To configure OSPF in SVI interfaces, you must enable Multicast over Multicast (MOM). This allows OSPF to establish neighbor adjacencies between SVIs.

Configuring OSPF Protocol (GUI)

Procedure

-
- Step 1** Choose **Configuration > Routing Protocol > OSPF** and click **Add**.
 - Step 2** In the **Add Route** page, select the router from the drop-down list.
 - Step 3** Enter the **Process ID**. It identifies the router's OSPF routing process to other routers.
 - Step 4** Enter a **Router ID**.
 - Step 5** Enable the **BFD** to create a Bidirectional Forwarding Detection session between two systems. BFD provides a short-duration method of detecting failures in the forwarding path between two adjacent switches, including the interfaces, data links, and forwarding planes. OSPF is a registered protocol with BFD and will receive forwarding path detection failure messages from BFD. You can either configure BFD support for OSPF globally on all interfaces or configure it selectively on one or more interfaces. BFD timers are negotiated, and the BFD peers will begin to send BFD control packets to each other at the negotiated interval.

Step 6 Enable the **NSR** to allow a router with redundant Route Processors (RPs) to maintain its Open Shortest Path First (OSPF) state and adjacencies across planned and unplanned RP switchovers. It does this by checkpointing state information from OSPF on the active RP to the standby RP. Later, following a switchover to the standby RP, OSPF can use this checkpointed information to continue operation without interruption.

Optionally, you can check the corresponding check box to enable VRF and select the VRF Name. In case you have not configured the VRF, you can follow the link to configure it on the **Interface > VRF** page.

Step 7 For advanced options, check the **Advanced** radio button and populate the following fields:

IP Address—Enter the address of the destination network for this route.

Wildcard—Enter the subnet mask used on that network.

Area—The OSPF area number for that network. Each router in a particular OSPF area maintains a topological database for that area.

Step 8 Click **Save & Apply to Device**.

Configuring OSPF (CLI)

To enable OSPF in each physical interface, perform the following:

1. Configure a clear-text password (or) message digest key in an OSPF-enabled interface.
2. Create an OSPF routing process.
3. Specify the range of IP addresses to associate with the routing process.
4. Assign area IDs to be associated with that range.

Note To enable OSPF in SVI interfaces, you must enable Multicast over Multicast (MOM) using the **wireless multicast ip-address** command. This allows OSPF to establish neighbor adjacencies between SVIs.

The following topics describe procedures to configure routing protocol:

Configuring Basic OSPF Parameters (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	router ospf process-id Example:	Enables OSPF routing. The <i>process-id</i> is an internally used identification parameter that is

	Command or Action	Purpose
	Device(config)# router ospf 1	locally assigned and can be any positive integer. Each OSPF routing process has a unique value. Note The OSPF for Routed Access supports a maximum of 1000 dynamically learned routes.
Step 3	network <i>address wildcard-mask area area-id</i> Example: Device(config-router)# network 10.10.10.0 255.255.255.0 area 1	Defines a network on which the OSPF runs an area ID for that interface. You can use the <i>wildcard-mask</i> to define one or more interfaces to be associated with a specific OSPF area. The <i>area-id</i> can be a decimal value or an IP address.
Step 4	bfd all-interfaces Example: Device(config-router)# bfd all-interfaces	Enables Bidirectional Forwarding Detection (BFD) in all interfaces.
Step 5	end Example: Device(config-router)# end	Returns to privileged EXEC mode.

Configuring OSPF Interfaces (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	interface gigabitethernet <i>interface-number</i> Example: Device(config)# interface GigabitEthernet 2	Specifies interface to configure OSPF interfaces.
Step 3	ip address <i>ip-address mask-address</i> Example: Device(config-if)# ip address 10.10.10.2 255.255.255.0	Configures IP address for the OSPF interface.
Step 4	ip ospf authentication message-digest Example: Device(config-if)# ip ospf authentication message-digest	Enables message digest for a specific interface.

	Command or Action	Purpose
Step 5	ip ospf authentication message-digest-key <i>key-number md5 password</i> Example: Device(config-if)# ip ospf authentication message-digest-key 1 md5 cisco123	Enables message digest key for the OSPF.
Step 6	ip ospf value area <i>area-id</i> Example: Device(config-if)# ip ospf 1 area 1	Assigns interface and its network to OSPF process and area.
Step 7	ip ospf bfd Example: Device(config-if)# ip ospf bfd	Enables BFD in an interface.
Step 8	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Enabling Layer 3 Access on Policy Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Policy**.
 - Step 2** Select a policy profile and in the **Edit Policy Profile** window, go to the advanced policy profile properties.
 - Step 3** Under the **Advanced** tab, enable **L3 Access** on the policy profile so that client traffic on a WLAN that has this policy can benefit from Layer 3 forwarding.
 - Step 4** Click **Apply to Device**.
-

Enabling Layer 3 Access on Policy Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode

	Command or Action	Purpose
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy default-policy-profile	Configures a wireless policy profile.
Step 3	shutdown Example: Device(config-wireless-policy)# shutdown	Disables the wireless policy profile.
Step 4	l3-access Example: Device(config-wireless-policy)# l3-access	Enables L3 access in the wireless policy profile.
Step 5	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables the wireless policy profile.

Configuring Multicast Traffic

Enabling Multicast Traffic without VRF (GUI)

Procedure

-
- Step 1** Choose **Configuration > Services > Multicast**.
- Step 2** In the **PIM and Multicast Routing** section, configure multicast routing globally by enabling **Distributed Multicast-Routing**.
- Step 3** Configure PIM RP-Address in the **PIM Configuration** sub-section. This configuration is required so that receivers can find the multicast source in the network. Choose the configuration options from below:
- Enter the address to statically configure the RP Address.
 - Enable Auto RP Listener to dynamically discover RP in a PIM-SM network.
- Step 4** Click **Save & Apply to Device**.
- Step 5** Designate the interface on which multicast traffic should be sent. To do so, go to **Configuration > Layer 2 > VLAN** and select the **SVI** interface.
- Step 6** Enable the **PIM Sparse Mode** protocol to allow the SVI interface to participate in sparse mode multicast traffic transmission and multicast shared tree. This ensures that, clients in that VLAN are able to receive multicast traffic from different multicast groups (sources).
- Step 7** Select the IGMP version from the drop- down list to direct multicast packets better. When this feature is enabled, the controller gathers IGMP reports from the clients, processes them, creates unique multicast group

IDs (MGIDs) from the IGMP reports after selecting the Layer 3 multicast address and the VLAN number, and sends the IGMP reports to the infrastructure switch.

Step 8 Select **IPv4** checkbox and enter the details.

Step 9 Click **Save & Apply to Device**.

Enabling Multicast Traffic without VRF (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	ip multicast-routing distributed Example: Device(config)# ip multicast-routing distributed	Enables IP multicast routing. The distributed keyword enables multicast globally.
Step 3	wireless multicast ip-address Example: Device(config)# wireless multicast 224.0.0.0	Enables multicast traffic.
Step 4	ip pim rp-address ip-address Example: Device(config)# ip pim rp-address 169.254.0.0	Configures address of a PIM Rendezvous Point (RP).
Step 5	interface interface-type-number Example: Device(config)# interface Vlan11	Selects an interface connected to hosts on which PIM can be enabled.
Step 6	description description Example: Device(config-if)# description "Client SVI"	Adds a description for the VLAN.
Step 7	ip address ip-address mask-address Example: Device(config-if)# ip address 209.165.200.225 255.255.255.0	Enables IP address on an interface.
Step 8	no ip proxy-arp Example:	Disables proxy ARP.

	Command or Action	Purpose
	<code>Device(config-if)# no ip proxy-arp</code>	
Step 9	ip pim sparse-mode Example: <code>Device(config-if)# ip pim sparse-mode</code>	Enables PIM-SM mode.
Step 10	ip ospf authentication message-digest Example: <code>Device(config-if)# ip ospf authentication message-digest</code>	Enables OSPF authentication for a specific interface.
Step 11	ip ospf authentication message-digest-key <i>key-number md5 password</i> Example: <code>Device(config-if)# ip ospf message-digest-key 1 md5 cisco123</code>	Enables message digest key for the OSPF.
Step 12	no mop enabled Example: <code>Device(config-if)# no mop enabled</code>	Disables the maintenance operation protocol (MOP) for an interface.
Step 13	no mop sysid Example: <code>Device(config-if)# no mop sysid</code>	Disables the task of sending MOP periodic system ID messages.
Step 14	end Example: <code>Device(config-if)# end</code>	Returns to privileged EXEC mode.

Enabling Multicast Traffic with PIM-SSM (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: <code>Device# configure terminal</code>	Enters global configuration mode
Step 2	ip multicast-routing distributed Example: <code>Device(config)# ip multicast-routing distributed</code>	Enables IP multicast routing. The distributed keyword enables MDS globally.

	Command or Action	Purpose
Step 3	wireless multicast <i>ip-address</i> Example: Device(config)# wireless multicast 224.0.0.0	Enables multicast traffic. For information about the multicast traffic, see Wireless Multicast .
Step 4	ip pim ssm default Example: Device(config)# ip pim ssm default	Configures PIM-SSM on all network devices. Note The default SSM range is 232.0.0.0/8 . So, if you do not configure different range, the default SSM range is used.
Step 5	ip pim ssm range <i>access-list</i> Example: Device(config)# ip pim ssm range access-list	Defines SSM range of IP multicast addresses.
Step 6	interface <i>interface-type-number</i> Example: Device(config)# interface Vlan11	Selects an interface connected to hosts on which PIM can be enabled.
Step 7	description <i>description</i> Example: Device(config-if)# description "Client SVI"	Adds a description for the VLAN.
Step 8	ip address <i>ip-address mask-address</i> Example: Device(config-if)# ip address 209.165.200.225 255.255.255.0	Enables IP address on an interface.
Step 9	no ip proxy-arp Example: Device(config-if)# no ip proxy-arp	Disables proxy ARP.
Step 10	ip pim sparse-mode Example: Device(config-if)# ip pim sparse-mode	Enables PIM-SM on an interface.
Step 11	end Example: Device(config-if)# end	Returns to privileged EXEC mode.

Selective NAT Support

Selective implies that only certain subset of options are supported in Cisco IOS XE 17.13.1 release.

Enabling Static NAT without VRF (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	interface <i>interface-type number</i> Example: Device (config)# interface GigabitEthernet2	Specifies an interface and enters the interface configuration mode.
Step 3	ip address <i>ip-address mask-address</i> Example: Device (config-if)# ip address 209.165.200.224 255.255.255.224	Sets the IP address for an interface.
Step 4	ip nat outside Example: Device (config-if)# ip nat outside	Connects the interface to the outside network.
Step 5	end Example: Device (config-if)# end	Exits the interface configuration mode and enters global configuration mode.
Step 6	interface <i>interface-type number</i> Example: Device (config)# interface GigabitEthernet3	Specifies a different interface and enters the interface configuration mode.
Step 7	ip address <i>ip-address mask-address</i> Example: Device (config-if)# ip address 10.10.10.10 255.255.255.0	Sets the IP address for an interface.
Step 8	ip nat inside Example: Device (config-if)# ip nat inside	Marks the interface as connected to the inside.

	Command or Action	Purpose
Step 9	end Example: Device(config-if)# end	Exits the interface configuration mode and enters global configuration mode.
Step 10	ip nat inside source static <i>local-ip global-ip</i> Example: Device(config)# ip nat inside source static 10.10.10.100 209.165.200.226	Translates between an inside local address and inside global address.

Enabling Static NAT with VRF (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	interface <i>interface-type-number</i> Example: Device(config)# interface GigabitEthernet2	Specifies an interface and enters the interface configuration mode.
Step 3	vrf forwarding <i>vrf-name</i> Example: Device(config-if)# vrf forwarding guest	Activates multiprotocol VRF on an interface.
Step 4	ip address <i>ip-address mask-address</i> Example: Device(config-if)# ip address 209.165.200.224 255.255.255.224	Enables IP address on an interface.
Step 5	ip nat outside Example: Device(config-if)# ip nat outside	Marks the interface as connected to the outside.
Step 6	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 7	interface <i>interface-type-number</i> Example: Device(config)# interface GigabitEthernet3	Specifies an interface and enters the interface configuration mode.

	Command or Action	Purpose
Step 8	vrf forwarding <i>vrf-name</i> Example: Device(config-if)# vrf forwarding guest	Activates multiprotocol VRF on an interface.
Step 9	ip address <i>ip-address mask-address</i> Example: Device(config-if)# ip address 10.10.10.10 255.255.255.0	Enables IP address on an interface.
Step 10	ip nat inside Example: Device(config-if)# ip nat inside	Marks the interface as connected to the inside.
Step 11	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 12	ip nat inside source static <i>local-ip global-ip vrf vrf_name [match-in-vrf]</i> Example: Device(config)# ip nat inside source static 10.10.10.101 209.165.200.227 vrf guest match-in-vrf	Translates between an inside local address and inside global address. Note The match-in-vrf keyword is optional and required when the same VRF is configured in the inside and outside NAT interface. For more information about match-in-vrf, see https://www.cisco.com/c/en/us/td/docs/ios-xml/ios/ipaddr_nat/configuration/xr-16/nat-xe-16-book/iadnat-match-vrf.html

Enabling Dynamic NAT without VRF (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	interface <i>interface-type number</i> Example:	Specifies an interface and enters the interface configuration mode.

	Command or Action	Purpose
	Device(config)# interface GigabitEthernet2	
Step 3	ip address <i>ip-address mask-address</i> Example: Device(config-if)# ip address 209.165.200.224 255.255.255.224	Sets the IP address for an interface.
Step 4	ip nat outside Example: Device(config-if)# ip nat outside	Marks the interface as connected to the outside.
Step 5	interface <i>interface-type number</i> Example: Device(config)# interface GigabitEthernet3	Specifies a different interface and enters the interface configuration mode.
Step 6	ip address <i>ip-address mask-address</i> Example: Device(config-if)# ip address 10.10.10.10 255.255.255.0	Sets the IP address for an interface.
Step 7	ip nat inside Example: Device(config-if)# ip nat inside	Marks the interface as connected to the inside.
Step 8	ip nat pool <i>name start-ip end-ip {netmask netmask prefix-length prefix-length}</i> Example: Device(config)# ip nat pool test_nat_pool 209.165.200.228 209.165.200.230 netmask 255.255.255.252	Defines a pool of network addresses for NAT.
Step 9	access-list <i>access-list-number permit ip source-address [source-wildcard-bits] host destination-address</i> Example: Device(config)# access-list 101 permit ip 10.10.10.102 0.0.0.255 host 209.165.200.235	Defines a standard access list for the addresses to be translated. Note The host keyword is optional for access-list configuration. It depends on the type of ACL you want to configure.
Step 10	ip nat inside source list <i>access-list-number pool name overload</i> Example: Device(config)# ip nat inside source list 101 pool test_nat_pool overload	Establishes dynamic source translation with overloading using the defined access list.

	Command or Action	Purpose
Step 11	end Example: Device(config)# exit	Returns to privileged EXEC mode.

Enabling Dynamic NAT with VRF (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	interface <i>interface-type-number</i> Example: Device(config)# interface GigabitEthernet2	Specifies an interface and enters the interface configuration mode.
Step 3	vrf forwarding <i>vrf-name</i> Example: Device(config-if)# vrf forwarding guest	Activates multiprotocol VRF on an interface.
Step 4	ip address <i>ip-address mask-address</i> Example: Device(config-if)# ip address 209.165.200.224 255.255.255.224	Enables IP address on an interface.
Step 5	ip nat outside Example: Device(config-if)# ip nat outside	Marks the interface as connected to the outside.
Step 6	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 7	interface <i>interface-type-number</i> Example: Device(config)# interface GigabitEthernet3	Specifies an interface and enters the interface configuration mode.
Step 8	vrf forwarding <i>vrf-name</i> Example: Device(config-if)# vrf forwarding guest	Activates multiprotocol VRF on an interface.

	Command or Action	Purpose
Step 9	ip address <i>ip-address mask-address</i> Example: Device(config-if)# ip address 10.10.10.10 255.255.255.0	Enables IP address on an interface.
Step 10	ip nat inside Example: Device(config-if)# ip nat inside	Marks the interface as connected to the inside.
Step 11	end Example: Device(config-if)# end	Returns to privileged EXEC mode.
Step 12	ip access-list standard <i>name</i> Example: Device(config)# ip access-list standard 50	Defines a standard IPv4 access list using a name. The <i>name</i> can be a number from 1 to 99.
Step 13	<i>sequence-number</i> permit <i>host-network wildcard-address</i> Example: Device(config-if)# 10 permit 10.10.10.103 0.0.0.255	Specifies the forwarded packet. Note <i>sequence-number</i> refers to the number where the rule should be in the list. Hence, lower the sequence number higher the priority for the rule.
Step 14	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.
Step 15	ip nat pool <i>name start-ip end-ip {netmask netmask prefix-length prefix-length}</i> Example: Device(config)# ip nat pool 13_access_pool 209.165.200.236 209.165.200.238 netmask 255.255.255.252	Defines a pool of network addresses for NAT.
Step 16	ip nat inside source list <i>access-list-number pool name vrf vrf-name match-in-vrf overload</i>	Establishes dynamic source translation with overloading using the defined access list.

	Command or Action	Purpose
	Example: <pre>Device(config)# ip nat inside source list 50 pool 13_access_pool vrf vrf-2 match-in-vrf overload</pre>	Note The match-in-vrf keyword is optional and required when the same VRF is configured in the inside and outside NAT interface. For more information about match-in-vrf, see https://www.cisco.com/c/en/us/td/docs/ios-xml/ios/ipaddr_nat/configuration/xe-16/nat-xe-16-book/iadnat-match-vrf.html
Step 17	end Example: <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.

Enabling Timeout for NAT (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode
Step 2	ip nat translation [icmp-timeout tcp-timeout timeout udp-timeout] number-of-seconds Example: <pre>Device(config)# ip nat translation timeout 30</pre>	Specifies timeouts for NAT translations. The following timeout options are supported: <ul style="list-style-type: none"> • icmp-timeout: ICMP packets timeout. • tcp-timeout: TCP packets timeout. • timeout: Global timeout for all protocol types. • udp-timeout: UDP packets timeout.
Step 3	end Example: <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.

Selective Internal DHCP with VRF Support

Enabling Internal DHCP with VRF (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy l3-sample	Configures WLAN policy profile and enters wireless policy configuration mode.
Step 3	description <i>profile-policy-description</i> Example: Device(config-wireless-policy)# description "Sample guest policy"	Adds a description for the policy profile.
Step 4	aaa-override Example: Device(config-wireless-policy)# aaa-override	Configures AAA policy override.
Step 5	ipv4 dhcp opt82 Example: Device(config-wireless-policy)# ipv4 dhcp opt82	Enables DHCP Option 82 for the wireless clients.
Step 6	ipv4 dhcp opt82 vrf Example: Device(config-wireless-policy)# ipv4 dhcp opt82 vrf	Enables VRF on DHCP Option 82.
Step 7	ipv4 dhcp server <i>ip-address</i> vrf <i>vrf-name</i> Example: Device(config-wireless-policy)# ipv4 dhcp server 10.1.1.1 vrf sample_guest	Configures the WLAN's IPv4 DHCP server IP address and VRF name.
Step 8	shutdown Example: Device(config-wireless-policy)# shutdown	Disables the wireless policy profile.

	Command or Action	Purpose
Step 9	l3-access Example: Device(config-wireless-policy)# l3-access	Enables L3 access in the wireless policy profile.
Step 10	nac Example: Device(config-wireless-policy)# nac	Configures Network Access Control in the policy profile.
Step 11	vlan <i>vlan-id</i> Example: Device(config-wireless-policy)# vlan 55	Maps the VLAN to a policy profile. If <i>vlan-id</i> is not specified, the default native vlan 1 is applied. The valid range for <i>vlan-id</i> is 1 to 4096.
Step 12	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables the wireless policy profile.

Verifying Routing Protocol Details

To verify the OSPF details, use the following command:

```
Device# show ip ospf 1
Routing Process "ospf 1" with ID 31.31.31.1
Start time: 00:01:46.103, Time elapsed: 03:12:34.745
Supports only single TOS(TOS0) routes
Supports opaque LSA
Supports Link-local Signaling (LLS)
Supports area transit capability
Supports NSSA (compatible with RFC 3101)
Supports Database Exchange Summary List Optimization (RFC 5243)
Event-log enabled, Maximum number of events: 1000, Mode: cyclic
Router is not originating router-LSAs with maximum metric
Initial SPF schedule delay 50 msec
Minimum hold time between two consecutive SPF's 200 msec
Maximum wait time between two consecutive SPF's 5000 msec
Incremental-SPF disabled
Initial LSA throttle delay 50 msec
Minimum hold time for LSA throttle 200 msec
Maximum wait time for LSA throttle 5000 msec
Minimum LSA arrival 100 msec
LSA group pacing timer 240 secs
Interface flood pacing timer 33 msec
Retransmission pacing timer 66 msec
EXCHANGE/LOADING adjacency limit: initial 300, process maximum 300
Number of external LSA 0. Checksum Sum 0x000000
Number of opaque AS LSA 0. Checksum Sum 0x000000
Number of DCbitless external and opaque AS LSA 0
Number of DoNotAge external and opaque AS LSA 0
Number of areas in this router is 1. 1 normal 0 stub 0 nssa
Number of areas transit capable is 0
External flood list length 0
```

```

IETF NSF helper support enabled
Cisco NSF helper support enabled
Reference bandwidth unit is 100 mbps
Area 1
  Number of interfaces in this area is 3
Area has no authentication
SPF algorithm last executed 03:11:47.277 ago
SPF algorithm executed 9 times
Area ranges are
Number of LSA 5. Checksum Sum 0x0212EE
Number of opaque link LSA 0. Checksum Sum 0x000000
Number of DCbitless LSA 0
Number of indication LSA 0
Number of DoNotAge LSA 0
Flood list length 0

```

To verify the OSPF database details, use the following command:

```

Device# show ip ospf 1 database
OSPF Router with ID (31.31.31.1) (Process ID 1)

  Router Link States (Area 1)

Link ID          ADV Router      Age           Seq#           Checksum Link count
31.31.31.1       31.31.31.1     1470         0x8000000C    0x00289A 3
50.50.50.1       50.50.50.1     1745         0x8000000A    0x001018 3
51.51.51.1       51.51.51.1     1500         0x8000000A    0x008EFB 2

  Net Link States (Area 1)

OSPF LSA errors

Type 0, Length 0, Data 0, Checksum 0

To verify the OSPF neighbor details, use the following command:

Device# show ip ospf 1 neighbor

Neighbor ID	Pri	State	Dead Time	Address	Interface
51.51.51.1	1	FULL/DR	00:00:37	31.31.31.2	GigabitEthernet4
50.50.50.1	1	FULL/DR	00:00:39	30.30.30.2	GigabitEthernet3

To verify the OSPF neighbor summary, use the following command:

Device#show ip ospf 1 neighbor summary

OSPF Router with ID (31.31.31.1) (Process ID 1)

DOWN	0
ATTEMPT	0
INIT	0
2WAY	0
EXSTART	0
EXCHANGE	0
LOADING	0
FULL	2
Total count	2 (Undergoing NSF 0)

To verify the OSPF event details, use the following command:

```
Device# show ip ospf 1 events

      OSPF Router with ID (31.31.31.1) (Process ID 1)

Verifying Multicast Traffic Details

To verify if a multicast group supports SSM or not, use the following command:

```

Device# show ip mroute
IP Multicast Routing Table
Flags: D - Dense, S - Sparse, B - Bidir Group, s - SSM Group, C - Connected,
  L - Local, P - Pruned, R - RP-bit set, F - Register flag,
  T - SPT-bit set, J - Join SPT, M - MSDP created entry, E - Extranet,
  X - Proxy Join Timer Running, A - Candidate for MSDP Advertisement,
  U - URD, I - Received Source Specific Host Report,
  Z - Multicast Tunnel, z - MDT-data group sender,
  Y - Joined MDT-data group, y - Sending to MDT-data group,
  G - Received BGP C-Mroute, g - Sent BGP C-Mroute,
  N - Received BGP Shared-Tree Prune, n - BGP C-Mroute suppressed,
  Q - Received BGP S-A Route, q - Sent BGP S-A Route,
  V - RD & Vector, v - Vector, p - PIM Joins on route,
  x - VxLAN group, c - PFP-SA cache created entry,
  * - determined by Assert, # - iif-starg configured on rpf intf,
  e - encaps-helper tunnel flag, l - LISP decap ref count contributor

```

```

Outgoing interface flags: H - Hardware switched, A - Assert winner, p - PIM Join
                        t - LISP transit group
Timers: Uptime/Expires
Interface state: Interface, Next-Hop or VCD, State/Mode

(*, 239.0.0.158), 00:00:07/stopped, RP 15.1.1.2, flags: SJC

```
Group: 239.255.255.250 Source: 0.0.0.0 Vlan: 12
Client: 11.1.1.4 Port: Ca2 Blacklisted: no
```

To verify the multicast group summary details, use the following command:

```
Device# show wireless multicast group summary
IPv4 groups
-----
MGID      Group                Vlan
-----
4160     239.255.255.250    12
4161     239.255.255.250    12
```

```
IPv6 groups
-----
MGID      Group                Vlan
-----
```

To verify the IGMP snooping groups, use the following command:

```
Device# show ip igmp snooping groups
Vlan      Group                Type      Version  Port List
-----
12        239.0.0.158         igmp     v2       Ca2
12        239.255.255.250    igmp     v2       Ca2
```

To verify the IGMP snooping, use the following command:

```
Device# show ip igmp snooping
Global IGMP Snooping configuration:
-----
IGMP snooping           : Enabled
Global PIM Snooping     : Disabled
IGMPv3 snooping (minimal) : Enabled
Report suppression      : Enabled
TCN solicit query       : Disabled
TCN flood query count   : 2
Robustness variable     : 2
Last member query count : 2
Last member query interval : 1000
.
.
.
Vlan 11:
-----
IGMP snooping           : Enabled
Pim Snooping            : Disabled
IGMPv2 immediate leave  : Disabled
Multicast router learning mode : pim-dvmrp
CGMP interoperability mode : IGMP_ONLY
Robustness variable     : 2
Last member query count : 2
Last member query interval : 1000

Vlan 12:
-----
IGMP snooping           : Enabled
Pim Snooping            : Disabled
IGMPv2 immediate leave  : Disabled
Multicast router learning mode : pim-dvmrp
CGMP interoperability mode : IGMP_ONLY
Robustness variable     : 2
```

```
Last member query count      : 2
Last member query interval   : 1000
```

To verify the active streams from any sources, use the following command:

```
Device# show ip mroute active
Active IP Multicast Sources - sending >= 4 kbps

Group: 239.255.0.1, (?)
  Source: 192.168.33.32 (?)
  Rate: 10 pps/115 kbps(1sec), 235 kbps(last 23 secs), 87 kbps(life avg)
```

To verify the TTL related issues in the path for the given stream, use the following command:

```
Device# show ip traffic | include bad hop count
0 format errors, 0 checksum errors, 1529 bad hop count
```

To verify the RPF failures, use the following command:

```
Device# show ip mroute count | inc RPF failed|Other
Other counts: Total/RPF failed/Other drops(OIF-null, rate-limit etc)
  RP-tree: Forwarding: 0/0/0/0, Other: 2/2/0
  RP-tree: Forwarding: 3/0/74/0, Other: 3/0/0
  Source: 32.32.32.32/32, Forwarding: 218747/2/74/1, Other: 218747/0/0
  RP-tree: Forwarding: 0/0/0/0, Other: 0/0/0
  Source: 9.4.168.10/32, Forwarding: 31/0/146/0, Other: 3841861/0/3841830
```

Verifying Static NAT Details

Verifying Static NAT Details without VRF

To verify the static IP NAT statistics without VRF, use the following command:

```
Device# show ip nat statistics
Total active translations: 1 (1 static, 0 dynamic; 0 extended)
Outside interfaces:
Vlan62
Inside interfaces:
Vlan55
Hits: 1474 Misses: 0
Reserved port setting disabled provisioned no
Expired translations: 1
Dynamic mappings:
nat-limit statistics:
max entry: max allowed 0, used 0, missed 0
In-to-out drops: 0 Out-to-in drops: 0
Pool stats drop: 0 Mapping stats drop: 0
Port block alloc fail: 0
IP alias add fail: 0
Limit entry add fail: 0
```

To verify the static NAT without VRF on active chassis, use the following command:

```
Device# show platform software nat chassis active F0 translation
Pro Inside global Inside local Outside local Outside global
--- 62.1.1.15 155.1.100.1 --- ---
--- 62.1.1.16 155.1.0.4 --- ---

ipv4_nat_res_port_out2in_pkts 0
ipv4_nat_ipc_retry_fail 0
ipv4_nat_cfg_rcvd 2
ipv4_nat_cfg_rsp 2

```

To clear the NAT details, use the following commands:

```

clear platform software nat chassis active F0 translation forced
clear ip nat statistics

```

Verifying NAT Timeout Details

To verify the NAT timeout details, use the following command:

```

Device# show platform software nat chassis active r0 timeout
Dump NAT timeout config

Type: generic, Timeout (sec): 86400, Enabled: Yes
Type: tcp, Timeout (sec): 86400, Enabled: Yes
Type: tcp-pptp, Timeout (sec): 86400, Enabled: Yes
Type: udp, Timeout (sec): 60, Enabled: Yes
Type: tcp-fin-reset, Timeout (sec): 60, Enabled: Yes
Type: tcp-syn, Timeout (sec): 60, Enabled: Yes
Type: dns, Timeout (sec): 60, Enabled: Yes
Type: icmp, Timeout (sec): 60, Enabled: Yes
Type: skinny, Timeout (sec): 60, Enabled: Yes

```

```
Type: icmp-error, Timeout (sec): 60, Enabled: Yes
Type: esp, Timeout (sec): 300, Enabled: Yes
Type: rtmap, Timeout (sec): 3600, Enabled: Yes
```

Verifying Internal DHCP with VRF Details

To verify the internal DHCP details, use the following command:

```
Device# show run int Vlan55
Building configuration...

Current configuration : 290 bytes
!
interface Vlan55
vrf forwarding sample_guest
ip address 55.55.55.2 255.255.255.0
no ip proxy-arp
ip nat inside
ip cef accounting non-recursive external
ip ospf authentication message-digest
ip ospf message-digest-key 1 md5 cisco123
no autostate
no mop enabled
no mop sysid
end
```

To verify the NAT datapath statistics, use the following command:

```
Device# show run int Loopback1
Building configuration...

Current configuration : 90 bytes
!
interface Loopback1
vrf forwarding sample_guest
ip address 7.7.7.1 255.255.255.0
end

ip dhcp pool l3_sample_guest
vrf sample_guest
network 55.55.55.0 255.255.255.0
default-router 55.55.55.2
```

To verify the IP entries from database, use the following command:

```
Device# show wireless device-tracking database ip
```

IP	MAC	VRF-NAME	ZONE/VRF-TABLE-ID	STATE	DISCOVERY
55.55.55.2	001e.bd11.a0ff		0x00000003	Reachable	Local
55.55.55.6	58a0.239b.d25f	sample_guest	0x00000003	Reachable	IPv4 DHCP

Verifying Layer 3 Access Details

To verify whether Layer 3 access is enabled for a specific policy profile, use the following command:

```
Device# show wireless profile policy detailed default-policy-profile
Policy Profile Name      : default-policy-profile
Description              : default policy profile
Status                  : ENABLED
VLAN                    : 20
.
.
.
L3 Forwarding           : ENABLED
```

To view whether the Layer 3 access is enabled under policy profile, use the following command:

```
Device# show wireless profile policy all
Policy Profile Name      : default-policy-profile
Description              : default policy profile
Status                  : ENABLED
VLAN                    : 20
.
.
.
L3 Forwarding           : ENABLED
```

To verify the client information, use the following command:

```
Device# show wireless client mac-address <mac-address> detail
Client MAC Address : a886.ddb2.05e9
.
.
.
L3 Forwarding: Enabled
```

To verify the client gateway details, use the following command:

```
Device# show wireless client mac-address 0024.d742.46e4 detail | inc Gateway
.
.
.
Client Gateway IPv4 Address : 117.117.117.1
```

Note The client gateway is displayed only if the client performs DHCP.
If the client learns IP using static or ARP, the client gateway will not be displayed.

Information About Network Mobility Services Protocol

Cisco Network Mobility Services Protocol (NMSP) is a secure two-way protocol that can be run over a connection-oriented (TLS) or HTTPS transport. The wireless infrastructure runs the NMSP server and Cisco Connected Mobile Experiences (Cisco CMX) acts as an NMSP client. The controller supports multiple services and multiple Cisco CMXs can connect to the NMSP server to get the data for the services (location of wireless devices, probe RSSI, hyperlocation, wIPS, and so on.) over the NMSP or HTTPS session.

NMSP defines the intercommunication between Cisco CMX and the controller. Cisco CMX communicates to the controller over a routed IP network. Both publish-subscribe and request-reply communication models are supported. Typically, Cisco CMX establishes a subscription to receive services data from the controller in the form of periodic updates. The controller acts as a data publisher, broadcasting services data to multiple CMXs. Besides subscription, Cisco CMX can also send requests to the controller, causing the controller to send a response back.

The following is a list of the Network Mobility Services Protocol features:

- NMSP is disabled by default.
- NMSP communicates with Cisco CMX using TCP, and uses TLS for encryption.

- Wireless intrusion prevention system (wIPS) is supported only over TCP and TLS.
- Bidirectional communication is supported and Cisco CMX can send a message asynchronously over the established channel.

Note HTTPS is not supported for data transport between controller and Cisco CMX.

Radioactive Tracing for NMSP

This feature collects and provides all CMX-related events.

When a controller is added to CMX with an existing logging or serviceability tools, the following occurs:

- CMX reaches out to the controller through SNMP and CLI.
- Configures the CMX hash key on the controller.
- CMX requests the controller to open an NMSP connection.

RA tracing simplifies troubleshooting by allowing:

- RA trace the CMX IP on the controller.
- Collect all logs about it.

Enabling NMSP on Premises Services

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	nmsp enable Example: Device(config)# <code>nmsp enable</code>	Enables NMSP on premises services. Note By default, the NMSP is enabled on the controller.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Modifying the NMSP Notification Interval for Clients, RFID Tags, and Rogues

NMSP manages communication between the Cisco Connected Mobile Experience (Cisco CMX) and the controller for incoming and outgoing traffic. If your application requires more frequent location updates, you can modify the NMSP notification interval (to a value between 1 and 180 seconds) for clients, active RFID tags, and rogue access points and clients.

Note The TCP port (16113) that the controller and Cisco CMX communicate over must be open (not blocked) on any firewall that exists between the controller and the Cisco CMX for NMSP to function.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	nmosp notification interval {rssi {clients rfid rogues {ap client } spectrum interferers } interval} Example: Device(config)# <code>nmosp notification interval rssi rfid 50</code>	Sets the NMSP notification interval value for clients, RFID tags, rogue clients, and access points. <i>interval</i> -NMSP notification interval value, in seconds for RSSI measurement. Valid range is from 1 to 180.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Modifying the NMSP Notification Threshold for Clients, RFID Tags, and Rogues

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	location notify-threshold {clients rogues ap tags } <i>threshold</i> Example: Device(config)# location notify-threshold clients 5	Configures the NMSP notification threshold for clients, RFID tags, rogue clients, and access points. <i>threshold</i> - RSSI threshold value in db. Valid range is from 0 to 10, with a default value of 0..
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring NMSP Strong Cipher

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	nmsp strong-cipher Example: Device(config)# nmsp strong-cipher	Enable strong ciphers for NMSP server, which contains "ECDHE-RSA-AES128-GCM-SHA256;, ECDHE-ECDSA-AES128-GCM-SHA256;, AES256-SHA256:AES256-SHA;, and AES128-SHA256:AES128-SHA". Normal cipher suite contains, "ECDHE-RSA-AES128-GCM-SHA256;, ECDHE-ECDSA-AES128-GCM-SHA256;, and AES128-SHA".
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Verifying NMSP Settings

To view the NMSP capabilities of the controller, use the following command:

```
Device# show nmsp capability
Service          Subservice
-----
RSSI              Rogue, Tags, Mobile Station,
```

```
Spectrum          Aggregate Interferer, Air Quality, Interferer,
Info              Rogue, Mobile Station,
Statistics        Rogue, Tags, Mobile Station,
AP Monitor        Subscription
On Demand Services Device Info
AP Info           Subscription
```

To view the NMSP notification intervals, use the following command:

```
Device# show nmsp notification interval
NMSP Notification Intervals
```

```
-----
RSSI Interval:
Client           : 2 sec
RFID             : 50 sec
Rogue AP         : 2 sec
Rogue Client     : 2 sec
Spectrum         : 2 sec
```

To view the connection-specific statistics counters for all CMX connections, use the following command:

```
Device# show nmsp statistics connection
NMSP Connection Counters
```

```
-----
CMX IP Address: 10.22.244.31, Status: Active
State:
  Connections : 1
  Disconnections : 0
  Rx Data Frames : 13
  Tx Data Frames : 99244
  Unsupported messages : 0
Rx Message Counters:
  ID  Name                               Count
-----
   1  Echo Request                         6076
   7  Capability Notification                2
  13  Measurement Request                   5
  16  Information Request                   3
  20  Statistics Request                    2
  30  Service Subscribe Request             1

Tx Message Counters:
  ID  Name                               Count
-----
   2  Echo Response                         6076
   7  Capability Notification                1
  14  Measurement Response                  13
  15  Measurement Notification              91120

Examples: NMSP Settings Configuration

This example shows how to configure the NMSP notification interval for RFID tags:

```
Device# configure terminal
Device(config)# nmsp notification interval rssi rfid 50
Device(config)# end
Device# show nmsp notification interval
```

This example shows how to configure the NMSP notification interval for clients:

```
Device# configure terminal
Device(config)# nmsp notification interval rssi clients 180
Device(config)# end
Device# show nmsp notification interval
```

NMSP by AP Groups with Subscription List from CMX

The Cisco CMX group support allows you to send only the required Network Mobility Services Protocol (NMSP) data to Cisco CMX (applicable to both on-premises and cloud-based CMX). The Cisco CMX can subscribe to NMSP data of specific APs or AP groups based on the active services in the wireless controller.

This feature helps in load balancing and optimizing the data flow load, when the APs are distributed across different CMX servers. The Cisco CMX server creates a CMX AP group giving it a unique name and groups the APs under it.

Note The Cisco CMX AP Group is the list of Cisco APs managed by the Cisco CMX for location services. This AP group is not the same as the wireless controller AP group.

This feature supports the following services:

- Client
- Probe client filtering
- Hyperlocation
- BLE Services

Note NMSP subscription is available only for those services that are in enabled state in the wireless controller.

Verifying NMSP by AP Groups with Subscription List from CMX

To verify mobility services group subscription summary of all CMX connections, use the following command:

```
Device# show nmsp subscription group summary
```

```
CMX IP address: 127.0.0.1
Groups subscribed by this CMX server:
Group name: Group1
```

To view the services that are subscribed for an AP group by a CMX connection, use the following command:

```
Device# show nmsp subscription group details services group-name cmx-IP-address
```

```
CMX IP address: 127.0.0.1
CMX Group name: Group1
CMX Group filtered services:
Service          Subservice
-----
RSSI             Mobile Station,
Spectrum
Info
Statistics
```

To view the AP MAC list that is subscribed for an AP group by a CMX connection, use the following command:

```
Device show nmsp subscription group detail ap-list group-name cmx-IP-address
```

```
CMX IP address: 127.0.0.1
CMX Group name: Group1
CMX Group AP MACs:
: 0000.0000.7002 0000.0000.6602 0099.0000.0002 0000.00bb.0002

To view all the AP lists subscribed by all CMXs, use the following command:

```
Device# show nmsp subscription group detail ap-list <group> <cmx-ip>
```

To view all the services subscribed by all CMXs, use the following command:

```
Device# show nmsp subscription group detail services <group> <cmx-ip>
```

Probe RSSI Location

The Probe RSSI Location feature allows the wireless controller and Cisco CMX to support the following:

- Load balancing
- Coverage Hole detection
- Location updates to CMX

When a wireless client is enabled, it sends probe requests to identify the wireless networks in the vicinity and also to find the received signal strength indication (RSSI) associated with the identified Service Set Identifiers (SSIDs).

The wireless client periodically performs active scanning in background even after being connected to an access point. This helps them to have an updated list of access points with best signal strength to connect. When the wireless client can no longer connect to an access point, it uses the access point list stored to connect to another access point that gives it the best signal strength. The access points in the WLAN gather these probe requests, RSSI and MAC address of the wireless clients and forwards them to the wireless controllers. The Cisco CMX gathers this data from the wireless controller and uses it to compute the updated location of the wireless client when it roams across the network.

Configuring Probe RSSI

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	wireless probe filter Example: <pre>Device(config)# wireless probe filter</pre>	<p>Enables filtering of unacknowledged probe requests from AP to improve the location accuracy. Filtering is enabled by default.</p> <p>Use the no form of the command to disable the feature. This will forward both acknowledged and unacknowledged probe requests to the controller.</p>
Step 3	wireless probe limit <i>limit-value interval</i> Example: <pre>Device(config)# wireless probe limit 10 100</pre>	<p>Configures the number of probe request reported to the wireless controller from the AP for the same client on a given interval.</p> <p>Use the no form of the command to revert to the default limit, which is 2 probes at an interval of 500 ms.</p>
Step 4	wireless probe locally-administered-mac Example: <pre>Device(config)# wireless probe locally-administered-mac</pre>	<p>Enables the reporting of probes from clients having locally administered MAC address.</p>
Step 5	location algorithm rssi-average Example: <pre>Device(config)# location algorithm rssi-average</pre>	<p>Sets the probe RSSI measurement updates to a more accurate algorithm but with more CPU overhead.</p>
Step 6	location algorithm simple Example: <pre>Device(config)# location algorithm simple</pre>	<p>(Optional) Sets the probe RSSI measurement updates to a faster algorithm with smaller CPU overhead, but less accuracy.</p> <p>Use the no form of the command to revert the algorithm type to the default one, which is <i>rssi-average</i>.</p>
Step 7	location expiry client <i>interval</i> Example: <pre>Device(config)# location expiry client 300</pre>	<p>Configures the timeout for RSSI values.</p> <p>The no form of the command sets it to a default value of 15.</p>
Step 8	location notify-threshold client <i>threshold-db</i> Example: <pre>Device(config)# location notify-threshold client 5</pre>	<p>Configures the notification threshold for clients.</p> <p>The no form of the command sets it to a default value of 0.</p>
Step 9	location rssi-half-life client <i>time-in-seconds</i> Example: <pre>Device(config)# location rssi-half-life client 20</pre>	<p>Configures half life when averaging two RSSI readings.</p> <p>To disable this option, set the value to 0.</p>

What to do next

Use the **show wireless client probing** command to view each probing client (associated and probing only) by batch of 10 MAC addresses.

RFID Tag Support

The controller enables you to configure radio frequency identification (RFID) tag tracking. RFID tags are small wireless battery-powered tags that continuously broadcast their own signal and are affixed to assets for real-time location tracking. They operate by advertising their location using special 802.11 packets, which are processed by access points, the controller, and the Cisco CMX. Only active RFIDs are supported. A combination of active RFID tags and wireless controller allows you to track the current location of equipment. *Active* tags are typically used in real-time tracking of high-value assets in *closed-loop* systems (that is,) systems in which the tags are not intended to physically leave the control premises of the tag owner or originator.

General Guidelines

- You can verify the RFID tags on the controller.
- High Availability for RFID tags are supported.

Configuring RFID Tag Support

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless rfid Example: Device(config)# wireless rfid	Enables RFID tag tracking. The default value is enabled. Use the no form of this command to disable RFID tag tracking.
Step 3	wireless rfid timeout <i>timeout-value</i> Example: Device(config)# wireless rfid timeout 90	Configures the RFID tag data timeout value to cleanup the table. The timeout value is the amount of time that the controller maintains tags before expiring them. For example, if a tag is configured to beacon every 30 seconds, we recommend that you set the timeout value to 90 seconds (approximately three times the beacon value). The default value is 1200 seconds.

Verifying RFID Tag Support

To view the summary of RFID tags that are clients, use the following command:

```
Device# show wireless rfid client
```

To view the detailed information for an RFID tag, use the following command:

```
Device# show wireless rfid detail <rfid-mac-address>
```

```

Information About Application Visibility and Control

Application Visibility and Control (AVC) is a subset of the entire Flexible NetFlow (FNF) package that can provide traffic information. The AVC feature employs a distributed approach that benefits from NBAR running on the access point (AP) or controller whose goal is to run deep packet inspection (DPI) and reports the results using FNF messages.

AVC enables you to perform real-time analysis and create policies to reduce network congestion, costly network link usage, and infrastructure upgrades. Traffic flows are analyzed and recognized using the NBAR2 engine. The specific flow is marked with the recognized protocol or application. This per-flow information can be used for application visibility using FNF. After the application visibility is established, a user can define control rules with policing mechanisms for a client.

Using AVC rules, you can limit the bandwidth of a particular application for all the clients joined on the WLAN. These bandwidth contracts coexist with per-client downstream rate limiting that takes precedence over the per-application rate limits.

FNF feature is supported in wireless, and relies on the NetFlow enablement on the controller for all modes: flex, local and Fabric.

In local mode, the NBAR runs on the controller hardware and the process client traffic flows through the data plane of the controller using the AP CAPWAP tunnels.

In FlexConnect or Fabric mode, NBAR runs on the AP, and only statistics are sent to the controller. When operating in these two modes, APs regularly send FNFv9 reports back to the controller. The controller's FNF feature consumes those FNFv9 reports to provide the application statistics shown by AVC.

The Fabric mode of operation does not populate the FNF cache. It relays the FNFv9 reports at the time they arrive. As a result, some configuration of flow monitors, for example, cache timeout, is not taken into account.

The behavior of the AVC solution changes based on the wireless deployments. The following sections describe the commonalities and differences in all scenarios:

Local Mode

- NBAR is enabled on the controller.
- AVC does not push the FNF configuration to the APs.
- Roaming events are ignored.

However, AVC supports L3 roams in local mode as traffic flows through the anchor controller (where NBAR was initially processing the roaming client's traffic when the client joined).

- IOSd needs to trigger NBAR attach.
- Supports flow monitor cache.
- Supports NetFlow exporter.

Flex Mode

- NBAR is enabled on an AP
- AVC pushes the FNF configuration to the APs.
- Supports context transfer for roaming in AVC-FNF.
- Supports flow monitor cache.
- Supports NetFlow exporter.

Fabric Mode

- NBAR is enabled on an AP.
- AVC pushes the FNF configuration to the APs.
- Supports context transfer for roaming in AVC-FNF.
- Flow monitor cache is not supported.
- Supports NetFlow exporter (for the C9800 embedded on Catalyst switches for SDA, there is no FNF cache on the box).

Prerequisites for Application Visibility and Control

- The access points should be AVC capable.
However, this requirement is not applicable in Local mode.
- For the control part of AVC (QoS) to work, the application visibility feature with FNF has to be configured.

Restrictions for Application Visibility and Control

- IPv6 (including ICMPv6 traffic) packet classification is not supported in FlexConnect mode and Fabric mode. However, it is supported in Local mode.
- Layer 2 roaming is not supported across controller controllers.
- Multicast traffic is not supported.
- AVC is supported only on the following access points:
 - Cisco Catalyst 9100 Series Access Points
 - Cisco Aironet 1800 Series Access Points
 - Cisco Aironet 2700 Series Access Point
 - Cisco Aironet 2800 Series Access Point
 - Cisco Aironet 3700 Series Access Points
 - Cisco Aironet 3800 Series Access Points
 - Cisco Aironet 4800 Series Access Points
 - Cisco Industrial Wireless 3702 Access Point
- AVC is not supported on Cisco Aironet 702W, 702I (128 M memory), and 1530 Series access points.
- Only the applications that are recognized with App visibility can be used for applying QoS control.
- Data link is not supported for NetFlow fields in AVC.
- You cannot map the same WLAN profile to both the AVC-not-enabled policy profile and the AVC-enabled policy profile.
- AVC is not supported on the management port (Gig 0/0).
- NBAR-based QoS policy configuration is allowed only on wired physical ports. Policy configuration is not supported on virtual interfaces, for example, VLAN, port channel and other logical interfaces.

When AVC is enabled, the AVC profile supports only up to 23 rules, which includes the default DSCP rule. The AVC policy will not be pushed down to the AP, if rules are more than 23.

AVC Configuration Overview

To configure AVC, follow these steps:

1. Create a flow monitor using the **record wireless avc basic** command.

2. Create a wireless policy profile.
3. Apply the flow monitor to the wireless policy profile.
4. Create a wireless policy tag.
5. Map the WLAN to the policy profile
6. Attach the policy tag to the APs.

Create a Flow Monitor

The NetFlow configuration requires a flow record, a flow monitor, and a flow exporter. This configuration should be the first step in the overall AVC configuration.

Note In Flex mode and Local mode, the default values for **cache timeout active** and **cache timeout inactive** commands are not optimal for AVC. We recommend that you set both the values to 60 in the flow monitor. For Fabric mode, the cache timeout configuration does not apply.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	flow monitor <i>monitor-name</i> Example: Device(config)# flow monitor fm_avc	Creates a flow monitor.
Step 3	record wireless avc {ipv4 ipv6} basic Example:	Specifies the basic IPv4 or IPv6 wireless AVC flow template.

	Command or Action	Purpose
	<pre>Device(config-flow-monitor)# record wireless avc ipv6 basic</pre>	<p>Note If you want to have both Application Performance Monitoring (APM) and AVC-FNF in the device simultaneously, use the record wireless avc {ipv4 ipv6} assurance command, which is a superset of the fields contained in record wireless avc {ipv4 ipv6} basic command. If the containing flow monitor is configured with the local exporter using destination wlc local command, AVC-FNF will populate the statistics exactly as that of the record wireless avc {ipv4 ipv6} basic configuration. As a result, both APM and AVC-FNF can be configured simultaneously with two flow monitors per direction, per IP version, in local (central switching) mode.</p> <p>Note The record wireless avc basic command is same as record wireless avc ipv4 basic command. However, record wireless avc ipv4 basic command is not supported in Flex or Fabric modes. In such scenarios, use the record wireless avc basic command.</p>
Step 4	<p>cache timeout active <i>value</i></p> <p>Example:</p> <pre>Device(config-flow-monitor)# cache timeout active 60</pre>	Sets the active flow timeout in seconds.
Step 5	<p>cache timeout inactive <i>value</i></p> <p>Example:</p> <pre>Device(config-flow-monitor)# cache timeout inactive 60</pre>	Sets the inactive flow timeout in seconds.

Configuring a Flow Monitor (GUI)

Before you begin

You must have created a flow exporter to export data from the flow monitor.

Procedure

-
- Step 1** Choose **Configuration > Services > Application Visibility** and go to the **Flow Monitor** tab .
 - Step 2** In the **Monitor** area, click **Add** to add a flow monitor.
 - Step 3** In the **Flow Monitor** window, add a flow monitor and a description.
 - Step 4** Select the Flow exporter from the drop-down list to export the data from the flow monitor to a collector.

Note To export wireless netflow data, use the templates below:

- ETA (Encrypted Traffic Analysis)
- wireless avc basic
- wireless avc basic IPv6

- Step 5** Click **Apply to Device** to save the configuration.
-

Create a Flow Record

The default flow record cannot be edited or deleted. If you require a new flow record, you need to create one and map it to the flow monitor from CLI.

Procedure

	Command or Action	Purpose
Step 1	flow record <i>flow_record_name</i> Example: Device(config)# flow record record1	Creates a flow record. Note When a custom flow record is configured in Flex and Fabric modes, the optional fields (fields that are not present in record wireless avc basic) are ignored.
Step 2	description <i>string</i> Example: Device(config-flow-record)# description IPv4flow	(Optional) Describes the flow record as a maximum 63-character string.

	Command or Action	Purpose
Step 3	match ipv4 protocol Example: Device(config-flow-record)# match ipv4 protocol	Specifies a match to the IPv4 protocol.
Step 4	match ipv4 source address Example: Device(config-flow-record)# match ipv4 source address	Specifies a match to the IPv4 source address-based field.
Step 5	match ipv4 destination address Example: Device(config-flow-record)# match ipv4 destination address	Specifies a match to the IPv4 destination address-based field.
Step 6	match transport source-port Example: Device(config-flow-record)# match transport source-port	Specifies a match to the transport layer's source port field.
Step 7	match transport destination-port Example: Device(config-flow-record)# match transport destination-port	Specifies a match to the transport layer's destination port field.
Step 8	match flow direction Example: Device(config-flow-record)# match flow direction	Specifies a match to the direction the flow was monitored in.
Step 9	match application name Example: Device(config-flow-record)# match application name	Specifies a match to the application name. Note This action is mandatory for AVC support because this allows the flow to be matched against the application.
Step 10	match wireless ssid Example: Device(config-flow-record)# match wireless ssid	Specifies a match to the SSID name identifying the wireless network.
Step 11	collect counter bytes long Example: Device(config-flow-record)# collect counter bytes long	Collects the counter field's total bytes.

	Command or Action	Purpose
Step 12	collect counter packets long Example: Device(config-flow-record)# collect counter bytes long	Collects the counter field's total packets.
Step 13	collect wireless ap mac address Example: Device(config-flow-record)# collect wireless ap mac address	Collects the BSSID with the MAC addresses of the access points that the wireless client is associated with.
Step 14	collect wireless client mac address Example: Device(config-flow-record)# collect wireless client mac address	Collects the MAC address of the client on the wireless network.

Create a Flow Exporter

You can create a flow exporter to define the export parameters for a flow. This is an optional procedure for configuring flow exporter parameters.

Note For the AVC statistics to be visible at the controller, you should configure a local flow exporter using the following commands:

- **flow exporter** *my_local*
- **destination local wlc**

Also, your flow monitor must use this local exporter for the statistics to be visible at the controller.

Procedure

	Command or Action	Purpose
Step 1	flow exporter <i>flow-export-name</i> Example: Device(config)# flow exporter export-test	Creates a flow monitor.
Step 2	description <i>string</i> Example: Device(config-flow-exporter)# description IPv4flow	Describes the flow record as a maximum 63-character string.

	Command or Action	Purpose
Step 3	destination {hostname/ipv4address hostname/ipv6address local {wlc}} Example: Device(config-flow-exporter)# destination local wlc	Specifies the hostname or IP address of the system or the local WLC to which the exporter sends data.
Step 4	transport udp port-value Example: Device(config-flow-exporter)# transport udp 1024	(Optional) Configures the destination UDP port to reach the external collector. The default value is 9995. Note This step is required only for external collectors; not required for local wlc collector.
Step 5	option application-table timeout seconds Example: Device(config-flow-exporter)# option application-table timeout 500	(Optional) Specifies the application table timeout option, in seconds. The valid range is from 1 to 86400.
Step 6	end Example: Device(config-flow-exporter)# end	Returns to privileged EXEC mode.
Step 7	show flow exporter Example: Device# show flow exporter	(Optional) Verifies your configuration.

Configuring a Policy Tag

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag policy policy-tag-name Example: Device(config-policy-tag)# wireless tag policy rr-xyz-policy-tag	Configures policy tag and enters policy tag configuration mode.
Step 3	end Example:	Saves the configuration and exits configuration mode and returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config-policy-tag)# end	

Attaching a Policy Profile to a WLAN Interface (GUI)

Procedure

-
- Step 1** Choose **Configuration** > **Tags & Profiles** > **Tags**.
- Step 2** On the **Manage Tags** page, click **Policy** tab.
- Step 3** Click **Add** to view the **Add Policy Tag** window.
- Step 4** Enter a name and description for the policy tag.
- Step 5** Click **Add** to map WLAN and policy.
- Step 6** Choose the WLAN profile to map with the appropriate policy profile, and click the tick icon.
- Step 7** Click **Save & Apply to Device**.
-

Attaching a Policy Profile to a WLAN Interface (CLI)

Before you begin

- Do not attach different AVC policy profiles on the same WLAN across different policy tags.

The following is an example of incorrect configuration:

```
wireless profile policy avc_pol1
  ipv4 flow monitor fm-avc1 input
  ipv4 flow monitor fm-avc1 output
  no shutdown
wireless profile policy avc_pol2
  ipv4 flow monitor fm-avc2 input
  ipv4 flow monitor fm-avc2 output
  no shutdown
wireless tag policy avc-tag1
  wlan wlan1 policy avc_pol1
wireless tag policy avc-tag2
  wlan wlan1 policy avc_pol2
```

This example violates the restriction stated earlier, that is, the WLAN *wlan1* is mapped to 2 policy profiles, *avc_pol1* and *avc_pol2*. This configuration is, therefore, incorrect because the WLAN *wlan1* should be mapped to either *avc_pol1* or *avc_pol2* everywhere.

- Conflicting policy profiles on the same WLAN are not supported. For example, policy profile (with and without AVC) applied to the same WLAN in different policy tags.

The following is an example of an incorrect configuration:

```
wireless profile policy avc_pol1
  no shutdown
```

```
wireless profile policy avc_pol2
  ipv4 flow monitor fm-avc2 input
  ipv4 flow monitor fm-avc2 output
  no shutdown
wireless tag policy avc-tag1
  wlan wlan1 policy avc_pol1
wireless tag policy avc-tag2
  wlan wlan1 policy avc_pol2
```

In this example, a policy profile with and without AVC is applied to the same WLAN in different tags.

Procedure

	Command or Action	Purpose
Step 1	wireless tag policy <i>avc-tag</i> Example: Device(config)# wireless tag policy avc-tag	Creates a policy tag.
Step 2	wlan <i>wlan-avc</i> policy <i>avc-policy</i> Example: Device(config-policy-tag)# wlan wlan_avc policy avc_pol	Attaches a policy profile to a WLAN profile.

What to do next

- Run the **no shutdown** command on the WLAN after completing the configuration.
- If the WLAN is already in **no shutdown** mode, run the **shutdown** command, followed by **no shutdown** command.

Attaching a Policy Profile to an AP

Procedure

	Command or Action	Purpose
Step 1	ap <i>ap-ether-mac</i> Example: Device(config)# ap 34a8.2ec7.4cf0	Enters AP configuration mode.
Step 2	policy-tag <i>policy-tag</i> Example: Device(config)# policy-tag avc-tag	Specifies the policy tag that is to be attached to the access point.

Verify the AVC Configuration

Procedure

	Command or Action	Purpose
Step 1	<p>show avc wlan <i>wlan-name</i> top <i>num-of-applications</i> applications {aggregate downstream upstream}</p> <p>Example:</p> <pre>Device# show avc wlan wlan_avc top 2 applications aggregate</pre>	<p>Displays information about top applications and users using these applications.</p> <p>Note Ensure that wireless clients are associated to the WLAN and generating traffic, and then wait for 90 seconds (to ensure the availability of statistics) before running the command.</p>
Step 2	<p>show avc client <i>mac</i> top <i>num-of-applications</i> applications {aggregate downstream upstream}</p> <p>Example:</p> <pre>Device# show avc client 9.3.4 top 3 applications aggregate</pre>	<p>Displays information about the top number of applications.</p> <p>Note Ensure that wireless clients are associated to the WLAN and generating traffic, and then wait for 90 seconds (to ensure the availability of statistics) before running the command.</p>
Step 3	<p>show avc wlan <i>wlan-name</i> application <i>app-name</i> top <i>num-of-clients</i> aggregate</p> <p>Example:</p> <pre>Device# show avc wlan wlan_avc application app top 4 aggregate</pre>	<p>Displays information about top applications and users using these applications.</p>
Step 4	<p>show ap summary</p> <p>Example:</p> <pre>Device# show ap summary</pre>	<p>Displays a summary of all the access points attached to the controller .</p>
Step 5	<p>show ap tag summary</p> <p>Example:</p> <pre>Device# show ap tag summary</pre>	<p>Displays a summary of all the access points with policy tags.</p>

Default DSCP on AVC

Configuring Default DSCP for AVC Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration** > **Services** > **QoS**.
- Step 2** Click **Add**.
- Step 3** Enter the **Policy Name**.
- Step 4** Click **Add Class-Maps**.
- Step 5** Choose **AVC** in the **AVC/User Defined** drop-down list.
- Step 6** Click either **Any** or **All** match type radio button.
- Step 7** Choose **DSCP** in the **Mark Type** drop-down list.
- Step 8**
- a) Check the **Drop** check box to drop traffic from specific sources.
 - b) If you do not want to drop the traffic, enter the **Police(kbps)** and choose the match type from the **Match Type** drop-down list. Choose the items from the available list and click move them to the selected list.
- Step 9** Click **Save**.
- Step 10** Click **Apply to Device**.
-

Configuring Default DSCP for AVC Profile

In Cisco Catalyst 9800 Series Wireless Controller, only up to 32 filters can be specified in the policy. As there was no way of classifying the packets that are not specified in the filters, now, you can mark down these packets in the policy.

The marking action can be applied to the traffic when creating a class map and creating a policy map.

Creating Class Map

Procedure

	Command or Action	Purpose
Step 1	Configure Terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	class class-map-name] Example: Device(config-pmap)# class-map avc-class	Creates a class map.

	Command or Action	Purpose
Step 3	<p>match protocol { <i>application-name</i> attribute category <i>category-name</i> attribute sub-category <i>sub-category-name</i> attribute application-group <i>application group-name</i></p> <p>Example:</p> <pre>Device(config)# class-map avc-class Device(config-cmap)# match protocol avc-media Device(config)# class-map class-avc-category Device(config-cmap)# match protocol attribute category avc-media Device# class-map class-avc-sub-category Device(config-cmap)# match protocol attribute sub-category avc-media Device# class-map avcS-webex-application-group Device(config-cmap)# match protocol attribute application-group webex-media</pre>	Specifies match to the application name, category name, subcategory name, or application group.
Step 4	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Creating Policy Map

Procedure

	Command or Action	Purpose
Step 1	<p>Configure Terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 2	<p>policy-map <i>policy-map-name</i></p> <p>Example:</p> <pre>Device(config)#policy-map avc-policy</pre>	<p>Creates a policy map by entering the policy map name, and enters policy-map configuration mode.</p> <p>By default, no policy maps are defined.</p> <p>The default behavior of a policy map is to set the DSCP to 0 if the packet is an IP packet and to set the CoS to 0 if the packet is tagged. No policing is performed.</p> <p>Note To delete an existing policy map, use the no policy-map policy-map-name global configuration command.</p>

	Command or Action	Purpose
Step 3	class [<i>class-map-name</i> class-default] Example: Device(config-pmap)# class-map avc-class	<p>Defines a traffic classification, and enters policy-map class configuration mode.</p> <p>By default, no policy map and class maps are defined.</p> <p>If a traffic class has already been defined by using the class-map global configuration command, specify its name for class-map-name in this command.</p> <p>A class-default traffic class is predefined and can be added to any policy. It is always placed at the end of a policy map. With an implied match any is included in the class-default class, all packets that have not already matched the other traffic classes will match class-default .</p> <p>Note To delete an existing class map, use the no class class-map-name policy-map configuration command.</p>
Step 4	set dscp <i>new-dscp</i> Example: Device(config-pmap-c)# set dscp 45	Classifies IP traffic by setting a new value in the packet. For dscp new-dscp , enter a new DSCP value to be assigned to the classified traffic. The range is 0 to 63.
Step 5	class <i>class-default</i>	Specifies the default class so that you can configure or modify its policy.
Step 6	set dscp default	Configures the default DSCP.
Step 7	end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

AVC-Based Selective Reanchoring

The AVC-Based Selective Reanchoring feature is designed to reanchor clients when they roam from one controller to another. Reanchoring of clients prevents the depletion of IP addresses available for new clients in Cisco WLC. The AVC profile-based statistics are used to decide whether a client must be reanchored or deferred. This is useful when a client is actively running a voice or video application defined in the AVC rules.

The reanchoring process also involves deauthentication of anchored clients. The clients get deauthenticated when they do not transmit traffic for the applications listed in the AVC rules while roaming between WLCs.

Restrictions for AVC-Based Selective Reanchoring

- This feature is supported only in local mode. FlexConnect and fabric modes are not supported.
- This feature is not supported in guest tunneling and export anchor scenarios.
- The old IP address is not released after reanchoring, until IP address' lease period ends.

Configuring the Flow Exporter

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	flow exporter name Example: Device(config)# flow exporter avc-reanchor	Creates a flow exporter and enters flow exporter configuration mode. Note You can use this command to modify an existing flow exporter too.
Step 3	destination local wlc Example: Device(config-flow-exporter)# destination local wlc	Sets the exporter as local.

Configuring the Flow Monitor

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	flow monitor monitor-name Example: Device(config)# flow monitor fm_avc	Creates a flow monitor and enters Flexible NetFlow flow monitor configuration mode. Note You can use this command to modify an existing flow monitor too.

	Command or Action	Purpose
Step 3	exporter <i>exporter-name</i> Example: Device(config-flow-monitor)# exporter avc-reanchor	Specifies the name of an exporter.
Step 4	record wireless avc basic Example: Device(config-flow-monitor)# record wireless avc basic	Specifies the flow record to use to define the cache.
Step 5	cache timeout active <i>value</i> Example: Device(config-flow-monitor)# cache timeout active 60	Sets the active flow timeout, in seconds.
Step 6	cache timeout inactive <i>value</i> Example: Device(config-flow-monitor)# cache timeout inactive 60	Sets the inactive flow timeout, in seconds.

Configuring the AVC Reanchoring Profile

Before you begin

- Ensure that you use the AVC-Reanchor-Class class map. All other class-map names are ignored by Selective Reanchoring.
- During boot up, the system checks for the existence of the AVC-Reanchor-Class class map. If it is not found, default protocols, for example, jabber-video, WiFi-calling, and so on, are created. If AVC-Reanchor-Class class map is found, configuration changes are not made and updates to the protocols that are saved to the startup configuration persist across reboots.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	class-map <i>cmap-name</i> Example: Device(config)# class-map AVC-Reanchor-Class	Configures the class map.

	Command or Action	Purpose
Step 3	match any Example: Device(config-cmap)# match any	Instructs the device to match with any of the protocols that pass through it.
Step 4	match protocol jabber-audio Example: Device(config-cmap)# match protocol jabber-audio	Specifies a match to the application name. You can edit the class-map configuration later, in order to add or remove protocols, for example, jabber-video, wifi-calling, and so on, if required.

Configuring the Wireless WLAN Profile Policy

Follow the procedure given below to configure the WLAN profile policy:

Note Starting with Cisco IOS XE Amsterdam 17.1.1, IPv6 flow monitor is supported on Wave 2 APs. You can attach two flow monitors in a policy profile per direction (input and output) and per IP version (IPv4 and IPv6) in local (central switching) mode, when NBAR runs in the controller. However, only one flow monitor is supported per direction (input and output) and per IP version (IPv4 and IPv6) in FlexConnect and fabric modes on Wave 2 APs, when NBAR runs on the corresponding AP.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>policy-name</i> Example: Device(config)# wireless profile policy default-policy-profile	Configures the WLAN policy profile and enters wireless policy configuration mode.
Step 3	shutdown Example: Device(config-wireless-policy)# shutdown	Disables the policy profile.
Step 4	no central switching Example: Device(config-wireless-policy)# no central switching	Disables central switching.

	Command or Action	Purpose
Step 5	ipv4 flow monitor <i>monitor-name</i> input Example: Device(config-wireless-policy)# ipv4 flow monitor fm_avc input	Specifies the name of the IPv4 ingress flow monitor.
Step 6	ipv4 flow monitor <i>monitor-name</i> output Example: Device(config-wireless-policy)# ipv4 flow monitor fm_avc output	Specifies the name of the IPv4 egress flow monitor.
Step 7	ipv6 flow monitor <i>monitor-name</i> input Example: Device(config-wireless-policy)# ipv6 flow monitor fm_v6_avc input	Specifies the name of the IPv6 ingress flow monitor.
Step 8	ipv6 flow monitor <i>monitor-name</i> output Example: Device(config-wireless-policy)# ipv6 flow monitor fm_v6_avc output	Specifies the name of the IPv6 egress flow monitor.
Step 9	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables the policy profile.

Verifying AVC Reanchoring

Use the following commands to verify the AVC reanchoring configuration:

```
Device# show wireless profile policy detailed avc_reanchor_policy
```

```
Policy Profile Name      : avc_reanchor_policy
Description              :
Status                   : ENABLED
VLAN                     : 1
Wireless management interface VLAN : 34
!
.
.
.
AVC VISIBILITY          : Enabled

CHAPTER 64

Software-Defined Application Visibility and Control

- [Information About Software-Defined Application Visibility and Control](#), on page 813
- [Enabling Software-Defined Application Visibility and Control on a WLAN \(CLI\)](#), on page 814
- [Configuring Software-Defined Application Visibility and Control Global Parameters \(CLI\)](#), on page 814

Information About Software-Defined Application Visibility and Control

Software-Defined Application Visibility and Control (SD-AVC) is a network-level AVC controller that aggregates application data from multiple devices and sources and provides composite application information.

SD-AVC collects application data from across the network and deploys protocol pack updates in a centralized manner. SD-AVC recognizes most enterprise network traffic and provides analytics, visibility, and telemetry into the network application recognition. SD-AVC profiles all the endpoints (including wireless bridged virtual machines) connected to the access nodes to perform anomaly detection operations, such as Network Address Translation (NAT). SD-AVC can discover and alert when the same MAC address is used simultaneously on different networks.

You can enable the Software-Defined Application Visibility and Control feature on a per-WLAN basis. Also, you can turn on and turn off the Software-Defined Application Visibility and Control functionalities independently.

Note If the SD-AVC process (stilepd) crashes, Capwapd process restart or AP reload is required to resume the SD-AVC operation.

Enabling Software-Defined Application Visibility and Control on a WLAN (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>policy-name</i> Example: Device(config)# wireless profile policy test-policy-profile	Configures WLAN policy profile and enters wireless policy configuration mode.
Step 3	no central switching Example: Device(config-wireless-policy)# no central switching	Disables central switching and enables local switching.
Step 4	ip nbar protocol-discovery Example: Device(config-wireless-policy)# ip nbar protocol-discovery	Enables application recognition on the wireless policy profile by activating the NBAR2 engine.
Step 5	end Example: Device(config-wireless-policy)# end	Exits wireless policy configuration mode and returns to privileged EXEC mode.

Configuring Software-Defined Application Visibility and Control Global Parameters (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	avc sd-service Example: Device(config-sd-service)# avc sd-service	Enables SD-AVC and enters software-definition service configuration mode.
Step 3	segment <i>segment-name</i> Example: Device(config-sd-service)# segment AppRecognition	Configures a segment name identifying a group of devices sharing the same application services.
Step 4	controller Example: Device(config-sd-service)# controller	Enters SD service controller configuration mode to configure connectivity parameters.
Step 5	address <i>ip-address</i> Example: Device(config-sd-service-controller)# address 209.165.201.0	Configures controller IP address. Supports only IPv4 address.
Step 6	destination-ports sensor-exporter <i>value</i> Example: Device(config-sd-service-controller)# destination-ports sensor-exporter 21730	Configures the destination port for communicating with the controller.
Step 7	dscp <i>dscp-value</i> Example: Device(config-sd-service-controller)# dscp 16	Enables DSCP marking.
Step 8	source-interface <i>interface interface-number</i> Example: Device(config-sd-service-controller)# source-interface GigabitEthernet21	Configures source interface for communicating with the controller.
Step 9	transport application-updates https url-prefix <i>url-prefix-name</i> Example: Device(config-sd-service-controller)# transport application-updates https url-prefix cisco	Configures transport protocols for communicating with the controller.
Step 10	vrf <i>vrf-name</i> Example: Device(config-sd-service-controller)# vrf doc-test	Associates the VRF with the source interface.

	Command or Action	Purpose
Step 11	end Example: Device (config-sd-service-controller) # end	Exits the SD service controller configuration mode and enters privileged EXEC mode.

Information About Cisco Hyperlocation

Cisco Hyperlocation is an ultraprecise location solution that allows you to track the location of wireless clients. This is possible with the Cisco Hyperlocation radio module in the Cisco Aironet 3600, 3700, and 4800 Series Access Points. The Cisco Hyperlocation module combines Wi-Fi and Bluetooth Low Energy (BLE) technologies to allow beacons, inventory, and personal mobile devices to be pinpointed.

Hyperlocation is also supported in Fabric mode. In particular, when the wireless controller is running on the switch, the controller takes the necessary steps to provision the APs, so that they can generate Hyperlocation VxLAN packets that can traverse the fabric network taking advantage of the fabric infrastructure and be correctly delivered to the destination CMX.

The Hyperlocation VxLAN packets are special packets marked with SGT 0 and using the L3VNID of the APs. For more information, refer to the SDA documentation.

The Cisco Hyperlocation radio module provides the following:

- WSM or WSM2 radio module functions that are extended to:
 - 802.11ac

- Wi-Fi Transmit
- 20-MHz, 40-MHz, and 80-MHz channel bandwidth.
- Expanded location functionality:
 - Low-latency location optimized channel scanning
 - 32-antenna angle of arrival (AoA); available only with the WSM2 module.

Note When using the WSM2 module (includes the WSM module and the antenna add-on), the accuracy of tracking the location of wireless clients can be as close as one meter.

Cisco Hyperlocation works in conjunction with Cisco Connected Mobile Experiences (CMX). Combining the Cisco Hyperlocation feature on Cisco Catalyst 9800 Series Wireless Controller with a CMX device allows you to achieve better location accuracy, which can result in delivering more targeted content to users. When you use CMX with Cisco CleanAir frequency scanning, it is simple to locate failed, lost, and even rogue beacons.

The Cisco Hyperlocation radio module with an integrated BLE radio allows transmission of Bluetooth Low Energy (BLE) broadcast messages by using up to 5 BLE transmitters. Cisco Catalyst 9800 Series Wireless Controller is used to configure transmission parameters such as interval for the beacons, universally unique identifier (UUID), and transmission power, per beacon globally for all the access points. Also, the controller can configure major, minor, and transmission power value of each AP to provide more beacon granularity.

Note The Cisco Hyperlocation feature must be enabled on the controller and CMX and CMX must be connected for BLE to work.

In the absence of a Cisco Hyperlocation radio module, Hyperlocation will still work in a modality named *Hyperlocation Local Mode*, which guarantees a slightly lower location accuracy in the range between five meters and seven meters. This is accomplished through CPU cycle stealing.

Using the controller, you can configure Cisco Hyperlocation for APs based on their profile.

Network Time Protocol Server

Cisco Hyperlocation requires the AP to be synchronized with regard to time. To achieve this, the controller sends network time protocol (NTP) information to the AP. The AP then uses the NTP server to synchronize its clock. Therefore, the AP needs connectivity to the NTP server.

APs can be geographically dispersed. Therefore, it is necessary to provide different NTP servers to different APs. This is achieved by allowing the configuration of NTP server information on a per AP profile basis. If NTP information is not configured on the AP profile, the controller uses one of the global NTP peers defined on its configuration or the management IP address is sent as the NTP server to be used if the controller is acting as an NTP server. If the NTP server is not available, Cisco Hyperlocation will be disabled.

Note In scale setup, the NTP server should be configured on the respective AP profiles, so that the APs and CA servers used for LSC provisioning are time synchronized. If the NTP server is not configured, a few APs would fail in LSC provisioning.

Bluetooth Low Energy Configuration

The BLE configuration is split into two parts: per-AP profile and per AP. The BLE feature can be configured partially from the AP profile (by default, the AP profile BLE configuration is applied) and partially per-AP (some or all the attributes are applied).

Table 59: BLE Configuration Details

Attribute	BLE Configuration Per AP Profile	BLE Configuration Per AP
Attributes with per-AP granularity (global for all the beacons)	<ul style="list-style-type: none"> • Interval • Advertised transmission power 	<ul style="list-style-type: none"> • Interval • Advertised transmission power
Attributes with per-AP per0-beacon granularity	<ul style="list-style-type: none"> • Transmission power • UUID • Status 	<ul style="list-style-type: none"> • Transmission power • UUID • Status • Major • Minor

Note The *default-ap-profile* BLE configuration can be considered the default BLE configuration because all the APs will join the *default-ap-profile* AP profile in case the other profiles are removed.

For more information about Cisco Hyperlocation, see the following documents:

- [Cisco Hyperlocation Solution](#)
- [Cisco CMX Configuration Guide to enable Cisco Hyperlocation](#)
- [Cisco CMX Release Notes](#)

Restrictions on Cisco Hyperlocation

- It is not possible to modify detection, trigger, and reset thresholds while Hyperlocation is in enabled state.
- Changes to the reset threshold are allowed for values in the range of zero to one less than the current threshold value. For example, if the current threshold reset value is 10, changes to the reset threshold are allowed for values in the range of 0 to 9.

- When Cisco Hyperlocation is in use on the Cisco Catalyst 9800 Series Wireless Controller in a non-Fabric deployment, CMX must be reachable through an SVI interface (VLAN). Deployments where CMX is reachable through an L3 port results in an error.
- In Fabric deployments, the wireless management interface (typically loopback interface) must not be in Fabric.
- It is not possible to set the wireless management interface to a loopback interface in non-Fabric deployments.

Support for IPv6 in Cisco Hyperlocation or BLE Configuration

Until Release 16.12, IPv4 was the only valid configuration. From Release 17.1 onwards, IPv6 is also supported for specific deployments.

Note CMX accepts only one IP configuration at a time (either IPv4 or IPv6).

The configuration combinations listed in the following tables are the valid deployments.

Table 60: Flex Deployment Mode

Controller Management Interface and AP	CMX
IPv4	IPv4
IPv6	IPv6

Table 61: Fabric Deployment Mode

Controller Management Interface and AP	CMX
IPv4	IPv4

Note Any other combination of IPv4 or IPv6 is not supported.

Configuring Cisco Hyperlocation (GUI)

Cisco Hyperlocation is a location solution that allows to track the location of wireless clients with the accuracy of one meter. Selecting this option disables all other fields in the screen, except NTP Server.

Procedure

- Step 1** In the **Configuration > Tags & Profiles > AP Join** page, click **Add**.

The **Add AP Join Profile** dialog box appears.

- Step 2** Under the **AP > Hyperlocation** tab, select the **Enable Hyperlocation** check box.
- Step 3** In the **Detection Threshold (dBm)** field, enter a value to filter out packets with low RSSI. You must enter a value between -100 dBm and -50 dBm.
- Step 4** In the **Trigger Threshold (cycles)** field, enter a value to set the number of scan cycles before sending a BAR to clients. You must enter a value between 0 and 99.
- Step 5** In the **Reset Threshold is required** field, enter a value to reset value in scan cycles after trigger. You must enter a value between 0 and 99.
- Step 6** Click **Save & Apply to Device**.

Configuring Cisco Hyperlocation (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap profile <i>profile-name</i> Example: Device(config)# <code>ap profile profile-name</code>	Configures an AP profile and enters AP profile configuration mode.
Step 3	[no] hyperlocation Example: Device(config-ap-profile)# <code>[no] hyperlocation</code>	Enables Cisco Hyperlocation feature on all the supported APs that are associated with this AP profile. Use the no form of the command to disable the Cisco Hyperlocation feature.
Step 4	[no] hyperlocation threshold detection <i>value-in-dBm</i> Example: Device(config-ap-profile)# <code>[no] hyperlocation threshold detection -100</code>	Sets threshold to filter out packets with low RSSI. The no form of this command resets the threshold to its default value. Valid range is between -100 and -50 .
Step 5	[no] hyperlocation threshold reset <i>value-btwn-0-99</i> Example: Device(config-ap-profile)# <code>[no] hyperlocation threshold reset 8</code>	Resets the value of scan cycles after a trigger. The no form of this command resets the threshold to its default value.
Step 6	[no] hyperlocation threshold trigger <i>value-btwn-1-100</i>	Sets the number of scan cycles before sending a block acknowledgment request (BAR) to

	Command or Action	Purpose
	Example: Device(config-ap-profile)# [no] hyperlocation threshold trigger 10	clients. The no form of this command resets the threshold to its default value.
Step 7	[no] ntp ip <i>ip-address</i> Example: Device(config-ap-profile)# [no] ntp ip 9.0.0.4	Sets the IP address of the NTP server. The no form of this command removes the NTP server.

Configuring Hyperlocation BLE Beacon Parameters for AP (GUI)

Procedure

-
- Step 1** In the **Configuration > Tags & Profiles > AP Join** page, click **Add**.
The **Add AP Join Profile** dialog box appears.
- Step 2** Under the **AP** tab, click **BLE**.
- Step 3** In the **Beacon Interval (Hz)** field, enter a value.
- Step 4** In the **Advertised Attenuation Level (dBm)** field, enter a value.
- Step 5** Select the check box against each ID and click **Reset**, if required.
- Step 6** Optional, click an ID to edit the values of the following fields, and click **Save**.
- **Status**
 - **Tx Power (dBm)**
 - **UUID**
- Step 7** Click **Save & Apply to Device**.
-

Configuring Hyperlocation BLE Beacon Parameters for AP (CLI)

Follow the procedure given below to configure hyperlocation BLE beacon parameters for an AP:

Procedure

	Command or Action	Purpose
Step 1	ap name <i>ap-name</i> hyperlocation ble-beacon <i>beacon-id</i> { enable major <i>major-value</i> minor <i>minor-value</i> txpwr <i>value-in-dBm</i> uuid <i>uuid-value</i> }	Configures Hyperlocation and related parameters for an AP, and the specified beacon ID: <ul style="list-style-type: none"> • enable—Enables BLE beacon on the AP.

	Command or Action	Purpose
	Example: <pre>Device# ap name test-ap hyperlocation ble-beacon 3 major 65535</pre>	<ul style="list-style-type: none"> • major <i>major-value</i>—Configures BLE beacon's major parameter. Valid value is between 0 and 65535; the default value is 0. • minor <i>minor-value</i>—Configures BLE beacon's minor parameter. Valid value is between 0 and 65535; the default value is 0. • txpwr <i>value-in-dBm</i>—Configures BLE beacon attenuation level. Valid value is between -52 dBm and 0 dBm. • uuid <i>uuid-value</i>—Configures a UUID.
Step 2	ap name <i>ap-name</i> hyperlocation ble-beacon advpwr <i>value-in-dBm</i> Example: <pre>Device# ap name test-ap hyperlocation ble-beacon advpwr 90</pre>	Configures BLE beacon's advertised attenuation level for an AP. The valid range for <i>value-in-dBm</i> is between -40 dBm and -100 dBm; the default value is -59 dBm (all values must be entered as positive integers).

Configuring Hyperlocation BLE Beacon Parameters (CLI)

Before you begin

For Hyperlocation BLE to be enabled, CMX must be fully joined and enabled for Hyperlocation.

Procedure

	Command or Action	Purpose
Step 1	ap profile <i>profile-name</i> Example: <pre>Device(config)# ap profile profile-name</pre>	Enables configuration for all the APs that are associated with the specified AP profile name.
Step 2	hyperlocation ble-beacon <i>beacon-id</i> Example: <pre>Device(config-ap-profile)# hyperlocation ble-beacon 3</pre>	Specifies the BLE beacon parameters and enters BLE configuration mode.
Step 3	enabled Example: <pre>Device(config-halo-ble)# enabled</pre>	Enables BLE for the beacon ID specified.
Step 4	exit Example:	Returns to AP profile configuration mode.

	Command or Action	Purpose
	Device(config-halo-ble)# exit	
Step 5	hyperlocation ble-beacon interval <i>value-in-hertz</i> Example: Device(config-ap-profile)# hyperlocation ble-beacon interval 1	Configures the BLE beacon interval as 1 Hz for the selected profile.
Step 6	hyperlocation ble-beacon advpwr <i>value-in-dBm</i> Example: Device(config-ap-profile)# hyperlocation ble-beacon advpwr 40	Configures the BLE beacon-advertised attenuation level. Valid range is between -40 dBm and -100 dBm. The default value is -59 dBm.

Information About AP Group NTP Server

Features such as Cisco Hyperlocation, BLE Angle of Arrival (AoA), and Intelligent Capture (iCAP) require precise time across APs within an AP group to achieve location accuracy. Because the controller and controller global NTP server are configured on the WAN, they might have large synchronization delays from the APs, and this might compromise location accuracy.

If all the APs in an AP group synchronize with the same NTP server, accurate data can be obtained to calculate the location. Configuring the NTP server locally for all the APs in an AP group helps achieve better synchronization among APs.

Configuring an AP Group NTP Server

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>profile-name</i> Example: Device(config)# ap profile <i>profile-name</i>	Configures an AP profile and enters AP profile configuration mode.
Step 3	[no] ntp ip <i>ip-address</i> Example: Device(config-ap-profile)# [no] ntp ip 9.0.0.4	Sets the IP address of the NTP server. The no form of this command removes the NTP server.

	Command or Action	Purpose
Step 4	<p>[no] ntp auth-key <i>key-index</i> type <i>type</i> format <i>format</i> key <i>encryption-type</i> <i>server-key</i></p> <p>Example:</p> <pre>Device(config-ap-profile)# ntp auth-key index 1 type md5 format ascii key 0 3434324</pre>	<p>Configures NTP server per AP profile to support authentication. The no ntp auth-key command removes the NTP server from each AP profile.</p> <p>Note For ASCII key, ensure that the length is less than 21 bytes. For HEX key, the length should be less than 41, using only numbers between 0-9 and characters from a-f.</p>

Configuring AP Timezone

Procedure

	Command or Action	Purpose
Step 1	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 2	<p>ap profile <i>profile-name</i></p> <p>Example:</p> <pre>Device(config)# ap profile test</pre>	Configures the AP profile and enters AP profile configuration mode.
Step 3	<p>timezone {use-controller delta hour <i>offset-hour</i> minute <i>offset-minute</i>}</p> <p>Example:</p> <pre>Device(config-ap-profile)# timezone delta hour -12 minute 2</pre>	<p>Configures the timezone offset for AP.</p> <p>You can configure the AP timezone only for each AP profile. You cannot configure timezone for each AP.</p> <p>To configure the timezone, either apply the current controller timezone or the time difference. By default, timezone is disabled.</p>

Information About BLE Concurrent Scanning and Beaconing

From Cisco IOS XE Cupertino 17.9.1, Cisco Catalyst Wi-fi6 APs in basic mode or Cisco IOx mode support concurrent scanning and beaoning. The BLE radio on an AP can stop a scan for beacon transmission and return to the scan after completing the beacon transmission.

This feature is supported only on Cisco Catalyst 9105ax, 9120ax, 9124, 9130, 9136, and Cisco Catalyst 916x APs.

BLE concurrent scanning and beaoning can be enabled from Cisco Spaces using the **Dual** mode under **Device Management > AP Beacon > Settings**.

Note BLE concurrent scanning and beacons is not supported when v-iBeacon is used. Supported advertisement profiles are iBeacon, Eddystone-URL, and Eddystone-UID.

Verifying BLE Concurrent Scanning and Beacons

Use the following commands to verify the status of concurrent scanning and beacons.

To display the advertisement profile, scan counters, and advertisement counters along with other information, use the following command from the AP console:

```
Device# show controllers IOTRadio ble 0 interface

Active BLE host interface      : /dev/ttyiot0
BLE Radio Status              : Powered on
Device Status                 : Open
Device Mode                   : Native
Device resets                 : 4
Last Reset Reason             : Watchdog Timer Reset
Heart beat status             : On
Scan Status                  : Enabled
Active Transmit Profile     : Eddystone URL
BLE MAC                       : 80:6F:B0:31:EF:74
Transmitted advertisement count
  since BLE enabled           : 0
Total scan records received   : 3617
```

To see whether the transmit profile configuration has been successfully pushed from Cisco Spaces to the AP, use the following command from the AP console:

```
Device# show controllers iOTRadio ble 0 broadcast

BLE Profile Config
-----
Active profile              : Eddystone UID

Scan Data                      :
```

To display both the overall and the per-AP configuration values and operational status, use the following command:

```
Device# show ap hyperlocation detail
```

```
Profile Name: house24
```

```
Hyperlocation operational status: Up
Reason: NTP server is not properly configured
Hyperlocation NTP server: 198.51.100.1
Hyperlocation admin status: Enabled
Hyperlocation detection threshold (dBm): -90
Hyperlocation trigger threshold: 8
Hyperlocation reset threshold: 7
```

AP Name	Radio MAC	Method	CMX IP	AP Profile
APe865.49d9.bfe0	e865.49ea.a4b0	WSM2+Ant	198.51.100.2	house24
APa89d.21b9.69d0	a89d.21b9.69d0	Local	198.51.100.3	house24
APe4aa.5d3f.d750	e4aa.5d5f.3630	WSM	198.51.100.4	house24

To display the overall (profile specific) configuration values and operational status for a given profile, use the following command:

```
Device# show ap profile profile-name hyperlocation summary
```

```
Profile Name: profile-name
Hyperlocation operational status: Up
Reason: N/A
Hyperlocation NTP server: 209.165.200.224
Hyperlocation admin status: Enabled
Hyperlocation detection threshold (dBm): -100
Hyperlocation trigger threshold: 10
Hyperlocation reset threshold: 8
```

To display both the overall (profile specific) and per-AP configuration values and operational status for a given profile, use the following command. The APs listed are only those APs that belong to the specified join profile.

```
Device# show ap profile profile-name hyperlocation detail
```

```
Profile Name: profile-name
Hyperlocation operational status: Up
Reason: N/A
Hyperlocation NTP server: 209.165.200.224
Hyperlocation admin status: Enabled
Hyperlocation detection threshold (dBm): -90
Hyperlocation trigger threshold: 8
Hyperlocation reset threshold: 7
```

AP Name	Radio MAC	Method	CMX IP
APf07f.0635.2d40	f07f.0635.2d40	WSM2+Ant	198.51.100.2
APf07f.0635.2d41	f07f.0635.2d41	Local	198.51.100.3
APf07f.0635.2d42	f07f.0635.2d42	WSM	198.51.100.4

To display configuration values for an AP profile, use the following command:

```
Device# show ap profile profile-name detailed
```

```
Hyperlocation :
  Admin State           : ENABLED
  PAK RSSI Threshold Detection: -100
  PAK RSSI Threshold Trigger : 10
  PAK RSSI Threshold Reset  : 8
.
.
.
```

To display the Cisco CMXs that are correctly joined and used by hyperlocation, use the following command:

```
Device# show ap hyperlocation cmx summary
```

```
Hyperlocation-enabled CMXs
```

IP	Port	Dest MAC	Egress src MAC	Egress VLAN	Ingress src MAC	Join time
198.51.100.4	2003	aaaa.bbbb.cccc	aabb.cccd.eeff	2	0000.0001.0001	12/14/18 09:27:14

To display the hyperlocation client statistics, use the following command:

```
Device# show platform hardware chassis active qfp
feature wireless wlclient cpp-client summary
```

```
Client Type Abbreviations:
  RG - REGULAR BL - BLE
  HL - HALO LI - LWFL INT
Auth State Abbreviations:
  UK - UNKNOWN IP - LEARN IP IV - INVALID
  L3 - L3 AUTH RN - RUN
Mobility State Abbreviations:
  UK - UNKNOWN IN - INIT
  LC - LOCAL AN - ANCHOR
  FR - FOREIGN MT - MTE
  IV - INVALID
EoGRE Abbreviations:
  N - NON EOGRE Y - EOGRE
CPP IF_H DPIDX MAC Address VLAN CT MCVL AS MS E WLAN POA
-----
```

0X32	0XF0000001	0000.0001.0001	9	HL	0	RN	LC	N	NULL
------	------------	----------------	---	----	---	----	----	---	------

To display the interface handle value statistics, use the following command:

```
Device# show platform hardware chassis active
qfp feature wireless wlclient datapath cpp-if-handle 0x32 statistics start
```

To display the recorded flow, use the following command:

```
Device# show platform hardware chassis active
qfp feature wireless wlclient datapath cpp-if-handle 0X32 statistics
```

	Pkts	Bytes
Rx	26	3628

To stop statistics capture, use the following command:

```
Device# show platform hardware chassis active
qfp feature wireless wlclient datapath cpp-if-handle 0x32 statistics stop
```

To view the APs requested by Cisco CMX with AP groups' support, use the following commands:

```
Device# show nmsp subscription group summary

CMX IP address: 198.51.100.4
  Groups subscribed by this CMX server:
    Group name: CMX_1198.51.100.4

Device# show nmsp subscription group detail ap-list CMX_198.51.100.1 198.51.100.1

CMX IP address: 198.51.100.1
CMX Group name: CMX_198.51.100.1
CMX Group AP MACs:
: aa:bb:cc:dd:ee:01 aa:bb:cc:dd:ee:02 aa:bb:cc:dd:ee:03 aa:bb:cc:dd:ee:03
```

To display the NTP IP address and authentication parameters, use the following command:

```
Device# show ap profile profile-name detailed
.
.
.
NTP Authentication : ENABLED
Key id : 2
Key type : SHA1
Key format : HEX
Key : 3a2275c74c250c362ca63e4af06fa3f3cd8d4aec
Encryption type : Clear
.
.
.
```

To display the NTP status for each AP, use the following command:

```
Device# show ap name AP-G1-230 ntp status

ap-name          enabled v4/v6 IPAddress      Status      Stratum LastSync  SyncOffset
AP-G1-230        Y          v4      198.51.100.5  AuthFail   4         1000     100
```

To display NTP status for all the APs, use the following command:

```
Device# show ap ntp status

ap-name          enabled v4/v6 IPAddress      Status      Stratum LastSync  SyncOffset
AP-G1-230        Y          v4      5.5.5.5     AuthFail   2         Never
AP-G1-231        Y          v4      5.5.5.10    Synced     3         1000     100
AP-G1-232        Y          v4      5.5.5.15    Synced     16        2000     50
```

To display the instant status of NTP synchronization in an AP, use the following command. The following output is from an AP and not from the controller.

```
Device# show ntp
```

!This error message is displayed when NTP is not configured.
 %Error: ntpd is not running

!The following output is displayed when NTP is configured.
 Stratum Version Last Received Delay Offset Jitter NTP server
 13 4 7sec ago 1.124ms 0.536ms 0.001ms 198.51.100.5

To display AP timezone information, use the following command:

```
Device# show ap timezone

AP Name      Status    Offsets(h/m)
-----
AP1          Disabled  0:0
AP2          Enabled   1:0
```

Verifying Hyperlocation BLE Beacon Configuration

To verify the list of configured BLE beacons, use the following command:

```
Device# show ap profile ap-profile-name hyperlocation ble-beacon
BLE Beacon interval (Hz): 1
BLE Beacon advertised attenuation value (dBm): -59

ID              UUID              TX Power(dBm) Status
-----
0 ffffffff-aaaa-aaaa-aaaa-aaaaaaaaaaaa 0 Enabled
1 ffffffff-bbbb-bbbb-bbbb-bbbbbbbbbbbb 0 Enabled
2 ffffffff-gggg-gggg-gggg-gggggggggggg 0 Enabled
3 ffffffff-dddd-dddd-dddd-dddddddddddd 0 Enabled
4 ffffffff-eeee-eeee-eeee-eeeeeeeeeeee 0 Enabled
```

Verifying Hyperlocation BLE Beacon Configuration for AP

To verify the Hyperlocation BLE Beacon configuration for an AP, use the following command:

```
Device# show ap name test-ap hyperlocation ble-beacon
BLE Beacon interval (Hz): 1
BLE Beacon advertised attenuation value (dBm): -60

ID Status UUID Major Minor TXPower(dBm)
-----
0 Enabled 99999999-9999-9999-9999-999999999999 8 0 -0
1 Enabled bbbbbbbb-bbbb-bbbb-bbbb-bbbbbbbbbbbb 8 1 -0
2 Enabled 88888888-8888-8888-8888-888888888888 8 2 -0
3 Enabled dddddddd-dddd-dddd-dddd-dddddddddddd 8 3 -0
4 Enabled eeeeeeee-eeee-eeee-eeee-eeeeeeeeeeee 8 4 -0
```

CHAPTER 66

FastLocate for Cisco Catalyst Series Access Points

- [Information About FastLocate, on page 833](#)
- [Restrictions on FastLocate, on page 833](#)
- [Supported Access Points, on page 834](#)
- [FastLocate Network Components, on page 834](#)
- [Configuring FastLocate \(GUI\), on page 835](#)
- [Verifying FastLocate on Cisco Catalyst APs, on page 835](#)

Information About FastLocate

Current Wi-Fi location technology relies on mobile devices sending received signal strength indication (RSSI) or location information, based on probe request messaging, to access points. This information is sent on most channels by the mobile device and received by neighbor APs on different channels. This helps in location estimation.

Wi-Fi clients are moving towards lesser probing to discover an AP. This helps to conserve battery power. Depending on the client, operating system, driver, battery, current, and client activity, device probing frequency varies anywhere from 10 seconds to 5 minutes. This variation results in inadequate data points to represent real-world movement.

Since data packets are more frequent than probe request packets, they can be aggregated better. FastLocate enables higher location refresh rates by collecting RSSI or location information through data packets received by the APs. Using these data packets, location-based services (LBS) updates are initiated by the network and are available more frequently.

Restrictions on FastLocate

In Fabric deployments, the Wireless Management Interface (WMI) cannot be an L3 interface (Loopback Interface).

Note It is recommended to use a VLAN interface as the WMI, if you want to use FastLocate in Fabric deployment.

Supported Access Points

Beginning with IOS XE 17.1.1, FastLocate feature is supported on the Cisco Catalyst 9120 Series Access Points.

In IOS XE 17.3.1, the following APs support the FastLocate feature:

- Cisco Catalyst 9130 Series Access Points
- Cisco Catalyst 9120 Series Access Points
- Cisco Aironet 4800 Series Access Points.
- Cisco Aironet 3800 Series Access Points.
- Cisco Aironet 2800 Series Access Points.

In addition, Cisco Aironet 4800 Series Access Points also supports the Angle of Arrival based location calculation (Hyperlocation).

When FastLocate is enabled, the Cisco RF ASIC radios of these APs act as a WSSI module and transform into a monitoring role and off-channel scanning mode. The Cisco RF ASIC radios scan through all the 2.4-GHz channels and 5-GHz channels in a linear fashion, with each channel scanned for 150 milliseconds. This period is called the dwell time.

The Cisco RF ASIC radios of the APs are synchronized with the NTP server. Using FastPath, all data packet RSSI records that are collected during one off-channel dwell is sent in a specific packet format to the Cisco controller, at the end of the dwell time.

FastLocate Network Components

For successful packet RSSI location computation, the following components with necessary functionalities are needed:

- Wireless client
 - Send data, management, and control packets
- Cisco Catalyst 9800 Series Wireless Controller
 - Configure NTP server information and location parameters on AP
 - Forward clients' RSSI related information to CMX/MSE via FastPath/datapath
- Cisco Catalyst 9120 Series AP
 - Location radio in monitor or equivalent role
 - Time synchronized with NTP server
 - Collect RSSI related data sent by clients (both associated and unassociated)
 - Send clients' RSSI data to the Cisco controller through CAPWAP
- Cisco CMX

- Parse fastpath location data received by WLC
- Calculate exact physical location of the client and render on GUI using algorithms

Configuring FastLocate (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
 - Step 2** On the **AP Join** page, click the **default-ap-profile** AP join profile.
 - Step 3** In the **Edit AP Join Profile** window, click the **AP** tab.
 - Step 4** Under **Hyperlocation**, select the **Enable Hyperlocation** check box.
 - Step 5** Click **Update & Apply to Device**.
-

Verifying FastLocate on Cisco Catalyst APs

To verify FastLocate, use the below commands on the AP:

```
Device# show ntp
```

```
Stratum    Version    Last Received    Delay    Offset    Jitter    NTP server
 1          4          123sec ago      1.169ms -3.262ms  10.050ms   7.7.7.2
```

```
Device# show ap fast-path statistics
```

```
total packets sent      : 90001
invalid app ID drops    : 0
application              : 0 (HALO)
packets sent (CAPWAP)   : 90001
packets sent (APP HOST INTF) : 0
admin state drops       : 0
no dest IP drops        : 0
```

To view FastLocate admin status details on the AP, use the following command:

```
Device# show capwap client rcb
```

```
Hyperlocation Admin State : Enabled
MSE Gateway MAC           : 00:50:56:86:0F:9D
WLC Hyperlocation Source Port: 9999
MSE IP Address             : 10.0.0.1
```

To view FastPath-related parameters on the AP like source and destination IP addresses, port numbers, and the gateway MAC address, use the following command:

```
Device# show ap fast-path configuration hyperlocation
```

```
source IP address       : 10.0.0.2
destination IP address: 10.0.0.1
```

```

source port (WLC)      : 9999
destination port (MSE): 2003
gateway MAC           : 00:50:56:86:0F:9D
ewlc hyperlocation MAC: 00:00:00:01:00:01

```

To verify FastLocate on the Cisco Catalyst controller, use the appropriate command given below.

To view the summary of applications that send fastpath or datapath data, use the below command. The hexcode for the HyperLocation and BLE port numbers are displayed.

```

Device# show platform hardware chassis active qfp feature wireless wlclient
cpp-client summary

```

```

Client Type Abbreviations:
RG - REGULAR      BL - BLE
HL - HALO         LI - LWFL INT
Auth State Abbreviations:
UK - UNKNOWN     IP - LEARN IP   IV - INVALID
L3 - L3 AUTH     RN - RUN
Mobility State Abbreviations:
UK - UNKNOWN     IN - INIT
LC - LOCAL       AN - ANCHOR
FR - FOREIGN     MT - MTE
IV - INVALID
EoGRE Abbreviations:
N - NON EOGRE   Y - EOGRE
CPP IF_H      DPIDX          MAC Address VLAN CT MCVL AS MS E WLAN POA
-----
0X31  0XF0000002 0000.0003.0001 122 BL 0 RN LC N NULL 0X32 0XF0000001 0000.0001.0001 122
HL 0 RN LC N NULL

```

To capture statistics of a selected application, use the below command:

```

Device# show platform hardware chassis active qfp feature wireless wlclient
datapath
cpp-if-handle register-code statistics start

```

The hex-value of the register-code is obtained from the **show platform hardware chassis active qfp feature wireless wlclient cpp-client summary** command mentioned earlier.

```

Device# show platform hardware chassis active qfp feature wireless wlclient
datapath cpp-if-handle 0x32 statistics start

```

To display the statistics of the selected application, use the below command:

```

Device# show platform hardware chassis active qfp feature wireless wlclient
datapath
cpp-if-handle register-code statistics

```

The hex-value of the register-code is obtained from the **show platform hardware chassis active qfp feature wireless wlclient cpp-client summary** command mentioned earlier.

```

Device# show platform hardware chassis active qfp feature wireless wlclient
datapath cpp-if-handle 0x32 statistics
      Pkts  Bytes
Rx    232  38850

```

CHAPTER 67

IoT Services Management

- [Information About IoT Services Management, on page 837](#)
- [Enabling the Dot15 Radio, on page 838](#)
- [Configuring the gRPC Token, on page 838](#)
- [Enabling gRPC in an AP Profile, on page 839](#)
- [Verifying BLE State and Mode, on page 839](#)
- [Verifying BLE Details, on page 840](#)
- [Verifying gRPC Summary, Status, and Statistics, on page 841](#)

Information About IoT Services Management

Cisco Catalyst 9800 devices running the Cisco IOS-XE image Version 17.3.2 support Cisco Spaces: IoT Services along with the Network Assurance on Cisco Catalyst Center. However, IoT Services and the Intelligent Capture (iCAP) port configuration are mutually exclusive. That is, if the iCAP feature needs to be enabled on a device, then IoT Services cannot be deployed. Similarly, if IoT Services needs to be enabled on a device, then iCAP feature cannot be deployed.

The following are the gRPC connections from AP:

- One gRPC connection from AP to Cisco Catalyst Center for iCAP.
- Other gRPC connection from AP to Cisco Catalyst Center Connector for IoT Services.

Following is a table that shows the pairs of configurations that can or cannot coexist on IOS-XE image version 17.3.2.

Cisco DNA-C Configuration	Cisco Spaces Configuration	Coexistence on IOS-XE Image Version 17.3.2
network-assurance enable	ap cisco-dna token <i>token</i>	yes
network-assurance icap server port <i>port</i>	ap cisco-dna token <i>token</i>	no

Cisco Spaces: IoT Services is an end-to-end solution. Hence, you do not need to manually enable IoT services or Dot15 radio on the controller. Dot15 radio is enabled or disabled automatically through Cisco Spaces. However, you can verify if Dot15 radio is enabled from the controller.

Similarly, Cisco Spaces enables gRPC in the **default ap profile configuration** of the controller. You do not need to manually enable it. However, you can verify the same on the controller.

Cisco Spaces enables the **apphost** configuration, which is required for the **default ap profile** configuration. If **apphost** is not enabled by Cisco Spaces, then you must manually enable it. This is required in order to host IOx applications on an AP.

Enabling the Dot15 Radio

When you enable the BLE radio configuration globally, the APs that are joined to the controller enable their BLE radio, if they have the BLE radio chip in their hardware. This configuration will be applied to all the APs that will join the controller after the configuration is enabled.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	no ap dot15 shutdown Example: Device(config)# no ap dot15 shutdown	Enables the dot15 radios for APs, globally.
Step 3	ap dot15 shutdown Example: Device(config)# ap dot15 shutdown	Disables the dot15 radio for all APs, globally.

Configuring the gRPC Token

Note

- The configuration is pushed automatically from Cisco Spaces. There is no need to manually enable gRPC on the **default ap profile** configuration. You can verify the same on the controller
- The NETCONF (NETCONF/YANG configuration) must be enabled on the device for the Cisco Spaces to push the required configuration to the controller. Secure Copy (**ip scp server enable**) must be enabled on the controller so that Cisco Spaces can push the gRPC certificate to the controller.
- The iCAP server port configuration should not be present in the configuration. If it exists, then run the iCAP server port 0 command.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Device# configure terminal	
Step 2	ap cisco-dna token {0 8} <i>cisco-token-number</i> Example: Device(config)# ap cisco-dna token 0 <i>cisco-token-number</i>	Configures the Cisco Spaces gRPC token. 0: Specifies the string as an UNENCRYPTED password. 8: Indicates the placeholder for backward compatibility.

Enabling gRPC in an AP Profile

The Manage Streams feature of Cisco Spaces pushes the gRPC configuration only to the default AP profile, currently. If you are using a different AP profile, you must manually configure gRPC.

The following procedure explains how to manually enable gRPC on an AP profile that is not the default-ap-profile. Cisco Spaces may not push gRPC on all the AP profiles. Therefore, the following commands can be used to enable gRPC for individual AP profiles.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile-name</i> Example: Device(config)# ap profile <i>ap-profile-name</i>	Configures the AP profile and enters the AP profile configuration mode.
Step 3	cisco-dna grpc Example: Device(config-ap-profile)# cisco-dna grpc	Enables the gRPC channel on the APs, in the AP profile.

Verifying BLE State and Mode

To verify the BLE state and mode, run the following command:

```
Device# show ap ble summary
AP Name      BLE AP State      BLE mode
-----
Axel-1       Up                 Advanced (IOx)
Axel-2       Up                 Advanced (IOx)
9117-1       Up                 Advanced (IOx)
3800-1       Up                 Base (Native)
1815         Up                 Base (Native)
9120-3       Up                 Advanced (IOx)
```

```

9120-1          Up          Base (Native)
9115-ax         Up          Base (Native)
9120-2         Up          Base (Native)

```

Verifying BLE Details

To verify BLE details, run the following command:

```

Device# show ap name APXXXX.BDXX.29XX ble detail
Mode report time      : 07/28/2020 09:40:57
Mode                  : Base (Native)
Radio mode            : BLE
Admin state report time : 07/28/2020 09:40:57
Admin state           : Up
Interface report time  : 07/28/2020 09:40:57
Interface              : MSMT
Interface state        : Open
Type                   : Integrated
Capability report time  : 07/14/2020 17:10:49
Capability              : BLE, Zigbee, USB,

```

Verifying gRPC Summary, Status, and Statistics

To verify the gRPC summary, run the following command:

```

Device# show ap grpc summary
AP Name      AP Mac      gRPC Status
-----
APXXXX.BDXX.F2XX  0cXX.bdXX.66XX  Up

```

To verify the packet statistics on the gRPC channel that also shows the transmit and receive failures, run the following command:

```

Device# show ap name APXXXX.BDXX.F2XX grpc detail
gRPC channel status : Up
Packets transmit attempts : 62
Packets transmit failures : 0
Packets receive count : 62
Packets receive failures : 0

```

CHAPTER 68

IoT Module Management in the Controller

- [Information About IoT Module Management in the Controller, on page 843](#)
- [Enabling a USB on the Controller, on page 843](#)
- [Verifying the USB Modules, on page 844](#)

Information About IoT Module Management in the Controller

The IoT Module Management feature uses the USB interface on the Cisco Catalyst 9105AXI, 9105AXW, 9115AX, 9117AX, 9120AX, and 9130AX Series access points (APs), to connect to the Cisco Internet of Things (IoT) connector. These APs host the third-party application software components, that act as containers. Cisco Catalyst Center helps in the provisioning, deployment, and life cycle management of the container applications on the APs. The controller and the APs are managed by Cisco Catalyst Center.

You can connect the USB modules to the APs, and then log in to the controller and run commands to enable the USB modules and the Cisco IOx application in the APs associated with an AP profile group.

Enabling a USB on the Controller

To enable a USB for all the APs connected in an AP profile and to enable Cisco IOx on all the APs, follow this procedure.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap profile <i>ap profile name</i> Example: Device(config)# <code>ap profile ap-profile-test</code>	Configures an AP profile and enters AP profile configuration mode. Note You can use the default AP profile (default-ap-profile) or create a named AP profile, as shown in the example in the adjacent column.

	Command or Action	Purpose
Step 3	apphost Example: Device(config-ap-profile)# apphost	Enables the apphost framework on Cisco APs.
Step 4	usb-enable Example: Device(config-ap-profile)# usb-enable	Enables a USB for Cisco APs.
Step 5	exit Example: Device(config-ap-profile)# exit	Exits AP profile configuration mode.
Step 6	copy running-config startup-config Example: Device(config)# copy running-config startup-config	Writes running configuration to the memory.

Verifying the USB Modules

To verify the state of USB modules, run the following command:

```
Device# show ap config general
USB Module Type      : USB Module
USB Module State     : Enabled
USB Operational State : Enabled
USB Override         : Disabled
```

To verify the apphost status, run the following command:

```
Device# show ap apphost summary
AP Name          AP Mac          Apphost Status      CAF Port
Apphost HW capable
-----
SS-2027          00xx.abXX.bXXX   Up                  8443          Yes
Axel-2036        04xx.40XX.aXXX   Up                  8443          Yes
Haida-PrePilot   0cxx.f8XX.0XXX   Up                  8443          Yes

SS-2005          6cXX.05XX.dXXX   Up                  8443          Yes
Vanc-2042        d4XX.bdXX.2XXX   Up                  8443          Yes
```

To verify the apphost status, run the following command:

```
Device# show ap module summary
AP Name          External Module      External Module PID  External Module Description
-----
Axel-2036        Enable 10xx/eaXX/100 CP2XXXX             USB to UART Bridge C
Haxx-PrePilot    Enable 10xx/eaXX/100 CP2XXXX             USB to UART Bridge C
APXXX.0XXX.EXX  Enable 10xx/eaXX/100 CP2XXXX             USB to UART Bridge C
SS-2005          Enable 10xx/eaXX/100 CP2XXXX             USB to UART Bridge C
Vaxx-2006        Enable 10xx/eaXX/100 CP2XXXX             USB to UART Bridge C
```

CHAPTER 69

Cisco Spaces

- [Cisco Spaces, on page 845](#)
- [Configuring Cisco Spaces, on page 845](#)
- [Verifying Cisco Spaces Configuration, on page 846](#)

Cisco Spaces

Cisco Spaces is the next generation indoor location services platform. The Network Mobility Services Protocol (NMSP) cloud-service of the wireless controller communicates with Cisco Spaces using HTTPS as a transport protocol.

Configuring Cisco Spaces

Follow the procedure given below to configure Cisco Spaces:

Before you begin

- **Configure DNS**—To resolve fully qualified domain names used by NMSP cloud-services, configure a DNS using the **ip name-server *server_address*** configuration command as shown in Step 2.
- **Import 3rd party root CAs**—The controller verifies the peer and the host based on the certificate that is sent by the CMX when a connection is established. However, root CAs are not preinstalled on the controller. You have to import a set of root CAs trusted by Cisco to the trustpool of the crypto PKI by using the **crypto pki trustpool import url <url>** configuration command as shown in Step 3.
- A successful registration to Cisco Spaces is required to enable **server url** and **server token** parameters configuration which is needed to complete this setup.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	ip name-server <i>namesvr-ip-addr</i> Example: Device(config)#ip name-server 10.10.10.205	Configures the DNS on the controller to resolve the FQDN names used by the NMSP cloud-services.
Step 3	crypto pki trustpool import url <i>url</i> Example: Device(config)#crypto pki trustpool import url http://www.cisco.com/security/pki/trs/ios.p7b	Imports the 3rd party root CA. The controller verifies the peer using the imported certificate.
Step 4	[no] nmsp cloud-services server url <i>url</i> Example: Device(config)# nmsp cloud-services server url https://cisco.com	Configures the URL used for cloud services. Use the no form of the command to delete the server url from the configuration.
Step 5	[no] nmsp cloud-services server token <i>token</i> Example: Device(config)# nmsp cloud-services server token test	Configures the authentication token for the NMSP cloud service. Use the no form of the command to delete the server token from the configuration.
Step 6	[no] nmsp cloud-services http-proxy <i>proxy-server port</i> Example: Device(config)# nmsp cloud-services http-proxy 10.0.0.1 10	(Optional) Configures HTTP proxy details for the NMSP cloud service. Use the no form of the command to disable the use of a HTTP proxy.
Step 7	[no] nmsp cloud-services enable Example: Device(config)# nmsp cloud-services enable	Enables NMSP cloud services. Use the no form of the command to disable the feature.

Verifying Cisco Spaces Configuration

Use the following commands to verify the Cisco Spaces configuration.

To view the status of active NMSP connections, use the following command:

```
Device# show nmsp status
```

```
MSE IP Address   Tx Echo Resp  Rx Echo Req   Tx Data   Rx Data   Transport
-----
9.9.71.78       0             0             1          1          TLS
64.103.36.133  0             0             1230       2391       HTTPs
```

To view the NMSP cloud service status, use the following command:

```
Device# show nmsp cloud-services summary
```

```
CMX Cloud-Services Status
```

```

EDCA Parameters

- [Enhanced Distributed Channel Access Parameters, on page 849](#)
- [Configuring EDCA Parameters \(GUI\), on page 849](#)
- [Configuring EDCA Parameters \(CLI\), on page 850](#)

Enhanced Distributed Channel Access Parameters

Enhanced Distributed Channel Access (EDCA) parameters are designed to provide preferential wireless channel access for voice, video, and other quality of service (QoS) traffic.

This section contains the following subsections:

Configuring EDCA Parameters (GUI)

Procedure

- Step 1** Choose **Configuration > Radio Configurations > Parameters**. Using this page, you can configure global parameters for 802.11a/n/ac (5 GHz) and 802.11b/g/n (2.4 GHz) radios.
- Note** You cannot configure or modify parameters, if the radio network is enabled. Disable the network status on the Configuration > Radio Configurations > Network page before you proceed.
- Step 2** In the **EDCA Parameters** section, choose an EDCA profile from the **EDCA Profile** drop-down list. Enhanced Distributed Channel Access (EDCA) parameters are designed to provide preferential wireless channel access for voice, video, and other quality-of-service (QoS) traffic.
- Step 3** For 802.11a/n/ac (5 GHz) radios, in the (DFS 802.11h) section, enter the local power constraint. You cannot configure power constraint if the DTPC Support check box on the **Configure > Radio Configurations > Network** page is checked. The valid range is between 0 dBm and 30 dBm.
- Step 4** Check the **Channel Switch Announcement Mode** check box, if you want the AP to announce when it is switching to a new channel and the new channel number. The default value is disabled.
- Step 5** Check the **Smart DFS** check box to enable Dynamic Frequency Selection (DFS) and avoid interference with the radar signals.

Step 6 Click **Apply**.

Configuring EDCA Parameters (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {5ghz 24ghz 6ghz} shutdown Example: Device(config)# <code>ap dot11 5ghz shutdown</code>	Disables the radio network.
Step 3	ap dot11 {5ghz 24ghz 6ghz} edca-parameters {client-load-based custom-voice fastlane optimized-video-voice optimized-voice svp-voice wmm-default} Example: Device(config)# <code>ap dot11 5ghz edca-parameters optimized-voice</code>	Enables specific EDCA parameters for the 802.11a, 802.11b/g, or 802.11 6-GHz network. Note The custom-voice option is not supported for Cisco Catalyst 9800 Series Wireless Controller. <ul style="list-style-type: none"> • client-load-based: Enables client load based EDCA configuration. • custom-voice: Enables custom voice parameters for the 802.11a or 802.11b/g network. • fastlane: Enables the fastlane parameters for the 802.11a or 802.11b/g network. • optimized-video-voice: Enables EDCA voice-optimized and video-optimized parameters for the 802.11a or 802.11b/g network. Choose this option when both voice and video services are deployed on your network. • optimized-voice: Enables non-SpectraLink voice-optimized profile parameters for the 802.11a or 802.11b/g network. Choose this option when voice services other than SpectraLink are deployed on your network. • svp-voice: Enables SpectraLink voice-priority parameters for the 802.11a or 802.11b/g network. Choose this option if SpectraLink phones are deployed on

	Command or Action	Purpose
		<p>your network to improve the quality of calls.</p> <ul style="list-style-type: none"> • wmm-default: Enables the Wi-Fi Multimedia (WMM) default parameters for the 802.11a or 802.11b/g network. This is the default option. Choose this option when voice or video services are not deployed on your network.
Step 4	<p>no ap dot11 {5ghz 24ghz 6ghz} shutdown</p> <p>Example:</p> <pre>Device(config)# no ap dot11 5ghz shutdown</pre>	Enables the radio network.
Step 5	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Returns to privileged EXEC mode.
Step 6	<p>show ap dot11 {5ghz 24ghz 6ghz} network</p> <p>Example:</p> <pre>Device# show ap dot11 5ghz network</pre>	Displays the current status of MAC optimization for voice.

CHAPTER 71

Adaptive Client Load-Based EDCA

- [Feature History for Adaptive Client Load-Based EDCA, on page 853](#)
- [Information About Adaptive Client Load-Based EDCA, on page 853](#)
- [Restrictions for Adaptive Client Load-Based EDCA, on page 854](#)
- [Configuration Workflow, on page 854](#)
- [Configuring Adaptive Client Load-Based EDCA \(GUI\), on page 854](#)
- [Configuring Adaptive Client Load-Based EDCA \(CLI\), on page 855](#)
- [Verifying Adaptive Client Load-Based EDCA Configuration, on page 855](#)

Feature History for Adaptive Client Load-Based EDCA

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Table 62: Feature History for Adaptive Client Load-Based EDCA

Release	Feature	Feature Information
Cisco IOS XE Bengaluru 17.5.1	Adaptive Client Load-Based EDCA	This Adaptive Client Load-Based EDCA feature dynamically changes Enhanced Distributed Channel Access (EDCA) parameters of clients based on the active client and load that significantly reduce collisions.

Information About Adaptive Client Load-Based EDCA

The static EDCA configuration is good for small number of clients. In an enterprise multiclient deployment scenario, access points (APs) experience excessive collisions as the number of clients increases resulting in significant performance degradation. To overcome such a scenario, the Adaptive Client Load-Based EDCA feature has been introduced.

This feature dynamically changes EDCA parameters of clients based on the active client and load that significantly reduce collisions.

Feature Scenario

Run-time EDCA configuration based on active clients and load.

Use Case

In a dense multiclient deployment scenario, when a customer was testing 40 iPads in a class room or auditorium setup, he observed that the channel utilization was 60 to 70 percent. The overall AP throughput was less because of air collusion and RTS retries.

After the adaptive client load-based EDCA feature was enabled, the overall throughput increased by 15 to 20 percent and collision decreased by 30 to 40 percent.

Restrictions for Adaptive Client Load-Based EDCA

- You must disable the 802.11b network if you want to access the 802.11a network.

Configuration Workflow

- [Configuring Adaptive Client Load-Based EDCA \(GUI\)](#)
- [Configuring Adaptive Client Load-Based EDCA \(CLI\)](#)

Configuring Adaptive Client Load-Based EDCA (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > Parameters** to configure global parameters for 802.11a/n/ac (5-GHz) and 802.11b/g/n (2.4-GHz) radios.
- Step 2** In the **EDCA Parameters** section, from the **EDCA Profile** drop-down list, choose an EDCA profile.
- Step 3** Click the **Client Load Based Configuration** toggle button to enable or disable. It is enabled by default.
- Step 4** For 802.11a/n/ac (5-GHz) radios, in the **DFS (802.11h)** section, enter the local power constraint. You cannot configure power constraint if the **DPTC Support** check box in **Configuration > Radio Configurations > Network** is checked. The valid range for power constraint is between 0 dBm and 30 dBm.
- Step 5** From the **Channel Switch Announcement Mode** drop-down list, choose either the **Loud** or **Quiet** mode.
- Step 6** Click the **Smart DFS** toggle button to enable or disable. It is enabled by default.
- Step 7** In the **11ax Parameters** section, enable or disable the following, using the corresponding toggle button:
- **Target Wakeup Time**
 - **Target Wakeup Time Broadcast**
 - **Multiple Bssid**
- Step 8** Enable BSS color globally for the 5-GHz and 2.4-GHz radios by checking the **BSS Color** check box.

Step 9 Click **Apply**.

Configuring Adaptive Client Load-Based EDCA (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 {24ghz 5ghz 6ghz} edca-parameters client-load-based Example: Device(config)# <code>ap dot11 24ghz</code> <code>edca-parameters client-load-based</code>	Enables client load-based EDCA configuration for 802.11 radios. Use the no form of this command to disable the configuration. Note To enable the configuration on an 802.11a radio, you must disable the 802.11b network.
Step 3	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.

Verifying Adaptive Client Load-Based EDCA Configuration

To verify whether the Adaptive Client Load-Based EDCA feature is enabled on an 802.11a or an 802.11b radio, use the following command:

```
Device# show ap dot11 24ghz network
Device# show ap dot11 5ghz network
EDCA profile type check           : default-wmm
Client Load Based EDCA Config    : Enabled
```

To verify whether the Adaptive Client Load-Based EDCA feature is enabled on an 802.11 6-GHz radio, use the following command:

```
Device# show ap dot11 6ghz network
.
.
.
EDCA profile type check           : default-wmm
Client Load Based EDCA Config    : Enabled
```

To verify whether the Adaptive Client Load-Based EDCA feature is enabled on APs, use the following command:

```
Device# show capwap client config
```

```
Client Load Based EDCA      : Enabled
```

To view the Adaptive EDCA parameters running on the driver, use the following command:

```
Device# show controllers dot11Radio 0/1
```

```

CHAPTER 72

802.11 parameters and Band Selection

- [Information About Configuring Band Selection, 802.11 Bands, and Parameters, on page 857](#)
- [Restrictions for Band Selection, 802.11 Bands, and Parameters, on page 859](#)
- [How to Configure 802.11 Bands and Parameters, on page 859](#)
- [Monitoring Configuration Settings for Band Selection, 802.11 Bands, and Parameters, on page 869](#)
- [Configuration Examples for Band Selection, 802.11 Bands, and Parameters, on page 876](#)

Information About Configuring Band Selection, 802.11 Bands, and Parameters

Band Select

Band select enables client radios that are capable of dual-band (2.4 and 5-GHz) operations to move to a less congested 5-GHz access point. The 2.4-GHz band is often congested. Clients on this band typically experience interference from Bluetooth devices, microwave ovens, and cordless phones as well as co-channel interference from other access points because of the 802.11b/g limit of 3 nonoverlapping channels. To prevent these sources of interference and improve overall network performance, configure band selection on the device.

Band select works by regulating probe responses to clients and it can be enabled on a per-WLAN basis. It makes 5-GHz channels more attractive to clients by delaying probe responses to clients on 2.4-GHz channels. In an access point, the band select table can be viewed by running the **show dot11 band-select** command. It can also be viewed by running the **show cont d0/d1 | begin Lru** command.

Note You can enable both band selection and aggressive load balancing on the controller. They run independently and do not impact one another.

Band Select Algorithm

The band select algorithm affects clients that use 2.4-GHz band. Initially, when a client sends a probe request to an access point, the corresponding client probe's Active and Count values (as seen from the band select table) become 1. The algorithm functions based on the following scenarios:

- Scenario1: Client RSSI (as seen from the **show cont d0/d1 | begin RSSI** command output) is greater than both Mid RSSI and Acceptable Client RSSI.

- Dual-band clients: No 2.4-GHz probe responses are seen at any time; 5-GHz probe responses are seen for all 5-GHz probe requests.
 - Single-band (2.4-GHz) clients: 2.4-GHz probe responses are seen only after the probe suppression cycle.
 - After the client's probe count reaches the configured probe cycle count, the algorithm waits for the Age Out Suppression time and then marks the client probe's Active value as 0. Then, the algorithm is restarted.
- Scenario2: Client RSSI (as seen from **show cont d0/d1 | begin RSSI**) lies between Mid-RSSI and Acceptable Client RSSI.
 - All 2.4-GHz and 5-GHz probe requests are responded to without any restrictions.
 - This scenario is similar to the band select disabled.

Note The client RSSI value (as seen in the **sh cont d0 | begin RSSI** command output) is the average of the client packets received, and the Mid RSSI feature is the instantaneous RSSI value of the probe packets. As a result, the client RSSI is seen as weaker than the configured Mid RSSI value (7-dB delta). The 802.11b probes from the client are suppressed to push the client to associate with the 802.11a band.

802.11 Bands

You can configure the 802.11b/g/n (2.4 GHz) and 802.11a/n (5 GHz) bands for the controller to comply with the regulatory requirements in your country. By default, both 802.11b/g/n and 802.11a/n are enabled.

This section contains the following subsections:

802.11n Parameters

This section provides instructions for managing 802.11n access points on your network. The 802.11n devices support the 2.4 and 5-GHz bands and offer high throughput data rates.

The 802.11n high throughput rates are available on all the 802.11n access points for the WLANs using WMM with no Layer 2 encryption or with WPA2/AES encryption enabled.

Note To disable MCS rates for 802.11n, 802.11ac and 802.11ax, ensure that at least one MCS rate is enabled. To disable 802.11n on the controller to force APs to use only legacy 802.11a/b/g rates, first disable 802.11ax and 802.11ac on the controller for a particular band. Irrespective of the APs mapped to a Custom-RF-Profile, disabling 802.11n globally on the controller applies to all the APs.

802.11h Parameters

802.11h informs client devices about channel changes and can limit the transmit power of those client devices.

Restrictions for Band Selection, 802.11 Bands, and Parameters

- Band selection-enabled WLANs do not support time-sensitive applications such as voice and video because of roaming delays.
- Band selection is supported only on Cisco Wave 2 and 802.11ax APs.
For more information about support on specific APs, see https://www.cisco.com/c/en/us/td/docs/wireless/access_point/feature-matrix/ap-feature-matrix.html.
- Band selection operates only on APs that are connected to a controller. A FlexConnect AP without a controller connection does not perform band selection after a reboot.
- The band-selection algorithm directs dual-band clients only from the 2.4-GHz radio to the 5-GHz radio of the same AP, and it only runs on an AP when both the 2.4-GHz and 5-GHz radios are up and running.
- It is not possible to enable or disable band selection and client load balancing globally through the controller GUI or CLI. You can, however, enable or disable band selection and client load balancing for a particular WLAN. Band selection and client load balancing are enabled globally by default.

How to Configure 802.11 Bands and Parameters

Configuring Band Selection (GUI)

Before you begin

Ensure that you have configured an AP Join Profile prior to configuring the primary and backup controllers.

Procedure

-
- Step 1** Choose **Configuration** > **Wireless Advanced** > **Band Select**.
 - Step 2** In the **Cycle Count** field, enter a value between 1 and 10. The cycle count sets the number of suppression cycles for a new client. The default cycle count is 2.
 - Step 3** In the **Cycle Threshold (milliseconds)** field, enter a value between 1 and 1000 milliseconds for the scan cycle period threshold. This setting determines the time threshold during which new probe requests from a client come from a new scanning cycle. The default cycle threshold is 200 milliseconds.
 - Step 4** In the **Age Out Suppression (seconds)** field, enter a value between 10 and 200 seconds. Age-out suppression sets the expiration time for pruning previously known 802.11b/g/n clients. The default value is 20 seconds. After this time elapses, clients become new and are subject to probe response suppression.
 - Step 5** In the **Age Out Dual Band (seconds)** field, enter a value between 10 and 300 seconds. The age-out period sets the expiration time for pruning previously known dual-band clients. The default value is 50 seconds. After this time elapses, clients become new and are subject to probe response suppression.
 - Step 6** In the **Client RSSI (dbm)** field, enter a value between -90 to -20. This is the average of the client packets received.
 - Step 7** In the **Client Mid RSSI (dbm)** field, enter a value between -90 to -20. This is the instantaneous RSSI value of the probe packets.

Step 8 On the **AP Join Profile** page, click the AP Join Profile name.

Step 9 Click **Apply**.

Configuring Band Selection (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless client band-select cycle-count <i>cycle_count</i> Example: Device(config)# <code>wireless client band-select cycle-count 3</code>	Sets the probe cycle count for band select. Valid range is between 1 and 10.
Step 3	wireless client band-select cycle-threshold <i>milliseconds</i> Example: Device(config)# <code>wireless client band-select cycle-threshold 5000</code>	Sets the time threshold for a new scanning cycle period. Valid range is between 1 and 1000.
Step 4	wireless client band-select expire suppression <i>seconds</i> Example: Device(config)# <code>wireless client band-select expire suppression 100</code>	Sets the suppression expire to the band select. Valid range is between 10 and 200.
Step 5	wireless client band-select expire dual-band <i>seconds</i> Example: Device(config)# <code>wireless client band-select expire dual-band 100</code>	Sets the dual band expire. Valid range is between 10 and 300.
Step 6	wireless client band-select client-rssi <i>client_rssi</i> Example: Device(config)# <code>wireless client band-select client-rssi 40</code>	Sets the client RSSI threshold. Valid range is between 20 and 90.
Step 7	wlan wlan_profile_name wlan_ID SSID_network_name band-select Example:	Configures band selection on specific WLANs. Valid range is between 1 and 512. You can enter up to 32 alphanumeric characters for <i>SSID_network_name</i> parameter.

	Command or Action	Purpose
	Device(config)# wlan wlan1 25 ssid12	
	Device(config-wlan)# band-select	

Configuring the 802.11 Bands (GUI)

Procedure

-
- Step 1** Choose **Configuration > Radio Configurations > Network**.
- Step 2** Click either **5 GHz Band** or **2.4 GHz Band**.
- Step 3** Uncheck the **Network Status** check box to disable the network in order to be able to configure the network parameters.
- Step 4** In the **Beacon Interval** field, enter the rate at which the SSID is broadcast by the APs, from 100 to 600 milliseconds. The default is 100 milliseconds.
- Step 5** For 802.11b/g/n (2.4-GHz) radios, to enable short preamble on the radio, check the **Short Preamble** check box. A short preamble improves throughput performance.
- Step 6** In the **Fragmentation Threshold (in bytes)** field, enter a value between 256 to 2346 bytes. Packets larger than the size you specify here will be fragmented.
- Step 7** Check the **DTPC Support** check box to advertise the transmit power level of the radio in the beacons and the probe responses. Client devices using dynamic transmit power control (DTPC) receive the channel and power level information from the access points and adjust their settings automatically. For example, a client device used primarily in Japan could rely on DTPC to adjust its channel and power settings automatically when it travels to Italy and joins a network there. You cannot configure a power constraint value on your 802.11a/n/ac (5-GHz) radio network if the **DTPC Support** check box is checked.
- Step 8** Click **Apply**.
- Step 9** In the **CCX Location Measurement** section, check the **Mode** check box to globally enable CCX radio management for the network. This parameter causes the APs connected to this device to issue broadcast radio measurement requests to clients running CCX v2 or later releases.
- Step 10** In the **Interval** field, enter a value to specify how often the APs must issue broadcast radio measurement requests.
- Step 11** Click **Apply**.
- Step 12** In the **Data Rates** section, choose a value to specify the rates at which data can be transmitted between the access point and the client:
- **Mandatory:** Clients must support this data rate in order to associate to an access point on the controller embedded wireless controller.
 - **Supported:** Any associated clients that support this data rate may communicate with the access point using that rate.
 - **Disabled:** The clients specify the data rates used for communication.
- Step 13** Click **Apply**.
- Step 14** Save the configuration.
-

Configuring the 802.11 Bands (CLI)

Follow the procedure given below to configure 802.11 bands and parameters:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap dot11 5ghz shutdown Example: Device (config)# <code>ap dot11 5ghz shutdown</code>	Disables the 802.11a band. Note You must disable the 802.11a band before configuring the 802.11a network parameters.
Step 3	ap dot11 24ghz shutdown Example: Device (config)# <code>ap dot11 24ghz shutdown</code>	Disables the 802.11b band. Note You must disable the 802.11b band before configuring the 802.11b network parameters.
Step 4	ap dot11 6ghz shutdown Example: Device (config)# <code>ap dot11 6ghz shutdown</code>	Disables the 802.11 6-GHz band. Note You must disable the 802.11 6-GHz band before configuring the 802.11 6-GHz network parameters.
Step 5	ap dot11 {5ghz 24ghz 6ghz} beaconperiod <i>time_unit</i> Example: Device (config)# <code>ap dot11 5ghz beaconperiod 500</code>	Specifies the rate at which the SSID is broadcast by the corresponding access point. The beacon interval is measured in time units (TUs). One TU is 1024 microseconds. You can configure the access point to send a beacon every 20 to 1000 milliseconds.
Step 6	ap dot11 {5ghz 24ghz 6ghz} fragmentation <i>threshold</i> Example: Device (config)# <code>ap dot11 5ghz fragmentation 300</code>	Specifies the size at which packets are fragmented. The threshold is a value between 256 and 2346 bytes (inclusive). Specify a low number for areas where communication is poor or where there is a great deal of radio interference.
Step 7	[no] ap dot11 {5ghz 24ghz 6ghz} dtpc Example: Device (config)# <code>ap dot11 5ghz dtpc</code> Device (config)# <code>no ap dot11 24ghz dtpc</code>	Enables access points to advertise their channels and transmit the power levels in beacons and probe responses. The default value is enabled. Client devices using dynamic transmit power control (DTPC) receive the channel-level and power-level

	Command or Action	Purpose
		<p>information from the access points and adjust their settings automatically. For example, a client device used primarily in Japan can rely on DTPC to adjust its channel and power settings automatically when it travels to Italy and joins a network there.</p> <p>The no form of the command disables the DTPC setting.</p>
Step 8	<p>wireless client association limit <i>number</i> interval <i>milliseconds</i></p> <p>Example:</p> <pre>Device(config)# wireless client association limit 50 interval 1000</pre>	<p>Specifies the maximum allowed clients that can be configured.</p> <p>You can configure the maximum number of association requests on a single access point slot at a given interval. The range of association limit that you can configure is from 1 to 100.</p> <p>The association request limit interval is measured between 100 to 10000 milliseconds.</p>
Step 9	<p>ap dot11 {5ghz 24ghz} rate <i>rate</i> {disable mandatory supported}</p> <p>Example:</p> <pre>Device(config)# ap dot11 5ghz rate 36 mandatory</pre>	<p>Specifies the rate at which data can be transmitted between the controller embedded wireless controller and the client.</p> <ul style="list-style-type: none"> • disable: Defines that the clients specify the data rates used for communication. • mandatory: Defines that the clients support this data rate in order to associate to an access point on the controller embedded wireless controller. • supported: Any associated clients that support this data rate can communicate with the access point using that rate. However, the clients are not required to use this rate in order to associate. • rate: Specifies the rate at which data is transmitted. For the 802.11a and 802.11b bands, the data is transmitted at the rate of 1, 2, 5.5, 6, 9, 11, 12, 18, 24, 36, 48, or 54 Mbps.
Step 10	<p>no ap dot11 5ghz shutdown</p> <p>Example:</p> <pre>Device(config)# no ap dot11 5ghz shutdown</pre>	<p>Enables the 802.11a band.</p> <p>Note The default value is enabled.</p>
Step 11	<p>no ap dot11 24ghz shutdown</p>	<p>Enables the 802.11b band.</p>

	Command or Action	Purpose
	Example: Device(config)# no ap dot11 24ghz shutdown	Note The default value is enabled.
Step 12	no ap dot11 6ghz shutdown Example: Device(config)# no ap dot11 6ghz shutdown	Enables the 802.11 6-GHz band. Note The default value is enabled.
Step 13	ap dot11 24ghz dot11g Example: Device(config)# ap dot11 24ghz dot11g	Enables or disables 802.11g network support. The default value is enabled. You can use this command only if the 802.11b band is enabled. If you disable this feature, the 802.11b band is enabled without 802.11g support.
Step 14	end Example: Device(config)# end	Returns to privileged EXEC mode.

Configuring a Band-Select RF Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Advanced**.
- Step 2** In the **Band Select** tab, enter a value between 1 and 10 in the **Cycle Count** field. The cycle count sets the number of suppression cycles for a new client. The default cycle count is 2.
- Step 3** In the **Cycle Threshold** field, enter a value between 1 and 1000 milliseconds for the scan cycle period threshold. This setting determines the time threshold during which new probe requests from a client come from a new scanning cycle. The default cycle threshold is 200 milliseconds.
- Step 4** In the **Age Out Suppression** field, enter a value between 10 and 200 seconds. Age-out suppression sets the expiration time for pruning previously known 802.11b/g/n clients. The default value is 20 seconds. After this time elapses, clients become new and are subject to probe response suppression.
- Step 5** In the **Age Out Dual Band** field, enter a value between 10 and 300 seconds. The age-out period sets the expiration time for pruning previously known dual-band clients. The default value is 50 seconds. After this time elapses, clients become new and are subject to probe response suppression.
- Step 6** In the **Client RSSI** field, enter a value between -90 dBm and -20 dBm. This is the minimum RSSI for a client to respond to a probe.
- Step 7** In the **Client Mid RSSI** field, enter a value between -20 dBm and -90 dBm. This parameter sets the mid-RSSI, whose value can be used for toggling 2.4 GHz probe suppression based on the RSSI value.
- Step 8** Click **Apply**.
-

Configuring a Band-Select RF Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 24ghz rf-profile <i>rf-profile</i> Example: Device(config)# ap dot11 24ghz rf-profile test1	Configures the RF profile name and enters RF profile configuration mode.
Step 3	band-select client {mid-rssi rssi} <i>dbm</i> Example: Device(config-rf-profile)# band-select client rssi -90	Sets the band-select client threshold.
Step 4	band-select cycle {count threshold} <i>count</i> Example: Device(config-rf-profile)# band-select cycle count 10	Sets the band-select cycle parameters.
Step 5	band-select expire {dual-band suppression} <i>time</i> Example: Device(config-rf-profile)# band-select expire dual-band 100	Configures the RF profile's band-select expiry time.
Step 6	band-select probe-response Example: Device(config-rf-profile)# band-select probe-response	Enables the RF profile's band-select probe response.

Configuring 802.11n Parameters (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > RF**.
- Step 2** Click **Add** to view the **Add RF Profile** window.
- Step 3** In the **802.11** tab, proceed as follows:
- Choose the required operational rates.
 - Select the required **802.11n MCS Rates** by checking the corresponding check boxes.

Step 4 Click **Save & Apply to Device**.

Configuring 802.11n Parameters (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap dot11 {5ghz 24ghz} dot11n Example: Device(config)# ap dot11 5ghz dot11n	Enables 802.11n support on the network. The no form of this command disables the 802.11n support on the network.
Step 3	ap dot11 {5ghz 24ghz} dot11n mcs tx rtu Example: Device(config)# ap dot11 5ghz dot11n mcs tx 20	Specifies the modulation and coding scheme (MCS) rates at which data can be transmitted between the access point and the client. <i>rtu</i> -The valid range is between 0 and 23. The no form of this command disables the MCS rates that are configured.
Step 4	wlan wlan_profile_name wlan_ID SSID_network_name wmm require Example: Device(config)# wlan wlan1 25 ssid12 Device(config-wlan)# wmm require	Enables WMM on the WLAN and uses the 802.11n data rates that you configured. The require keyword requires client devices to use WMM. Devices that do not support WMM cannot join the WLAN.
Step 5	ap dot11 {5ghz 24ghz} shutdown Example: Device(config)# ap dot11 5ghz shutdown	Disables the network.
Step 6	{ap no ap} dot11 {5ghz 24 ghz} dot11n a-mpdu tx priority {all 0-7} Example: Device(config)# ap dot11 5ghz dot11n a-mpdu tx priority all	Specifies the aggregation method used for 802.11n packets. Aggregation is the process of grouping packet data frames together, rather than transmitting them separately. Two aggregation methods are available: Aggregated MAC Protocol Data Unit (A-MPDU) and Aggregated MAC Service Data Unit (A-MSDU). Both A-MPDU and A-MSDU are performed in the software. You can specify the aggregation method for various types of traffic from the access point to the clients.

	Command or Action	Purpose
		<p>The list defines the priority levels (0-7) assigned per traffic type.</p> <ul style="list-style-type: none"> • 0—Best effort • 1—Background • 2—Spare • 3—Excellent effort • 4—Controlled load • 5—Video, less than 100-ms latency and jitter • 6—Voice, less than 100-ms latency and jitter • 7—Network control <p>You can configure each priority level independently, or you can use the all the parameters to configure all the priority levels at once. You can configure priority levels so that the traffic uses either A-MPDU transmission or A-MSDU transmission.</p> <ul style="list-style-type: none"> • When you use the ap command along with the other options, the traffic associated with that priority level uses A-MPDU transmission. • When you use the no ap command along with the other options, the traffic associated with that priority level uses A-MSDU transmission. <p>Configure the priority levels to match the aggregation method used by the clients. By default, A-MPDU is enabled for priority level 0, 4, and 5, and the rest are disabled. By default, A-MPDU is enabled for all priorities except 6 and 7.</p>
Step 7	<p>no ap dot11 {5ghz 24ghz} shutdown</p> <p>Example:</p> <pre>Device(config)# no ap dot11 5ghz shutdown</pre>	Re-enables the network.
Step 8	<p>ap dot11 {5ghz 24ghz} dot11n guard-interval {any long}</p> <p>Example:</p>	Configures the guard interval for the network.

	Command or Action	Purpose
	Device (config) # ap dot11 5ghz dot11n guard-interval long	
Step 9	ap dot11 {5ghz 24ghz} dot11n rifs rx Example: Device (config) # ap dot11 5ghz dot11n rifs rx	Configures the Reduced Interframe Space (RIFS) for the network.
Step 10	end Example: Device (config) # end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring 802.11h Parameters (CLI)

Procedure

	Command or Action	Purpose
Step 1	ap dot11 5ghz shutdown Example: Device (config) # ap dot11 5ghz shutdown	Disables the 802.11 network.
Step 2	ap dot11 6ghz shutdown Example: Device (config) # ap dot11 6ghz shutdown	Disables the 802.11 6-GHz network.
Step 3	{ap no ap} dot11 5ghz channelswitch mode <i>switch_mode</i> Example: Device (config) # ap dot11 5ghz channelswitch mode 0	Enables or disables the access point to announce when it is switching to a new channel. <i>switch_mode</i> --Enter 0 or 1 to specify whether transmissions are restricted until the actual channel switch (0) or are not restricted (1). The default value is disabled.
Step 4	[no] ap dot11 6ghz channelswitch quiet Example: Device (config) # ap dot11 5ghz channelswitch quiet	Enables or disables the access point to announce when it is switching to a new channel in quiet mode.
Step 5	ap dot11 5ghz power-constraint <i>value</i> Example: Device (config) # ap dot11 5ghz power-constraint 200	Configures the 802.11h power constraint value in dB. The valid range is from 0 to 255. The default value is 3.
Step 6	ap dot11 6ghz power-constraint <i>value</i> Example:	Configures the 802.11 6-GHz power constraint value in dB. The valid range is from 0 to 30. The default value is 3.

	Command or Action	Purpose
	<code>Device(config)# ap dot11 5ghz power-constraint 200</code>	
Step 7	no ap dot11 5ghz shutdown Example: <code>Device(config)# no ap dot11 5ghz shutdown</code>	Re-enables the 802.11a network.
Step 8	no ap dot11 6ghz shutdown Example: <code>Device(config)# no ap dot11 6ghz shutdown</code>	Re-enables the 802.11 6-GHz network.
Step 9	end Example: <code>Device(config)# end</code>	Returns to privileged EXEC mode.

Monitoring Configuration Settings for Band Selection, 802.11 Bands, and Parameters

Verifying Configuration Settings Using Band Selection and 802.11 Bands Commands

The following commands can be used to verify band selection, 802.11 bands, and parameters on the .

Table 63: Monitoring Configuration Settings Using Band Selection and 802.11 Band Commands

Command	Purpose
show ap dot11 5ghz network	Displays 802.11a band network parameters, 802.11a operational rates, 802.11n MCS settings, and 802.11n status information.
show ap dot11 24ghz network	Displays 802.11b band network parameters, 802.11b/g operational rates, 802.11n MCS settings, and 802.11n status information.
show ap dot11 6ghz network	Displays 802.116-GHz band network parameters, 802.11b/g operational rates, 802.11n MCS settings, and 802.11n status information.
show wireless dot11h	Displays 802.11h configuration parameters.
show wireless band-select	Displays band-select configuration settings.

Example: Viewing the Configuration Settings for the 6-GHz Band

```
Device# show ap dot11 6ghz network
```

Example: Viewing the Configuration Settings for the 6-GHz Band

```

Configuration Examples for Band Selection, 802.11 Bands, and Parameters

Examples: Band Selection Configuration

This example shows how to set the probe cycle count and time threshold for a new scanning cycle period for band select:

```

Device# configure terminal
Device(config)# wireless client band-select cycle-count 3
Device(config)# wireless client band-select cycle-threshold 5000
Device(config)# end

```

This example shows how to set the suppression expiry time to the band select:

```

Device# configure terminal
Device(config)# wireless client band-select expire suppression 100
Device(config)# end

```

This example shows how to set the dual-band expiry time for the band select:

```

Device# configure terminal
Device(config)# wireless client band-select expire dual-band 100
Device(config)# end

```

This example shows how to set the client RSSI threshold for the band select:

```

Device# configure terminal
Device(config)# wireless client band-select client-rssi 40
Device(config)# end

```

This example shows how to configure band selection on specific WLANs:

```

Device# configure terminal

```

```
Device(config)# wlan wlan1 25 ssid12
Device(config-wlan)# band-select
Device(config)# end
```

Examples: 802.11 Bands Configuration

This example shows how to configure 802.11 bands using beacon interval, fragmentation, and dynamic transmit power control:

```
Device# configure terminal
Device(config)# ap dot11 5ghz shutdown
Device(config)# ap dot11 24ghz shutdown
Device(config)# ap dot11 5ghz beaconperiod 500
Device(config)# ap dot11 5ghz fragmentation 300
Device(config)# ap dot11 5ghz dtpc
Device(config)# wireless client association limit 50 interval 1000
Device(config)# ap dot11 5ghz rate 36 mandatory
Device(config)# no ap dot11 5ghz shutdown
Device(config)# no ap dot11 24ghz shutdown
Device(config)# ap dot11 24ghz dot11g
Device(config)#end
```

Examples: 802.11n Configuration

This example shows how to configure 802.11n parameters for 5-GHz band using aggregation method:

```
Device# configure terminal
Device(config)# ap dot11 5ghz dot11n
Device(config)# ap dot11 5ghz dot11n mcs tx 20
Device(config)# wlan wlan1 25 ssid12
Device(config-wlan)# wmm require\
Device(config-wlan)# exit
Device(config)# ap dot11 5ghz shutdown
Device(config)# ap dot11 5ghz dot11n a-mpdu tx priority all
Device(config)# no ap dot11 5ghz shutdown
Device(config)#exit
```

This example shows how to configure the guard interval for 5-GHz band:

```
Device# configure terminal
Device(config)# ap dot11 5ghz dot11n
Device(config)# ap dot11 5ghz dot11n mcs tx 20
Device(config)# wlan wlan1 25 ssid12
Device(config-wlan)# wmm require\
Device(config-wlan)# exit
Device(config)# no ap dot11 5ghz shutdown
Device(config)# ap dot11 5ghz dot11n guard-interval long
Device(config)#end
```

This example shows how to configure the RIFS for 5-GHz band:

```
Device# configure terminal
Device(config)# ap dot11 5ghz dot11n
Device(config)# ap dot11 5ghz dot11n mcs tx 20
Device(config)# wlan wlan1 25 ssid12
```

```
Device(config-wlan) # wmm require\  
Device(config-wlan) # exit  
Device(config) # ap dot11 5ghz shutdown  
Device(config) # ap dot11 5ghz dot11n rifs rx  
Device(config) #end
```

Examples: 802.11h Configuration

This example shows how to configure the access point to announce when it is switching to a new channel using restriction transmission:

```
Device# configure terminal  
Device(config) # ap dot11 5ghz shutdown  
Device(config) # ap dot11 5ghz channelswitch mode 0  
Device(config) # no ap dot11 5ghz shutdown  
Device(config) #end
```

This example shows how to configure the 802.11h power constraint for 5-GHz band:

```
Device# configure terminal  
Device(config) # ap dot11 5ghz shutdown  
Device(config) # ap dot11 5ghz power-constraint 200  
Device(config) # no ap dot11 5ghz shutdown  
Device(config) #end
```

CHAPTER 73

NBAR Protocol Discovery

- [Introduction to NBAR Protocol Discovery, on page 879](#)
- [Configuring NBAR Protocol Discovery, on page 879](#)
- [Verifying Protocol Discovery Statistics, on page 880](#)

Introduction to NBAR Protocol Discovery

The NBAR Protocol Discovery feature provides an easy way of discovering the application protocols passing through an interface. Network Based Application Recognition (NBAR) determines which protocols and applications are currently running on the network. With Protocol Discovery, you can discover any protocol traffic that is supported by NBAR and obtain statistics that are associated with that protocol.

NBAR provides several classification features that identify applications and protocols from Layer 4 through Layer 7. NBAR is also used in Cisco Application Visibility and Control (AVC). With AVC, NBAR provides better application performance through better QoS and policing, and provides finer visibility about the network that is being used.

Configuring NBAR Protocol Discovery

Follow the procedure given below to enable protocol discovery:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy nbar-proto-policy	Configures a WLAN policy profile and enters wireless policy configuration mode.

	Command or Action	Purpose
Step 3	central switching Example: Device(config-wireless-policy)# central switching	Configures the wireless policy profile for central switching. Note NBAR Protocol Discovery is supported in local mode (central switching) and in FlexConnect (central switching) mode.
Step 4	ip nbar protocol-discovery Example: Device(config-wireless-policy)# ip nbar protocol-discovery	Enables application recognition on the wireless policy profile by activating the NBAR2 engine.

Verifying Protocol Discovery Statistics

To view protocol discovery statistics, use the following command:

```
Device# show ip nbar protocol-discovery wlan wlan-profile-name
wlan_profile_name (iif_id 0xF0400002)
Last clearing of "show ip nbar protocol-discovery" counters 00:07:12
```

Protocol	Input	Output
	-----	-----
	Packet Count	Packet Count
	Byte Count	Byte Count
	5min Bit Rate (bps)	5min Bit Rate (bps)
	5min Max Bit Rate (bps)	5min Max Bit Rate (bps)
	-----	-----
unknown	22	0
	4173	0
	0	0
	2000	0
dhcp	3	2
	1166	724
	0	0
	0	0
ping	2	2
	204	236
	0	0
	0	0
Total	27	4
	5543	960
	0	0
	2000	0

To clear protocol discovery statistics, use the following command:

```
Device# clear ip nbar protocol-discovery wlan wlan-profile-name
```

CHAPTER 74

Conditional Debug, Radioactive Tracing, and Packet Tracing

Introduction to Conditional Debugging

The Conditional Debugging feature allows you to selectively enable debugging and logging for specific features based on the set of conditions you define. This feature is useful in systems where a large number of features are supported.

The Conditional debug allows granular debugging in a network that is operating at a large scale with a large number of features. It allows you to observe detailed debugs for granular instances within the system. This is very useful when we need to debug only a particular session among thousands of sessions. It is also possible to specify multiple conditions.

A condition refers to a feature or identity, where identity could be an interface, IP Address, or a MAC address and so on.

This is in contrast to the general debug command, that produces its output without discriminating on the feature objects that are being processed. General debug command consumes a lot of system resources and impacts the system performance.

Introduction to Radioactive Tracing

Radioactive tracing (RA) provides the ability to stitch together a chain of execution for operations of interest across the system, at an increased verbosity level. This provides a way to conditionally print debug information (up to DEBUG Level or a specified level) across threads, processes and function calls.

Note

- The radioactive tracing supports First-Hop Security (FHS).
For more information on First Hop Security features, see *System Management > Wireless Multicast > Information About Wireless Multicast > Information About IPv6 Snooping*.
- The radioactive tracing filter does not work, if the certificate is not valid.
- For effective debugging of issues on mesh features, ensure that you add both Ethernet and Radio MAC address as conditional MAC for RA tracing, while collecting logs.
- To enable debug for wireless IPs, use the **debug platform condition feature wireless ip ip-address** command.

Table 64: Components Supporting Radio Active Tracing

Components	Details
SISF or FHS	The first-hop security features, includes IPv6 Address Glean and IPv6 Device Tracking. For more information, see <i>Information About IPv6 Snooping</i> .
LISP	Locator or ID Separation Protocol.

Conditional Debugging and Radioactive Tracing

Radioactive Tracing when coupled with Conditional Debugging, enable us to have a single debug CLI to debug all execution contexts related to the condition. This can be done without being aware of the various control flow processes of the feature within the box and without having to issue debugs at these processes individually.

Note

Use the **clear platform condition all** command to remove the debug conditions applied to the platform.

Location of Tracefiles

By default the tracefile logs will be generated for each process and saved into either the **/tmp/rp/trace** or **/tmp/fp/trace** directory. In this temp directory, the trace logs are written to files, which are of 1 MB size each. You can verify these logs (per-process) using the **show platform software trace message process_name chassis active R0** command. The directory can hold up to a maximum of 25 such files for a given process. When a tracefile in the **/tmp** directory reaches its 1MB limit or whatever size was configured for it during the boot time, it is rotated out to an archive location in the **/crashinfo** partition under **tracelogs** directory.

The **/tmp** directory holds only a single tracefile for a given process. Once the file reaches its file size limit it is rotated out to **/crashinfo/tracelogs**. In the archive directory, up to 25 files are accumulated, after which the oldest one is replaced by the newly rotated file from **/tmp**. File size is process dependent and some processes uses larger file sizes (upto 10MB). Similarly, the number of files in the **tracelogs** directory is also decided by the process. For example, WNCN process uses a limit of 400 files per instance, depending on the platform.

The tracefiles in the crashinfo directory are located in the following formats:

1. Process-name_Process-ID_running-counter.timestamp.gz
Example: IOSRP_R0-0.bin_0.14239.20151101234827.gz
2. Process-name_pmanlog_Process-ID_running-counter.timestamp.bin.gz
Example: wncmgrd_R0-0.27958_1.20180902081532.bin.gz

Configuring Conditional Debugging (GUI)

Procedure

- Step 1** Choose **Troubleshooting > Radioactive Trace**.
 - Step 2** Click **Add**.
 - Step 3** Enter the **MAC/IP Address**. The MAC address can be either in *xx:xx:xx:xx:xx:xx*, *xx-xx-xx-xx-xx-xx*, or *xxxx.xxxx.xxxx* format.
 - Step 4** Click **Apply to Device**.
 - Step 5** Click **Start** to start or **Stop** to stop the conditional debug.
 - Step 6** Click **Generate** to create a radioactive trace log.
 - Step 7** Click the radio button to set the time interval.
 - Step 8** Click the **Download Logs** icon that is displayed next to the trace file name, to download the logs to your local folder.
 - Step 9** Click the **View Logs** icon that is displayed next to the trace file name, to view the log files on the GUI page. Click **Load More** to view more lines of the log file.
 - Step 10** Click **Apply to Device**.
-

Configuring Conditional Debugging

Follow the procedure given below to configure conditional debugging:

Procedure

	Command or Action	Purpose
Step 1	debug platform condition feature wireless mac {mac-address} Example: Device# debug platform condition feature wireless mac b838.61a1.5433	Configures conditional debugging for a feature using the specified MAC address. Note This is supported with AP or client MAC/IP and also on CMX IP address and mobility peer IP.
Step 2	debug platform condition start Example: Device# debug platform condition start	Starts conditional debugging (this will start radioactive tracing if there is a match on one of the conditions above). Note This is supported with AP or client MAC/IP and also on CMX IP address and mobility peer IP.
Step 3	show platform condition OR show debug Example: Device# show platform condition Device# show debug	Displays the current conditions set.
Step 4	debug platform condition stop Example: Device# debug platform condition stop	Stops conditional debugging (this will stop radioactive tracing). Note This is supported with AP or client MAC/IP and also on CMX IP address and mobility peer IP.
Step 5	show logging profile wireless [counter [last]{x days/hours} filter mac {<mac address>} [to-file]{<destination>} Example: Device# show logging profile wireless start last 20 minutes to-file bootflash:logs.txt	Displays the logs from the latest wireless profile. Note You can use either the <i>show logging profile wireless</i> command or <i>show logging process</i> command to collect the logs.
Step 6	show logging process <process name> Example: Device# show logging process wncd to-file flash:wncd.txt	Displays the logs collection specific to the process.

	Command or Action	Purpose
Step 7	clear platform condition all Example: Device# <code>clear platform condition all</code>	Clears all conditions.

What to do next

Note The command **request platform software trace filter-binary wireless** {*mac-address*} generates 3 flash files:

- *collated_log_<.date..>*
- *mac_log <..date..>*
- *mac_database .. file*

Of these, *mac_log <..date..>* is the most important file, as it gives the messages for the MAC address we are debugging. The command **show platform software trace filter-binary** also generates the same flash files, and also prints the *mac_log* on the screen.

Radioactive Tracing for L2 Multicast

To identify a specific multicast receiver, specify the MAC address of the joiner or the receiver client, Group Multicast IP address and Snooping VLAN. Additionally, enable the trace level for the debug. The debug level will provide detailed traces and better visibility into the system.

```
debug platform condition feature multicast controlplane mac client-mac-addr ip  
group-ip-addr vlan id level debug level
```

Recommended Workflow for Trace files

The Recommended Workflow for Trace files is listed below:

1. To request the tracelogs for a specific time period.
EXAMPLE 1 day.
Use the command:
Device#**show logging process wncd to-file flash:wncd.txt**
2. The system generates a text file of the tracelogs in the location /flash:
3. Copy the file off the switchdevice. By copying the file, the tracelogs can be used to work offline. For more details on copying files, see section below.
4. Delete the tracelog file (.txt) file from /flash: location. This will ensure enough space on the switchdevice for other operations.

Copying Tracefiles Off the Box

An example of the tracefile is shown below:

```
Device# dir crashinfo:/tracelogs
Directory of crashinfo:/tracelogs/

50664 -rwx 760 Sep 22 2015 11:12:21 +00:00 plogd_F0-0.bin_0.gz
50603 -rwx 991 Sep 22 2015 11:12:08 +00:00 fed_pmanlog_F0-0.bin_0.9558.20150922111208.gz
50610 -rw- 11 Nov 2 2015 00:15:59 +00:00 timestamp
50611 -rwx 1443 Sep 22 2015 11:11:31 +00:00
auto_upgrade_client_sh_pmanlog_R0-.bin_0.3817.20150922111130.gz
50669 -rwx 589 Sep 30 2015 03:59:04 +00:00 cfgwr-8021_R0-0.bin_0.gz
50612 -rwx 1136 Sep 22 2015 11:11:46 +00:00 reflector_803_R0-0.bin_0.1312.20150922111116.gz
50794 -rwx 4239 Nov 2 2015 00:04:32 +00:00 IOSRP_R0-0.bin_0.14239.20151101234827.gz
50615 -rwx 131072 Nov 2 2015 00:19:59 +00:00 linux_iosd_image_pmanlog_R0-0.bin_0
```

The trace files can be copied using one of the various options shown below:

```
Device# copy crashinfo:/tracelogs ?
crashinfo: Copy to crashinfo: file system
flash: Copy to flash: file system
ftp: Copy to ftp: file system
http: Copy to http: file system
https: Copy to https: file system
null: Copy to null: file system
nvram: Copy to nvram: file system
rcp: Copy to rcp: file system
running-config Update (merge with) current system configuration
scp: Copy to scp: file system
startup-config Copy to startup configuration
syslog: Copy to syslog: file system
system: Copy to system: file system
tftp: Copy to tftp: file system
tmpsys: Copy to tmpsys: file system
```

The general syntax for copying onto a TFTP server is as follows:

```
Device# copy source: tftp:
Device# copy crashinfo:/tracelogs/IOSRP_R0-0.bin_0.14239.20151101234827.gz tftp:
Address or name of remote host []? 2.2.2.2
Destination filename [IOSRP_R0-0.bin_0.14239.20151101234827.gz]?
```

Note It is important to clear the generated report or archive files off the switch in order to have flash space available for tracelog and other purposes.

Configuration Examples for Conditional Debugging

The following is an output example of the *show platform condition* command.

```
Device# show platform condition
Conditional Debug Global State: Stop
Conditions Direction
```

```
-----|-----
MAC Address 0024.D7C7.0054 N/A
Feature Condition Type Value
```

```
-----|-----
Device#
```

The following is an output example of the *show debug* command.

```
Device# show debug
IOSXE Conditional Debug Configs:
Conditional Debug Global State: Start
Conditions Direction
```

```
-----|-----
MAC Address 0024.D7C7.0054 N/A
Feature Condition Type Value
```

```
-----|-----
Packet Infra debugs:
Ip Address Port
```

```
-----|-----
Device#
```

Verifying Conditional Debugging

The table shown below lists the various commands that can be used to verify conditional debugging:

Command	Purpose
show platform condition	Displays the current conditions set.
show debug	Displays the current debug conditions set.
show platform software trace filter-binary	Displays logs merged from the latest tracefile.
request platform software trace filter-binary	Displays historical logs of merged tracefiles on the system.

Example: Verifying Radioactive Tracing Log for SISF

The following is an output example of the *show platform software trace message ios chassis active R0 | inc sisf* command.

```
Device# show platform software trace message ios chassis active R0 | inc sisf
```

```
2017/10/26 13:46:22.104 {IOSRP_R0-0}{1}: [parser]: [5437]: UUID: 0, ra: 0 (note): CMD:
'show platform software trace message ios switch active R0 | inc sisf' 13:46:22 UTC Thu Oct
26 2017
```

```

Information About Packet Tracing

The Packet tracing feature cover details on how to perform data plane packet tracing for Cisco Catalyst 9800 Series Wireless Controller for Cloud software.

This feature identifies the following issues:

- Misconfiguration
- Capacity overload
- Software bugs while troubleshooting

This feature identifies what happens to a packet in your system. The conditional debugging packet tracing feature is used for accounting and capturing per-packet processing details for user-defined conditions.

You can trace packets on the controller using the following steps:

1. Enable conditional debugging on selected packets or traffic you want to trace on the controller.
2. Enable packet tracing (per-AP or per-Client).

Note You need to use per AP conditional debugging with MAC address as a filter when AP and controllers are in the same VLAN. If they are not in the same VLAN, the per AP packet tracing with MAC address does not capture packets as MAC address varies.

Limitation of Conditional Debugging Packet Tracing

MAC or IP filter only applies to the outer Ethernet or IP header, so if a packet is CAPWAP encapsulated, the MAC or IP does not apply to the inner 802.11 MAC or IP.

Configuring Conditional Debugging Packet Tracing

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	debug platform packet-trace packet <i>packet-count circular fia-trace data-size</i> <i>data-size</i> Example: Device# debug platform packet-trace packet 8192 circular fia-trace data-size 2048	Configures packet tracing to capture the last set of packets. Here, <i>packet-count</i> —Valid range is from 16 to 8192. <i>data-size</i> —Valid range is from 2048 to 16384 bytes.
Step 3	debug platform packet-trace copy packet <i>both size packet-size</i> Example: Device# debug platform packet-trace copy packet both size 2048	Configures packet tracing for a copy of packet data. Here, <i>packet-size</i> —Valid range is from 16 to 2048 bytes.
Step 4	debug platform condition interface { <i>intf-name</i> cpp } { mac ipv4 match } { both ingress egress } Example: Enables conditional debugging for TenGigabitEthernet 0/0/0 and match packets whose source and destination MAC is 0001.0001.0001: Device# debug platform condition interface TenGigabitEthernet 0/0/0 mac 0001.0001.0001 both	Enables conditional debugging for an interface, MAC, or IP filter. An interface refers to any physical port, port channel, internal vlan, SVI, or wireless client.
Step 5	debug platform condition start Example: Device# debug platform condition start	Starts conditional debugging packet tracing.
Step 6	debug platform condition stop Example: Device# debug platform condition stop	Stops conditional debugging packet tracing.
Step 7	show platform hardware chassis active qfp feature packet-trace packet all redirect bootflash:packet_trace.txt	Redirects all traced packets to bootflash.

	Command or Action	Purpose
	Example: <pre>Device# show platform hardware chassis active qfp feature packet-trace packet all redirect bootflash:packet_trace.txt</pre>	Converts the packet_trace.txt to pcap and downloads the pcap files. You can do so using the following link: http://wwwin-dharton-dev.cisco.com/pactrac2pcap.html

Configuring Conditional Debugging Packet Tracing per AP

Procedure

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	debug platform condition interface {<i>intf-name</i> cpp} {mac [<i>mac-address</i> access-list <i>acl-name</i>] ipv4 match} {both ingress egress} Example: <pre>Device# debug platform condition interface TenGigabitEthernet 0/0/0 mac 0001.0001.0001 both Device# debug platform condition interface TenGigabitEthernet 0/0/0 mac access-list mac-acl-name both</pre>	Enables conditional debugging with MAC filter. Herein, the CLI matches the packets whose source or destination MAC address is 0001.0001.0001.
Step 3	debug platform condition interface TenGigabitEthernet <i>intf-number</i> match mac {<i>H.H.H</i> any host} {both ingress egress} Example: <pre>Device# debug platform condition interface TenGigabitEthernet 0/0/0 match mac 0001.0001.0001 both</pre>	Enables conditional debugging with inline MAC ACL.
Step 4	debug platform condition interface TenGigabitEthernet <i>intf-number</i> ipv4 {<i>A.B.C.D/n</i> access-list <i>acl-name</i> both egress ingress} {both egress ingress} Example: <pre>Device# debug platform condition interface TenGigabitEthernet 0/0/0 ipv4 192.168.1.2/32 both Device# debug platform condition interface TenGigabitEthernet 0/0/0 ipv4 access-list ip-acl-name both</pre>	Enables conditional debugging with IP filter. Here, <i>intf-number</i> —Is the GigabitEthernet interface number. Valid range is from 1 to 32.

	Command or Action	Purpose
	Device# debug platform condition interface TenGigabitEthernet 0/0/0 match ipv4 192.168.1.2/32 both	

Configuring Conditional Debugging Packet Tracing per Client (GUI)

Procedure

-
- Step 1** Choose **Troubleshooting > Radioactive Trace**.
 - Step 2** Click **Add**.
 - Step 3** In the Add MAC/IP Address window, enter the **MAC/IP Address**.
 - Step 4** Click **Apply to Device**.
-

Configuring Conditional Debugging Packet Tracing per Client

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	debug platform condition interface { <i>intf-name</i> cpp <i>cpp-handle-index</i> } { mac ipv4 match [ipv4 ipv6 mac]} { both ingress egress } Example: Device# debug platform condition interface cpp 0xa0000001 match ipv4 protocol icmp host 192.168.1.100 host 192.168.1.1 both	Enables conditional debugging for a wireless client interface. Here, <i>cpp-handle-index</i> —Valid range is from 1 to 4294967295.

Verifying Conditional Debugging Packet Tracing Configuration

To view the summary of the traced packet, use the following command:

```
Device# show platform packet-trace summary
```

To view a specific traced packet, use the following command:

```
Device# show platform packet-trace packet packet-number
```

To view the wireless client interface handle, use the following command:

```
Device# show platform hardware chassis active qfp feature wireless wlclient cpp-client
mac-address client-mac details
Device# show platform hardware chassis active qfp feature wireless wlclient cpp-client
mac-address 8825.93b0.b51f details
Client Details for client cpp_if_handle: 0x34
Name : WLCLIENT-IF-0x00a0000001
Mac Addr : 8825.93b0.b51f
pal_if_handle : 0xa0000001
Mobility State : LOCAL
Multicast Action : FORWARD
Auth State : RUN
```

Feature History for Wireless Client Debug Bundle

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 65: Feature History for Client Debug Bundle

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.11.1	Wireless Client Debug Bundle	Client debug bundle includes AP logs along with the existing controller bundle, collected in a tar file through a single debug command.

Information About Wireless Client Debug Bundle

The log collection of client radioactive trace, packet capture, and the output of various **show** commands are useful in troubleshooting wireless client issues. In the earlier releases, logs were collected through various individual steps and commands. Now, client debug bundle collates radioactive trace debug logs, packet captures in a control plane, and the output of **show** commands related to clients, collected in a tar file through a single **debug** command. From Cisco IOS XE Cupertino 17.11.1, client debug bundle collates AP logs along with the existing controller bundle.

Note Client debug bundle is not supported on High Availability (HA) with Stateful Switch Over (SSO).

Note When you enable the **all** command option on the AP console, the command activates the debug logging for all clients, which can result in an excessive amount of logs being printed in the console.

Types of Logs Collected

The client debug bundle logs are collected in a tar file format on bootflash, through a single **debug** command.

The following example displays the file formats of logs collected from a client device with MAC address 8cXX.90XX.fdXX:

Example:

The final tar file that is generated is wireless_bundle_123456.UTC_Oct_20_2022.tar.

The following files are extracted from the wireless_bundle_123456.UTC_Oct_20_2022.tar file:

- wireless_bundle_8cXX.90XX.fdXX.tar (client radioactive trace debug log)
- epc_135790.UTC_Oct_20_2022.pcap (packet capture in a control plane)
- ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.tgz (AP logs)

The following files are extracted from wireless_bundle_8cXX.90XX.fdXX.tar client radioactive trace debug log file:

- show_tech_support_wireless_client_before_RA_start_8cXX.90XX.fdXX_134941.UTC_Oct_20_2022.txt
- ra_trace_8cXX.90XX.fdXX_135055.UTC_Oct_20_2022.log
- ra_trace_internal_8cXX.90XX.fdXX_135057.UTC_Oct_20_2022.log
- show_tech_support_wireless_client_after_RA_stop_8cXX.90XX.fdXX_135055.UTC_Oct_20_2022.txt

The following files are extracted from ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.tgz AP log file:

- ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.messages
- ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.syslogs
- ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.tech_cdb_0
- ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.tech_cdb_1

Collecting Wireless Client Debug Bundle (CLI)

Procedure

	Command or Action	Purpose
Step 1	debug wireless bundle client mac <i>H.H.H</i> Example: Device# debug wireless bundle client mac aaaa.bbbb.cccc	Adds client MAC addresses for which debug logs are required. You can add up to 32 client MAC addresses to the command. To delete the MAC addresses, run the no form of this command.
Step 2	debug wireless bundle client start Example:	Starts the collection of the client debug bundle for wireless clients.

	Command or Action	Purpose
	Device# debug wireless bundle client start	
Step 3	(Optional) debug wireless bundle client start ap-archive site-tag default-site-tag level {critical debug error verbose} Example: Device# debug wireless bundle client start ap-archive site-tag default-site-tag level debug	Enables the AP archive collection on a site tag. Specifies the AP archive levels as well.
Step 4	(Optional) debug wireless bundle client start epc Example: Device# debug wireless bundle client start epc	Enables embedded packet capture (EPC) in a control plane. Note If EPC is already enabled and is active from a different source, debug bundle with EPC cannot be started. To use EPC with debug bundle, stop EPC (enabled from a different source) and restart it with debug bundle.
Step 5	(Optional) debug wireless bundle client start monitor-time monitor-time Example: Device# debug wireless bundle client start monitor-time 30	Configures the maximum time, in minutes, to trace the condition. The default time is 30 minutes.
Step 6	(Optional) debug wireless bundle client stop-all collect {all mac H.H.H} Example: Device# debug wireless bundle client stop-all collect all	Stops the collection of the debug bundle for wireless clients.
Step 7	(Optional) debug wireless bundle client abort Example: Device# debug wireless bundle client abort	Cancels the collection of the debug bundle for wireless clients.

CHAPTER 75

Aggressive Client Load Balancing

- [Information About Aggressive Client Load Balancing](#), on page 895
- [Enabling Aggressive Client Load Balancing \(GUI\)](#), on page 896
- [Configuring Aggressive Client Load Balancing \(GUI\)](#), on page 896
- [Configuring Aggressive Client Load Balancing \(CLI\)](#), on page 897

Information About Aggressive Client Load Balancing

The Aggressive Client Load Balancing feature allows lightweight access points to load balance wireless clients across access points.

When a wireless client attempts to associate to a lightweight access point, the associated response packets are sent to a client with an 802.11 response packet including status code 17. This code 17 indicates that the corresponding AP is busy. The AP does not respond with the response 'success' if the AP threshold is not met, and with code 17 (AP busy) if the AP utilization threshold is exceeded, and another less busy AP hears the client request.

For example, if the number of clients on AP1 is more than the number of clients on AP2 and the load-balancing window, then AP1 is considered to be busier than AP2. When a client attempts to associate to AP1, the client receives an 802.11 response packet with status code 17, indicating that the access point is busy, and the client attempts to associate to a different access point.

You can configure the controller to deny client associations up to 10 times (if a client attempts to associate 11 times, it will be allowed to associate on the 11th try). You can also enable or disable load balancing on a particular WLAN, which is useful if you want to disable load balancing for a select group of clients, such as time-sensitive voice clients.

Note A voice client does not authenticate when delay is configured to more than 300 ms. To avoid this, configure a central-authentication, local-switching WLAN with Cisco Centralized Key Management (CCKM), configure a pagent router between an AP and WLC with a delay of 600 ms (300 ms UP and 300 ms DOWN), and try associating the voice client.

Note For a FlexConnect AP, the association is locally handled. The load-balancing decisions are taken at the controller. A FlexConnect AP sends an initial response to the client before knowing the result of the calculations in the controller. Load-balancing does not take effect when the FlexConnect AP is in standalone mode.

A FlexConnect AP does not send (re)association response with status 17 for load balancing the way local-mode APs do; instead, it first sends (re)association with status 0 (success) and then deauth with reason 5.

Note This feature is not supported on the APs joined on default-site-tag.
This feature is not supported on the APs across different named site-tags.
This feature is supported only on the APs within a named-site-tag.

Enabling Aggressive Client Load Balancing (GUI)

Procedure

- Step 1** Choose **Configuration > Wireless > WLANs > Wireless Networks**.
 - Step 2** Select a **WLAN** to view the **Edit WLAN** window.
 - Step 3** Click **Advanced** tab.
 - Step 4** Select the **Load Balance** check box to enable the feature.
 - Step 5** Click **Update & Apply to Device**.
-

Configuring Aggressive Client Load Balancing (GUI)

Procedure

- Step 1** Choose **Configuration > Wireless > Advanced**.
The **Load Balancing** window is displayed.
 - Step 2** In the **Aggressive Load Balancing Window (clients)** field, enter the number of clients for the aggressive load balancing client window.
 - Step 3** In the **Aggressive Load Balancing Denial Count** field, enter the load balancing denial count.
 - Step 4** Click **Apply**.
-

Configuring Aggressive Client Load Balancing (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enters privileged EXEC mode.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	wlan wlan-name Example: Device(config)# wlan test-wlan	Specifies the WLAN name.
Step 4	shutdown Example: Device(config-wlan)# shutdown	Disables the WLAN.
Step 5	load-balance Example: Device(config-wlan)# load-balance	Configures a guest controller as mobility controller, in order to enable client load balance to a particular WLAN. Configure the WLAN security settings as the WLAN requirements.
Step 6	no shutdown Example: Device(config-wlan)# no shutdown	Enables WLAN.
Step 7	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 8	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 9	ap dot11 {24ghz 5ghz} load-balancing denial denial-count Example: Device(config)# ap dot11 5ghz load-balancing denial 10	Configures the load balancing denial count.

	Command or Action	Purpose
Step 10	ap dot11 { 24ghz 5ghz } load-balancing window <i>number-of-clients</i> Example: Device(config)# ap dot11 5ghz load-balancing window 10	Configures the number of clients for the aggressive load balancing client window.
Step 11	end Example: Device(config-wlan)# end	Returns to privileged EXEC mode.
Step 12	show running-config section <i>wlan-name</i> Example: Device# show running-config section test-wlan	Displays a filtered section of the current configuration.

CHAPTER 76

RF based Automatic AP Load Balancing

- [Information about RF based Automatic AP Load Balancing, on page 899](#)
- [Configuring RF based Automatic AP Load Balancing, on page 900](#)
- [Disabling RF based Automatic AP Load Balancing, on page 902](#)
- [Verifying Automatic WNCd Load Balancing, on page 903](#)

Information about RF based Automatic AP Load Balancing

The RF based Automatic AP Load Balancing feature improves upon the existing Site Tag-Based Load Balancing feature, where the APs are load balanced by assigning them to wireless network control daemons (WNCd) based on site tags. If the APs in a named site tag are beyond the capacity of a WNCd, it may lead to uneven distribution of APs across the WNCd instances, resulting in high memory and CPU issues. Though the number of APs in a site tag can be limited to 1000 by using the **load** command, it may still lead to uneven distribution of APs if the AP load limit is not correctly configured. In some instances, all the APs belonging to a site tag may not be colocated as well.

The RF based Automatic AP Load Balancing feature uses Radio Resource Management (RRM) neighbor report-based AP grouping and load-balancing across WNCd instances.

When this feature is enabled, it forms AP clusters based on the RSSI received from AP neighbor reports. These clusters or neighborhoods are further split into sub-neighborhoods and smaller areas. The resulting groups of APs are then distributed evenly across the WNCd processes. The AP load balancing takes effect only after a controller reboot or through an AP CAPWAP reset triggered by the **ap neighborhood load-balance apply** command. When the RF based Automatic AP Load Balancing feature is active, it overrides other site tag-based load balancing.

Supported Platforms

- Cisco Catalyst 9800-80 Wireless Controller
- Cisco Catalyst 9800-40 Wireless Controller
- Cisco Catalyst 9800 Wireless Controller for Cloud
- Catalyst 9800 Embedded Wireless Controller for a Cisco switch

Prerequisites for RF based Automatic AP Load Balancing

Ensure that you run the feature on a stable network, where the APs are fully deployed and are given enough time to discover all the RF neighbors.

Restrictions for RF based Automatic AP Load Balancing

- You cannot use the same calendar profile for AP neighborhood policy or AP profile.
- This feature is supported only on APs in local and flex mode.
- You cannot run the feature when the overall load on the system is high.
- You cannot use the output of the **show wireless loadbalance tag affinity** command when the RF based Automatic AP Load Balancing feature is enabled.

Use Cases for RF based Automatic AP Load Balancing

1. This feature allows using a single site tag for all the deployed APs.
2. This feature provides better load balancing of the APs across WNCd instances when more number of APs are attached to a named-site tag than the available capacity of the WNCds in the controller.
3. This feature is suitable for large number of client intra-WNCd roaming scenarios. For example, if a controller is configured in a campus to manage APs of two separate buildings, then all the APs of that building are assigned to a single WNCd rather than allocating them to separate WNCds.

Guidelines for RF based Automatic AP Load Balancing

- For a new deployment, use the site tags and follow the current site tag recommendations to evenly distribute the APs, or use the **site tag load** command to automatically distribute the APs. Using site tags, you can ensure that all the APs of the same site tag goes to the same WNCd, which helps in troubleshooting and intra-WNCd roaming.
- If you are unable to use a site tag because you cannot group APs, or do not want to spend time designing site tags, use the default site tag or any named site tag and turn on the RF based Automatic AP Load Balancing feature.
- In an existing deployment, if you have high CPU issues because of an unbalanced system, use the auto RRM load balance system instead of redesigning the site tags.
- In an existing deployment, if you do not have any CPU load issues despite having an unbalanced system, do not change anything.

Configuring RF based Automatic AP Load Balancing

Before you begin

There are two phases of the RF based load-balancing algorithm enablement:

1. Running the algorithm: The RF based Automatic AP Load Balancing feature run can be scheduled based on calendar profile start time expiry using **ap neighborhood calendar-profile** command, or on-demand

start of the algorithm using the **ap neighborhood load-balance start** command. Calendar profile start timer can be scheduled daily, weekly, or monthly.

- Applying the algorithm: The RF based Automatic AP Load Balancing feature can be applied by controller reload or by using the **ap neighborhood load-balance apply** command when the **wireless load-balance ap method rf** configuration is enabled.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap neighborhood calendar-profile <i>calendar-profile</i> Example: Device(config)# ap neighborhood calendar-profile ap-calendar-profile	Configures an AP neighborhood calendar profile. Note After the calendar profile is set, it is optional to run Step 4 . However, if you want to immediately perform a load balance, run Step 4 .
Step 3	exit Example: Device(config)# exit	Returns to privileged EXEC mode.
Step 4	ap neighborhood load-balance start Example: Device# ap neighborhood load-balance start	(Optional) Starts AP neighborhood load-balance algorithm calculation and WNCd allocation.
Step 5	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 6	wireless load-balance ap method rf Example: Device(config)# wireless load-balance ap method rf	Configures RF-based AP load balancing.
Step 7	exit Example: Device(config)# exit	Returns to privileged EXEC mode.
Step 8	ap neighborhood load-balance apply Example:	Runs on-demand RRM-based AP load balancing.

	Command or Action	Purpose
	<pre>Device# ap neighborhood load balance apply</pre>	This command rebalances the APs using CAPWAP reset. If an AP is already in the correct WNCd instance, then it will not be CAPWAP reset. This command cannot be executed if the RRM-based AP load balancing algorithm is running, or algorithm results are not available.

Disabling RF based Automatic AP Load Balancing

Before you begin

RF based Automatic AP Load Balancing feature is disabled by default. The APs may remain load balanced based on algorithm data even after disabling all the feature configurations and clearing all the algorithm outputs. To rebalance all the APs based on the default method of site tags, reload the controller or perform a CAPWAP reset on all the APs.

Procedure

	Command or Action	Purpose
Step 1	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 2	<p>no wireless load-balance ap method rf</p> <p>Example:</p> <pre>Device(config)# no wireless load-balance ap method rf</pre>	Disables RF-based AP load balancing.
Step 3	<p>no ap neighborhood calendar-profile calendar-profile</p> <p>Example:</p> <pre>Device(config)# ap neighborhood calendar-profile ap-calendar-profile</pre>	Disables the AP neighborhood calendar profile.
Step 4	<p>exit</p> <p>Example:</p> <pre>Device(config)# exit</pre>	Returns to privileged EXEC mode.
Step 5	<p>ap neighborhood load-balance clear</p> <p>Example:</p> <pre>Device# ap neighborhood load-balance clear</pre>	Clears the AP neighborhood load-balance algorithm calculation and resource allocation.

Verifying Automatic WNCd Load Balancing

To verify the results of the RF-based algorithm and the result of the related load balancing, use the following **show** commands.

To view the AP neighborhood summary, use the following **show** command:

```
Device# show ap neighborhood summary

NH-ID = Neighborhood ID
AREA-ID = Area ID of neighborhood

Total number of neighborhood: 5
Total number of algorithm iterations: 1
Ideal AP capacity per WNCd instance: 210

Total number of neighborhood area: 14
```

NH-ID	AREA-ID	Process Name	Number of APs
0	0x00000000	WNCd_1	1
1	0x00000000	WNCd_0	2
2	0x00000000	WNCd_0	100
2	0x00000001	WNCd_0	100
2	0x00000002	WNCd_3	100
2	0x00000003	WNCd_4	50
3	0x00000000	WNCd_1	100
3	0x00000001	WNCd_1	100
3	0x00000002	WNCd_4	100
3	0x00000003	WNCd_4	50
4	0x00000000	WNCd_2	100

CHAPTER 77

Accounting Identity List

- [Configuring Accounting Identity List \(GUI\), on page 905](#)
- [Configuring Accounting Identity List \(CLI\), on page 905](#)
- [Configuring Client Accounting \(GUI\), on page 906](#)
- [Configuring Client Accounting \(CLI\), on page 906](#)

Configuring Accounting Identity List (GUI)

Procedure

- Step 1** Choose **Configuration > Security > AAA**.
 - Step 2** In the **AAA Method List** tab, go to the **Accounting** section, and click **Add**.
 - Step 3** In the **Quick Setup: AAA Accounting** window that is displayed, enter a name for your method list.
 - Step 4** Choose the type of authentication as identity, in the **Type** drop-down list.
 - Step 5** Choose the server groups you want to use to authenticate access to your network, from the **Available Server Groups** list and click **>** icon to move them to the **Assigned Server Groups** list.
 - Step 6** Click **Save & Apply to Device**.
-

Configuring Accounting Identity List (CLI)

Accounting is the process of logging the user actions and keeping track of their network usage. Whenever a user successfully executes an action, the RADIUS accounting server logs the changed attributes, the user ID of the person who made the change, the remote host where the user is logged in, the date and time when the command was executed, the authorization level of the user, and a description of the action performed and the values provided.

Follow the procedure given below to configure accounting identity list.

Before you begin

Configure the RADIUS server and AAA group server.

Procedure

	Command or Action	Purpose
Step 1	aaa accounting identity <i>named-list</i> start-stop group <i>server-group-name</i> Example: Device(config)# aaa accounting identity user1 start-stop group aaa-test	Enables accounting to send a start-record accounting notice when a client is authorized and a stop-record at the end. Note You can also use the default list, instead of a named list.

Whenever there is a change in the client attribute, for example, change in IP address, client roaming, and so on, an accounting interim update is sent to the RADIUS server.

Configuring Client Accounting (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Policy**.
 - Step 2** Click the **Policy Profile Name** and in the **Edit Policy Profile** window, go to the **Advanced** tab.
 - Step 3** From the **Accounting List** drop-down, select the appropriate accounting list for this policy profile. This will ensure that the policy profile undergoes that type of accounting you want to perform, before allowing it access to the network.
 - Step 4** Click **Save & Apply to Device**.
-

Configuring Client Accounting (CLI)

Follow the procedure given below to configure client accounting.

Before you begin

Ensure that RADIUS accounting is configured.

Procedure

	Command or Action	Purpose
Step 1	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy default-policy-profile	Configures WLAN policy profile and enters wireless policy configuration mode.
Step 2	shutdown Example:	Disables the policy profile.

	Command or Action	Purpose
	Device(config-wireless-policy)# shutdown	
Step 3	accounting-list <i>list-name</i> Example: Device(config-wireless-policy)# accounting-list user1	Sets the accounting list.
Step 4	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables the policy profile.

CHAPTER 78

Support for Accounting Session ID

- [Information About Accounting Session ID, on page 909](#)
- [Configuring an Accounting Session ID \(CLI\), on page 909](#)
- [Verifying an Account Session ID, on page 910](#)

Information About Accounting Session ID

Accounting ID is a unique identifier for a wireless client session. This ID helps to identify the accounting data of a client in the AAA server. Accounting session ID is generated by the AAA module.

From Cisco IOS XE Bengaluru, Release 17.4.1 onwards, Accounting Session ID is supported in the AAA access request, while authenticating wireless client using IEEE 802.1x method. In the Cisco IOS XE Amsterdam, Release 17.3.x and earlier releases, the Accounting Session ID was sent only as part of the accounting request. From Cisco IOS XE Bengaluru, Release 17.4.1 onwards, the Accounting Session ID is sent as part of the access request too.

Configuring an Accounting Session ID (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	radius-server attribute wireless 44 include-in-access-req Example: Device(config)# radius-server attribute wireless 44 include-in-access-req	Sends the RADIUS authentication attribute 44, in the access request packet.
Step 3	aaa accounting identity <i>accounting-list-name</i> start-stop group <i>server-group-name</i> Example:	Configures the accounting session identity of the AAA server.

	Command or Action	Purpose
	Device(config)# aaa accounting identity <i>accounting-list-name</i> start-stop group AAA_GROUP_1	
Step 4	wireless profile policy Example: Device(config)# wireless profile policy default-policy-profile <i>accounting-list-name</i> start-stop group AAA_GROUP_1	Configures the WLAN policy profile.
Step 5	accounting-list <i>accounting-list-name</i> Example: Device(config-wireless-policy)# accounting-list <i>accounting-list-name</i>	Configures the accounting list. Note The Accounting Session ID is added as part of the account request, only if radius-server attribute wireless 44 include-in-access-req is enabled along with the accounting configuration under the wireless policy.
Step 6	description <i>description-name</i> Example: Device(config-wireless-policy)# description <i>accounting-description</i>	Adds a description for the policy profile.
Step 7	vlan <i>vlan-id</i> Example: Device(config-wireless-policy)# vlan 40	Configures the VLAN name or ID.
Step 8	no shutdown Example: Device(config-wireless-policy)# no shutdown	Saves the configuration and exits configuration mode and returns to privileged EXEC mode.

Verifying an Account Session ID

To verify if an Account Session ID is populated, use the following command:

```
Device# show wireless pmk-cache
Number of PMK caches in total : 1
Type      Station      Entry Lifetime  VLAN Override  IP Override
Accounting-Session-Id  Audit-Session-Id      Username

-----
RSN      6c19.c0e6.a444      1768      NA
0x00000006      052DA8C1000000104E634C77      cwa-user
```

To display the current Accounting Session ID, use the following command:

```
Device# show wireless client mac-address<H.H.H>detail
Central NAT : DISABLED
Session Manager:
  Point of Attachment : capwap_90000005
  IIF ID               : 0x90000005
  Authorized           : TRUE
  Session timeout     : 1800
  Common Session ID: 000000000000000B14E9130A
  Acct Session ID   : 0x0000000c
  Last Tried Aaa Server Details:
    Server IP : 9.10.8.247
  Auth Method Status List
    Method : Dot1x
            SM State       : AUTHENTICATED
            SM Bend State  : IDLE
  Local Policies:
    Service Template : wlan_svc_default-policy-profile (priority 254)
    VLAN              : 1
  Server Policies:
    Absolute-Timer   : 1800
  Resultant Policies:
    VLAN Name        : default
    VLAN             : 1
    Absolute-Timer   : 1800
```

CHAPTER 79

Interim Accounting

- [Information About Interim Accounting](#), on page 913
- [Disabling Interim Accounting \(CLI\)](#), on page 914
- [Verifying Interim Accounting](#), on page 914

Information About Interim Accounting

RADIUS accounting sends accounting-request packets, with the relevant accounting information, from the network access server (NAS) to a RADIUS server.

Note The RADIUS accounting requests send data, such as VLAN ID, authentication methods, and so on, to a session.

RADIUS accounting covers the following updates:

- **Interim Updates:** When RADIUS accounting covers DHCP_TLVs, HTTP_TLVs, IP, or ROAM (state machine) changes, the updates are referred to as interim updates or interim accounting.
- **Periodic Updates:** When RADIUS accounting is specified by a timer value, the updates are referred to as periodic updates.

Note Disable the interim updates for the following reasons:

- They cause unnecessary traffic to be sent.
- They drive up error rates.
- They impact alarm thresholds and other metrics that are used for venue-authentication performance.

By default, the Interim Accounting feature is enabled with the **aaa accounting Identity default start-stop group radius** command.

Disabling Interim Accounting (CLI)

Before you begin

You must disable the Policy Profile before performing this procedure.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy default-policy-profile	Configures WLAN policy profile and enters wireless policy configuration mode.
Step 3	no accounting-interim Example: Device(config-wireless-policy)# no accounting-interim	Disables interim accounting.
Step 4	end Example: Device(config-wireless-policy)# end	Returns to privileged EXEC mode.

Verifying Interim Accounting

To verify the interim accounting updates, run the following command:

```
Device# show wireless profile policy detailed default-policy-profile | s Interim
Interim Accounting Updates: DISABLED
```

CHAPTER 80

Wireless Multicast

- [Information About Wireless Multicast, on page 915](#)
- [Prerequisites for Configuring Wireless Multicast, on page 918](#)
- [Restrictions on Configuring Wireless Multicast, on page 919](#)
- [Configuring Wireless Multicast, on page 919](#)
- [IPv6 Multicast-over-Multicast, on page 921](#)
- [Directed Multicast Service, on page 924](#)
- [Wireless Broadcast, Non-IP Multicast and Multicast VLAN, on page 926](#)
- [Multicast Filtering, on page 932](#)

Information About Wireless Multicast

If the network supports packet multicasting, the multicast method that the controller uses can be configured. The controller performs multicast routing in two modes:

- **Unicast mode:** The controller unicasts every multicast packet to every access point associated to the controller. This mode is inefficient and generates a lot of extra traffic in the device and the network, but is required on networks that do not support multicast routing (needed if the APs are on different subnets than the device's wireless management interface).
- **Multicast mode:** The controller sends multicast packets to a CAPWAP multicast group. This method reduces the overhead on the controller processor and shifts the work of packet replication to the network, which is much more efficient than the unicast method.

The FlexConnect mode has two submodes: local switching and central switching. In local switching mode, the data traffic is switched at the AP level and the controller does not see any multicast traffic. In central switching mode, the multicast traffic reaches the controller. However, IGMP snooping takes place at the AP.

When the multicast mode is enabled and the controller receives a multicast packet from the wired LAN, the controller encapsulates the packet using CAPWAP and forwards the packet to the CAPWAP multicast group address. The controller always uses the management VLAN for sending multicast packets. Access points in the multicast group receive the packet and forward it to all the BSSIDs mapped to the VLAN on which clients receive multicast traffic.

The controller supports all the capabilities of IGMP v1, including Multicast Listener Discovery (MLD) v1 snooping, but the IGMP v2 and IGMP v3 capabilities are limited. This feature keeps track of and delivers IPv6 multicast flows to the clients that request them. To support IPv6 multicast, global multicast mode should be enabled.

Internet Group Management Protocol (IGMP) snooping is introduced to better direct multicast packets. When this feature is enabled, the controller snooping gathers IGMP reports from the clients, processes them, creates unique multicast group IDs (MGIDs) based on the Layer 3 multicast address and the VLAN number, and sends the IGMP reports to the IGMP querier. The controller then updates the access-point MGID table on the corresponding access point with the client MAC address. When the controller receives multicast traffic for a particular multicast group, it forwards it to all the access points, but only those access points that have active clients listening or subscribed to that multicast group send multicast traffic on that particular WLAN. IP packets are forwarded with an MGID that is unique for an ingress VLAN and the destination multicast group. Layer 2 multicast packets are forwarded with an MGID that is unique for the ingress VLAN.

MGID is a 14-bit value filled in the 16-bit reserved field of wireless information in the CAPWAP header. The remaining two bits should be set to zero.

Multicast Optimization

Multicast optimization enables you to create a multicast VLAN that can be used for multicast traffic. One of the VLANs in the device can be configured as a multicast VLAN where multicast groups are registered. The clients are allowed to listen to a multicast stream on the multicast VLAN. The MGID is generated using the multicast VLAN and multicast IP addresses. If multiple clients on different VLANs of the same WLAN are listening to a single multicast IP address, a single MGID is generated. The device makes sure that all the multicast streams from the clients on this VLAN group always go out on the multicast VLAN to ensure that the upstream router has one entry for all the VLANs of the VLAN group. Only one multicast stream hits the VLAN group even if the clients are on different VLANs. Therefore, the multicast packets that are sent out over the network is just one stream.

Note When VLAN groups are defined and uses multicast communication, then you need to enable the multicast VLAN.

IPv6 Global Policies

IPv6 global policies provide storage and access policy database services. IPv6 ND inspection and IPv6 RA guard are IPv6 global policies features. Every time an ND inspection is configured globally, the policy attributes are stored in the software policy database. The policy is then applied to an interface, and the software policy database entry is updated to include this interface to which the policy is applied.

IPv6 RA guard is enabled by default on the controller. RA from the wired side should be forwarded to the wireless clients if the Stateless Address Auto-Configuration (SLAAC) is deployed in the network.

Information About IPv6 Snooping

The following sections provide information about IPv6 snooping.

IPv6 Neighbor Discovery Inspection

The IPv6 Neighbor Discovery Inspection, or IPv6 snooping feature bundles several Layer 2 IPv6 first-hop security features, including IPv6 Address Glean and IPv6 Device Tracking. IPv6 neighbor discovery (ND) inspection operates at Layer 2, or between Layer 2 and Layer 3, and provides IPv6 features with security and scalability. This feature mitigates some of the inherent vulnerabilities for the neighbor discovery mechanism,

such as attacks on duplicate address detection (DAD), address resolution, device discovery, and the neighbor cache.

IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables and analyzes ND messages in order to build a trusted binding table. IPv6 ND messages that do not have valid bindings are dropped. An ND message is considered trustworthy if its IPv6-to-MAC mapping is verifiable. This feature mitigates some of the inherent vulnerabilities for the neighbor discovery mechanism, such as attacks on duplicate address detection (DAD), address resolution, device discovery, and the neighbor cache.

When IPv6 ND inspection is configured on a target (which varies depending on platform target support and may include device ports, switch ports, Layer 2 interfaces, Layer 3 interfaces, and VLANs), capture instructions are downloaded to the hardware to redirect the ND protocol and Dynamic Host Configuration Protocol (DHCP) for IPv6 traffic up to the switch integrated security features (SISF) infrastructure in the routing device. For ND traffic, messages such as NS, NA, RS, RA, and REDIRECT are directed to SISF. For DHCP, UDP messages sourced from port 546 or 547 are redirected.

IPv6 ND inspection registers its "capture rules" to the classifier, which aggregates all rules from all features on a given target and installs the corresponding ACL down into the platform-dependent modules. Upon receiving redirected traffic, the classifier calls all entry points from any registered feature (for the target on which the traffic is being received), including the IPv6 ND inspection entry point. This entry point is the last to be called, so any decision (such as drop) made by another feature supersedes the IPv6 ND inspection decision.

IPv6 Device Tracking

IPv6 device tracking provides IPv6 host liveness tracking so that a neighbor table can be immediately updated when an IPv6 host disappears.

IPv6 First-Hop Security Binding Table

The IPv6 First-Hop Security Binding Table recovery mechanism feature enables the binding table to recover in the event of a device reboot. A database table of IPv6 neighbors connected to the device is created from information sources such as ND snooping. This database, or binding, table is used by various IPv6 guard features to validate the link-layer address (LLA), the IPv4 or IPv6 address, and prefix binding of the neighbors to prevent spoofing and redirect attacks.

This mechanism enables the binding table to recover in the event of a device reboot. The recovery mechanism will block any data traffic sourced from an unknown source; that is, a source not already specified in the binding table and previously learned through ND or DHCP gleaning. This feature recovers the missing binding table entries when the resolution for a destination address fails in the destination guard. When a failure occurs, a binding table entry is recovered by querying the DHCP server or the destination host, depending on the configuration.

Recovery Protocols and Prefix Lists

The IPv6 First-Hop Security Binding Table Recovery Mechanism feature introduces the capability to provide a prefix list that is matched before the recovery is attempted for both DHCP and NDP.

If an address does not match the prefix list associated with the protocol, then the recovery of the binding table entry will not be attempted with that protocol. The prefix list should correspond to the prefixes that are valid for address assignment in the Layer 2 domain using the protocol. The default is that there is no prefix list, in which case the recovery is attempted for all addresses. The command to associate a prefix list to a protocol is **protocol {dhcp | ndp} [prefix-list prefix-list-name]**.

IPv6 Address Glean

IPv6 address glean is the foundation for many other IPv6 features that depend on an accurate binding table. It inspects ND and DHCP messages on a link to glean addresses, and then populates the binding table with these addresses. This feature also enforces address ownership and limits the number of addresses any given node is allowed to claim.

The following figure shows how IPv6 address glean works.

Figure 21: IPv6 Address Glean

Prerequisites for Configuring Wireless Multicast

- To participate in IP multicasting, the multicast hosts, routers, and multilayer switches must have IGMP operating.
- When enabling multicast mode on the controller, a CAPWAP multicast group address should also be configured. Access points listen to the CAPWAP multicast group using IGMP.

- You must be cautious when using IGMPv3 with switches that are enabled for IGMP snooping. The IGMPv3 messages are different from the messages used in IGMP Version 1 (IGMPv1) and Version 2 (IGMPv2). If your switch does not recognize IGMPv3 messages, the hosts do not receive traffic when IGMPv3 is used.

IGMPv3 devices do not receive multicast traffic in either cases:

- When IGMP snooping is disabled.
- When IGMPv2 is configured on the interface.

It is recommended to enable IGMPv3 on all intermediate or other Layer 3 network devices. Primarily, on each subnet used by multicast devices including controller and AP subnets.

Restrictions on Configuring Wireless Multicast

The following are the restrictions for configuring IP multicast forwarding:

- Access points in monitor mode, sniffer mode, or rogue-detector mode do not join the CAPWAP multicast group address.
- The CAPWAP multicast group configured on the controllers should be different for different controllers.
- Multicast routing should not be enabled for the management interface.
- Multicast with VLAN group is only supported in local mode AP.
- Multicast traffic from wireless clients in non-multicast VLAN should be routed by the uplink switch.
- Multicast traffic on an AAA overridden VLAN is not supported.

Restrictions for IPv6 Snooping

The IPv6 snooping feature is not supported on EtherChannel ports.

Configuring Wireless Multicast

The following sections provide information about the various wireless multicast configuration tasks:

Configuring Wireless Multicast-MCMC Mode (CLI)

Procedure

	Command or Action	Purpose
Step 1	wireless multicast <i>ip-addr</i> Example: Device(config)# wireless multicast 231.1.1.1	Enables multicast-over-multicast. Use the no form of this command to disable the feature.

	Command or Action	Purpose
Step 2	end Example: Device(config)# end	Exits configuration mode.

Configuring Wireless Multicast-MCUC Mode

Note The wireless multicast to unicast (MCUC) mode is only supported in 9800-CL small template.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless multicast Example: Device(config)# wireless multicast	Enables the multicast traffic for wireless clients.
Step 3	end Example: Device(config)# end	Exits configuration mode.

Configuring Multicast Listener Discovery Snooping (GUI)

Procedure

- Step 1** Choose **Configuration > Services > Multicast**.
- Step 2** Click **MLD Snooping**.
- Step 3** In the **MLD Snooping** section, click the toggle button to enable or disable MLD snooping.
- Step 4** Enter the **MLD Query Interval**, in milliseconds. The value range is between 100 ms and 32767 ms. The default value is 1000 ms.
- Step 5** Move the required VLAN IDs listed in the **Disabled** section to the **Enabled** section. (By default, this feature is disabled on the VLAN.)

You can also search for a VLAN ID using the search field. You can click **Disable All** to move all the VLAN IDs from the **Enabled** list to the **Disabled** list, or click **Enable All** to move all the VLAN IDs from the **Disabled** list to the **Enabled** list.

Step 6 Click **Apply to Device**.

Configuring IPv6 MLD Snooping

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# ipv6 mld snooping	Enters global configuration mode.
Step 2	ipv6 mld snooping Example: Device(config)# ipv6 mld snooping	Enables MLD snooping.

Verifying the Multicast VLAN Configuration

To view the multicast VLAN associated with a policy profile along with the VLAN assigned to that profile, use the following command:

```
Device# show wireless profile policy detail default-policy-profile

Policy Profile Name      : default-policy-profile
Description              : default policy profile
Status                  : ENABLED
VLAN                    : vlan-pool1
Multicast VLAN       : 84
Client count            : 0
Passive Client          : DISABLED
```

To view the multicast VLAN associated with a client, use the following command:

```
Device# show wireless client mac ac2b.6e4b.551e detail

Client MAC Address : ac2b.6e4b.551e
Client IPv4 Address : 84.84.0.20
.....
VLAN : 82
Access VLAN : 82
Multicast VLAN: 84
```

IPv6 Multicast-over-Multicast

IPv6 multicast allows a host to send a single data stream to a subset of all the hosts (group transmission) simultaneously. When IPv6 Multicast over Multicast is configured, all the APs join the IPv6 multicast address, and the multicast traffic from the wireless controller to the AP flows over the IPv6 multicast tunnel.

In mixed deployments (IPv4 and IPv6), the APs might join the wireless controller over IPv4 or IPv6. To enable Multicast over Multicast in mixed deployments, configure both IPv4 and IPv6 multicast tunnels. The IPv4 APs have a unicast IPv4 CAPWAP tunnel and join the IPv4 multicast group. The IPv6 APs will have a unicast IPv6 CAPWAP tunnel and joins the IPv6 multicast group.

Note Mixed mode of Multicast over Unicast and Multicast over Multicast over IPv4 and IPv6 is not supported in Cisco IOS XE Gibraltar 16.10.1.

Table 66: Multicast Support Per Platform

Platform	Multicast Support - Multicast over Unicast	Multicast Support - Multicast over Multicast
Cisco Catalyst 9800-40 Wireless Controller	No	Yes
Cisco Catalyst 9800-80 Wireless Controller	No	Yes
Cisco Catalyst 9800 Wireless Controller for Cloud - Small Template	Yes	Yes
Cisco Catalyst 9800 Wireless Controller for Cloud - Medium Template	No	Yes
Cisco Catalyst 9800 Wireless Controller for Cloud - Large Template	No	Yes
Cisco Catalyst 9800-L Wireless Controller	Yes	Yes

Configuring IPv6 Multicast-over-Multicast (GUI)

Procedure

-
- Step 1** Choose **Configuration > Services > Multicast**.
 - Step 2** From the **AP Capwap Multicast** drop-down list, select **Multicast**.
 - Step 3** Enter the **AP Capwap IPv6 Multicast group Address**.
 - Step 4** Click **Apply**.
-

Configuring IPv6 Multicast-over-Multicast

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless multicast { ipv4-address ipv6 ipv6-address } Example: Device(config)# wireless multicast ipv6 ff45:1234::86	Configures IPv6 multicast-over-multicast address.

Verifying IPv6 Multicast-over-Multicast

To verify the IPv6 multicast-over-multicast configuration, use the following commands:

```
Device# show wireless multicast

Multicast : Enabled
AP Capwap Multicast : Multicast
AP Capwap IPv4 Multicast group Address : 231.1.1.1
AP Capwap IPv6 Multicast group Address : ff45:1234::86
Wireless Broadcast : Disabled
Wireless Multicast non-ip-mcast : Disabled

Device# show running-configuration | inc multicast

show run | inc multicast:--

wireless multicast
wireless multicast ipv6 ff45:1234::86
wireless multicast 231.1.1.1
```

Verifying the Multicast Connection Between the Controller and the AP

Cisco Catalyst 9800 Series Wireless Controller initiates a ping request that passes through the CAPWAP multicast tunnel onto the CAPWAP multicast receiver, which is the AP. In response, the AP pings the packets for CAPWAP multicast group IP address, and sends back the response to the controller. You can view the statistics on the AP for transmitted and received traffic to analyze the data that are sent and received through the multicast tunnel. Alternatively, you can also verify by enhancing the existing statistics on the AP for transmitted and received traffic to explicitly list the joins, leaves, data packets transmitted and received through the multicast tunnel.

To confirm if the APs receive multicast to multicast (mom) traffic sent by the controller, use the following command

```
Device# show ap multicast mom

AP Name                MOM-IP      TYPE MOM-  STATUS
```

```

-----
SS-E-1                IPv4                Up
SS-E-2                IPv4                Up
9130E-r3-sw2-g1012    IPv4                Up
9115i-r3-sw2-te1-0-38 IPv4                Up
AP9120-r3-sw3-Gi1-0-46 IPv4                Up
ap3800i-r2-sw1-te2-0-2 IPv4                Up

```

Directed Multicast Service

The Directed Multicast Service (DMS) feature allows a client to request access points (AP) to transmit multicast packets as unicast frames. After receiving this request, an AP buffers the multicast traffic for a client and transmits it as a unicast frame when the client wakes up. This allows the client to receive the multicast packets that were ignored while in sleep mode (to save battery power) and also ensures Layer 2 reliability. The unicast frames are transmitted to the client at a potentially higher wireless link rate, which enables the client to receive the packet quickly by enabling the radio for a shorter duration, thus saving more battery power. Without DMS, the client has to wake up at each Delivery Traffic Indication Map (DTIM) interval to receive multicast traffic.

Configuring Directed Multicast Service(GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > WLANs > Wireless Networks**.
 - Step 2** Select a **WLAN** to view the **Edit WLAN** window.
 - Step 3** Click **Advanced** tab.
 - Step 4** Check the **Directed Multicast Service** check box to enable the feature.
 - Step 5** Click **Update & Apply to Device**.
-

Configuring Directed Multicast Service

Before you begin

- This feature is enabled on receiving a request from a client. Ensure that this feature is configured under WLAN.
- This feature is supported only on 802.11v-capable clients, such as Apple iPad and Apple iPhone.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	wlan profile-name Example: Device(config)# wlan test5	Configures the WLAN profile and enters WLAN profile configuration mode.
Step 3	shutdown Example: Device(config-wlan)# shutdown	Disables the WLAN profile.
Step 4	dms Example: Device(config-wlan)# dms	Configures DMS processing per WLAN.
Step 5	no shutdown Example: Device(config-wlan)# no shutdown	Enables the WLAN profile.

Verifying the Directed Multicast Service Configuration

To verify the status of the DMS configuration on the controller, use **show** commands below. The DMS status is displayed under *IEEE 802.11v Parameters*.

```
Device# show wlan id 5

WLAN Profile Name      : test
=====
Identifier              : 5
Network Name (SSID)    : test
Status                  : Disabled
Broadcast SSID         : Enabled
Universal AP Admin     : Disabled
Max Associated Clients per WLAN : 0
Max Associated Clients per AP per WLAN : 0
Max Associated Clients per AP Radio per WLAN : 200
!
.
.
.
Assisted-Roaming
  Neighbor List        : Disabled
  Prediction List     : Disabled
  Dual Band Support    : Disabled

! DMS status is displayed below.

IEEE 802.11v parameters
  Directed Multicast Service : Enabled
  BSS Max Idle              : Disabled
  Protected Mode            : Disabled
  Traffic Filtering Service  : Disabled
  BSS Transition            : Enabled
  Disassociation Imminent   : Disabled
  Optimized Roaming Timer   : 40
  Timer                     : 200
  WNM Sleep Mode            : Disabled
```

```

802.11ac MU-MIMO : Disabled
802.11ax parameters
  OFDMA Downlink : unknown
  OFDMA Uplink : unknown
  MU-MIMO Downlink : unknown
  MU-MIMO Uplink : unknown
  BSS Color : unknown
  Partial BSS Color : unknown
  BSS Color Code

```

To verify the status of the DMS configuration on the controller for clients, use the following command:

```

Device# show wireless client mac-address 6c96.cff2.83a0 detail | inc 11v

11v BSS Transition : implemented
11v DMS Capable : Yes

```

To verify the DMS request and response statistics, use the following command:

```

Device# show wireless stats client detail | inc DMS

Total DMS requests received in action frame : 0
Total DMS responses sent in action frame : 0
Total DMS requests received in Re-assoc Request : 0
Total DMS responses sent in Re-assoc Response : 0

```

To verify the DMS configuration Cisco Aironet 2700 and 3700 Series APs, use the following command:

```

AP# show controllers dot11Radio 0/1 | begin Global DMS

Global DMS - requests:0 uc:0 drop:408
DMS enabled on WLAN(s): dms-open
test-open

```

To verify the DMS configuration on the Cisco Aironet 2800, 3800, and 4800 Series APs, use the following command:

```

AP# show multicast dms all

vapid    client                dmsid    TClas
0        1C:9E:46:7C:AF:C0    1        mask:0x55, version:4, proto:0x11, dscp:0x0, sport:0,
dport:9, sip:0.0.0.0, dip:224.0.0.251

```

Wireless Broadcast, Non-IP Multicast and Multicast VLAN

Restrictions

- Wireless broadcast does not support VLAN groups.
- When a VLAN pool is mapped to the WLAN profile, support for forwarding non-IPv4 multicast and broadcast is unavailable.
- Non-IPv4 multicasts and broadcasts are restricted to clients on the VLAN mapped to the WLAN and are not forwarded on VLANs returned by AAA override.

Configuring Non-IP Wireless Multicast (CLI)

Before you begin

- The non-IP Multicast feature is disabled globally, by default.
- For non-IP multicast, global wireless multicast must be enabled for traffic to pass.
- This feature is not supported in Fabric or Flex deployments.

Procedure

	Command or Action	Purpose
Step 1	wireless multicast non-ip Example: Device(config)# wireless multicast non-ip	Enables non-IP multicast in all the VLANs. By default, the non-IP multicast in all the VLANs is in Disabled state. Wireless multicast must be enabled for the traffic to pass. Use the no form of this command to disable non-IP multicast in all the VLANs.
Step 2	wireless multicast non-ip vlan <i>vlanid</i> Example: Device(config)# wireless multicast non-ip vlan 5	Enables non-IP multicast per VLAN. By default, non-IP multicast per VLAN is in Disabled state. Both wireless multicast and wireless multicast non-IP must be enabled for traffic to pass. Use the no form of this command to disable non-IP multicast per VLAN.
Step 3	end Example: Device(config)# end	Exits configuration mode.

Configuring Wireless Broadcast (GUI)

Procedure

-
- Step 1** Choose **Configuration > Services > Multicast**.
- Step 2** In the Multicast page, change the status of the **Wireless Broadcast** to enabled to broadcast packets for wireless clients.
The default value is disabled.
- Step 3** From the Disabled VLAN table, click the arrow adjacent to the VLAN ID in the **Disabled** state to the **Enabled** state to enable broadcast packets for a VLAN.
The default value is disabled.
- Step 4** Save the configuration.
-

Configuring Wireless Broadcast (CLI)

Before you begin

- This feature is applicable only to non-ARP and DHCP broadcast packets.
- This feature is disable globally, by default.
- This feature is not supported in Fabric or Flex deployments.

Procedure

	Command or Action	Purpose
Step 1	wireless broadcast Example: Device(config)# wireless broadcast	Enables broadcast packets for wireless clients. By default, the broadcast packets for wireless clients is in Disabled state. Enabling wireless broadcast enables broadcast traffic for each VLAN. Use the no form of this command to disable broadcasting packets.
Step 2	wireless broadcast vlan <i>vlanid</i> Example: Device(config)# wireless broadcast vlan 3	Enables broadcast packets for single VLAN. By default, the Broadcast Packets for a Single VLAN feature is in Disabled state. Wireless broadcast must be enabled for broadcasting. Use the no form of this command to disable broadcast traffic for each VLAN.
Step 3	end Example: Device(config)# end	Exits configuration mode.

Configuring Multicast-over-Multicast for AP Multicast Groups (CLI)

Procedure

	Command or Action	Purpose
Step 1	ap capwap multicast <i>IP address</i> Example: Device(config)# ap capwap multicast 239.4.4.4	Configures an all-AP multicast group to send a single packet to all the APs.
Step 2	wireless multicast <i>IP address</i> Example: Device(config)# wireless multicast 239.4.4.4	Enables Multicast-over-Multicast for multicasting client multicast group traffic to all the APs through the underlying all-AP multicast group. <i>IP address</i> —Multicast-over-multicast IP address.

	Command or Action	Purpose
Step 3	end Example: Device(config)# end	Exits configuration mode.

Verifying Wireless Multicast

Table 67: Commands for Verifying Wireless Multicast

Command	Description
show wireless multicast	Displays the multicast status and IP multicast mode, and each VLAN's broadcast and non-IP multicast status. Also displays the Multicast Domain Name System (mDNS) bridging state.
show wireless multicast group summary	Displays all (Group and VLAN) lists and the corresponding MGID values.
show wireless multicast [source <i>source</i>] group <i>group</i> vlan <i>vlanid</i>	Displays details of the specified (S,G,V) and shows all the clients associated with and their MC2UC status.
show ip igmp snooping wireless mcast-ipc-count	Displays the number of multicast IPCs per MGID sent to the wireless controller module.
show ip igmp snooping wireless mgid	Displays the MGID mappings.
show ip igmp snooping igmpv2-tracking	Displays the client-to-SGV mappings and the SGV-to-client mappings.
show ip igmp snooping querier vlan <i>vlanid</i>	Displays the IGMP querier information for the specified VLAN.
show ip igmp snooping querier detail	Displays the detailed IGMP querier information of all the VLANs.
show ipv6 mld snooping querier vlan <i>vlanid</i>	Displays the MLD querier information for the specified VLAN.
show ipv6 mld snooping wireless mgid	Displays MGIDs for the IPv6 multicast group.

Multicast Optimization

Multicast used to be based on the group of the multicast addresses and the VLAN as one entity, MGID. With the VLAN group, duplicate packets might increase. Using the VLAN group feature, every client listens to the multicast stream on a different VLAN. As a result, the device creates different MGIDs for each multicast address and the VLAN. Therefore, the upstream router sends a copy for each VLAN, which results in as many copies as the number of VLANs in the group. Because the WLAN remains the same for all the clients, multiple copies of the multicast packet are sent over the wireless network. To suppress the duplication of a multicast stream on the wireless medium between the device and the access points, the multicast optimization feature can be used.

Multicast optimization enables you to create a multicast VLAN that can be used for multicast traffic. One of the VLANs in the device can be configured as a multicast VLAN where multicast groups are registered. The clients are allowed to listen to a multicast stream on the multicast VLAN. The MGID is generated using the multicast VLAN and multicast IP addresses. If multiple clients on different VLANs of the same WLAN are listening to a single multicast IP address, a single MGID is generated. The device makes sure that all the multicast streams from the clients on this VLAN group always go out on the multicast VLAN to ensure that the upstream router has one entry for all the VLANs of the VLAN group. Only one multicast stream hits the VLAN group even if the clients are on different VLANs. Therefore, the multicast packets that are sent out over the network is just one stream.

Configuring IP Multicast VLAN for WLAN (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Policy**.
- Step 2** Click **Add**.
- Step 3** In the **General** tab, enter the **Name** and **Description**.
- Step 4** Enable the **Central Switching** and **Central Association** toggle buttons.
- Step 5** In the **Access Policies** tab, under the **VLAN** settings, choose the vlans from the **VLAN/VLAN Group** drop-down list and enter the **Multicast VLAN**.
- Step 6** Click **Apply to Device**.
-

Configuring IP Multicast VLAN for WLAN

Before you begin

- This feature is not supported in Fabric or Flex deployments.
- Multicast VLAN is used for both IPv4 and IPv6 multicast forwarding to APs.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy profile-policy Example: Device(config)# wireless profile policy default-policy-profile	Configures WLAN policy profile and enters wireless policy configuration mode.

	Command or Action	Purpose
Step 3	central association Example: Device(config-wireless-policy)# central association	Configures central association for locally switched clients.
Step 4	central switching Example: Device(config-wireless-policy)# central switching	Configures WLAN for central switching.
Step 5	description <i>policy-profile-name</i> Example: Device(config-wireless-policy)# description "test"	(Optional) Adds a description for the policy profile.
Step 6	vlan <i>vlan-name</i> Example: Device(config-wireless-policy)# vlan 32	Assigns the profile policy to the VLAN.
Step 7	multicast vlan <i>vlan-id</i> Example: Device(config-wireless-policy)# multicast vlan 84	Configures multicast for the VLAN.
Step 8	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables the profile policy.

Verifying the Multicast VLAN Configuration

To view the multicast VLAN associated with a policy profile along with the VLAN assigned to that profile, use the following command:

```
Device# show wireless profile policy detail default-policy-profile
```

```
Policy Profile Name      : default-policy-profile
Description              : default policy profile
Status                  : ENABLED
VLAN                    : vlan-pool1
Multicast VLAN       : 84
Client count            : 0
Passive Client          : DISABLED
```

To view the multicast VLAN associated with a client, use the following command:

```
Device# show wireless client mac ac2b.6e4b.551e detail
```

```
Client MAC Address : ac2b.6e4b.551e
Client IPv4 Address : 84.84.0.20
```

```

.....
VLAN : 82
Access VLAN : 82
Multicast VLAN: 84

```

Multicast Filtering

Information About Multicast Filtering

In Cisco IOS XE Amsterdam, Release 17.2.1, the Multicast Filtering feature is supported on Layer 3 for IPv4.

You can enable or disable the multicast filtering feature per WLAN from the controller. When you enable this feature, the APs drop the Internet Group Management Protocol (IGMP) join request from a client that is part of the WLAN, for any Layer 3 multicast group address. When you disable this feature, the APs honor the IGMP join request from the client that is part of the WLAN.

In the Cisco IOS XE Amsterdam, Release 17.3.1, the Multicast Filtering feature is supported on Layer 3 for IPv6.

You can enable or disable the Multicast Filtering feature per WLAN, from the controller. The following table shows the AP behavior with IPv4 and IPv6:

The Multicast Filtering feature is disabled by default.

Table 68: Multicast Filtering per WLAN

Multicast Filtering Feature Status	IPv4	IPv6
Enabled	AP drops the Internet Group Management Protocol (IGMP) membership report from a client that is a part of a WLAN.	AP drops the Multicast Listener Discovery (MLD) report with multicast group address scope value greater than three, from a client that is a part of a WLAN.
Disabled	AP honors the IGMP membership report from the client that is a part of a WLAN.	AP honors the MLD report from the client that is a part of a WLAN.

Supported L3 Multicast Report for Filtering

APs will not honor and drop IGMP and MLD join requests from a client part of WLAN for any L3 multicast group address as per the below filtering options:

- IPv4: IGMP versions to be filtered:
 - V1 membership report (0x12)
 - V2 membership report (0x16)
 - V3 membership report (0x22)
- IPv6: ICMPv6 types to be filtered, except link-local multicast packets:

- Multicast Listener report: MLD Version 1 (131)
- Multicast Listener report: MLD Version 2 (143)

Note Filtering of supported types will prevent the creation or addition of a client entry to the AP multicast group table.

Configuring Multicast Filtering

Perform the procedure given here to create a policy profile and then enable Multicast Filtering on a WLAN:

Before you begin

Create a WLAN.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>profile-policy</i> Example: Device(config)# wireless profile policy rr-xyz-policy-1	Configures a WLAN policy profile and enters wireless policy configuration mode.
Step 3	multicast filter Example: Device(config-wireless-policy)#multicast filter	Configures a multicast filter. (Use the no form of this command to disable the feature.)

What to do next

1. Create a policy tag. For more information about creating policy tags, see *Configuring a Policy Tag (CLI)*.
2. Map the policy tag to an AP. For more information about mapping a policy tag to an AP, see *Attaching a Policy Tag and Site Tag to an AP (CLI)*.

Verifying Multicast Filtering

To verify if multicast filtering is enabled, use the **show wireless profile policy detailed *named-policy-profile*** command:

```
Device# show wireless profile policy detailed named-policy-profile
Policy Profile Name           : named-policy-profile
```

```
Description          :  
Status                : DISABLED  
VLAN                  : 91  
Multicast VLAN        : 0  
OSEN client VLAN      :  
Multicast Filter      : ENABLED
```

CHAPTER 81

Map-Server Per-Site Support

- [Information About Map Server Per Site Support, on page 935](#)
- [Configuring the Default Map Server \(GUI\), on page 936](#)
- [Configuring the Default Map Server \(CLI\), on page 936](#)
- [Configuring a Map Server Per Site \(GUI\), on page 937](#)
- [Configuring a Map Server Per Site \(CLI\), on page 937](#)
- [Creating a Map Server for Each VNID \(GUI\), on page 938](#)
- [Creating a Map Server for Each VNID, on page 938](#)
- [Creating a Fabric Profile and Associating a Tag and VNID \(GUI\), on page 939](#)
- [Creating a Fabric Profile and Associating a Tag and VNID \(CLI\), on page 939](#)
- [Verifying the Map Server Configuration, on page 940](#)

Information About Map Server Per Site Support

The Map Server Per Site feature supports per-site map server and the selection of map server based on the client's subnet. This enables the controller to support multiple sites and to segregate each site's traffic.

This feature is applicable to both Enterprise and Guest map servers. For the Layer 2 virtual extensible LAN network identifier-based (L2VNID-based) map server, the appropriate map server should be selected based on the L2 VNID.

The following list shows the map server selection order for AP query and client registration:

- Per-L3 VNID map server
- Per site (ap-group) map server
- Default or global map server

Benefits

Some of the benefits of using Map Server Per Site feature are listed below:

- You can use a single large site with horizontal scaling of the map server and border nodes.
- You can share the controller across multiple sites, with each site can having its own map server and virtual network or VNID and still segment traffic from each site.
- You can share Guest map-server across multiple sites while keeping the Enterprise map-server separate.

- You can use the same SSID across different sites. Within a site, they can belong to a different virtual network domain.

Configuring the Default Map Server (GUI)

Procedure

-
- Step 1** Choose **Configuration > Wireless > Fabric**.
 - Step 2** On the **Fabric** page, click the **Control Plane** tab.
 - Step 3** In the **Control Plane Name** list, click **default-control-plane**.
 - Step 4** In the **Edit Control Plane** window that is displayed, click **Add**.
 - Step 5** Enter the IP address of the map server.
 - Step 6** Set the **Password Type** as either **Unencrypted** or **AES**.
 - Step 7** Enter the **Pre Shared Key**.
 - Step 8** Click **Save**.
 - Step 9** Click **Update & Apply to Device**.
-

Configuring the Default Map Server (CLI)

Follow the procedure given below to configure the default map server.

Before you begin

- The global map server is the default map server that is used for both AP query (when an AP joins) as well as for client registration (when a client joins).
- We recommend that you configure map servers in pairs to ensure redundancy because the LISP control-plane does not support redundancy inherently.
- To share a map server set, create a map server group, which can be shared across site profiles, fabric profiles, Layer 2 and Layer3 VNID, as well with the default map server.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wireless fabric control-plane <i>control-plane-name</i>	Configures the control plane name.

	Command or Action	Purpose
	Example: Device(config)# wireless fabric control-plane test-map	If you do not provide a control plane name, the default-control-plane that is auto generated is used.
Step 3	ip address <i>ip-address</i> key <i>pre-shared-key</i> Example: Device((config-wireless-cp)#ip address 10.12.13.14 key secret	Configures IP address and the key for the control plane.

Configuring a Map Server Per Site (GUI)

Before you begin

Ensure that you have configured an AP Join Profile prior to configuring the primary and backup controllers.

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > AP Join**.
 - Step 2** On the **AP Join Profile** page, click the AP Join Profile name.
 - Step 3** In the **Edit AP Join Profile** window, click the **CAPWAP** tab.
 - Step 4** In the **High Availability** tab under **Backup Controller Configuration**, check the **Enable Fallback** check box.
 - Step 5** Enter the primary and secondary controller names and IP addresses.
 - Step 6** Click **Update & Apply to Device**.
-

Configuring a Map Server Per Site (CLI)

Follow the procedure given below to configure per-site MAP server under site-tag.

Before you begin

You can configure map server for each site or each AP group. . If a map server is not configured for each VNID or subnet, per-site map server is used for AP queries and client registration.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	wireless tag site <i>site-tag</i> Example: Device(config)# wireless tag site test-site	Configures a site tag and enters site tag configuration mode.
Step 3	fabric control-plane <i>map-server-name</i> Example: Device(config-wireless-site)# fabric control-plane test-map	Associates a fabric control plane name with a site tag.

Creating a Map Server for Each VNID (GUI)

Procedure

-
- Step 1** Click **Configuration > Wireless Plus > Fabric > Fabric Configuration**.
 - Step 2** In the **Profiles** tab, click **Add** to add a new Fabric Profile.
 - Step 3** In the **Add New Profile** window that is displayed, enter a name and description for the profile.
 - Step 4** Specify the L2 VNID and SGT Tag details.
 - Step 5** In the **Map Servers** section, specify the IP address and preshared key details for Server 1.
 - Step 6** Optionally, you can specify the IP address and preshared key details for Server 2.
 - Step 7** Click **Save & Apply to Device**.
-

Creating a Map Server for Each VNID

Follow the procedure given below to configure map server for each VNID in Layer 2 and Layer 3 or a map server for a client VNID.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	Choose one of the following: <ul style="list-style-type: none"> • wireless fabric name <i>vnid-map</i> l2-vnid <i>l2-vnid</i> l3-vnid <i>l3vnid</i> ip <i>network-ip</i> <i>subnet-mask</i> control-plane <i>control-plane-name</i> 	Configures a map server for each VNID in Layer 2 and Layer 3 or a map server for a client VNID.

	Command or Action	Purpose
	<ul style="list-style-type: none"> • wireless fabric name <i>vnid-map l2-vnid l2-vnid control-plane control-plane-name</i> <p>Example:</p> <pre>Device(config)# wireless fabric name test1 l2-vnid 12 l3-vnid 10 ip 10.8.6.2 255.255.255.236 control-plane cp1</pre> <p>Example:</p> <pre>Device(config)# wireless fabric name test1 l2-vnid 22 control-plane cp1</pre>	

Creating a Fabric Profile and Associating a Tag and VNID (GUI)

Procedure

-
- Step 1** Click **Configuration > Wireless > Fabric**.
 - Step 2** In the **Profiles** tab on **Fabric Configuration** page, click **Add** to add a new profile.
 - Step 3** In the **Add New Profile** window that is displayed, enter a name and description for the profile.
 - Step 4** Specify the L2 VNID and SGT Tag details.
 - Step 5** Click **Save & Apply to Device**.
-

Creating a Fabric Profile and Associating a Tag and VNID (CLI)

Follow the procedure given below to create a fabric profile and associate the VNID to which the client belongs and the SGT tag to this profile.

Procedure

	Command or Action	Purpose
Step 1	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 2	<p>wireless profile fabric <i>fabric-profile-name</i></p> <p>Example:</p> <pre>Device(config)# wireless profile fabric test-fabric</pre>	Configures a fabric profile.
Step 3	<p>sgt-tag <i>value</i></p> <p>Example:</p>	Configures an SGT tag.

	Command or Action	Purpose
	Device(config-wireless-fabric)# sgt-tag 5	
Step 4	client-l2-vnid <i>vnid</i> Example: Device(config-wireless-fabric)# client-l2-vnid 10	Configures a client Layer 2 VNID.

Verifying the Map Server Configuration

Use the following commands to verify the map server configuration:

```
Device# show wireless fabric summary
```

```
Fabric Status      : Enabled
```

```
Control-plane:
```

Name	IP-address	Key	Status
test-map	10.12.13.14	test1	Down

```
Fabric VNID Mapping:
```

Name	L2-VNID	L3-VNID	IP Address	Subnet
Control plane name				
test1	12	10	10.6.8.9	255.255.255.236
test2				

```
Device# show wireless fabric vnid mapping
```

```
Fabric VNID Mapping:
```

Name	L2-VNID	L3-VNID	IP Address	Subnet	Control Plane Name
fabric1	1	0	9.6.51.0	255.255.255.0	
map-server-name					

```
Device# show wireless profile fabric detailed profile-name
```

```
Profile-name      : fabric-ap
VNID              : 1
SGT               : 500
Type              : Guest
```

```
Control Plane Name      Control-Plane IP      Control-Plane Key
```

Ent-map-server	5.4.3.2	guest_1
----------------	---------	---------

```
Device# show ap name ap-name config general
```

```

CHAPTER 82

Volume Metering

- [Volume Metering, on page 943](#)
- [Configuring Volume Metering, on page 943](#)

Volume Metering

The Volume Metering feature allows you to configure the interval at which an access point (AP) updates client accounting statistics to the controller and in turn to the RADIUS server. Currently, the report is sent from an AP to the controller every 90 seconds. With this feature, you can configure the time from 5 to 90 seconds. This helps reduce the delay in accounting data usage by a device.

Configuring Volume Metering

Follow the procedure given below to configure volume metering:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>profile-name</i> Example: Device(config)# ap profile yy-ap-profile	Configures an AP profile and enters ap profile configuration mode.
Step 3	dot11 24ghz reporting-interval <i>reporting-interval</i> Example: Device(config-ap-profile)# dot11 24ghz reporting-interval 60	Configures the dot11 parameters.

	Command or Action	Purpose
Step 4	dot11 5ghz reporting-interval <i>reporting-interval</i> Example: <pre>Device(config-ap-profile)# dot11 5ghz reporting-interval 60</pre>	Configures the dot11 parameters.
Step 5	exit Example: <pre>Device(config-ap-profile)# exit</pre>	Returns to global configuration mode.
Step 6	aaa accounting update periodic <i>interval-in-minutes</i> Example: <pre>Device(config)# aaa accounting update periodic 75</pre>	Sets the time interval (in minutes) at which the controller sends interim accounting updates of the client to the RADIUS server.
Step 7	exit Example: <pre>Device(config)# exit</pre>	Exits configuration mode and returns to privileged EXEC mode.

CHAPTER 83

Enabling Syslog Messages in Access Points and Controller for Syslog Server

- [Information About Enabling Syslog Messages in Access Points and Controller for Syslog Server, on page 945](#)
- [Configuring Syslog Server for an AP Profile, on page 947](#)
- [Configuring Syslog Server for the Controller \(GUI\), on page 948](#)
- [Configuring Syslog Server for the Controller , on page 949](#)
- [Information About Syslog Support for Client State Change, on page 950](#)
- [Configuring Syslog Support for Client State Change \(CLI\), on page 951](#)
- [Sample Syslogs, on page 951](#)
- [Verifying Syslog Server Configurations, on page 952](#)

Information About Enabling Syslog Messages in Access Points and Controller for Syslog Server

The Syslog server on access points and controller has many levels and facilities.

The following are the Syslog levels:

- Emergencies
- Alerts
- Critical
- Errors
- Warnings
- Notifications
- Informational
- Debugging

The following options are available for the Syslog facility:

- auth—Authorization system.

- cron—Cron/ at facility.
- daemon—System daemons.
- kern—Kernel.
- local0—Local use.
- local1—Local use.
- local2—Local use.
- local3—Local use.
- local4—Local use.
- local5—Local use.
- local6—Local use.
- local7—Local use.
- lpr—Line printer system.
- mail—Mail system.
- news—USENET news.
- sys10—System use.
- sys11—System use.
- sys12—System use.
- sys13—System use.
- sys14—System use.
- sys9—System use.
- syslog—Syslog itself.
- user—User process.
- uucp—Unix-to-Unix copy system.

Note For more information about the usage of the syslog facilities and levels, refer to [RFC 5424](#) (*The Syslog Protocol*).

Configuring Syslog Server for an AP Profile

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# <code>ap profile xyz-ap-profile</code>	Configures an AP profile and enters the AP profile configuration mode.
Step 3	syslog facility Example: Device(config-ap-profile)# <code>syslog facility</code>	Configures the facility parameter for Syslog messages.
Step 4	syslog host <i>ip-address</i> Example: Device(config-ap-profile)# <code>syslog host 9.3.72.1</code>	Configures the Syslog server IP address and parameters.
Step 5	syslog level {alerts critical debugging emergencies errors informational notifications warnings} Example: Device(config-ap-profile)# <code>syslog level</code>	Configures the Syslog server logging level. The following are the Syslog server logging levels: <ul style="list-style-type: none"> • emergencies—Signifies severity 0. Implies that the system is not usable. • alerts—Signifies severity 1. Implies that an immediate action is required. • critical—Signifies severity 2. Implies critical conditions. • errors—Signifies severity 3. Implies error conditions. • warnings—Signifies severity 4. Implies warning conditions. • notifications—Signifies severity 5. Implies normal but significant conditions. • informational—Signifies severity 6. Implies informational messages. • debugging—Signifies severity 7. Implies debugging messages.

	Command or Action	Purpose
		<p>Note To know the number of Syslog levels supported, you need to select a Syslog level. Once a Syslog level is selected, all the levels below it are also enabled.</p> <p>If you enable <i>critical</i> Syslog level then all levels below it are also enabled. So, all three of them, namely, <i>critical</i>, <i>alerts</i>, and <i>emergencies</i> are enabled.</p>
Step 6	<p>end</p> <p>Example:</p> <pre>Device(config-ap-profile)# end</pre>	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuring Syslog Server for the Controller (GUI)

Procedure

-
- Step 1** Choose **Troubleshooting > Logs**.
- Step 2** Click **Manage Syslog Servers** button.
- Step 3** In **Log Level Settings**, from the **Syslog** drop-down list, choose a security level.
- Step 4** From the **Message Console** drop-down list, choose a logging level.
- Step 5** In **Message Buffer Configuration**, from the **Level** drop-down list, choose a server logging level.
- Step 6** In **Size (bytes)**, enter the buffer size. The value can range between 4096 to 2147483647.
- Step 7** In **IP Configuration** settings, click **Add**.
- Step 8** Choose the **Server Type**, from the **IPv4 / IPv6** or **FQDN** option.
- Step 9** For Server Type **IPv4 / IPv6**, enter the **IPv4 / IPv6 Server Address**. For Server Type **FQDN**, enter the **Host Name**, choose the IP type and the appropriate **VRF Name** from the drop-down lists.
- To delete a syslog server, click 'x' next to the appropriate server entry, under the **Remove** column.
- Note** When creating a host name, spaces are not allowed.
- Step 10** Click **Apply to Device**.
- Note** When you click on **Apply to Device**, the changes are configured. If you click on **Cancel**, the configurations are discarded.
-

Configuring Syslog Server for the Controller

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	logging host {hostname ipv6} Example: Device(config)# <code>logging host 124.3.52.62</code>	Enables Syslog server IP address and parameters.
Step 3	logging facility {auth cron daemon kern local0 local1 local2 local3 local4 local5 local6 local7 lpr mail news sys10 sys11 sys12 sys13 sys14 sys9 syslog user uucp} Example: Device(config)# <code>logging facility syslog</code>	Enables facility parameter for the Syslog messages. You can enable the following facility parameter for the Syslog messages: <ul style="list-style-type: none"> • auth—Authorization system. • cron—Cron facility. • daemon—System daemons. • kern—Kernel. • local0 to local7—Local use. • lpr—Line printer system. • mail—Mail system. • news—USENET news. • sys10 to sys14 and sys9—System use. • syslog—Syslog itself. • user—User process. • uucp—Unix-to-Unix copy system.
Step 4	logging trap {severity-level alerts critical debugging emergencies errors informational notifications warnings} Example: Device(config)# <code>logging trap 2</code>	Enables Syslog server logging level. <i>severity-level</i> - Refers to the logging severity level. The valid range is from 0 to 7. The following are the Syslog server logging levels: <ul style="list-style-type: none"> • emergencies—Signifies severity 0. Implies that the system is not usable.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • alerts—Signifies severity 1. Implies that an immediate action is required. • critical—Signifies severity 2. Implies critical conditions. • errors—Signifies severity 3. Implies error conditions. • warnings—Signifies severity 4. Implies warning conditions. • notifications—Signifies severity 5. Implies normal but significant conditions. • informational—Signifies severity 6. Implies informational messages. • debugging—Signifies severity 7. Implies debugging messages. <p>Note To know the number of Syslog levels supported, you need to select a Syslog level. Once a Syslog level is selected, all the levels below it are also enabled.</p> <p>If you enable <i>critical</i> Syslog level then all levels below it are also enabled. So, all three of them, namely, <i>critical</i>, <i>alerts</i>, and <i>emergencies</i> are enabled.</p>
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Information About Syslog Support for Client State Change

When a client joins, dissociates, or rejoins a wireless network, the Syslog Support for Client State Change feature enables you to track client details such as IP addresses, AP names, and so on.

A syslog is generated in the following scenarios:

- When a client moves to RUN state.
- When a client gets a new IP (IPv4 or IPv6) address in the RUN state.
- When a client in RUN state is deleted.

Note When Syslog Support for Client State Change feature is enabled, and the AP moves from standalone to connected, you may observe that usernames are null in **syslog messages and in client detail** for the 802.1X clients associated with that AP. You can ignore this behavior, as it does not have any operational impact. The usernames will get updated after 30 seconds.

Configuring Syslog Support for Client State Change (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless client syslog-detailed Example: Device(config)# wireless client syslog-detailed	Enables detailed syslogs for client events.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.

Sample Syslogs

802.11x Authentication

The following example shows a client IP update:

```
Oct 1 14:41:27.785 IST: %CLIENT_ORCH_LOG-7-CLIENT_IP_UPDATED:
Chassis 1 R0/0: wncd: Username (dev2), MAC: 0062.xxxx.0077,
IP fe80::262:aff:xxxx:77 101.6.2.119 2001:300:8:0:362:aff:xxxx:77 2001:300:8:0:762:aff:xxxx:77
2001:300:8:0:562:aff:xxxx:77 2001:300:8:0:962:aff:xxxx:77 2001:300:8:0:462:aff:xxxx:77
IP address updated, associated to AP (Asim_06-11) with SSID (dev_abcd_wlan_1)
```

The following example shows a client RUN state:

```
Oct 1 14:41:27.779 IST: %CLIENT_ORCH_LOG-7-CLIENT_MOVED_TO_RUN_STATE:
Chassis 1 R0/0: wncd: Username (dev2), MAC: 0062.xxxx.006a, IP 101.xxxx.2.106 associated
to AP
(Asim_06-10) with SSID (dev_abcd_wlan_1)
```

Open Authentication

The following example shows a client IP update:

```
Sep 18 03:22:35.902: %CLIENT_ORCH_LOG-7-CLIENT_IP_UPDATED:
Chassis 1 R0/0: wncd: Username (null), MAC: 6014.xxxx.c5fb, IP 9.9.xxxx.252
fe80::643c:87c1:xxxx:c1c4 IP address updated,
associated to AP (AP2C5A.xxxx.159A) with SSID (test1)
```

The following example shows a client RUN state:

```
Sep 18 03:22:35.257: %CLIENT_ORCH_LOG-7-CLIENT_MOVED_TO_RUN_STATE:
Chassis 1 R0/0: wncd: Username (null), MAC: 6014.xxxx.c5fb, IP 9.9.xxxx.252 associated to
AP (AP2C5A.xxxx.159A) with SSID (test1)
```

The following example shows a client delete state:

```
Sep 18 03:24:45.083: %CLIENT_ORCH_LOG-7-CLIENT_MOVED_TO_DELETE_STATE:
Chassis 1 R0/0: wncd: Username (null), MAC: 6014.xxxx.c5fb, IP fe80::643c:xxxx:e316:c1c4
2001:300:42:0:643c:87c1:xxxx:c1c4
2001:300:42:0:xxxx:82ce:1ae4:5a32 9.9.xxxx.252 disconnected from AP (AP2C5A.xxxx.159A) with
SSID (test1)
```

Verifying Syslog Server Configurations

Verifying Global Syslog Server Settings for all Access Points

To view the global Syslog server settings for all access points that joins the controller, use the following command:

```
Device# show ap config general
Cisco AP Name : APA0F8.4984.5E48

CHAPTER 84

Login Banner

- [Information About Login Banner, on page 957](#)
- [Configuring a Login Banner \(GUI\), on page 957](#)
- [Configuring a Login Banner, on page 958](#)

Information About Login Banner

Login banner is used to display a warning or message when you try to login to the controller.

To create a login banner, you must configure a delimiting character that notifies the system that the following text string must be displayed as the banner, and then the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the banner. The delimiting character can be any single character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string for the banner.

Note When HTTP authentication is configured using TACACS+/RADIUS, the banner message does not display on the Web UI.

Configuring a Login Banner (GUI)

Procedure

- Step 1** Choose **Configuration > Security > Web Auth**.
- Step 2** Click the **Web Auth Parameter Map**.
- Step 3** In the **General** tab, click the **Banner Text** radio button under **Banner Type**.
- Step 4** Enter the **Banner Text**, **Maximum HTTPS connections** and **Init-State Timeout (secs)**.
- Step 5** Choose the type from the **Type** drop-down list.
- Step 6** Enter the **Virtual IPv4 Address**, **Virtual IPv4 Hostname** and **Virtual IPv6 Hostname**, **Watch List Expiry Timeout (secs)**, **Sleeping Client Timeout (minutes)** and choose the trustpoint from the **Trustpoint** drop-down list.

Step 7 Check or uncheck the **Turn-on Consent with Email, Web Auth intercept HTTPS, Watch List Enable, Captive Bypass Portal, Disable Success Window, Disable Logout Window** and **Sleeping Client Status** check boxes.

Step 8 Click **Update & Apply** .

Configuring a Login Banner

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	banner login c message c Example: Device(config)# banner login \$ Access for authorized users only. Please enter your username and password. \$	Specifies the login message. <ul style="list-style-type: none"> • c— Enters the delimiting character of your choice, for example, a pound sign (#), and press the Return key. The delimiting character signifies the beginning and end of the banner text. Characters after the ending delimiter are discarded. • message— Enters a login message up to 255 characters. You cannot use the delimiting character in the message.
Step 4	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Step 5	show running-config Example: Device# show running-config	Verifies your entries.
Step 6	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

CHAPTER 85

Wi-Fi Alliance Agile Multiband

- [Introduction to Wi-Fi Alliance Agile Multiband, on page 959](#)
- [Limitations of MBO, on page 961](#)
- [Configuring MBO on a WLAN, on page 961](#)
- [Verifying MBO Configuration, on page 962](#)

Introduction to Wi-Fi Alliance Agile Multiband

The Wi-Fi Alliance Agile Multiband (MBO) feature enables better use of Wi-Fi network resources. This feature is built on the fundamental premise that both Wi-Fi networks and client devices have information that can enable better roaming decisions and improve the overall performance of Wi-Fi networks and user experience.

Note This feature applies to MBO certified clients only.

This feature certifies the interoperability of a bundle of features that are defined by the IEEE standard amendments 802.11k, 802.11v, and 802.11u, as well as the Wi-Fi-Alliance defined specifications. These technologies are used to exchange access points (AP), band, and channel preferences, link quality, and status information between AP and client device.

MBO focuses on the following:

- Interactions between the wireless clients and APs
- Exchange of AP and client knowledge about the wireless medium (such as RF neighbors)
- Allow clients to work with APs and take intelligent decisions on the connection and improve the quality of service.

Wi-Fi Alliance Agile Multiband Topology

Multiple components form a Wi-Fi Agile Multiband wireless infrastructure network, which may vary based on the wireless network deployment.

The following figure depicts the system topology for connecting Wi-Fi Agile Multiband devices.

Figure 22: Wi-Fi Agile Multiband Wireless Infrastructure Network

The following components form a Wi-Fi Agile Multiband wireless infrastructure network:

- Access Point (AP): A Wi-Fi Agile Multiband wireless infrastructure network contains one or more Wi-Fi Agile Multiband APs.
- WLAN Controller: A Wi-Fi Agile Multiband wireless infrastructure network contains zero or more WLAN controllers that provide centralized management and other features to the interconnected APs.
- Client Station (STA): A Wi-Fi Agile Multiband wireless infrastructure network contains zero or more STAs. These client STAs are single WLAN capable only.
- RADIUS Server: A Wi-Fi Agile Multiband wireless infrastructure network contains zero or more RADIUS Servers that provide Authentication, Authorization, and Accounting (AAA) services.

Supported MBO Components

MBO AP Capability

A new information element is added to the Beacon, Probe Response, Association Response and Re Association Response Frames for 802.11ax APs to inform clients about MBO support.

Note The new information element indicates that Cisco APs are not cellular data aware.

When an SSID is configured on an AP, the MBO AP capability is enabled.

802.11k/v/r Support

One of the prerequisites for MBO is that APs need to support 802.11k/v/r standard-based technologies. Each of the technologies has their own requirements, such as:

- 802.11k – For 802.11k, send the preferred list of AP neighbors to the client upon request and send a beacon request to a client when AP requires a beacon report from the client.
- 802.11v – For 802.11v, steer the client to a less congested AP (not in a MBO client's non-prefer/non-operable channel list that is sent during the association request and/or WNM notification request) using BSS transition.
- 802.11r – The 802.11r MBO-related capabilities are not supported.

802.11u ANQP or GAS Support

For MBO, the 802.11ax APs must have 802.11u ANQP or GAS support.

The following are the prerequisites:

- ANQP responds to the ANQP request for a neighbor report ANQP-element.
- Before authentication, Layer 2 transport needs to be available in the network between a mobile device and server for an advertisement protocol frame.

MBO Beacon Request

Whenever an AP sends a beacon request to the client, the MBO-compliant client responds with a beacon report.

MBO Associate Disallowed IE

Cisco APs include an **Associate Disallowed IE** in their Beacon/Probe response/(Re) association response when they cannot accommodate any new client.

Limitations of MBO

All non-802.11ax access points are not supported.

Configuring MBO on a WLAN

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wlan wlan-name wlan-id ssid Example:	Configures a WLAN and enters the WLAN configuration mode.

	Command or Action	Purpose
	Device(config)# wlan wlan-demo 1 ssid-demo	Note If you use WPA2 WLAN while configuring MBO for WLAN, you need to enable PMF in your configuration.
Step 3	mbo Example: Device(config-wlan)# mbo	Configures MBO support on WLAN. Note Use the no mbo command to disable MBO configuration.
Step 4	end Example: Device(config-wlan)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Verifying MBO Configuration

To view the MBO configuration, use the following command:

```
Device# show wlan id 1
WLAN Profile Name      : wlan-demo
=====
Identifier              : 1
Description             :
Network Name (SSID)    : ssid-demo
Status                 : Disabled
Broadcast SSID         : Enabled
802.11ax parameters
  OFDMA Downlink       : Enabled
  OFDMA Uplink         : Enabled

CHAPTER 86

SNMP Traps

- [Information About Configuring SNMP Traps, on page 965](#)
- [Configuring SNMP Traps \(GUI\), on page 966](#)
- [Enabling Access Points Traps \(CLI\), on page 966](#)
- [Enabling Wireless Client Traps \(CLI\), on page 967](#)
- [Enabling Mesh Traps \(CLI\), on page 967](#)
- [Enabling RF Traps \(CLI\), on page 968](#)
- [Enabling Rogue, Mobility, RRM, and General Traps \(CLI\), on page 968](#)
- [Verifying SNMP Wireless Traps, on page 969](#)

Information About Configuring SNMP Traps

Simple Network Management Protocol (SNMP) Traps are alert messages sent from a remote SNMP-enabled device such as the controller, to an SNMP manager. Traps are unreliable because the receiver does not send acknowledgments when the device receives traps. Hence, the sender cannot determine if the traps were received.

In order to configure the controller to send SNMP notifications, you must enter at least one **snmp-server host** command. If you do not enter an **snmp-server host** command, no notifications are sent.

In order to enable multiple hosts, you must specify separate **snmp-server host** command for each host. You can specify multiple notification types in the command for each host. When multiple **snmp-server host** commands are given for the same host and notification of either trap or inform, each command overwrites the previous command. Only the last **snmp-server host** command is taken into account. For example, if you enter an **snmp-server host** inform command for a host and then enter another **snmp-server host** inform command for the same host, the second command replaces the first.

Specify the **snmp-server enable traps wireless <TrapName>** command in order to specify which SNMP notifications are sent globally. In order for a host to receive wireless notifications, at least one **snmp-server enable traps wireless <TrapName>** command and the **snmp-server host** command for that host must be enabled. However, some notification types cannot be controlled with the **snmp-server enable** command. And some notification types are enabled by default. For example, few AP related traps **crash**, **register**, and **noradiocards** are enabled by default.

Configuring SNMP Traps (GUI)

Procedure

-
- Step 1** Choose **Administration > Management > SNMP**.
The SNMP page is displayed. By default, the SNMP mode is disabled. To enable or disable SMNP, click the **SNMP Mode** toggle button.
 - Step 2** Choose the **Wireless Traps** tab.
By default, all SNMP wireless traps are disabled except the **Access Point** trap. To enable all the wireless traps, click **Enable All**.
 - Step 3** Select the wireless SNMP trap that you wish to enable. Click the **Select All** check box to enable all the trapflags present in the trap. For example, to enable all the trapflags in the **Mesh** trap section, check the **Select All** check box present at the right-hand corner of the section. Uncheck the **Select All** check box to remove selection.

Note In the **Access Point** trap, **Crash**, **No Radio Cards**, and **Register** trapflags are enabled by default. Select **Broken Antenna** trapflag to detect broken antenna. Select **AP Stats** trapflag to enable a trap for AP statistics.
 - Step 4** Click **Apply**.
-

Enabling Access Points Traps (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	snmp-server enable traps wireless AP Example: Device# snmp-server enable traps wireless AP	Enables wireless SNMP traps for access points.
Step 3	trapflags ap { authorization broken-antenna crash interfaceup ipaddrfallback mfp mode noradiocards register } Example: Device# trapflags ap authorization	Enables or disables sending AP related trapflags. The crash , noradiocards , and register trapflags are enabled by default.

Enabling Wireless Client Traps (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	snmp-server enable traps wireless bsnMobileStation Example: Device# snmp-server enable traps wireless bsnMobileStation	Enables wireless client traps.
Step 3	trapflags client dot11 { assocfail associate authenticate authfail deauthenticate disassociate } Example: Device# trapflags client dot11 assocfail	Enables or disables dot11 related trapflags for clients.
Step 4	trapflags client excluded Example: Device# trapflags client excluded	Enables the excluded trapflags for clients.

Enabling Mesh Traps (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	snmp-server enable traps wireless MESH Example: Device# snmp-server enable traps wireless MESH	Enables wireless mesh traps.
Step 3	trapflags mesh { abate-snr authentication-failure child-moved 	Enables or disables mesh trapflags.

	Command or Action	Purpose
	excessive-children excessive-hopcount onset-snr parent-change } Example: Device# trapflags mesh abate-snr	

Enabling RF Traps (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	snmp-server enable traps wireless bsnAutoRF Example: Device# snmp-server enable traps wireless bsnAutoRF	Enables wireless RF related traps.
Step 3	trapflags rrm-params{ channels tx-power } Example: Device# trapflags rrm-params channels	Enables or disables sending RRM parameter update related traps.
Step 4	trapflags rrm-profile{ coverage interference load noise } Example: Device# trapflags rrm-profile coverage	Enables or disables RRM profile related traps.

Enabling Rogue, Mobility, RRM, and General Traps (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	snmp-server enable traps wireless rogue Example: Device# snmp-server enable traps wireless rogue	Enables traps for wireless rogue.
Step 3	trapflags rogue-ap Example: Device# trapflags rogue-ap	Enables rogue AP detection trapflag.
Step 4	trapflags rogue-client Example: Device# trapflags rogue-client	Enables rogue client detection trapflag.
Step 5	snmp-server enable traps wireless wireless_mobility Example: Device# snmp-server enable traps wireless wireless_mobility	Enables traps for wireless mobility.
Step 6	trapflags anchor Example: Device# trapflags anchor	Enables anchor trapflags.
Step 7	snmp-server enable traps wireless RRM Example: Device# snmp-server enable traps wireless RRM	Enables traps for wireless RRM.
Step 8	trapflags rrm-params group Example: Device# trapflags rrm-params group	Enables or disables the RRM parameter related traps, when the RF manager group changes.
Step 9	snmp-server enable traps wireless bsnGeneral Example: Device# snmp-server enable traps wireless bsnGeneral	Enables general controller traps.

Verifying SNMP Wireless Traps

To verify the various SNMP traps enabled, use the following command:

```
Device# show run | sec trapflag
trapflags ap crash
trapflags ap noradiocards
```

```
trapflags ap register
trapflags rogue-client
```

CHAPTER 87

Disabling Clients with Random MAC Address

- [Information About Disabling Clients with Random MAC Addresses, on page 971](#)
- [Configuring Random MAC Address Deny \(CLI\), on page 971](#)
- [Verifying Denial of Clients with a Random MAC Address, on page 972](#)

Information About Disabling Clients with Random MAC Addresses

Wireless clients used to associate with a wireless network using the MAC address that is assigned, for the Wi-Fi network interface card (NIC), during manufacture. This globally unique MAC address assigned by the manufacturer is also known as burn-in address (BIA). BIA tracks end users with the help of the MAC address of the Wi-Fi. To improve the privacy of end user products, a locally enabled random MAC address is enabled for Wi-Fi operations.

Prior to Cisco IOS XE Bengaluru 17.5.1 Release, clients joining a wireless network using a random MAC address could not be tracked with ease. From Cisco IOS XE Bengaluru 17.5.1 Release onwards, the controller is equipped with a knob that denies the entry of clients with a random MAC address into the network. When the *local-admin-mac deny* knob is enabled on the controller, the association of a client joining the network with a random MAC address is rejected. By default, this feature is disabled on the controller.

This feature is not supported in Cisco Wave 1 access points.

Configuring Random MAC Address Deny (CLI)

To stop the entry of clients with a random MAC addresses from joining a wireless network, enable the random MAC address deny knob, by following the steps given below.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.

	Command or Action	Purpose
Step 2	wlan <i>wlan-profile-name</i> <1-4096> <i>SSID-network-name</i> Example: Device(config)# wlan <i>wlan-profile-name</i> 8 <i>ssid-network-name</i>	Configures the WLAN policy profile.
Step 3	shutdown Example: Device(config-wlan)# shutdown	Shuts down the WLAN.
Step 4	[no] local-admin-mac deny Example: Device(config-wlan)# local-admin-mac deny	Enables the random MAC address deny knob. Use the no form of this command to disable the feature.
Step 5	no shutdown Example: Device(config-wlan)# no shutdown	Enables the WLAN.
Step 6	end Example: Device(config-wlan)# end	Saves the configuration, exits the configuration mode, and returns to privileged EXEC mode.

Verifying Denial of Clients with a Random MAC Address

To verify the denial of a client with a random MAC address, run the **show wlan name** *wlan-profile-name* | **begin locally** command:

```
Device# show wlan name laa | begin locally
Locally Administered Address Configuration
Deny LAA clients                : Enabled
```

To verify if a client address is a random MAC address, run the **show wireless client mac-address** *MAC-address* **detail** command:

```
Device# show wireless client mac-address 72xx.38xx.2axx detail
Client MAC Address : 72xx.38xx.2axx
Client MAC Type   : Locally Administered Address
Client IPv4 Address : 9.1.1.1
Client IPv6 Addresses : fexx::71xx:27xx:a7xx:efxx
Client Username   : 72xx.38xx.2axx
```

To verify how many random MAC clients are present in the system, run the **show wireless stats client detail** command:

```
Device# show wireless stats client detail
Client Summary
-----
Current Clients : 1
Excluded Clients: 0
Disabled Clients: 0
Foreign Clients : 0
```

```
Anchor Clients : 0
Local Clients  : 1
Idle Clients   : 0
Locally Administered MAC Clients: 1
```

To display the statistics of a specific client, run the **show wlan id <1-4096> client stats** command:

```
Device# show wlan id 8 client stats
Wlan Profile Name: wlan-profile, Wlan Id: 8
Current client state statistics:
```

```
-----
Authenticating      : 0
Mobility            : 0
IP Learn            : 0
WebAuth Pending     : 0
Run                 : 1
Locally Administered MAC Clients : 1
```

Note Run the **show configuration wlan wlan-name** command on an AP, to view the status of the locally administered address (LAA) on the WLAN.

CHAPTER 88

Dataplane Packet Logging

- [Information About Dataplane Packet Logging, on page 975](#)
- [Enabling or Disabling Debug Level \(CLI\), on page 976](#)
- [Enabling Packet Logging in Global and Filtered Buffer in Ingress Path \(CLI\), on page 976](#)
- [Enabling Packet Logging in Global and Filtered Buffer in Punt-Inject Path \(CLI\), on page 977](#)
- [Verifying Dataplane Packet Logging, on page 978](#)
- [Clearing Logs and Conditions in Global and Filtered Trace Buffers, on page 979](#)

Information About Dataplane Packet Logging

While onboarding wireless clients, you might encounter problems arising from client IP address allocation, Address Resolution Protocol (ARP) resolution, and so on, which require debugging. For rapid debugging of such issues on the controller, the Dynamic Host Configuration Protocol (DHCP), Neighbor Discovery, and ARP packets that go to and from the wireless clients are unconditionally logged.

Packet-logging serviceability captures connectivity information related to wireless clients. Serviceability is divided into the following categories:

- **Global Trace Log:** Global trace logging is a mechanism to capture client connectivity information, and is enabled by default.
- **Filtered Trace Log:** To start packet logging on a filtered trace buffer, you must enable filters using **debug** commands. Filters capture only the specific packet type or the packets based on the MAC address of the clients.

The following are the features of packet logging:

- In addition to DHCP, Neighbor Discovery, and ARP packets, you can also add or remove other packet capture filters.
- Display filters are set to pick a subset of logged packets.
- Packet-logging data provides information such as the client MAC address, client IP address, VLAN, interface, packet type and time delta, that is required for debugging.

Enabling or Disabling Debug Level (CLI)

To enable or disable debug information for global and filtered logic, follow these steps.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	[no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer debug-level {all error info trace warning} Example: Device# debug platform hardware chassis active qfp feature wireless datapath trace-buffer debug-level all	Enables the debug level information for global and filtered logic. Use the no form of this command to disable the feature.

Enabling Packet Logging in Global and Filtered Buffer in Ingress Path (CLI)

To enable packet logging in global and filtered buffer in the ingress path, follow these steps.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	[no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer ingress global-trace Example: Device# [no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer ingress global-trace	Enables the Quantum Flow Processor on global trace buffer in the ingress path. Use the no form of this command to disable the feature.
Step 3	[no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer	Enables the condition for CAPWAP to log packet information to the filtered trace buffer.

	Command or Action	Purpose
	ingress filtered-trace capwap {ipv4 <i>A.B.C.D</i> ipv6 <i>X:X:X::X</i> keepalive } Example: <pre>Device# [no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer ingress filtered-trace capwap ipv4 209.165.200.224/27</pre>	Use the no form of this command to disable the feature.
Step 4	[no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer ingress filtered-trace wclient {ipv6-nd ipv6-ra mac-address <i>H.H.H</i> } Example: <pre>Device# [no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer ingress filtered-trace wclient ipv6-nd</pre>	<p>Enables the condition to log packet information of the wireless client to the filtered trace buffer.</p> <p>Use the no form of this command to disable the feature.</p>

Enabling Packet Logging in Global and Filtered Buffer in Punt-Inject Path (CLI)

To enable packet logging in global and filtered trace buffer in the punt-inject path, follow these steps.

Procedure

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	<p>Enables privileged EXEC mode.</p> <p>Enter your password, if prompted.</p>
Step 2	[no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer punt-inject global-trace Example: <pre>Device# [no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer punt-inject global-trace</pre>	<p>Enables the Quantum Flow Processor in global trace buffer in the punt-inject path.</p> <p>Use the no form of this command to disable the feature.</p>
Step 3	[no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer punt-inject filtered-trace capwap {ipv4 <i>A.B.C.D</i> ipv6 <i>X:X:X::X</i> keepalive } Example:	<p>Enables the condition for CAPWAP to log packet information to the filtered trace buffer in the punt-inject path.</p> <p>Use the no form of this command to disable the feature.</p>

	Command or Action	Purpose
	Device# [no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer punt-inject filtered-trace capwap ipv4 209.165.200.224/27	
Step 4	<p>[no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer punt-inject filtered-trace wlclient {ipv6-nd ipv6-ra mac-address H.H.H}</p> <p>Example:</p> <pre>Device# [no] debug platform hardware chassis active qfp feature wireless datapath trace-buffer punt-inject filtered-trace wlclient lpv6-nd</pre>	<p>Enables the condition to log packet information of the wireless client to the filtered trace buffer, in the punt-inject path.</p> <p>Use the no form of this command to disable the feature.</p>

Verifying Dataplane Packet Logging

To show trace buffer-configured conditions, use the following command:

```
Device# show platform hardware chassis active qfp feature wireless trace-buffer ingress conditions
LogTrace Event: Enabled
Trace wlclient-MACs:
    8c85.90ee.ca92
allow_all_AP_kalives: enabled
AP_kalive cnt=1, AP_kalive6 cnt=0
IP0: 49.1.0.73
```

To view all the log entries in the filtered trace buffer, use the following command:

```
Device# show platform hardware chassis active qfp feature wireless trace-buffer ingress filtered-trace all
Trace wlclient-MACs: 8c85.90ee.ca92
Trace-Buffer for Ingress: Enabled
Total allocated global-log buffer: 16384
Total allocated filtered-log v=buffers: 4096

<0 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49, dt=213207 c=0
<1 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49, dt=213236 c=0
<2 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49, dt=213264 c=0
<3 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49, dt=213293 c=0
<4 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49, dt=213321 c=0
<5 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49, dt=213350 c=0
```

To view the number of entries based on a count, use the following command:

```
Device# show platform hardware chassis active qfp feature wireless trace-buffer ingress filtered-trace 3
Trace wlclient-MACs: 8c85.90ee.ca92
Trace-Buffer for Ingress: Enabled
Total allocated global-log buffer: 16384
```

```
Total allocated filtered-log v=buffers: 4096

<18 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49, dt=213720
c=0
<19 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49, dt=213748

<20 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49, dt=213777
c=0

>> 3 entries displayed
    21 entries found in filtered-log buffer
    21 entries ever collected for filtered-log buffer
```

Clearing Logs and Conditions in Global and Filtered Trace Buffers

To clear conditions and logs in the global and filtered trace buffers, use the following commands:

```
Device# clear platform hardware chassis active qfp feature wireless trace-buffer ingress
all
Trace, clear all trace configuration & buffer.
```

```
Device# clear platform hardware chassis active qfp feature wireless trace-buffer ingress
conditions
Trace, clear trace configuration
```

```
Device# clear platform hardware chassis active qfp feature wireless trace-buffer ingress
filtered-trace
Trace, clear trace Q
```

```
Device# clear platform hardware chassis active qfp feature wireless trace-buffer ingress
global-trace
Trace, clear trace global Q
```

Streaming Telemetry

- [Information About Streaming Telemetry](#) , on page 981
- [Gather Points](#), on page 981
- [Subscription](#), on page 982
- [Transport](#) , on page 983
- [Scale Considerations](#) , on page 983
- [Session](#), on page 983
- [Configuring Telemetry on a Cisco Catalyst 9800 Series Wireless Controller](#), on page 984
- [On-Change Telemetry Support](#) , on page 991
- [Supported XPathS for On-Change Subscription](#), on page 991
- [Troubleshooting Telemetry Support](#), on page 995
- [Cisco Catalyst Center Client Event and SSID Telemetry Filter](#), on page 997

Information About Streaming Telemetry

Streaming telemetry is a new paradigm in monitoring the health of a network. It provides a mechanism to efficiently stream configuration and operational data of interest from the Cisco Catalyst 9800 Series Wireless Controller. This streamed data is transmitted in a structured format to remote management stations for monitoring and troubleshooting purposes.

This topic explains how to enable the telemetry support the Wi-Fi and system health-related data. Not that telemetry support can be enhanced up to a scale of 1000 access points (APs) and 15000 clients. A single collector setup can be used to subscribe to the requested XPathS. A telemetry feed can be used to subscribe to data elements to monitor APs and clients effectively. Data is provided through the native Cisco wireless models.

Gather Points

Gather points are the top-level XPathS and act as the smallest unit of data exported by a target. Any subscription to an XPath raises to the level of the Gather point, and the target sends updates comprising of all the leaves defined under this Gather point. For example, when you subscribe to an XPath `/access-point-operdata/radio-oper-data/vap-oper-config/ssid`, which is part of the Gather point `/access-point-operdata/radio-oper-data/vap-oper-config`, the reply will comprise of all the attributes that are a part of the Gather point, in this case, AP-VAP-ID, SSID, and WLAN ID.

The following lists the supported Gather points for an XPathS.

Table 69: Supported Gather Points and Subscription Intervals

Supported Gather Point	Subscription Interval
<i>wireless-access-point-oper:access-point-oper-data/ethernet-mac-wtp-mac-map</i>	>=15 mins
<i>/wireless-access-point-oper:access-point-oper-data/capwap-data</i>	>=15 mins
<i>/wireless-access-point-oper:access-point-oper-data/cdp-cache-data/</i>	>=15 mins
<i>/wireless-access-point-oper:access-point-oper-data/radio-oper-stats</i>	>=60 secs
<i>/wireless-access-point-oper:access-point-oper-data/radio-oper-data</i>	>=180 secs
<i>/wireless-access-point-oper:access-point-oper-data/oper-data</i>	>=180 secs

Subscription

A subscription binds one or more Gather points and destinations. A Multicast Default (MDT) streams data for each Gather point at the configured frequency (cadence-based streaming).

Transport

The protocol that is used for the connection between a publisher and a receiver is known as the transport protocol, and this decides how data are transmitted. This protocol is independent of the management protocol for configured subscriptions. The supported transport protocols are gNMI and gRPC. The gNMI transport protocol supports JSON encoding of data, while gRPC supports Key-value Google Protocol Buffers (kvGPB) encoding.

Scale Considerations

The following table provides the scale numbers that are applicable to the native model for an XPath set.

Table 70: Scaling Considerations to the Native Model

Attribute	Scale
AP	4000
Client	15000
SSID Per AP	6
BSSID per AP	12
Neighbors per AP	60 (30x2)
Number of Physical Neighbor APs	49
Number of Neighbor Records	60000 records

Session

You can choose to initiate the subscription by establishing a telemetry session between the controller and the receiver. A telemetry session can be initiated using:

- gNMI Dial-In Mode
- gRPC Dial-Out Mode

gNMI Dial-In-Mode

In a dial-in mode, a Model-Driven Telemetry (MDT) receiver dials in to the controller, and subscribes dynamically to one or more Gather points or subscriptions. The controller acts as the server, and the receiver as the client. The controller streams telemetry data through the same session. The dial-in mode of subscriptions is dynamic, which gets terminated when the receiver cancels the subscription or when the session is terminated.

gRPC- Dial-Out-Mode

In a dial-out mode, the controller dials out to the receiver. Here the controller acts as a client and receiver acts as a server. In this mode, Gather points and destinations are configured and bound together into one or more subscriptions. The controller continually attempts to establish a session with each destination in the subscription, and streams data to the receiver. The dial-out mode of subscriptions is persistent.

Figure 23: Telemetry Session

The following figure explains the telemetry session:

Configuring Telemetry on a Cisco Catalyst 9800 Series Wireless Controller

To configure telemetry on a Cisco Catalyst 9800 Series Wireless Controller, perform the following:

1. Enable gNXI in an Insecure Mode
2. Enable gNXI in a Secure Mode
3. Verify the Status of the Subscription
4. Manage Configured Subscriptions

Enabling gNXI in Insecure Mode (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode

	Command or Action	Purpose
	Example: Device# enable	Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	gnxi Example: Device(config)# gnxi	Starts the gNXI process.
Step 4	gnxi server Example: Device(config)# gnxi server	Enables the gNXI server in insecure mode.
Step 5	gnxi port <i>port-number</i> Example: Device(config)# gnxi 50000	Sets the gNXI port. The default insecure gNXI port is 9339.
Step 6	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 7	show gnxi state Example: Device# show gnxi state	Displays the status of gNXI server.

Example

The following is a sample output of the **show gnxi state** command:

```
Device# show gnxi state
State Status
-----
Enabled Up
```

Enabling gNXI in Secure Mode (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enables privileged EXEC mode Enter your password, if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	gnxi Example: Device(config)# gnxi	Starts the gNXI process.
Step 4	gnxi secure-server Example: Device(config)# gnxi secure-server	Enables the gNXI server in secure mode.
Step 5	gnxi secure-trustpoint <i>trustpoint-name</i> Example: Device(config)# gnxi secure-trustpoint	Specifies the trustpoint and certificate set that gNXI uses for authentication.
Step 6	gnxi secure-client-auth Example: Device(config)# gnxi secure-client-auth	(Optional) The gNXI process authenticates the client certificate against the root certificate.
Step 7	gnxi secure-port Example: Device(config)# gnxi secure-port	(Optional) Sets the gNXI port. <ul style="list-style-type: none"> The default insecure gNXI port is 9339.
Step 8	end Example: Device(config)# end	Returns to privileged EXEC mode.
Step 9	show gnxi state Example: Device# show gnxi state	Displays the gNXI servers status.

Example

The following is sample output from the **show gnxi state** command:

```
Device# show gnxi state
State Status
-----
Enabled Up
```

Verifying the Status of a Telemetry Subscription on a Cisco Catalyst 9800 Series Wireless Controller

To verify the status of a subscription, use the following command:

```
Device# show telemetry ietf subscription all
Device# show telemetry ietf subscription 101
Device# show telemetry ietf subscription 101 detail
Device# show telemetry ietf subscription 101 receiver
Device# show telemetry internal connection
Device# show telemetry internal subscription all stats
Device# show telemetry receiver all
Device# show telemetry receiver name <receivers-name>
Device# show telemetry connection all
```

Managing Configured Subscriptions on a Cisco Catalyst 9800 Series Wireless Controller

Use the `show platform software ndbman switch {switch-number | active| standby} models` command to display the list of YANG models that support on-change subscription.

Note Currently, you can only use the gRPC protocol for managing configured subscriptions.

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enables privileged EXEC mode Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	telemetry ietf subscription <i>id</i> Example: Device(config)# telemetry ietf subscription 112	Creates a telemetry subscription and enters telemetry-subscription mode.
Step 4	encoding encode-kvgpb Example: Device(config-mdt-subs)# encoding encode-kvgpb	Specifies the Key-value Google Protocol Buffers (kvGPB) encoding.

	Command or Action	Purpose
Step 5	filter xpath <i>path</i> Example: Device(config-mdt-subs)# filter xpath /wireless-access-point-oper:access-point-oper-data/ospwep-data	Specifies the XPath filter for the subscription.
Step 6	source-address { <i>A.B.C.D / X:X:X:X::X</i> } Example: Device(config-mdt-subs)# source-address ip-address 209.165.200.225 2001:DB8::1	Configures the source IP address on the telemetry subscription interface.
Step 7	stream yang-push <i>path</i> Example: Device(config-mdt-subs)# stream yang-push	Configures a stream for the subscription.
Step 8	update-policy { on-change periodic } <i>period</i> Example: Device(config-mdt-subs)# update-policy periodic 3000	Configures a periodic update policy for the subscription.
Step 9	receiver ip address <i>ip-address receiver-port</i> protocol <i>protocol profile name</i> Example: Device(config-mdt-subs)# receiver ip address 209.165.201.1 protocol grpc-tcp	Configures a periodic update policy for the subscription.
Step 10	end Example: Device(config-mdt-subs)# end	Exits telemetry-subscription configuration mode and returns to privileged EXEC mode.

Zero Trust Telemetry

To configure zero trust telemetry on a Cisco Catalyst 9800 Series Wireless Controller, perform the following:

1. Define a protocol
2. Define a named receiver
3. Configure telemetry subscription

Define a Protocol

Before you begin

Define crypto trustpoints (CAforMDTserver and IDforWLCclient) and certificates before the telemetry configuration.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	telemetry protocol grpc profile <i>profile-name</i> Example: Device(config)# telemetry protocol grpc profile mtlsyang	Configures the protocol gRPC profile and enters gRPC profile name.
Step 3	ca-trustpoint <i>ca-for-mdt-server</i> Example: Device(config-mdt-protocol-grpc-profile)# ca-trustpoint CAforMDTserver	Adds the server CA trustpoint.
Step 4	id-trustpoint <i>wlc-id-trustpoint</i> Example: Device(config-mdt-protocol-grpc-profile)# id-trustpoint IDforWLCclient	Adds the client ID trustpoint.

Define a Named Receiver

This procedure defines:

- FQDN DNS name
- Crypto protocol definition

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	telemetry receiver protocol <i>receiver-name</i> Example: Device(config)# telemetry receiver protocol collector	Configures the receiver name.

	Command or Action	Purpose
Step 3	host name <i>FQDN-receiver</i> Example: Device (config-mdt-protocol-receiver) # host name collector-telemetry.cisco.com 57500	Adds FQDN DNS name of receiver.
Step 4	protocol grpc-tls profile <i>profile-name</i> Example: Device (config-mdt-protocol-receiver) # protocol grpc-tls profile mtlsyang	Defines the gRPC TLS profile named mtlsyang.

Configure Telemetry Subscription

This procedure configures:

- Xpath
- Named receiver
- Protocol

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enables privileged EXEC mode Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	telemetry ietf subscription <i>id</i> Example: Device (config) # telemetry ietf subscription 113	Creates a telemetry subscription and enters telemetry-subscription mode.
Step 4	encoding encode-kvgpb Example: Device (config-mdt-subs) # encoding encode-kvgpb	Specifies the Key-value Google Protocol Buffers (kvGPB) encoding.
Step 5	filter xpath <i>path</i> Example: Device (config-mdt-subs) # filter xpath /wireless-ble-ltr-oper:ble-ltr-oper-data/ble-ltr-ap-streaming	Specifies the XPath filter for the subscription.

	Command or Action	Purpose
Step 6	source-address { <i>A.B.C.D / X:X:X:X::X</i> } Example: Device (config-mdt-sub) # source-address ip-address 209.165.200.225 2001:DB8::1	Configures the source IP address on the telemetry subscription interface.
Step 7	stream yang-push Example: Device (config-mdt-sub) # stream yang-push	Configures a stream for the subscription.
Step 8	update-policy { on-change periodic } <i>period</i> Example: Device (config-mdt-sub) # update-policy periodic 6000	Configures a periodic update policy for the subscription.
Step 9	receiver-type protocol Example: Device (config-mdt-sub) # receiver-type protocol	Configures type protocol for receiver.
Step 10	receiver name <i>receiver-name</i> Example: Device (config-mdt-sub) # receiver name collector	Specifies the receiver name.
Step 11	end Example: Device (config-mdt-sub) # end	Exits telemetry-subscription configuration mode and returns to privileged EXEC mode.

On-Change Telemetry Support

From Cisco IOS XE Cupertino 17.7.1 onwards, on-change telemetry support is provided to a subset of XPath.

Supported XPath for On-Change Subscription

The following table lists the supported XPath for on-change subscription.

Table 71: Supported Gather Points and XPath

Gather Points	XPaths
/access-point-oper-data/radio-operdata/	/access-point-oper-data/radio-operdata/ phy-ht-cfg/cfg-data/curr-freq

Gather Points	XPaths
	/access-point-oper-data/radio-operdata/ phy-ht-cfg/cfg-data/chan-width
	/access-point-oper-data/radio-oper-data/current-band-id
/access-point-oper-data/capwap-data	/access-point-oper-data/capwap-data/name
	/access-point-oper-data/capwapdata/ device-detail/wtp-version/sw-ver/version
	/access-point-oper-data/capwap- data/device-detail/wtp-version/sw-ver/release
	/access-point-oper-data/capwapdata/ device-detail/wtp-version/sw-ver/maint
	/access-point-oper-data/capwapdata/ device-detail/wtp-version/sw-ver/build
	/access-point-oper-data/capwap-data/ap-state/ap- operation-state
	/access-point-oper-data/capwapdata/ device-detail/static-info/board-data/wtp-serial-num
/access-point-oper-data/oper-data	/access-point-oper-data/oper-data/ap-ip-data/ap-ip-addr
	/access-point-oper-dat/oper-data/ap-pow/power-type

The following table lists the XPathS that are introduced in Cisco-IOS-XE-wireless-ap-global-oper-transform.yang model that is displayed through telemetry feed.

Table 72: Supported Gather Points and XPathS (Cisco-IOS-XE-wireless-ap-global-oper-transform.yang)

Gather Points	XPaths
/ap-global-oper-data/ap-join-stats/wtp-mac	/ap-global-oper-data/ap-join-stats/ap-join-info/ap-ethernet-mac
	/ap-global-oper-data/ap-join-stats/ap-join-info/ap-name
	/ap-global-oper-data/ap-join-stats/ap-join-info/ap-ip-addr
	/ap-global-oper-data/ap-join-stats/ap-join-info/is-joined
	/ap-global-oper-data/ap-join-stats/ap-join-info/last-error-type
	/ap-global-oper-data/ap-join-stats/ap-disconnect-reason

The following table lists the XPathS that are introduced in Cisco-IOS-XE-aaa-oper.yang model to support aaa/radius/radsec and displayed through telemetry feed.

Table 73: Supported Gather Points and XPathS (Cisco-IOS-XE-aaa-oper.yang)

Gather Points	Xpaths
/aaa-data/aaa-radius-stats/	/aaa-data/aaa-radius-stats/radsec-pkt-cnt-idletime
	/aaa-data/aaa-radius-stats/radsec-send-hs-start-cnt
	/aaa-data/aaa-radius-stats/radsec-hs-success-cnt
	/aaa-data/aaa-radius-stats/radsec-total-tx-pkt-cnt
	/aaa-data/aaa-radius-stats/radsec-total-rx-pkt-cnt
	/aaa-data/aaa-radius-stats/radsec-total-conn-rst-cnt
	/aaa-data/aaa-radius-stats/radsec-conn-rst-cnt-idle
	/aaa-data/aaa-radius-stats/radsec-conn-rst-cnt-noresp
	/aaa-data/aaa-radius-stats/radsec-conn-rst-cnt-malpkt
	/aaa-data/aaa-radius-stats/radsec-conn-rst-cnt-err
	/aaa-data/aaa-radius-stats/radsec-conn-rst-cnt-peer
	/aaa-data/aaa-radius-stats/num-aaa-lib-inst
	/aaa-data/aaa-radius-stats/server-detail
/aaa-data/aaa-radius-global-stats	/aaa-data/aaa-radius-global-stats/access-rejects
	/aaa-data/aaa-radius-global-stats/access-accepts
	/aaa-data/aaa-radius-global-stats/authen-responses-seen
	/aaa-data/aaa-radius-global-stats/authen-with-response
	/aaa-data/aaa-radius-global-stats/authen-without-response
	/aaa-data/aaa-radius-global-stats/authen-avg-response-delay
	/aaa-data/aaa-radius-global-stats/authen-max-response-delay
	/aaa-data/aaa-radius-global-stats/authen-timeouts
	/aaa-data/aaa-radius-global-stats/authen-duplicate-id
	/aaa-data/aaa-radius-global-stats/authen-bad-authenticators
	/aaa-data/aaa-radius-global-stats/acct-responses-seen
	/aaa-data/aaa-radius-global-stats/acct-with-response

Gather Points	Xpaths
	/aaa-data/aaa-radius-global-stats/acct-without-response
	/aaa-data/aaa-radius-global-stats/acct-avg-response-delay
	/aaa-data/aaa-radius-global-stats/acct-max-response-delay
	/aaa-data/aaa-radius-global-stats/acct-timeouts
	/aaa-data/aaa-radius-global-stats/acct-duplicate-id
	/aaa-data/aaa-radius-global-stats/acct-bad-authenticators
	/aaa-data/aaa-radius-global-stats/stats-time

The following table lists the XPathS that are introduced in Cisco-IOS-XE-wireless-mesh-rpc.yang model to support the mesh-related EXEC commands:

Table 74: Supported EXEC CLIs and XPathS (Cisco-IOS-XE-wireless-mesh-rpc.yang)

EXEC CLI	XPath
ap name <ap-name> [no] mesh ethernet [0 1 2 3] mode trunk vlan allowed <vlan-id>	/set-rad-mesh-ethernet-trunk-allowed-vlan
ap name <ap-name> [no] mesh ethernet [0 1 2 3] mode trunk vlan native	/set-rad-mesh-ethernet-trunk-native-vlan
ap name <ap-name> mesh linktest <dst AP MAC> <data rate> <packets/sec> <packet size> <duration>	/exec-linktest-ap
ap name <ap-name> [no] mesh ethernet [0 1 2 3] mode access <vlan-id>	/set-rad-mesh-ethernet-access-vlan
ap name <ap-name> [no] mesh block-child	/set-rad-mesh-block-child
ap name <ap-name> [no] mesh vlan-trunking	/set-rad-mesh-trunking
ap name <ap-name> [no] mesh daisy-chaining strict-rap	/set-rad-mesh-daisy-chain-strict-rap
ap name <ap-name> [no] mesh daisy-chaining	/set-rad-mesh-daisy-chain-mode
ap name <ap-name> [no] mesh parent preferred	/set-rad-mesh-preferred-parent-ap
ap name <ap-name> mesh backhaul rate dot11 ac mcs <mcs-index> ss <1-4>	/set-rad-mesh-bhaul-tx-rate
ap name <ap-name> mesh backhaul radio dot11 5ghz [slot <slot-id>]	/set-rad-mesh-bhaul-radio
ap name <ap-name> mesh security psk provisioning delete	/set-rad-mesh-security-psk-provisioning-delete

EXEC CLI	XPath
ap name <ap-name> mesh vlan-trunking native <vlan-id>	/set-rad-mesh-trunking-vlan

The following table lists the XPaths that are introduced in Cisco-IOS-XE-aaa-oper.yang model to support radius EXEC commands:

Table 75: Supported EXEC CLIs and XPaths (Cisco-IOS-XE-aaa-oper.yang)

EXEC CLIs	XPaths
show radius statistic	/aaa-data/aaa-radius-global-stats/

Troubleshooting Telemetry Support

This document outlines a set of commands for gathering data from Cisco Catalyst 9800 Series Wireless Controller, specifically focused on addressing gRPC telemetry-related issues in support of TAC cases.

Here are a few factors to consider when conducting troubleshooting steps:

- Provide a clear problem description.
- What has changed in the network?
- What was the previous working day/time?
- What is the impact of this problem?

Note Run all the **show** commands with **show clock** or **terminal exec prompt timestamp** once to log timestamps automatically.

General Guidelines

For every issue, run the following commands:

1. Device# terminal length 0
2. Device# show clock
3. Device# show tech-support wireless
4. Device# request platform software trace archive last 1

Perform Basic Checks

1. Verify that the requisite processes (particularly pubd) are running using the following commands:

```
show platform software yang-management process
```
2. Capture and validate the telemetry-specific configuration using the following command:

```
show running-config | section telemetry
```

3. Check the validity of any subscriptions using the following command:

```
show telemetry ietf subscription all
```

4. Check the validity of any named receivers using the following command:

```
show telemetry receiver all
```

5. Verify the telemetry subscription states using the following command:

```
show telemetry internal subscription all stats
```

Check Connectivity Issues

1. Check the state of the subscription receiver using the following commands:

```
show telemetry ietf subscription <id> receiver
```

2. Check the state of telemetry connections using the following command:

```
show telemetry connection all
```

3. Check which subscriptions use a particular connection using the following command:

```
show telemetry connection <index> subscription
```

Capture Debug Logs

1. Enable the following debug options:

```
set platform software trace mdt-pubd chassis active r0 mdt-ctrl debug
set platform software trace mdt-pubd chassis active r0 pubd debug
set platform software trace mdt-pubd chassis active r0 green-be debug
set platform software trace mdt-pubd chassis active r0 green-fe debug
set platform software trace mdt-pubd chassis active r0 dbal debug
set platform software trace mdt-pubd chassis active r0 tdllib debug
set platform software trace ios chassis active r0 green-be debug
set platform software trace ios chassis active r0 dbal debug
set platform software trace ios chassis active r0 tdllib debug
```

2. Recreate the problem.

3. Collect debug logs:

```
request platform software trace archive last <days>
```

4. Disable debugging using the following commands:

```
set platform software trace mdt-pubd chassis active r0 mdt-ctrl notice
set platform software trace mdt-pubd chassis active r0 pubd notice
set platform software trace mdt-pubd chassis active r0 green-be notice
set platform software trace mdt-pubd chassis active r0 green-fe notice
set platform software trace mdt-pubd chassis active r0 dbal notice
set platform software trace mdt-pubd chassis active r0 tdllib notice
set platform software trace ios chassis active r0 green-be notice
set platform software trace ios chassis active r0 dbal notice
set platform software trace ios chassis active r0 tdllib notice
```

General Telemetry Diagnostics

To capture general telemetry diagnostics, use the following command:

```
show telemetry internal diagnostics
```

Generate a Core

Generate a core using the following commands:

1. `show clock`
2. `configure terminal`
3. `service internal`
4. `end`
5. `request platform software process core mdt-pubd chassis active r0`

Disable Logging

Disable the logging using the following commands:

1. `configure terminal`
2. `no service internal`
3. `end`

Capture CPU Memory

To capture CPU memory details use the following commands:

- `show processes cpu platform sorted | i pubd`
- `show processes memory platform sorted | s pubd`

Cisco Catalyst Center Client Event and SSID Telemetry Filter

Feature History for Cisco Catalyst Center Client Event and SSID Telemetry Filter

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 76: Feature History for Cisco Catalyst Center Client Event and SSID Telemetry Filter

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.10.1	Cisco Catalyst Center Client Event and SSID Telemetry Filter	This feature filters out telemetry data for a configured SSID on the controller and AP.

Information About Cisco Catalyst Center Client Event and SSID Telemetry Filter

Locations such as airports, shopping malls, and so on have wireless guest networks with thousands of transient guest clients. The transient guest clients mix the telemetry data and its subsequent health scores with clients that require assurance (for instance, in a corporate WLAN). This poses a scaling challenge as Cisco Catalyst Center tries to keep up with the receiving high-frequency telemetry data and maintaining history of the transient clients.

This feature addresses the requirement by filtering out the telemetry data for a configured SSID on the controller and AP.

Figure 24: High-Level End-to-End System Flow for Cisco Catalyst Center Client Event and SSID Telemetry Filter

357857

Cisco Catalyst Center configures the Complex Event Processing (CEP) transform with the SSID for which the telemetry data needs to be filtered out along with the subscriptions. The Publishing Daemon (PubD) module in the controller filters out the data based on the configured transform.

Note The Cisco Catalyst Center automation takes care of pushing the transforms. You must enable or disable filtering for a specific SSID in the controller GUI.

To debug the filtering done at PubD, run the following commands in the controller:

```
Device# set platform software trace mdt-pubd chassis active r0 pubd debug
set platform software trace mdt-pubd chassis active r0 mdt-xfrm debug
```

Cisco Catalyst Center configures WLAN for which iCAP data needs to be filtered in an AP profile. The controller then pushes the configuration to the corresponding APs. The AP then programs the **aptrace** module to drop the packets and events for the filtered SSID. The filtered data covers the following:

- Client events
- Client statistics
- AP or RF statistics
- Partial PCAP
- Anomaly detection

Restrictions for Cisco Catalyst Center Client Event and SSID Telemetry Filter

- CLI configuration is applicable for WLAN and not SSID. The Cisco Catalyst Center automation covers one-to-one mapping of WLAN to SSID.
- Controller does not send any notification to Cisco Catalyst Center at the beginning or at the end of filtering.
- Controller GUI configuration is not supported.

Supported Workflow for Cisco Catalyst Center Client Event and SSID Telemetry Filter

- Creating WLANs.
- Mapping WLAN to a Policy Profile.
- Creating a filter for WLAN in AP Join Profile.

Enabling iCAP Filtering in APs (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# ap profile xyz-ap-profile	Configures an AP profile and enters AP profile configuration mode.
Step 3	description <i>ap-profile-name</i> Example: Device(config-ap-profile)# description "xyz ap profile"	Adds a description for the AP profile.
Step 4	icap subscription client exclude telemetry-data wlan <i>wlan-profile-name</i> Example: Device(config-ap-profile)# icap subscription client exclude telemetry-data wlan wlan-name	Enables iCAP filtering in APs.

Disabling Client Telemetry Data for a WLAN (YANG)

To disable the client telemetry data for a WLAN, use the following RPC model:

```
<nc:rpc xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0"
message-id="urn:uuid:0a77124f-c563-469d-bd21-cc625a9691cc">
<nc:edit-config>
<nc:target>
<nc:running/>
</nc:target>
<nc:config>
<site-cfg-data xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-site-cfg">
<ap-cfg-profiles>
<ap-cfg-profile>
<profile-name nc:operation="merge">default-ap-profile</profile-name>
<icap-client-exclude-cfgs>
<icap-client-exclude-cfg nc:operation="merge">
<wlan-profile nc:operation="merge">tel</wlan-profile>
</icap-client-exclude-cfg>
</cap-client-exclude-cfgs>
</ap-cfg-profile>
</ap-cfg-profiles>
</site-cfg-data>
</nc:config>
</nc:edit-config>
</nc:rpc>
```

For more information on YANG models, see the *Cisco IOS XE Programmability Configuration Guide* and YANG Data Models on Github at <https://github.com/YangModels/yang/tree/master/vendor/cisco/xe>.

You can contact the Developer Support Community for NETCONF/YANG features using the following link:

<https://developer.cisco.com/>

Verifying Client Telemetry Data for a WLAN

To verify the client telemetry data for a WLAN, use the following command:

```
Device# show running-config | section profile
ap profile default-ap-profile
  capwap retransmit count 8
  capwap timers primary-discovery-timeout 3000
  country IN
  description "default ap profile"
  icap subscription client exclude telemetry-data wlan guest
```

CHAPTER 90

Application Performance Monitoring

- [Feature History for Application Performance Monitoring, on page 1001](#)
- [Information About Application Performance Monitoring, on page 1001](#)
- [Restrictions for Application Performance Monitoring, on page 1002](#)
- [Workflow, on page 1002](#)
- [Verify Application Performance Monitoring, on page 1006](#)

Feature History for Application Performance Monitoring

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 77: Feature History for Application Performance Monitoring

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.10.1	Application Performance Monitoring	This feature collects and exports assurance-related metrics (per application) of the flows forwarded through AP to the Cisco DNA Centre Assurance application.

Information About Application Performance Monitoring

Application Performance Monitoring feature collects and exports assurance-related metrics (per application) of the flows that are forwarded through specific interfaces of the access point to the Cisco Catalyst Center Assurance application. This feature supports two monitors—a general assurance monitor that computes quantitative metrics for TCP and UDP flows and qualitative metrics for TCP flows and a media monitor that computes qualitative and quantitative metrics for real-time protocol (RTP) flows. Voice applications such as Microsoft Teams and Session Initiation Protocol (SIP) use RTP monitors, while other applications use TCP and UDP monitor.

A flow monitor can be attached to:

- A interface that monitors all the flows from the attachment point.

- A wireless profile policy (the wireless profile policy that is associated with a WLAN or SSID) that monitors all the traffic passing through it.

Assurance performance monitoring is supported on the following platforms:

- Cisco Catalyst 9800 Series Controllers (9800-80, 9800-40, 9800-L, and 9800-CL)
- Cisco Catalyst 9100 Series APs (FlexConnect and fabric mode)
- Cisco Catalyst 9300 Series and 9400 Series switches (fabric mode)

Restrictions for Application Performance Monitoring

- Local flow exporter is not supported.
- The following commands are not supported:
 - **show avc wlan application top**
 - **show avc client top application**
- You cannot configure Application Performance Monitoring and Application Visibility and Control basic on a single policy profile. You can configure them only on two separate policy profiles.
- During CAPWAP restart, AP moves to standby mode, and the nitro engine is disabled. When CAPWAP is up and the nitro engine is enabled, an attempt is made to classify the flows. Since there is not enough information to classify the applications, they are marked as unknown. When the AP rejoins CAPWAP, client traffic gets marked or classified correctly.
- When a client roams while an application has an active-session, the specific session traffic is marked as unknown. The client has to start a new session to mark or classify the traffic correctly.

Workflow

Create a Flow Monitor

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	flow monitor <i>monitor-name</i> Example: Device(config)# flow monitor avc_assurance	Creates a flow monitor.

	Command or Action	Purpose
Step 3	description <i>description</i> Example: Device(config-flow-monitor)# description assurance monitor ID is 90	Adds a description to the flow monitor.
Step 4	record wireless avc {ipv4 ipv6} assurance Example: Device(config-flow-monitor)# record wireless avc ipv4 assurance	Specifies the IPv4 assurance metrics for wireless.
Step 5	exit Example: Device(config-flow-monitor)# exit	Returns to global configuration mode.
Step 6	flow monitor <i>monitor-name</i> Example: Device(config)# flow monitor avc_assurance_rtp	Creates a flow monitor.
Step 7	description <i>description</i> Example: Device(config-flow-monitor)# description assurance-rtp monitor ID is 94	Adds a description to the flow monitor.
Step 8	record wireless avc {ipv4 ipv6} assurance-rtp Example: Device(config-flow-monitor)# record wireless avc ipv4 assurance-rtp	Specifies the IPv4 assurance RTP metrics for wireless.
Step 9	end Example: Device(config-flow-monitor)# end	Returns to privileged EXEC mode.

Create a Wireless WLAN Profile Policy

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	wireless profile policy <i>policy-name</i> Example: Device(config)# wireless profile policy AVC_POL	Configures the WLAN policy profile and enters wireless policy configuration mode.
Step 3	shutdown Example: Device(config-wireless-policy)# shutdown	Disables the policy profile.
Step 4	no central switching Example: Device(config-wireless-policy)# no central switching	Disables central switching.
Step 5	ipv4 flow monitor <i>monitor-name</i> input Example: Device(config-wireless-policy)# ipv4 flow monitor avc_assurance input	Specifies the name of the IPv4 ingress flow monitor.
Step 6	ipv4 flow monitor <i>monitor-name</i> input Example: Device(config-wireless-policy)# ipv4 flow monitor avc_assurance_rtp input	Specifies the name of the IPv4 ingress flow monitor.
Step 7	ipv4 flow monitor <i>monitor-name</i> output Example: Device(config-wireless-policy)# ipv4 flow monitor avc_assurance output	Specifies the name of the IPv4 egress flow monitor.
Step 8	ipv4 flow monitor <i>monitor-name</i> output Example: Device(config-wireless-policy)# ipv4 flow monitor avc_assurance_rtp output	Specifies the name of the IPv4 egress flow monitor.
Step 9	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables the policy profile.
Step 10	end Example: Device(config-wireless-policy)# end	Returns to privileged EXEC mode.

Create a Policy Tag

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless tag policy <i>policy-tag-name</i> Example: Device(config-policy-tag)# wireless tag policy mywlan_ssid	Configures a policy tag and enters policy tag configuration mode.
Step 3	wlan <i>wlan-avc</i> policy <i>policy</i> Example: Device(config-policy-tag)# wlan mywlan_ssid policy AVC_POL	Attaches the policy tag to a WLAN.
Step 4	end Example: Device(config-policy-tag)# end	Returns to privileged EXEC mode.

Attach the Policy Profile to an AP

Procedure

	Command or Action	Purpose
Step 1	ap <i>ap-ether-mac</i> Example: Device(config)# ap 9412.1212.1201	Enters AP configuration mode.
Step 2	policy-tag <i>policy-tag</i> Example: Device(config-ap-tag)# policy-tag mywlan_ssid	Specifies the policy tag that is to be attached to the AP.
Step 3	end Example: Device(config-ap-tag)# end	Returns to privileged EXEC mode.

Verify Application Performance Monitoring

Use the following commands to verify application performance monitoring configuration.

To check application performance monitoring statistics, use the following commands:

```
Device# show flow exporter statistics

Flow Exporter apm_exp:
  Packet send statistics (last cleared 4w1d ago):
    Successfully sent:          2082          (216624 bytes)
!Packet sent count sent from controller to Cisco Cisco Catalyst Center
  Reason not given:           1099          (114296 bytes)

  Client send statistics:
    Client: Flow Monitor avc
      Records added:            0
      Bytes added:              0
```

```
Device# show flow monitor assurance cache

Cache type:                    Normal (Platform cache)
Cache size:                     200000
Current entries:                 0
High Watermark:                 1
!Controller flow monitor cache statistics

Flows added:                    6
Flows aged:                      6
  - Active timeout      (    10 secs)    6
```

To check status of application performance monitoring, use the following command

```
Device# show avc status

VAP FNF-STATUS AVC-QOS-STATUS SD AVC-STATUS APM-STATUS
!APM-STATUS contains IPv4, IPv6 assurance and assurance-rtp monitors.

0  Disabled  Disabled  Enabled  IPV4, IPV4-RTP, IPV6, IPV6-RTP
1  Disabled  Disabled  Disabled Disabled
2  Disabled  Disabled  Disabled Disabled
3  Disabled  Disabled  Disabled Disabled
4  Disabled  Disabled  Disabled Disabled
5  Disabled  Disabled  Disabled Disabled
6  Disabled  Disabled  Disabled Disabled
7  Disabled  Disabled  Disabled Disabled

9  Disabled  Disabled  Disabled Disabled
10 Disabled  Disabled  Disabled Disabled
11 Disabled  Disabled  Disabled Disabled
12 Disabled  Disabled  Disabled Disabled
13 Disabled  Disabled  Disabled Disabled
14 Disabled  Disabled  Disabled Disabled
15 Disabled  Disabled  Disabled Disabled
```

CHAPTER 91

Wireless Clients Threshold Warning

- [Information About Wireless Clients Threshold Warning, on page 1007](#)
- [Configuring a Warning Period, on page 1007](#)
- [Configuring Client Threshold, on page 1008](#)

Information About Wireless Clients Threshold Warning

Cisco IOS XE Bengaluru 17.6.x introduces the Wireless Clients Threshold Warning feature, which allows you to configure a warning message when the number of simultaneous wireless clients on the controller breaches a set threshold. By default, the threshold is set to 75 percent of the total capacity. For example, Cisco Catalyst 9800-80 Wireless Controller supports up to 64,000 clients, and the threshold is set at 48,000 client. When the threshold is breached, the controller sends notifications to the corresponding user using syslog messages, SNMP traps, and NETCONF/Yang notifications.

The Wireless Clients Threshold Warning feature allows you to take note of the impending wireless client limit and act on it before reaching the maximum limit, or modify the number of wireless clients allowed on a controller, as required.

The Wireless Clients Threshold Warning feature is enabled by default. To disable the feature, use the **no wireless max-warning** command.

Configuring a Warning Period

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless max-warning period <i>interval-in-mins</i> Example: Device(config)# wireless max-warning period 20	Configures the periodicity of the wireless client check. Valid values range from 1 to 60 minutes.

	Command or Action	Purpose
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.

Configuring Client Threshold

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless max-warning threshold clients <i>threshold_percentage</i> Example: Device(config)# wireless max-warning threshold clients 90	Configures the warning threshold percentage for the maximum number of wireless clients. Valid values range from 50 to 100 percent.
Step 3	end Example: Device(config)# end	Returns to privileged EXEC mode.

CHAPTER 92

Intelligent Capture Hardening

- [Feature History for Cisco Intelligent Capture Hardening](#), on page 1009
- [Information About Cisco Intelligent Capture Hardening](#), on page 1009
- [Configuring Anomaly Detection in AP Profile \(CLI\)](#), on page 1010
- [Configuring Anomaly Detection in an Access Point \(CLI\)](#), on page 1011
- [Verifying Anomaly Detection and RF Statistics](#), on page 1012

Feature History for Cisco Intelligent Capture Hardening

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 78: Feature History for Cisco Intelligent Capture Hardening

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.12.1	Cisco Intelligent Capture (iCAP) Hardening	The following enhancements are made to the iCAP feature: <ul style="list-style-type: none">• Anomaly Detection• RF Statistics

Information About Cisco Intelligent Capture Hardening

The Cisco Intelligent Capture (iCAP) feature aims at making troubleshooting for wireless clients and APs easier. When there are onboarding issues for wireless clients or AP transmission issues, network operators can find out the cause by using the Cisco Catalyst Center GUI. The Cisco Catalyst Center gathers data from the wireless controller and APs, and displays an aggregated view.

The following enhancements are made to the iCAP feature:

- Anomaly Detection
- RF Statistics

Anomaly Detection

Anomaly Detection is the capability of Cisco APs to detect possible anomalies in the lifecycle of wireless clients and APs.

This functionality is crucial as it allows you to determine if there is an issue in the network, to identify what happened, and avoid the same problem in the future.

APs send individual anomalies to Cisco Catalyst Center every time an anomaly is detected. To prevent Cisco Catalyst Center from getting bombarded with anomaly events of the same type and from the same client, enhancements are made to collapse repeated events, and multiple events are aggregated for the same client if the events occur within a certain time frame.

Anomaly-detection configurations are enhanced on the controller to provision and display the iCAP status.

RF Statistics

The Cisco Catalyst Center receives RF statistics of connected APs. Until Cisco IOS XE Dublin 17.11.1, the data received was basic statistical information. However, from Cisco IOS XE Dublin 17.12.1 onwards, per AP statistical information is directly sent from the wireless controller through iCAP subscription to specific APs.

Configuring Anomaly Detection in AP Profile (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# onfigure terminal	Enters global configuration mode.
Step 2	ap profile <i>ap-profile</i> Example: Device(config)# ap profile <i>ap-profile</i>	Configures an AP profile and enters AP profile configuration mode.
Step 3	icap subscription client anomaly-detection report-individual enable Example: Device(config-ap-profile)# icap subscription client anomaly-detection report-individual enable	Enables individual reports for client anomaly-detection subscription.
Step 4	icap subscription client anomaly-detection report-individual enable aggregate Example: Device(config-ap-profile)# icap subscription client anomaly-detection report-individual enable aggregate	Enables individual reports aggregation for client anomaly-detection subscription. This command is disabled by default.

	Command or Action	Purpose
Step 5	icap subscription client anomaly-detection report-individual per-client throttle <i>number-of-event-reports</i> Example: <pre>Device(config-ap-profile)# icap subscription client anomaly-detection report-individual per-client throttle 20</pre>	Configures event reports per client, every five minutes. The value of an event report ranges from 0 to 50 reports. The default value is five reports.
Step 6	icap subscription client anomaly-detection report-individual per-type throttle <i>number-of-event-reports</i> Example: <pre>Device(config-ap-profile)# icap subscription client anomaly-detection report-individual per-type throttle 50</pre>	Configures event reports per type, every five minutes. The value of an event report ranges from 0 to 100 reports. The default value is five reports.

Configuring Anomaly Detection in an Access Point (CLI)

Procedure

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enters privileged EXEC mode.
Step 2	ap name <i>ap-name</i> icap subscription client anomaly-detection report-individual enable Example: <pre>Device# ap name ap1 icap subscription client anomaly-detection report-individual enable</pre>	Enables individual reports for client anomaly-detection subscription for a single AP.
Step 3	ap name <i>ap-name</i> icap subscription client anomaly-detection report-individual enable aggregate Example: <pre>Device# ap name ap1 icap subscription client anomaly-detection report-individual enable</pre>	Enables individual reports aggregation for client anomaly-detection subscription, for a single AP.
Step 4	ap name <i>ap-name</i> icap subscription client anomaly-detection report-individual per-client throttle <i>number-of-event-reports</i> Example:	Configures event reports per client, every five minutes, for a single AP. The value of an event report ranges from 0 to 50 reports.

	Command or Action	Purpose
	Device# ap name apl icap subscription client anomaly-detection report-individual per-client throttle 20	
Step 5	ap name <i>ap-name</i> icap subscription client anomaly-detection report-individual per-type throttle <i>number-of-event-reports</i> Example: Device# ap name apl icap subscription client anomaly-detection report-individual per-type throttle 50	Configures event reports per type, every five minutes, for a single AP. The value of an event report ranges from 0 to 100 reports.

Verifying Anomaly Detection and RF Statistics

To verify the current status of the anomaly-detection subscription of an AP, use the following command:

```
Device# show ap name cisco-AP icap subscription client anomaly-detection chassis active R0
Per-AP ICap configuration
```

```
Anomaly detection subscription
State                : enabled
Client filter        : 006b.f107.a520
Client filter        : 006b.f107.a521
DHCP timeout (seconds) : 5
Trigger AP packet trace : enabled
Report Individual    : enabled
Report Individual aggregate : enabled
Report Individual throttled events (per 5 minute) : 5
Report Individual per type throttled events (per 5 minute) : 14
Report Individual per client throttled events (per 5 minute) : 15
Report Summary       : disabled
Report Summary frequency (minutes) : 5
```

To verify RF statistics, use the following command:

Note The controller **show** command is enhanced to display data from the **txTotalDrops** counter.

```
Device# show wireless client mac-address 00XX.ecXX.7aXX detail
.
.
.
Client Statistics:
Number of Bytes Received from Client : 62861
Number of Bytes Sent to Client : 6754
Number of Packets Received from Client : 455
Number of Packets Sent to Client : 65
Number of Data Retries : 0
Number of RTS Retries : 0
Number of Tx Total Dropped Packets: x
Number of Duplicate Received Packets : 0
Number of Decrypt Failed Packets : 0
Number of Mic Failed Packets : 0
Number of Mic Missing Packets : 0
Number of Policy Errors : 0
```

```
Radio Signal Strength Indicator : -21 dBm  
Signal to Noise Ratio : 73 dB
```

```
.  
. .  
. . .
```

CHAPTER 93

Amazon S3 Support

- [Information About Amazon S3 Support, on page 1015](#)
- [Configuring Amazon S3 Support, on page 1015](#)
- [Verifying Amazon S3 Support, on page 1017](#)

Information About Amazon S3 Support

In Cisco Catalyst devices, the need for storage capacity is growing due to factors such as larger software images and increased logging rates demanded by customers. Additionally, there is a growing need to distribute software images, provide service maintenance updates (SMUs), and run diverse scripts across numerous devices. The built-in persistent storage available in the devices falls short of meeting these demands. In such situations, a reliable cloud storage solution becomes crucial for enhancing the existing onboard storage by seamlessly incorporating cloud-based storage solutions.

From IOS-XE 17.13.1 release, Amazon S3 or Amazon Simple Storage Service is supported for Cisco Catalyst 9800 Series Wireless Controllers. The Amazon S3 is a service offered by Amazon Web Services (AWS) that provides scalable storage infrastructure through a web service interface. Using Amazon S3, you can seamlessly supplement built-in persistent storage with cloud-based storage.

Restrictions and Guidelines

- The cloud storage is accessible only to the active device.
- Cloud reachability can be established through any service port, including device management ports, or forwarding interfaces on the device.
- Multiple cloud storage configuration profiles can be created for the same S3 bucket with different configuration parameters.
- Virtual device instances (like C9800-CL) hosted on AWS can use the Identity and Access Management (IAM) role infrastructure to access S3 storage.

Configuring Amazon S3 Support

Before you begin

- Ensure that connectivity to the cloud is established.

- Ensure that you have the AWS Identity and Access Management (IAM) access key ID and the secret key ID.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	cloud-services aws s3 profile <i>profile-name</i> Example: Device(config)# cloud-services aws s3 profile 9800_XT_HD	Configures an Amazon S3 cloud services profile. Use only alphanumeric characters for the profile name. Underscore (_) is the only special character that is supported.
Step 3	bucket <i>bucket-name</i> mount-point <i>mount-point</i> Example: Device(config-s3fs-profile)# bucket 9800-B1 mount-point s3-mount	Configures the Amazon S3 storage bucket and its mountpoint. A bucket is a container for objects stored in Amazon S3. The mountpoint refers to the directory on your local file system where you mount your Amazon S3 bucket.
Step 4	description <i>profile-description</i> Example: Device(config-s3fs-profile)# description 9800-External-Storage	(Optional) Adds a description to the Amazon S3 cloud services profile, which can be up to 255 alphanumeric characters.
Step 5	vrf mgmt-intf Example: Device(config-s3fs-profile)# vrf mgmt-Intf	(Optional) Configures the management interface as the VRF interface. The default interface is the forwarding interface.
Step 6	access-key key-id <i>iam-id</i> secret-key {0 8}<i>secret-key</i> Example: Device(config-s3fs-profile)# access-key key-id iam-key-id secret-key 0 *****	Configures the AWS S3 access credentials. Use the same access key ID and the secret key created for the IAM role on the AWS console.
Step 7	permissions read-write Example: Device(config-s3fs-profile)# permissions read-write	(Optional) Sets the Amazon S3 bucket permission as read and write. By default, read-only permission is enabled.
Step 8	region <i>region</i> Example:	Specifies the Amazon S3 region where the cloud-based storage is used.

	Command or Action	Purpose
	Device(config-s3fs-profile)# region us-west-1	
Step 9	proxy {http-server https-server} url-ip port port-num Example: Device(config-s3fs-profile)# proxy https-server 192.0.2.1 port 12	(Optional) Configures HTTP or HTTPS server URL or IPv4 address, along with the port details.
Step 10	no shutdown Example: Device(config-s3fs-profile)# no shutdown	Saves the configuration and enables it for Amazon S3 services.
Step 11	exit Example: Device(config-s3fs-profile)# exit	Returns to global configuration mode.

Verifying Amazon S3 Support

To view a summary of all the Amazon S3 profiles, use the following command.

```
Device# show cloud-services aws s3 summary
```

```
Profile Name           Profile Status  Service Status
-----
test                   Started        Active
test2                  Started        Active
```

To view the operational information of a Amazon S3 profile, use the following command.

```
Device# show cloud-services aws s3 profile s1
```

```
Profile Details
```

```
Profile Name      : s1
Bucket Name       : pb-s3-test1
Mount Point       : test
Bucket Permission : Read-Only
Region            : us-west-1
VRF               : Global
```

```
S3 Service Details
```

```
Service Status    : Active
Service PID       : 31934
Mount Time        : 09/28/23 17:06:25
Service Log Level : Notice
```

CHAPTER 94

Amazon Web Services CloudWatch

- [Information About Amazon Web Services CloudWatch Support, on page 1019](#)
- [Configuring Amazon Web Services CloudWatch Profile, on page 1020](#)
- [Verifying AWS CloudWatch Configuration, on page 1021](#)

Information About Amazon Web Services CloudWatch Support

The Amazon Web Services (AWS) cloud platform offers a service named CloudWatch, which facilitates the monitoring and observability of server system logs, metrics, and events. By integrating CloudWatch on AWS Elastic Compute Cloud (EC2) instances and on on-premise servers, you can efficiently transmit their logs, events, and metrics to the AWS CloudWatch server. The AWS CloudWatch service allows you to gain insights into applications, resources, and services running on the AWS infrastructure. It helps to ensure performance, troubleshoot issues, and effectively maintain the overall health of the controllers.

When the AWS CloudWatch agent is active on the controller, it gathers the system logs from the controller and transmits them to the AWS CloudWatch server. The AWS CloudWatch service is disabled by default.

The AWS CloudWatch agent helps you to do the following:

- Collect internal system-level metrics from AWS EC2 instances across operating systems.
- Collect system-level metrics from on-premise devices.

Benefits of Using Amazon Web Services CloudWatch Service

- **A unified monitoring and observability platform:** All device logs are consolidated in a single location, facilitating easy event monitoring and seamless action using the cloud services tools.
- **Enhanced operational efficiency and resource optimization:** Automate the processes and establish alarms for specific events or logs, thereby improving operational performance and resource management.
- **Gain valuable insights from logs:** Analyze and visualize the logs, allowing you to take appropriate actions based on the events and logs.

The AWS CloudWatch feature is supported on the following controllers: Cisco Catalyst 9800-40, 9800-80, 9800-L, and 9800-CL (private [VMware ESXI, KVM, Hyper-V] and public cloud [AWS C9800-CL instances only] platforms).

Configuring Amazon Web Services CloudWatch Profile

The AWS CloudWatch agent transmits buffered syslog messages to the AWS CloudWatch service. The agent scans and retrieves logs recorded in files within a designated directory, which can be a single file or a wildcard pattern to encompass multiple files. You can specify the storage location of the files in the AWS CloudWatch agent profile. As and when files are updated, the AWS CloudWatch agent dynamically reads their content.

Before you begin

- Create CloudWatch group and streams in AWS.
- Create access credentials in AWS.
- [Set a Private Configuration Key for Password Encryption](#)
- Ensure that you have the AWS Identity and Access Management (IAM) access key ID and the secret key.
- You can run the optional **logging buffered** and **logging persistent** commands to log syslogs to AWS CloudWatch.

For information about how to create CloudWatch group and streams, see the AWS documentation at: <https://docs.aws.amazon.com/IAM/latest/UserGuide/introduction.html>

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	cloud-services aws cloudwatch profile <i>profile-name</i> Example: Device(config)# cloud-services aws cloudwatch profile test-profile	Configures an AWS CloudWatch profile.
Step 3	description <i>profile-description</i> Example: Device(config-cloudwatch-profile)# description test-controller	(Optional) Adds a description to the AWS CloudWatch profile.
Step 4	proxy https-server <i>url-ip port port-num</i> Example: Device(config-cloudwatch-profile)# proxy https-server 192.0.2.1 port 12	(Optional) Configures HTTP or HTTPS server URL or IP address, along with the port details.
Step 5	vrf mgmt-intf Example:	(Optional) Configures the management interface as the VRF interface.

	Command or Action	Purpose
	<code>Device(config-cloudwatch-profile)# vrf mgmt-Intf</code>	Use this option if the agent traffic has to be sent through management interface. By default, data port interface is used. Do not use this command where the management interface is not available, for example, in C9800-CL public cloud instances.
Step 6	access-key key-id iam-id secret-key {0 8}secret-key Example: <code>Device(config-cloudwatch-profile)# access-key key-id iam-key-id secret-key 0 *****</code>	Configures the AWS CloudWatch access credentials. Use the same access key ID and the secret key created for the IAM user on the AWS console.
Step 7	region region Example: <code>Device(config-cloudwatch-profile)# region us-west-1</code>	Specifies the AWS region where CloudWatch server is running on the cloud provider.
Step 8	log group-name group-name stream-name stream-name [file-path file-path] Example: <code>Device(config-cloudwatch-profile)# log group-name techgroup stream-name techstream file-path /home/test/statusReport</code>	Specifies the AWS CloudWatch log group name, log stream name, and an optional log file path. If log file path is not provided, the default syslog path (/bootflash/syslog/*) is used. The log group and log stream used here must be the same as those created on the AWS CloudWatch server. The log file path, if specified, need not be the same as the buffered logging persistent storage path directory or file name.
Step 9	no shutdown Example: <code>Device(config-cloudwatch-profile)# no shutdown</code>	Saves the configuration and enables it for AWS CloudWatch services.
Step 10	exit Example: <code>Device(config-cloudwatch-profile)# exit</code>	Returns to global configuration mode.

Verifying AWS CloudWatch Configuration

To view summary of AWS CloudWatch profiles, run the following command:

```
Device# show cloud-services aws cloudwatch summary
```

```
Profile Name                               Profile Status  Service Status
```

```
-----  
demo3                Started      Active  
demo4                Started      Active
```

To view details of a specific AWS CloudWatch profile, run the following command:

```
Device# show cloud-services aws cloudwatch profile demo3
```

Profile Details

```
Profile Name       : demo3  
VRF                : Global  
Region            : ap-northeast-1
```

CloudWatch Service Details

```
Service Status    : Active  
Service PID       : 31785  
Service Log Level : Notice
```

Log Details

```
Log Group Name          Log Stream Name          Log  
File  
-----  
test                    katar2
```

CHAPTER 95

Kernel Minidump and Trustzone Upgrade

- [Verifying Minidump Configuration, on page 1025](#)

Information About Kernel Minidump and Trustzone Upgrade

When a kernel crash occurs on 802.11AX APs, only AP console logs are accessible for identifying the cause of the crash. However, these logs often do not provide sufficient information to pinpoint the exact reason for the crash. From Cisco IOS XE 17.14.1 release, the Kernel Minidump and Trustzone Upgrade feature offers a more effective method for diagnosing kernel crashes.

The Kernel Minidump and Trustzone Upgrade feature helps to collect specific sections and data structures containing essential information for debugging kernel crashes within the driver. When you enable this feature, it stores references to crucial kernel or driver data structures and data in a TLV structure within kernel memory. Subsequently, after the AP crash and reboot process, the TLV-referenced data structures are saved to the flash memory and can be exported for further analysis. The TLV data is stored in the `/storage/cores` directory

Trust Zone Upgrade

In APs with Qualcomm Software Development Kit (QSDK) version 11.3, the trust zone collects CPU registers following a crash and saves them in memory for later retrieval during kernel crash dump process. To facilitate the kernel crash dump, the trust zone is updated automatically to the latest version for those APs that have the Kernel Minidump and Trustzone Upgrade feature enabled.

Note The trust zone upgrade is a one-time activity. Disabling the Kernel Minidump and Trustzone Upgrade feature or downgrading the controller software to a previous release from Cisco IOS XE 17.14.1 does not roll back the trust zone upgrade.

In Cisco IOS XE 17.14.1, the Kernel Minidump and Trustzone Upgrade feature is supported only on the following APs:

- Cisco Catalyst 9124 Series Access Points
- Cisco Catalyst 9136 Series Access Points

Configuring Minidump from Access Point (CLI)

Before you begin

- Ensure that clients are not connected to the AP.
- Keep the AP in standalone mode to prevent the AP from receiving conflicting payloads from the controller.
- Configuration pushed from the controller always overrides the value configured on the AP.

Procedure

	Command or Action	Purpose
Step 1	configure boot minidump enable Example: Device# configure boot minidump enable	Enables kernel core dump collection on the AP.

Configuring Minidump from Controller (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ap profile <i>profile-name</i> Example: Device(config)# ap profile default-ap-profile	Configures an AP profile and enters AP profile configuration mode.
Step 3	core-dump kernel limit <i>limit</i> Example: Device(config-ap-profile)# core-dump kernel limit 4	Configures the maximum number of kernel core dumps to be collected on an AP. Valid range is from 0 to 5.
Step 4	core-dump kernel type mini-dump Example: Device(config-ap-profile)# core-dump kernel type mini-dump	Configures the type of kernel core dump to be collected on the AP. Use the core-dump kernel type disable command to disable kernel core dump.

	Command or Action	Purpose
		<p>Note Changing the core dump type from disabled to full-dump or mini-dump or vice versa will cause the APs to reboot.</p> <p>When you enable the full-dump option, the Kernel Minidump feature gets deactivated.</p>
Step 5	<p>end</p> <p>Example:</p> <pre>Device(config-ap-profile)# end</pre>	Returns to global configuration mode.

Verifying Minidump Configuration

To view the mini-dump configuration on the controller, use the following command:

```
Device# show ap name AP3C57.31C5.99D0 config general | sec Kernel core dump

Kernel core dump :
  Configured limit           : 3
  Kernel core dumps collected on AP : 1
  Kernel core dump type      : Mini dump
```

To view the mini-dump configuration on the AP, use the following command:

```
AP# show boot

--- Boot Variable Table ---
BOOT path-list:      part1
Console Baudrate:   115200
Enable Break:       yes
Manual Boot:        yes
Memory Debug:       no
Crashkernel:        no
Minidump:           yes # Indicates Minidump is enabled.
SCRUB_LIMIT:        40 (default)
Kdump Limit:        5 # Configured limit. (this came from WLC via payload)
Kdump Collected:   0 # Number of times the feature ran after it was enabled.
Debug init:         0
```

MAC Filtering

- [MAC Filtering, on page 1029](#)
- [Configuring MAC Filtering for Local Authentication \(CLI\), on page 1031](#)
- [Configuring MAC Filtering \(GUI\), on page 1032](#)
- [Configuring MAB for External Authentication \(CLI\), on page 1032](#)

MAC Filtering

You can configure the controller to authorize clients based on the client MAC address by using the MAC filtering feature.

When MAC filtering is enabled, the controller uses the MAC address as the client identity. The authentication server has a database of client MAC addresses that are allowed network access. The controller sends the authentication server a RADIUS-access/request frame with a username and password based on the client MAC address as soon as it gets the association request from the client. If authorization succeeds, the controller sends a successful association response to the client. If authorization fails, the controller rejects the client association.

Clients that were authorized with MAC filtering can be re-authenticated through the WLAN session timeout feature.

MAC Filtering Configuration Guidelines

- MAC filtering authentication occurs at the 802.11 association phase and delays the association response until authentication is done. If you use a RADIUS server for MAC filtering, it is advised to keep a low latency between the controller and the RADIUS server. When latency is too high, the client might timeout while waiting for the association response.
- MAC filtering can be combined with other authentication methods such as 802.1X, Pre-Shared Key or it can be used alone.
- MAC addresses can be spoofed and MAC filtering does not consist in a security measure.
- Many clients can use a private MAC address to connect and change it at every session, therefore making it harder to identify devices through their MAC address.

Note If wlan-profile-name is configured for a user, guest user authentication is allowed only from that WLAN. If wlan-profile-name is not configured for a user, guest user authentication is allowed on any WLAN.

The AP fails to join the controller due to an authentication rejection on the RADIUS server. The failure occurs on the Cisco Catalyst 9800 controller, only when the RADIUS server is configured to authenticate the APs with method MAB as endpoints. The reason is that the RADIUS calling-station-id attribute is required for MAB authentication and is not present within the access request packet during the AP join. The workaround is to use a different AP authentication method than MAB as endpoints such as PAP-ASCII using a username and a password.

If you want the client to connect to SSID1, but not to SSID2 using mac-filtering, ensure that you configure **aaa-override** in the policy profile.

In the following example, when a client with MAC address 1122.3344.0001 tries to connect to a WLAN, the request is sent to the local RADIUS server, which checks the presence of the client MAC address in its attribute list (FILTER_1 and FILTER_2). If the client MAC address is listed in an attribute list (FILTER_1), the client is allowed to join the WLAN (WLAN_1) that is returned as *ssid attribute* from the RADIUS server. The client is rejected, if the client MAC address is not listed in the attribute list.

Local RADIUS Server Configuration

```
!Configures an attribute list as FILTER_2
aaa attribute list FILTER_2
!Defines an attribute type that is to be added to an attribute list.
attribute type ssid "WLAN_2"

!Username with the MAC address is added to the filter
username 1122.3344.0001 mac aaa attribute list FILTER_2

!
aaa attribute list FILTER_1
attribute type ssid "WLAN_1"
username 112233440001 aaa attribute list FILTER_1
```

Controller Configuration

```
! Sets authorization to the local radius server
aaa authorization network MLIST_MACFILTER local

!A WLAN with the SSID WLAN_2 is created and MAC filtering is set along with security
parameters.
wlan WLAN_2 2 WLAN_2
mac-filtering MLIST_MACFILTER
no security wpa
no security wpa wpa2 ciphers

!WLAN with the SSID WLAN_1 is created and MAC filtering is set along with security parameters.
wlan WLAN_1 1 WLAN_1

no security wpa wpa2 ciphers aes
no security wpa akm dot1x
security web-auth
security web-auth authentication-list WEBAUTH

! Policy profile to be associated with the above WLANs
wireless profile policy MAC_FILTER_POLICY
aaa-override
```

```
vlan 504
no shutdown
```

Configuring MAC Filtering for Local Authentication (CLI)

Follow the procedure given below to configure MAB for local authentication.

Before you begin

Configure AAA local authentication.

Configure the username for WLAN configuration (local authentication) using **username mac-address mac** command.

Note The mac-address must be in the following format: *abcdabcdabcd*

Procedure

	Command or Action	Purpose
Step 1	wlan profile-name wlan-id Example: wlan CR1_SSID_mab-local-default 1 CR1_SSID_mab-local-default	Specifies the WLAN name and ID.
Step 2	mac-filtering default Example: Device(config-wlan)# mac-filtering default	Sets MAC filtering support for the WLAN.
Step 3	no security wpa Example: Device(config-wlan)# no security wpa	Disables WPA security.
Step 4	no security wpa akm dot1x Example: Device(config-wlan)# no security wpa akm dot1x	Disables security AKM for dot1x.
Step 5	no security wpa wpa2 Example: Device(config-wlan)# no security wpa wpa2	Disables WPA2 security.
Step 6	no security wpa wpa2 ciphers aes Example: Device(config-wlan)# no security wpa wpa2 ciphers aes	Disables WPA2 ciphers for AES.

	Command or Action	Purpose
Step 7	no shutdown Example: Device(config-wlan)# no shutdown	Enables the WLAN.

Configuring MAC Filtering (GUI)

Before you begin

Configure AAA external authentication.

Procedure

-
- Step 1** Choose **Configuration > Wireless > WLANs**.
 - Step 2** On the **Wireless Networks** page, click the name of the WLAN.
 - Step 3** In the **Edit WLAN** window, click the **Security** tab.
 - Step 4** In the **Layer2** tab, check the **MAC Filtering** check box to enable the feature.
 - Step 5** With MAC Filtering enabled, choose the **Authorization List** from the drop-down list.
 - Step 6** Save the configuration.
-

Configuring MAB for External Authentication (CLI)

Follow the procedure given below to configure MAB for external authentication.

Before you begin

Configure AAA external authentication.

Procedure

	Command or Action	Purpose
Step 1	wlan wlan-name wlan-id ssid-name Example: wlan CR1_SSID_mab-ext-radius 3 CR1_SSID_mab-ext-radius	Specifies the WLAN name and ID.
Step 2	mac-filtering list-name Example: Device(config-wlan)# mac-filtering ewlc-radius	Sets the MAC filtering parameters. Here, <i>ewlc-radius</i> is an example for the <i>list-name</i>

	Command or Action	Purpose
Step 3	no security wpa Example: Device(config-wlan)# no security wpa	Disables WPA security.
Step 4	no security wpa akm dot1x Example: Device(config-wlan)# no security wpa akm dot1x	Disables security AKM for dot1x.
Step 5	no security wpa wpa2 Example: Device(config-wlan)# no security wpa wpa2	Disables WPA2 security.
Step 6	mab request format attribute {1 groupsize size separator separator [lowercase uppercase] 2 {0 7 LINE} LINE password 32 vlan access-vlan} Example: Device(config)# mab request format attribute 1 groupsize 4 separator	Optional. Configures the delimiter while using MAC filtering in a WLAN. Here, 1- Specifies the username format used for MAB requests. groupsize size- Specifies the number of hex digits per group. The valid values range from 1 to 12. separator separator- Specifies how to separate groups. The separators are comma, semicolon, and full stop. lowercase- Specifies the username in lowercase format. uppercase- Specifies the username in uppercase format. 2- Specifies the global password used for all the MAB requests. 0- Specifies the unencrypted password. 7- Specifies the hidden password. LINE- Specifies the encrypted or unencrypted password. <i>password-</i> LINE password. 32- Specifies the NAS-Identifier attribute. vlan- Specifies a VLAN. access-vlan- Specifies the configured access VLAN.

	Command or Action	Purpose
Step 7	no security wpa wpa2 ciphers aes Example: Device(config-wlan)# no security wpa wpa2 ciphers aes	Disables WPA2 ciphers for AES.
Step 8	no shutdown Example: Device(config-wlan)# no shutdown	Enables the WLAN.

CHAPTER 97

Web-Based Authentication

This chapter describes how to configure web-based authentication on the device. It contains these sections:

- [Local Web Authentication Overview, on page 1035](#)
- [How to Configure Local Web Authentication, on page 1043](#)
- [Configuration Examples for Local Web Authentication, on page 1067](#)
- [External Web Authentication \(EWA\), on page 1073](#)
- [Authentication for Sleeping Clients, on page 1078](#)
- [Sleeping Clients with Multiple Authentications, on page 1080](#)
- [Multi Authentication Combination with 802.1X Authentication and Local Web Authentication, on page 1086](#)

Local Web Authentication Overview

Web authentication is a Layer 3 security solution designed for providing easy and secure guest access to hosts on WLAN with open authentication or appropriate layer 2 security methods. Web authentication allows users to get authenticated through a web browser on a wireless client, with minimal configuration on the client side. It allows users to associate with an open SSID without having to set up a user profile. The host receives an IP address and DNS information from the DHCP server, however cannot access any of the network resources until they authenticate successfully. When the host connects to the guest network, the WLC redirects the host to an authentication web page where the user needs to enter valid credentials. The credentials are authenticated by the WLC or an external authentication server and if authenticated successfully is given full access to the network. Hosts can also be given limited access to particular network resources before authentication for which the pre-authentication ACL functionality needs to be configured.

The following are the different types of web authentication methods:

- **Local Web Authentication (LWA):** Configured as Layer 3 security on the controller, the web authentication page and the pre-authentication ACL are locally configured on the controller. The controller intercepts http(s) traffic and redirects the client to the internal web page for authentication. The credentials entered by the client on the login page is authenticated by the controller locally or through a RADIUS or LDAP server.
- **External Web Authentication (EWA):** Configured as Layer 3 security on the controller, the controller intercepts http(s) traffic and redirects the client to the login page hosted on the external web server. The credentials entered by the client on the login page is authenticated by the controller locally or through a RADIUS or LDAP server. The pre-authentication ACL is configured statically on the controller.

- **Central Web Authentication (CWA):** Configured mostly as Layer 2 security on the controller, the redirection URL and the pre-authentication ACL reside on ISE and are pushed during layer 2 authentication to the controller. The controller redirects all web traffic from the client to the ISE login page. ISE validates the credentials entered by the client through HTTPS and authenticates the user.

Use the local web authentication feature, known as web authentication proxy, to authenticate end users on host systems that do not run the IEEE 802.1x supplicant.

When a client initiates an HTTP session, local web authentication intercepts ingress HTTP packets from the host and sends an HTML login page to the users. The users enter their credentials, which the local web authentication feature sends to the authentication, authorization, and accounting (AAA) server for authentication.

If authentication succeeds, local web authentication sends a Login-Successful HTML page to the host and applies the access policies returned by the AAA server.

If authentication fails, local web authentication forwards a Login-Fail HTML page to the user, prompting the user to retry the login. If the user exceeds the maximum number of attempts, local web authentication forwards a Login-Expired HTML page to the host, and the user is excluded with the exclusion reason as Web authentication failure.

When a client reaches maximum HTTP connections (maximum of 200 connections when configured), it will cause Transmission Control Protocol (TCP) resets and client exclusion.

Note You should use either global or named parameter-map under WLAN (for method-type, custom, and redirect) for using the same web authentication methods, such as consent, web consent, and webauth. Global parameter-map is applied by default, if none of the parameter-map is configured under WLAN.

Note The traceback that you receive when webauth client tries to do authentication does not have any performance or behavioral impact. It happens rarely when the context for which FFM replied back to EPM for ACL application is already dequeued (possibly due to timer expiry) and the session becomes 'unauthorized'.

Note When command authorization is enabled as a part of AAA Authorization configuration through TACACS and the corresponding method list is not configured as a part of the HTTP configuration, WebUI pages will not load any data. However, some wireless feature pages may work as they are privilege based and not command based.

Based on where the web pages are hosted, the local web authentication can be categorized as follows:

- *Internal*—The internal default HTML pages (Login, Success, Fail, and Expire) in the controller are used during the local web authentication.
- *Customized*—The customized web pages (Login, Success, Fail, and Expire) are downloaded onto the controller and used during the local web authentication.
- *External*—The customized web pages are hosted on the external web server instead of using the in-built or custom web pages.

Based on the various web authentication pages, the types of web authentication are as follows:

- *Webauth*—This is a basic web authentication. Herein, the controller presents a policy page with the user name and password. You need to enter the correct credentials to access the network.
- *Consent or web-passthrough*—Herein, the controller presents a policy page with the Accept or Deny buttons. You need to click the Accept button to access the network.
- *Webconsent*—This is a combination of webauth and consent web authentication types. Herein, the controller presents a policy page with Accept or Deny buttons along with user name or password. You need to enter the correct credentials and click the Accept button to access the network.

**Note**

- You can view the webauth parameter-map information using the **show running-config** command output.
- The wireless Web-Authentication feature does not support the bypass type.
- Change in web authentication parameter map redirect login URL does not occur until a AP rejoin happens. You must enable and disable the WLAN to apply the new URL redirection.

**Note**

We recommend that you follow the Cisco guidelines to create a customized web authentication login page. If you have upgraded to the latest versions of Google Chrome or Mozilla Firefox browsers, ensure that your webauth bundle has the following line in the *login.html* file:

```
<body onload="loadAction();">
```

Device Roles

With local web authentication, the devices in the network have these specific roles:

- *Client*—The device (workstation) that requests access to the network and the controller and responds to requests from the controller. The workstation must be running an HTML browser with Java Script enabled.
- *Authentication server*—Authenticates the client. The authentication server validates the identity of the client and notifies the controller that the client is authorized to access the network and the controller services or that the client is denied.
- *Controller*—Controls the physical access to the network based on the authentication status of the client. The controller acts as an intermediary (proxy) between the client and the authentication server, requesting identity information from the client, verifying that information with the authentication server, and relaying a response to the client.

Figure 25: Local Web Authentication Device Roles

Authentication Process

When the page is hosted on the controller, the controller uses its virtual IP (a non-routable IP like 192.0.2.1 typically) to serve the request. If the page is hosted externally, the web redirection sends the client first to the virtual IP, which then sends the user again to the external login page while it adds arguments to the URL, such as the location of the virtual IP. Even when the page is hosted externally, the user submits its credentials to the virtual IP.

When you enable local web authentication, these events occur:

- The user initiates an HTTP session.
- The HTTP traffic is intercepted, and authorization is initiated. The controller sends the login page to the user. The user enters a username and password, and the controller sends the entries to the authentication server.
- If the authentication succeeds, the controller downloads and activates the user's access policy from the authentication server. The login success page is sent to the user.
- If the authentication fails, the controller sends the login fail page. The user retries the login. If the maximum number of attempts fails, the controller sends the login expired page, and the host is placed in a watch list. After the watch list times out, the user can retry the authentication process.
- If authentication server is not available, after the web authentication retries, the client moves to the excluded state and the client receives an Authentication Server is Unavailable page.
- The controller reauthenticates a client when the host does not respond to an ARP probe on a Layer 2 interface, or when the host does not send any traffic within the idle timeout on a Layer 3 interface.
- Web authentication sessions can not apply new VLAN as part of the authorization policy, as the client already has been assigned an IP address and you will not be able to change the IP address in the client, in case the VLAN changes.
- If the terminate action is default, the session is dismantled, and the applied policy is removed.

Note Do not use semicolons (;) while configuring username for GUI access.

Local Web Authentication Banner

With Web Authentication, you can create a default and customized web-browser banners that appears when you log in to the controller.

The banner appears on both the login page and the authentication-result pop-up pages. The default banner messages are as follows:

- *Authentication Successful*
- *Authentication Failed*
- *Authentication Expired*

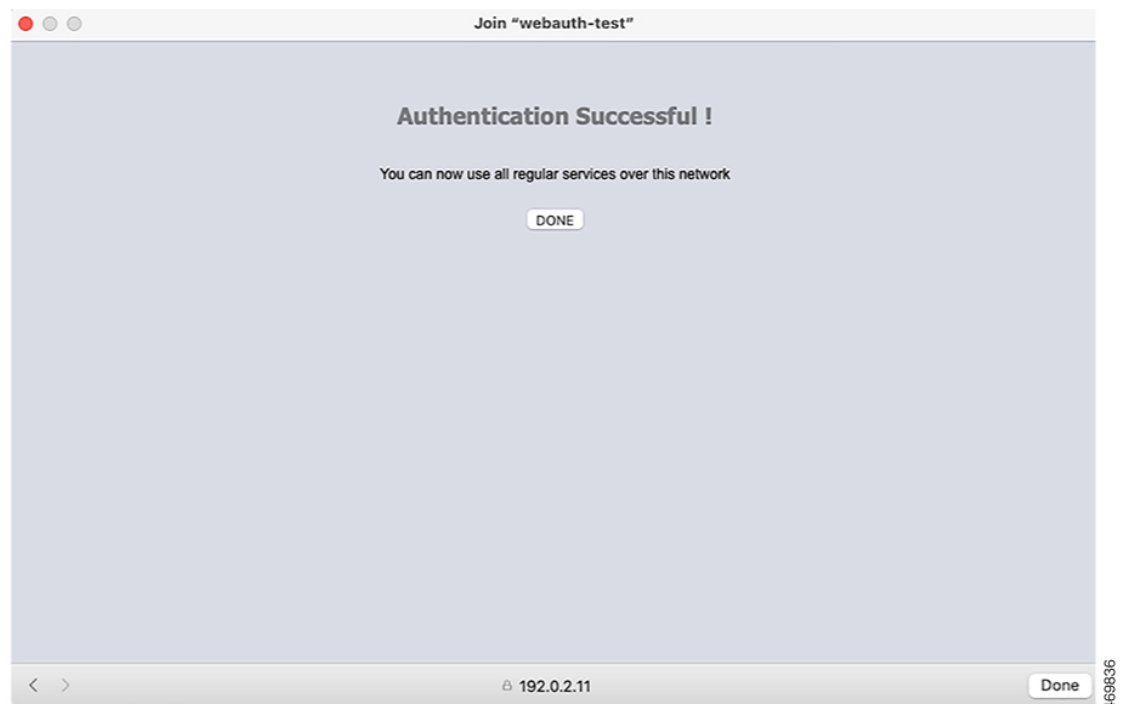

The Local Web Authentication Banner can be configured as follows:

- Use the following global configuration command:

```
Device(config)# parameter map type webauth global
Device(config-params-parameter-map)# banner ?
file <file-name>
text <Banner text>
title <Banner title>
```

The default banner *Cisco Systems* and *Switch host-name Authentication* appear on the Login Page. *Cisco Systems* appears on the authentication result pop-up page.

Figure 26: Authentication Successful Banner

The banner can be customized as follows:

- Add a message, such as switch, router, or company name to the banner:

- New-style mode—Use the following global configuration command:

```
parameter-map type webauth global
```

```
banner text <text>
```

- Add a logo or text file to the banner:

- New-style mode—Use the following global configuration command:

```
parameter-map type webauth global
```

```
banner file <filepath>
```

Figure 27: Customized Web Banner

If you do not enable a banner, only the username and password dialog boxes appear in the web authentication login screen, and no banner appears when you log into the switch.

Figure 28: Login Screen With No Banner

Customized Local Web Authentication

During the local web authentication process, the switch's internal HTTP server hosts four HTML pages to deliver to an authenticating client. The server uses these pages to notify you of these four authentication process states:

- Login: Your credentials are requested
- Success: The login was successful
- Fail: The login failed
- Expire: The login session has expired because of excessive login failures

Note Virtual IP address is mandatory to configure custom web authentication.

From Cisco IOS XE Dublin 17.11.1, special characters such as *ö* or *à* are supported in the login portal for banner title and banner text. The number of characters supported on the banner text has been doubled to 400. To support special characters, ensure that you configure the **exec-character-bits** command under the line console (for serial port) or line vty (for SSH).

**Note**

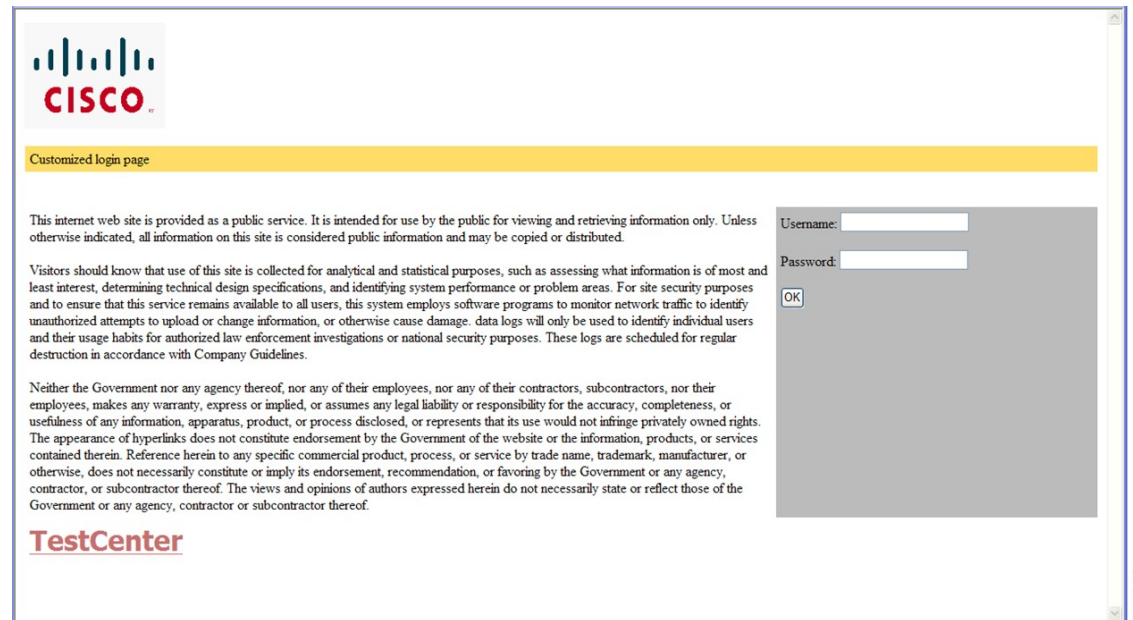

- If the banner text string exceeds the maximum limit of 400 characters, an error message is displayed and the configuration is rejected. Also, the parser has a limitation of 254 characters per line (including the CLI keywords). If you want to use more than 254 characters, ensure that you split it into two or multiple lines.
- The webauth login page displays only the default banner strings if banner command is not configured.

Guidelines

- You can substitute your own HTML pages for the default internal HTML pages.
- You can use a logo or specify text in the *login*, *success*, *failure*, and *expire* web pages.
- On the banner page, you can specify text in the login page.
- The pages are in HTML.
- You must include an HTML redirect command in the success page to access a specific URL.
- The URL string must be a valid URL (for example, <http://www.cisco.com>). An incomplete URL might cause *page not found* or similar errors on a web browser.
- If you configure web pages for HTTP authentication, they must include the appropriate HTML commands (for example, to set the page time out, to set a hidden password, or to confirm that the same page is not submitted twice). The custom page samples in the webauth bundle are provided with the image and the details of what you can and cannot change.
- The CLI command to redirect users to a specific URL is not available when the configured login form is enabled. The administrator should ensure that the redirection is configured in the web page.
- If the CLI command redirecting users to specific URL after authentication occurs is entered and then the command configuring web pages is entered, the CLI command redirecting users to a specific URL does not take effect.
- Configured web pages can be copied to the switch boot flash or flash.
- The login page can be on one flash, and the success and failure pages can be another flash (for example, the flash on the active switch or a member switch).
- You must configure all four pages.
- All of the logo files (image, flash, audio, video, and so on) that are stored in the system directory (for example, flash, disk0, or disk) and that are displayed on the login page must use *web_auth_<filename>* as the file name.
- The configured authentication proxy feature supports both HTTP and SSL.

You can substitute your HTML pages for the default internal HTML pages. You can also specify a URL to which users are redirected after authentication occurs, which replaces the internal Success page.

Figure 29: Customizable Authentication Page

Redirection URL for Successful Login Guidelines

When configuring a redirection URL for successful login, consider these guidelines:

- If the custom authentication proxy web pages feature is enabled, the redirection URL feature is disabled and is not available in the CLI. You can perform redirection in the custom-login success page.
- If the redirection URL feature is enabled, a configured auth-proxy-banner is not used
- To remove the specification of a redirection URL, use the **no** form of the command.
- If the redirection URL is required after the web-based authentication client is successfully authenticated, then the URL string must start with a valid URL (for example, http://) followed by the URL information. If only the URL is given without http://, then the redirection URL on successful authentication might cause page not found or similar errors on a web browser.

How to Configure Local Web Authentication

Configuring Default Local Web Authentication

The following table shows the default configurations required for local web authentication.

Table 79: Default Local Web Authentication Configuration

Feature	Default Setting
AAA	Disabled

Feature	Default Setting
RADIUS server <ul style="list-style-type: none"> • IP address • UDP authentication port • Key 	<ul style="list-style-type: none"> • None specified
Default value of inactivity timeout	3600 seconds
Inactivity timeout	Disabled

Information About the AAA Wizard

The AAA wizard helps you to add the authentication, authorization, and accounting details without having to access multiple windows.

Note When command authorization is enabled as a part of AAA Authorization configuration through TACACS and the corresponding method list is not configured as a part of the HTTP configuration, WebUI pages will not load any data. However, some wireless feature pages may work as they are privilege-based and not command based.

Note Note the following limitations for a TACACS+ user on the 9800 WebUI:

- Users with privilege level 1-10 can only view the **Monitor** tab.
- Users with privilege level 15 have full access.
- Users with privilege level 15 and a command set allowing specific commands only, is not supported.

Note When you configure the AAA authentication and authorization attributes, the following format must be followed:

- protocol:attr=bla
- protocol:attr#0=bla
- protocol:attr#*=bla
- attr=bla
- attr#0=bla
- attr#*=bla

attr is mapped to the supported AAA attributes. If *attr* is an unknown or undefined attribute, a warning message *parse unknown cisco vsa* is displayed when you configure the **radius-server disallow unknown vendor-code** command. Otherwise, the transaction will be treated as a failure.

We recommend that you configure the command as per the format discussed above. Otherwise, the transaction fails. Whenever the passed attribute does not match any of the patterns mentioned, then AAA fails to decode that specific attribute and marks the request as a failure.

To edit the details entered using the wizard, use the respective screens.

Procedure

Step 1 Choose **Configuration > Security > AAA**.

Step 2 Click **+ AAA Wizard**.

The **Add Wizard** page is displayed.

Step 3 Click **RADIUS** tab.

The RADIUS server option is enabled by default. You can switch between the **Basic** and **Advanced** options using the radio buttons.

- a) In the **Name** field, enter the name of the RADIUS server.
- b) In the **IPv4 / IPv6 Server Address** field, enter the IPv4 or IPv6 address, or hostname.
- c) Check the **PAC Key** check box to enable the Protected Access Credential (PAC) authentication key option.
- d) From the **Key Type** drop-down list, choose the authentication key type.
- e) In the **Key** field, enter the authentication key.
- f) In the **Confirm Key** field, re-enter the authentication key.
- g) Click the **Advanced** radio button.

This enables the **Advanced** options.

- h) In the **Auth Port** field, enter the authorization port number.
- i) In the **Acct Port** field, enter the accounting port number.
- j) In the **Server Timeout** field, enter the timeout duration, in seconds.
- k) In the **Retry Count** field, enter the number of retries.

- l) Use the **Support for CoA** toggle button to enable or disable change of authorization (CoA).

Step 4

Check the **TACACS+** check box.

This enables the TACACS+ options. You can switch between the **Basic** and **Advanced** options using the radio buttons.

- a) In the **Name** field, enter the TACACS+ server name.
- b) In the **IPv4 / IPv6 Server Address** field, enter the IPv4 or IPv6 address, or hostname.
- c) In the **Key** field, enter the authentication key.
- d) In the **Confirm Key** field, re-enter the authentication key.
- e) Click the **Advanced** radio button.

This enables the **Advanced** options.

- f) In the **Port** field, enter the port number to use.
- g) In the **Server Timeout** field, enter the timeout duration, in seconds.

Step 5

Check the **LDAP** check box.

This enables the LDAP options. You can switch between the **Basic** and **Advanced** options using the radio buttons.

- a) In the Server Name field, enter the **LDAP** server name.
- b) In the **IPv4 / IPv6 Server Address** field, enter the IPv4 or IPv6 address, or hostname.
- c) In the **Port Number** field, enter the port number to use.
- d) From the **Simple Bind** drop-down list, choose the authentication key type.
- e) In the **User Base DN** field, enter the details.
- f) Click the **Advanced** radio button.

This enables the **Advanced** options.

- g) From the **User Attribute** drop-down list, choose the user attribute.
- h) In the **User Object Type** field, enter the object type details and click the + icon.

The objects that have been added are listed in the area below. Use the x mark adjacent to each object to remove it.

- i) In the **Server Timeout** field, enter the timeout duration, in seconds.
- j) Check the **Secure Mode** check box to enable secure mode.

Checking this enables the **Trustpoint Name** drop-down list.

- k) From the **Trustpoint Name** drop-down list, choose the trustpoint.
- l) Click **Next**.

This enables the **Server Group Association** page and the RADIUS tab is selected by default.

Step 6

Perform the following actions under **RADIUS** tab.

- a) In the **Name** field, enter the name of the RADIUS server group.
- b) From the **MAC-Delimiter** drop-down list, choose the delimiter to be used in the MAC addresses that are sent to the RADIUS servers.
- c) From the **MAC Filtering** drop-down list, choose a value based on which to filter MAC addresses.
- d) To configure the dead time for the server group and direct AAA traffic to alternative groups of servers that have different operational characteristics, in the **Dead-Time** field, enter the amount of time, in minutes, after which a server is assumed to be dead.

- e) Choose the servers that you want to include in the server group from the **Available Servers** list and move them to the **Assigned Servers** list.
- f) Click **Next**.

The **TACACS+** window is displayed, if you have selected **TACACS+** in server configuration.

Step 7 Use the **TACACS+** window to enter the following details:

- a) In the **Name** field, enter the name of the TACACS+ server group.
- b) From the **Available Servers** list, choose the servers that you want to include in the server group from the list and move them to the **Assigned Servers** list.
- c) Click **Next**.

The **LDAP** window is displayed, if you have selected **LDAP** under server configuration.

Step 8 Use the **LDAP** window to enter the following details:

- a) In the **Name** field, enter the name of the LDAP server group.
- b) From the **Available Servers** list, choose the servers that you want to include in the server group from the list and move them to the **Assigned Servers** list.

Step 9 Click **Next**.

The **MAP AAA** window is displayed.

Use the check boxes to enable the **Authentication**, **Authorization**, and **Accounting** tabs. You cannot unselect all the three options. At least one option has to be selected.

Step 10 Use the **Authentication** tab to enter the authentication details:

- a) In the **Method List Name** field, enter the name of the method list.
- b) From the **Type** drop-down list, choose the type of accounting that you want to perform before allowing access to the network.
- c) From the **Group Type** drop-down list, choose a value depending on whether you want to assign a group of servers as your access server, or want to use a local server to authenticate access.

If you choose the local option, the **Fallback** to local option is removed.

- d) Check the **Fallback to local** check box to configure a local server to act as a fallback method when servers in the group are unavailable.
- e) From the **Available Server Groups** list, choose the server groups that you want to use to authenticate access to your network and click the > icon to move them to the **Assigned Server Groups** list.

Step 11 Check the **Authorization** check box to configure the authorization details:

- a) In the **Method List Name** field, enter the name of the method list.
- b) From the **Type** drop-down list, choose the type of authorization you want to perform before allowing access to the network.
- c) From the **Group Type** drop-down list, choose a value depending on whether you want to assign a group of servers as your access server, or want to use a local server to authorize access.

If you choose the local option, the **Fallback** to local option is removed.

- d) Check the **Fallback to local** check box to configure a local server to act as a fallback method when the servers in the group are unavailable.
- e) From the **Available Server Groups** list, choose the server groups you want to use to authorize access to your network and click > icon to move them to the **Assigned Server Groups** list.

- Step 12** Check the **Accounting** check box to configure the accounting details:
- In the **Method List Name** field, enter the name of the method list.
 - From the **Type** drop-down list, choose the type of accounting that you want to perform.
 - From the **Available Server Groups** list, choose the server groups that you want to use to authorize access to your network and click the > icon to move them to the **Assigned Server Groups** list.
- Step 13** Click **Apply to Device**.

Configuring AAA Authentication (GUI)

Note The WebUI does not support the ipv6 radius source-interface under AAA radius server group configuration.

Procedure

- Choose **Configuration > Security > AAA**.
- In the **Authentication** section, click **Add**.
- In the **Quick Setup: AAA Authentication** window that is displayed, enter a name for your method list.
- Choose the type of authentication you want to perform before allowing access to the network, in the **Type** drop-down list.
- Choose if you want to assign a group of servers as your access server, or if you want to use a local server to authenticate access, from the **Group Type** drop-down list.
- To configure a local server to act as a fallback method when servers in the group are unavailable, check the **Fallback to local** check box.
- Choose the server groups you want to use to authenticate access to your network, from the **Available Server Groups** list and click > icon to move them to the **Assigned Server Groups** list.
- Click **Save & Apply to Device**.

Configuring AAA Authentication (CLI)

Procedure

	Command or Action	Purpose
Step 1	aaa new-model Example: Device(config)# aaa new-model	Enables AAA functionality.

	Command or Action	Purpose
Step 2	<p>aaa authentication login {default <i>named_authentication_list</i>} group <i>AAA_group_name</i></p> <p>Example:</p> <pre>Device(config)# aaa authentication login default group group1</pre>	<p>Defines the list of authentication methods at login.</p> <p>named_authentication_list refers to any name that is not greater than 31 characters.</p> <p>AAA_group_name refers to the server group name. You need to define the server-group server_name at the beginning itself.</p>
Step 3	<p>aaa authorization network {default <i>named</i>} group <i>AAA_group_name</i></p> <p>Example:</p> <pre>Device(config)# aaa authorization network default group group1</pre>	Creates an authorization method list for web-based authorization.
Step 4	<p>tacacs server <i>server-name</i></p> <p>Example:</p> <pre>Device(config)# tacacs server yourserver</pre>	Specifies an AAA server.
Step 5	<p>address {<i>ipv4</i> <i>ipv6</i>}<i>ip_address</i></p> <p>Example:</p> <pre>Device(config-server-tacacs)# address ipv4 10.0.1.12</pre>	Configures the IP address for the TACACS server.
Step 6	<p>single-connection</p> <p>Example:</p> <pre>Device(config-server-tacacs)# single-connection</pre>	Multiplexes all packets over a single TCP connection to TACACS server.
Step 7	<p>tacacs-server host {<i>hostname</i> <i>ip_address</i>}</p> <p>Example:</p> <pre>Device(config)# tacacs-server host 10.1.1.1</pre>	Specifies a AAA server.

Configuring the HTTP/HTTPS Server (GUI)

Procedure

-
- Step 1** Choose **Administration > Management > HTTP/HTTPS/Netconf**.
- Step 2** In the **HTTP/HTTPS Access Configuration** section, enable HTTP Access and enter the port that will listen for HTTP requests. The default port is 80. Valid values are 80, and ports between 1025 and 65535.
- Step 3** Enable **HTTPS Access** on the device and enter the designated port to listen for HTTPS requests. The default port is 1025. Valid values are 443, and ports between 1025 and 65535. On a secure HTTP connection, data to and from an HTTP server is encrypted before being sent over the Internet. HTTP with SSL encryption provides a secure connection to allow such functions as configuring a switch from a Web browser.
- Step 4** Choose the **Personal Identity Verification** as enabled or disabled.
- Step 5** In the **HTTP Trust Point Configuration** section, enable **Enable Trust Point** to use Certificate Authority servers as trustpoints.
- Step 6** From the **Trust Points** drop-down list, choose a trust point.
- Step 7** In the **Timeout Policy Configuration** section, enter the HTTP timeout policy in seconds. Valid values can range from 1 to 600 seconds.
- Step 8** Enter the number of minutes of inactivity allowed before the session times out. Valid values can range from 180 to 1200 seconds.
- Step 9** Enter the server life time in seconds. Valid values can range from 1 to 86400 seconds.
- Step 10** Enter the maximum number of requests the device can accept. Valid values range from 1 to 86400 requests.
- Step 11** Save the configuration.
-

Configuring the HTTP Server (CLI)

To use local web authentication, you must enable the HTTP server within the device. You can enable the server for either HTTP or HTTPS.

Note The Apple psuedo-browser will not open if you configure only the **ip http secure-server** command. You should also configure the **ip http server** command.

Follow the procedure given below to enable the server for either HTTP or HTTPS:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	ip http server Example: Device(config)# ip http server	Enables the HTTP server. The local web authentication feature uses the HTTP server to communicate with the hosts for user authentication.
Step 3	ip http secure-server Example: Device(config)# ip http secure-server	Enables HTTPS. You can configure custom authentication proxy web pages or specify a redirection URL for successful login. Note To ensure secure authentication when you enter the ip http secure-server command, the login page is always in HTTPS (secure HTTP) even if the user sends an HTTP request.
Step 4	end Example: Device(config)# end	Exits configuration mode.

Allowing Special Characters for Serial Port

Before you begin

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	line console <i>line-num</i> Example: Device(config)# line console 0	Configures the primary terminal line number.
Step 3	exec-timeout <i>mins sec</i> Example: Device(config-line)# exec-timeout 12 0	Configures the time to disconnect idle EXEC sessions.

	Command or Action	Purpose
Step 4	login authentication <i>word</i> default Example: Device(config-line)# login authentication NO_LOGIN	Configures login authentication checking. It can be authentication list with a name or the default authentication list.
Step 5	exec-character-bit {7 8} Example: Device(config-line)# exec-character-bit 8	Configures the character widths of EXEC command characters.
Step 6	stopbits {1 1.5 2} Example: Device(config-line)# stopbits 1	Configures the stop bits for the console port.
Step 7	end Example: Device(config-line)# end	Returns to privileged EXEC mode.

Allowing Special Characters for VTY Port

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	parameter-map type webauth global Example: Device(config)# parameter-map type webauth global	Creates a parameter map and enters parameter-map webauth configuration mode.
Step 3	banner text <i>text</i> Example: Device(config-params-parameter-map)# banner text #Hëllö#	<p>You can create a custom banner (of up to 400 characters) by entering <i>c</i> <code><banner-text></code> <i>c</i>, where <i>c</i> is a delimiting character.</p> <p>If the string exceeds the maximum limit of 400 characters, an error message is displayed and the configuration is rejected. Also, the parser has a limitation of 254 characters per line (including the CLI keywords). If you want to use more than 254 characters, ensure that you split it into two or multiple lines.</p>

	Command or Action	Purpose
		The webauth login page displays only the default banner strings, if banner command is not configured.
Step 4	end Example: Device(config-params-parameter-map)# end	Returns to privileged EXEC mode.

Configuring HTTP and HTTPS Requests for Web Authentication

Information About Configuring HTTP and HTTPS Requests for Web Authentication

Using the Configuring HTTP and HTTPS Requests for Web Authentication feature, you can have HTTPS access to device management and HTTP access to web authentication. To control the HTTP and HTTPS requests being sent to the web authentication module, run the **secure-webauth-disable** and **webauth-http-enable** commands in the global parameter map mode.

Note The **secure-webauth-disable** and **webauth-http-enable** commands are not enabled by default; you must configure them explicitly.

The following table describes the various CLI combinations:

Table 80: CLI Combinations

Admin (Device Management)		WebAuthentication		Required Configurations	
HTTP Access	HTTPS Access	HTTP Access	HTTPS Access	Admin	Web Authentication
No	Yes	Yes	Yes	no ip http server ip http secure-server	no ip http server ip http secure-server parameter-map type webauth global webauth-http-enable
No	Yes	No	Yes	no ip http server ip http secure-server	no ip http server ip http secure-server

Admin (Device Management)		WebAuthentication		Required Configurations	
HTTP Access	HTTPS Access	HTTP Access	HTTPS Access	Admin	Web Authentication
No	Yes	Yes	No	no ip http server ip http secure-server	no ip http server ip http secure-server parameter-map type webauth global webauth-http-enable secure-webauth-disable
No	Yes	No	No	no ip http server ip http secure-server	no ip http server ip http secure-server parameter-map type webauth global secure-webauth-disable
No	No	No	Yes	no ip http server no ip http secure-server	Not Supported
No	No	Yes	No	no ip http server no ip http secure-server	no ip http server no ip http secure-server parameter-map type webauth global webauth-http-enable
Yes	No	Yes	No	ip http server no ip http secure-server	ip http server no ip http secure-server
Yes	Yes	Yes	No	ip http server ip http secure-server	ip http server ip http secure-server parameter-map type webauth global secure-webauth-disable

**Note**

- The **ip http server** and **ip http secure-server** commands allow access for HTTP and HTTPS, respectively. For example, in the first row of the table, for HTTP access to web authentication, you do not require the **ip http server** command. You can use the new **webauth-http-enable** command under the global parameter map, to allow HTTP access.
- For HTTPS access to webauth, the **ip http secure-server** command is required. Therefore, HTTPS access for both admin and web authentication are enabled in the first row. To disable HTTPS access for web authentication, configure the **secure-webauth-disable** command. For example, in the fourth row of the table, HTTPS access is disabled for web authentication because the **secure-webauth-disable** command is configured.

Guidelines and Limitations

The following are the guidelines and limitations for configuring HTTP and HTTPS requests for web authentication:

- You cannot enable HTTPS web authentication without enabling HTTPS for device management.
- If the **secure-webauth-disable** command is configured, central web authentication cannot be performed, if the initial request from the client is `https://<>`.

Configuring HTTP and HTTPS Requests for Web Authentication (CLI)

To configure the HTTP and HTTPS requests being sent to the webauth module, complete the steps given below:

Procedure

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	no ip http server Example: Device(config)# no ip http server	Sets the HTTP server to its default.
Step 4	ip http {server secure-server} Example: Device(config)# ip http server	Enables the HTTP server or the HTTP secure server.

	Command or Action	Purpose
Step 5	parameter-map type webauth global Example: Device(config)# parameter-map type webauth global	Enables the global parameter map mode.
Step 6	secure-webauth-disable Example: Device(config-params-parameter-map)# secure-webauth-disable	Disables HTTP secure server for web authentication.
Step 7	webauth-http-enable Example: Device(config-params-parameter-map)# webauth-http-enable	Enables HTTP server for web authentication.

Creating a Parameter Map (GUI)

Procedure

-
- Step 1** Choose **Configuration > Security > Web Auth**.
 - Step 2** Click **Add**.
 - Step 3** Click **Policy Map**.
 - Step 4** Enter **Parameter Name**, **Maximum HTTP connections**, **Init-State Timeout(secs)** and choose **webauth** in the **Type** drop-down list.
 - Step 5** Click **Apply to Device**.
-

Creating Parameter Maps

Configuring Local Web Authentication (GUI)

Procedure

-
- Step 1** Choose **Configuration > Security > Web Auth**.
 - Step 2** On the **Web Auth** page, click **Add**.
 - Step 3** In the **Create Web Auth Parameter** window that is displayed, enter a name for the parameter map.
 - Step 4** In the **Maximum HTTP Connections** field, enter the maximum number of HTTP connections that you want to allow.
 - Step 5** In the **Init-State Timeout** field, enter the time after which the init state timer should expire due to user's failure to enter valid credentials in the login page.

- Step 6** Choose the type of Web Auth parameter.
- Step 7** Click **Apply to Device**.
- Step 8** On the **Web Auth** page, click the name of the parameter map.
- Step 9** In the **Edit WebAuth Parameter** window that is displayed, choose the required **Banner Type**.
- If you choose **Banner Text**, enter the required banner text to be displayed.
 - If you choose **File Name**, specify the path of the file from which the banner text has to be picked up.
- Step 10** Enter the virtual IP addresses as required.
- Step 11** Set appropriate status of **WebAuth Intercept HTTPS, Captive Bypass Portal**.
- Step 12** Set appropriate status for **Disable Success Window, Disable Logout Window, and Login Auth Bypass for FQDN**.
- Step 13** Check the **Sleeping Client Status** check box to enable authentication of sleeping clients and then specify the **Sleeping Client Timeout** in minutes. Valid range is between 10 minutes and 43200 minutes.
- Step 14** Click the **Advanced** tab.
- Step 15** To configure external web authentication, perform these tasks:
- a) In the **Redirect for log-in** field, enter the name of the external server to send login request.
 - b) In the **Redirect On-Success** field, enter the name of the external server to redirect after a successful login.
 - c) In the **Redirect On-Failure** field, enter the name of the external server to redirect after a login failure.
 - d) (Optional) Under **Redirect to External Server** in the **Redirect Append for AP MAC Address** field, enter the AP MAC address.
 - e) (Optional) In the **Redirect Append for Client MAC Address** field, enter the client MAC address.
 - f) (Optional) In the **Redirect Append for WLAN SSID** field, enter the WLAN SSID.
 - g) In the **Portal IPV4 Address** field, enter the IPv4 address of the portal to send redirects.
 - h) In the **Portal IPV6 Address** field, enter the IPv6 address of the portal to send redirects, if IPv6 address is used.
- Step 16** To configure customized local web authentication, perform these tasks:
- a) Under **Customized Page**, specify the following pages:
 - **Login Failed Page**
 - **Login Page**
 - **Logout Page**
 - **Login Successful Page**
- Step 17** Click **Update & Apply**.

Configuring the Internal Local Web Authentication (CLI)

Follow the procedure given below to configure the internal local web authentication:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	parameter-map type webauth <i>{parameter-map-name global}</i> Example: Device(config)# <code>parameter-map type webauth sample</code>	Creates the parameter map. The parameter-map-name must not exceed 99 characters.
Step 3	end Example: Device(config-params-parameter-map) # <code>end</code>	Returns to privileged EXEC mode.

Configuring the Customized Local Web Authentication (CLI)

Follow the procedure given below to configure the customized local web authentication:

Note Virtual IP address is mandatory for custom web authentication.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	parameter-map type webauth <i>parameter-map-name</i> Example: Device(config)# <code>parameter-map type webauth sample</code>	Configures the webauth type parameter. Note You need to configure a virtual IP in the global parameter map to use the customized web authentication bundle.
Step 3	type {authbypass consent webauth webconsent} Example:	Configures webauth sub-types, such as passthru, consent, webauth, or webconsent.

	Command or Action	Purpose
	Device(config-params-parameter-map) # type webauth	
Step 4	custom-page login device <i>html-filename</i> Example: Device(config-params-parameter-map) # custom-page login device bootflash:login.html	Configures the customized login page.
Step 5	custom-page login expired device <i>html-filename</i> Example: Device(config-params-parameter-map) # custom-page login expired device bootflash:loginexpired.html	Configures the customized login expiry page.
Step 6	custom-page success device <i>html-filename</i> Example: Device(config-params-parameter-map) # custom-page success device bootflash:loginsuccess.html	Configures the customized login success page.
Step 7	custom-page failure device <i>html-filename</i> Example: Device(config-params-parameter-map) # custom-page failure device bootflash:loginfail.html	Configures the customized login failure page.
Step 8	end Example: Device(config-params-parameter-map) # end	Returns to privileged EXEC mode.

Configuring the External Local Web Authentication (CLI)

Follow the procedure given below to configure the external local web authentication:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Device# <code>configure terminal</code>	
Step 2	<p>parameter-map type webauth <i>parameter-map-name</i></p> <p>Example:</p> <pre>Device(config)# parameter-map type webauth sample</pre>	Configures the webauth type parameter.
Step 3	<p>type {authbypass consent webauth webconsent}</p> <p>Example:</p> <pre>Device(config-params-parameter-map)# type webauth</pre>	Configures the webauth sub-types, such as authbypass, consent, passthru, webauth, or webconsent.
Step 4	<p>redirect [for-login on-failure on-success] <i>URL</i></p> <p>Example:</p> <pre>Device(config-params-parameter-map)# redirect for-login http://www.cisco.com/login.html</pre>	<p>Configures the redirect URL for the login, failure, and success pages.</p> <p>Note In the redirect url, you need to press <i>Ctrl+v</i> and type <i>?</i> to configure the <i>?</i> character.</p> <p>The <i>?</i> character is commonly used in URL when ISE is configured as an external portal.</p>
Step 5	<p>redirect portal {ipv4 ipv6} ip-address</p> <p>Example:</p> <pre>Device(config-params-parameter-map)# redirect portal ipv4 23.0.0.1</pre>	<p>Configures the external portal IPv4 address.</p> <p>Note The IP address should be one of the associated IP addresses of the domain and not a random IP address when using FQDN. It is recommended to use the FQDN URL here, if a given domain resolves to more than a single IP address.</p>
Step 6	<p>end</p> <p>Example:</p> <pre>Device(config-params-parameter-map)# end</pre>	Returns to privileged EXEC mode.

Configuring the Web Authentication WLANs

Follow the procedure given below to configure WLAN using web auth security and map the authentication list and parameter map:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan profile-name wlan-id ssid-name Example: Device(config)# wlan mywlan 34 mywlan-ssid	Specifies the WLAN name and ID. <i>profile-name</i> is the WLAN name which can contain 32 alphanumeric characters. <i>wlan-id</i> is the wireless LAN identifier. The valid range is from 1 to 512. <i>ssid-name</i> is the SSID which can contain 32 alphanumeric characters.
Step 3	no security wpa Example: Device(config-wlan)# no security wpa	Disables the WPA security.
Step 4	security web-auth Example: Device(config-wlan)# security web-auth	Enables web authentication for WLAN.
Step 5	security web-auth {authentication-list authentication-list-name parameter-map parameter-map-name} Example: Device(config-wlan)# security web-auth authentication-list webauthlistlocal Device(config-wlan)# security web-auth parameter-map sample	Enables web authentication for WLAN. Here, <ul style="list-style-type: none"> • authentication-list <i>authentication-list-name</i>: Sets the authentication list for IEEE 802.1x. • parameter-map <i>parameter-map-name</i>: Configures the parameter map.

	Command or Action	Purpose
		Note When security web-auth is enabled, you get to map the default authentication-list and global parameter-map . This is applicable for authentication-list and parameter-map that are not explicitly mentioned.
Step 6	end Example: Device(config-wlan)# end	Returns to privileged EXEC mode.

Configuring Pre-Auth Web Authentication ACL (GUI)

Before you begin

Ensure that you have configured an access control list (ACL) and a WLAN.

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > WLANs**.
 - Step 2** Click the name of the WLAN.
 - Step 3** In the **Edit WLAN** window, click the **Security** tab and then click the **Layer3** tab.
 - Step 4** Click **Show Advanced Settings**.
 - Step 5** In the **Preauthentication ACL** section, choose the appropriate ACL to be mapped to the WLAN.
 - Step 6** Click **Update & Apply to Device**.
-

Configuring Pre-Auth Web Authentication ACL (CLI)

Follow the procedure given below to configure pre-auth web authentication ACL:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 2	<p>access-list <i>access-list-number</i> {deny permit} <i>hostname source-wildcard-bits</i></p> <p>Example:</p> <pre>Device(config)# access-list 2 deny your_host 10.1.1.1 log</pre>	<p>Creates an ACL list.</p> <p>The <i>access-list-number</i> is a decimal number from 1 to 99, 100 to 199, 300 to 399, 600 to 699, 1300 to 1999, 2000 to 2699, or 2700 to 2799.</p> <p>Enter deny or permit to specify whether to deny or permit if the conditions are matched.</p> <p>The <i>source</i> is the source address of the network or host from which the packet is being sent specified as:</p> <ul style="list-style-type: none"> • The 32-bit quantity in dotted-decimal format. • The keyword any as an abbreviation for <i>source</i> and <i>source-wildcard</i> of 0.0.0.0 255.255.255.255. You do not need to enter a source-wildcard. • The keyword host as an abbreviation for <i>source</i> and <i>source-wildcard</i> of source 0.0.0.0. <p>(Optional) The <i>source-wildcard</i> applies wildcard bits to the source.</p>
Step 3	<p>wlan <i>profile-name wlan-id ssid-name</i></p> <p>Example:</p> <pre>Device(config)# wlan mywlan 34 mywlan-ssid</pre>	<p>Creates the WLAN.</p> <p><i>profile-name</i> is the WLAN name which can contain 32 alphanumeric characters.</p> <p><i>wlan-id</i> is the wireless LAN identifier. The valid range is from 1 to 512.</p> <p><i>ssid-name</i> is the SSID which can contain 32 alphanumeric characters.</p>
Step 4	<p>ip access-group web <i>access-list-name</i></p> <p>Example:</p> <pre>Device(config-wlan)# ip access-group web name</pre>	<p>Maps the ACL to the web auth WLAN.</p> <p><i>access-list-name</i> is the IPv4 ACL name or ID.</p>
Step 5	<p>end</p> <p>Example:</p> <pre>Device(config-wlan)# end</pre>	<p>Returns to privileged EXEC mode.</p>

Configuring the Maximum Web Authentication Request Retries

Follow these steps to configure the maximum web authentication request retries:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 3	wireless security web-auth retries <i>number</i> Example: Device(config)# <code>wireless security web-auth retries 2</code>	<i>number</i> is the maximum number of web auth request retries. The valid range is 0 to 20.
Step 4	end Example: Device(config)# <code>end</code>	Returns to privileged EXEC mode.

Configuring a Local Banner in Web Authentication Page (GUI)

Procedure

-
- Step 1** Choose **Configuration > Security > Web Auth**.
- Step 2** In the **Webauth Parameter Map** tab, click the parameter map name. The **Edit WebAuth Parameter** window is displayed.
- Step 3** In the **General** tab and choose the required Banner Type:
- If you choose **Banner Text**, enter the required banner text to be displayed.
 - If you choose **File Name**, specify the path of the file from which the banner text has to be picked up.
- Step 4** Click **Update & Apply**.
-

Configuring a Local Banner in Web Authentication Page (CLI)

Follow the procedure given below to configure a local banner in web authentication pages.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	parameter-map type webauth <i>param-map</i> Example: Device(config)# <code>parameter-map type webauth param-map</code>	Configures the web authentication parameters. Enters the parameter map configuration mode.
Step 3	banner [<i>file</i> <i>banner-text</i> <i>title</i>] Example: Device(config-params-parameter-map)# <code>banner http C My Switch C</code>	Enables the local banner. Create a custom banner by entering <i>C banner-text C</i> (where <i>C</i> is a delimiting character), or <i>file</i> that indicates a file (for example, a logo or text file) that appears in the banner, or <i>title</i> that indicates the title of the banner.
Step 4	end Example: Device(config-params-parameter-map)# <code>end</code>	Returns to privileged EXEC mode.

Configuring Type WebAuth, Consent, or Both

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device # <code>configure terminal</code>	Enters global configuration mode.
Step 2	parameter-map type webauth <i>parameter-map name</i> Example: Device (config) # <code>parameter-map type webauth webparalocal</code>	Configures the webauth type parameter.

	Command or Action	Purpose
Step 3	type consent Example: Device (config-params-parameter-map) # type consent	Configures webauth type as consent. You can configure the type as webauth, consent, or both (webconsent).
Step 4	end Example: Device (config-params-parameter-map) # end	Returns to privileged EXEC mode.
Step 5	show running-config section parameter-map type webauth <i>parameter-map</i> Example: Device (config) # show running-config section parameter-map type webauth test	Displays the configuration details.

Configuring Preauthentication ACL

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan <i>wlan-name</i> Example: Device (config)# wlan ramban	For <i>wlan-name</i> , enter the profile name.
Step 3	shutdown Example: Device (config-wlan)# shutdown	Disables the WLAN.
Step 4	ip access-group web <i>preauthrule</i> Example: Device (config-wlan)# ip access-group web preauthrule	Configures ACL that has to be applied before authentication.
Step 5	no shutdown Example: Device (config)# no shutdown	Enables the WLAN.
Step 6	end	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Example: Device (config-wlan)# end	
Step 7	show wlan name <i>wlan-name</i> Example: Device# show wlan name ramban	Displays the configuration details.

Configuring TrustPoint for Local Web Authentication

Before you begin

Ensure that a certificate is installed on your controller . Using trustpoint controller presents the domain specific certificate that client browser trusts when it gets redirected to *.com portal.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	parameter-map type webauth global Example: Device (config)# parameter-map type webauth global	Creates the parameter map.
Step 3	trustpoint <i>trustpoint-name</i> Example: Device (config-params-parameter-map)# trustpoint <i>trustpoint-name</i>	Configures trustpoint for local web authentication.
Step 4	end Example: Device (config-params-parameter-map)# end	Returns to privileged EXEC mode.

Configuration Examples for Local Web Authentication

Example: Obtaining Web Authentication Certificate

This example shows how to obtain web authentication certificate.

```
Device# configure terminal
Device(config)# crypto pki import cert pkcs12 tftp://9.1.0.100/ldapserver-cert.p12 cisco
Device(config)# end
Device# show crypto pki trustpoints cert
Trustpoint cert:
  Subject Name:
    e=rkannajr@cisco.com
    cn=sthaliya-lnx
    ou=WNBU
    o=Cisco
    l=SanJose
    st=California
    c=US
    Serial Number (hex): 00
  Certificate configured.
Device# show crypto pki certificates cert
Certificate
  Status: Available
  Certificate Serial Number (hex): 04
  Certificate Usage: General Purpose
  Issuer:

```

Example: Choosing the Default Web Authentication Login Page

This example shows how to choose a default web authentication login page.

```

Device# configure terminal
Device(config)# parameter-map type webauth test
This operation will permanently convert all relevant authentication commands to their CPL
control-policy equivalents. As this conversion is irreversible and will
disable the conversion CLI 'authentication display [legacy|new-style]', you are strongly
advised to back up your current configuration before proceeding.
Do you wish to continue? [yes]: yes

```

```

Device(config)# wlan wlan50
Device(config-wlan)# shutdown
Device(config-wlan)# security web-auth authentication-list test
Device(config-wlan)# security web-auth parameter-map test
Device(config-wlan)# no shutdown
Device(config-wlan)# end
Device# show running-config | section wlan50
wlan wlan50 50 wlan50
 security wpa akm cckm
 security wpa wpa1
 security wpa wpa1 ciphers aes
 security wpa wpa1 ciphers tkip
 security web-auth authentication-list test
 security web-auth parameter-map test
 session-timeout 1800
 no shutdown

Device# show running-config | section parameter-map type webauth test
parameter-map type webauth test
 type webauth

```

Example: Choosing a Customized Web Authentication Login Page from an IPv4 External Web Server

This example shows how to choose a customized web authentication login page from an IPv4 external web server.

```

Device# configure terminal
Device(config)# parameter-map type webauth global
Device(config-params-parameter-map)# virtual-ip ipv4 192.0.2.1.
Device(config-params-parameter-map)# parameter-map type webauth test
Device(config-params-parameter-map)# type webauth
Device(config-params-parameter-map)# redirect for-login http://9.1.0.100/login.html
Device(config-params-parameter-map)# redirect portal ipv4 9.1.0.100
Device(config-params-parameter-map)# end
Device# show running-config | section parameter-map
parameter-map type webauth global
virtual-ip ipv4 192.0.2.1.
parameter-map type webauth test
 type webauth
redirect for-login http://9.1.0.100/login.html
redirect portal ipv4 9.1.0.100
security web-auth parameter-map rasagna-auth-map
security web-auth parameter-map test

```

Example: Choosing a Customized Web Authentication Login Page from an IPv6 External Web Server

This example shows how to choose a customized web authentication login page from an IPv6 external web server.

```

Device# configure terminal
Device(config)# parameter-map type webauth global
Device(config-params-parameter-map)# virtual-ip ipv6 2001:DB8::/48
Device(config-params-parameter-map)# parameter-map type webauth test

```

```

Device(config-params-parameter-map) # type webauth
Device(config-params-parameter-map) # redirect for-login http://9:1:1::100/login.html
Device(config-params-parameter-map) # redirect portal ipv6 9:1:1::100
Device(config-params-parameter-map) # end
Device# show running-config | section parameter-map
parameter-map type webauth global
virtual-ip ipv6 2001:DB8::/48
parameter-map type webauth test
type webauth
redirect for-login http://9:1:1::100/login.html
redirect portal ipv6 9:1:1::100
security web-auth parameter-map rasagna-auth-map
security web-auth parameter-map test

```

Example: Assigning Login, Login Failure, and Logout Pages per WLAN

This example shows how to assign login, login failure and logout pages per WLAN.

```

Device# configure terminal
Device(config)# parameter-map type webauth test
Device(config-params-parameter-map) # custom-page login device flash:loginsantosh.html
Device(config-params-parameter-map) # custom-page login expired device flash:loginexpire.html
Device(config-params-parameter-map) # custom-page failure device flash:loginfail.html
Device(config-params-parameter-map) # custom-page success device flash:loginsuccess.html
Device(config-params-parameter-map) # end
Device# show running-config | section parameter-map type webauth test
parameter-map type webauth test
type webauth
redirect for-login http://9.1.0.100/login.html
redirect portal ipv4 9.1.0.100
custom-page login device flash:loginsantosh.html
custom-page success device flash:loginsuccess.html
custom-page failure device flash:loginfail.html
custom-page login expired device flash:loginexpire.html

```

Example: Configuring Preauthentication ACL

This example shows how to configure preauthentication ACL.

```

Device# configure terminal
Device(config)# wlan fff
Device(config-wlan) # shutdown
Device(config-wlan) # ip access-group web preauthrule
Device(config-wlan) # no shutdown
Device(config-wlan) # end
Device# show wlan name fff

```

Example: Configuring Webpassthrough

This example shows how to configure webpassthrough.

```

Device# configure terminal
Device(config)# parameter-map type webauth webparalocal
Device(config-params-parameter-map) # type consent
Device(config-params-parameter-map) # end

```

```
Device# show running-config | section parameter-map type webauth test
parameter-map type webauth test
type webauth
redirect for-login http://9.1.0.100/login.html
redirect portal ipv4 9.1.0.100
```

Verifying Web Authentication Type

To verify the web authentication type, run the following command:

```
Device# show parameter-map type webauth all
Type Name
-----
Global global
Named webauth
Named ext
Named redirect
Named abc
Named glbal
Named ewa-2

Device# show parameter-map type webauth global
Parameter Map Name : global
Banner:
Text : Cisco
Type : webauth
Auth-proxy Init State time : 120 sec
Webauth max-http connection : 100
Webauth logout-window : Enabled
Webauth success-window : Enabled
Consent Email : Disabled
Sleeping-Client : Enabled
Sleeping-Client timeout : 60 min
Virtual-ipv4 : 192.0.2.1.
Virtual-ipv4 hostname :
Webauth intercept https : Disabled
Webauth Captive Bypass : Disabled
Webauth bypass intercept ACL :
Trustpoint name :
HTTP Port : 80
Watch-list:
Enabled : no
Webauth login-auth-bypass:

Device# show parameter-map type webauth name global
Parameter Map Name : global
Type : webauth
Auth-proxy Init State time : 120 sec
Webauth max-http connection : 100
Webauth logout-window : Enabled
Webauth success-window : Enabled
Consent Email : Disabled
Sleeping-Client : Disabled
Webauth login-auth-bypass:
```

External Web Authentication (EWA)

Configuring EWA with Single WebAuth Server Address and Default Ports (80/443) (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	aaa authentication login Example: Device(config)# aaa authentication login WEBAUTH local	Defines the authentication method at login.
Step 3	parameter-map type webauth <i>parameter-map-name</i> Example: Device(config)# parameter-map type webauth ISE-Ext-Webauth_IP	Creates the parameter map. The <i>parameter-map-name</i> must not exceed 99 characters.
Step 4	type webauth Example: Device(config-params-parameter-map)# type webauth	Configures the webauth type parameter.
Step 5	redirect for-login <i>URL-String</i> Example: Device(config-params-parameter-map)# redirect for-login https://192.168.0.98/portal/registration.html	Configures the URL string for redirect during login.
Step 6	redirect portal ipv4 <i>ip-address</i> Example: Device(config-params-parameter-map)# redirect portal ipv4 192.168.0.98	Configures the external portal IPv4 address.
Step 7	exit Example: Device(config-params-parameter-map)# exit	Returns to global configuration mode.

	Command or Action	Purpose
Step 8	wlan <i>wlan-name wlan-id SSID-name</i> Example: Device(config)# wlan EWLC3-GUEST 3 EWLC3-GUEST	Configures a WLAN.
Step 9	no security ft adaptive Example: Device(config-wlan)# no security ft adaptive	Disables adaptive 11r.
Step 10	no security wpa Example: Device(config-wlan)# no security wpa	Disables WPA security.
Step 11	no security wpa wpa2 Example: Device(config-wlan)# no security wpa wpa2	Disables WPA2 security.
Step 12	no security wpa wpa2 ciphers aes Example: Device(config-wlan)# no security wpa wpa2 ciphers aes	Disables WPA2 ciphers for AES.
Step 13	no security wpa akm dot1x Example: Device(config-wlan)# no security wpa akm dot1x	Disables security AKM for dot1x.
Step 14	security web-auth Example: Device(config-wlan)# security web-auth	Enables web authentication for WLAN.
Step 15	security web-auth authentication-list <i>authenticate-list-name</i> Example: Device(config-wlan)# security web-auth authentication-list WEBAUTH	Enables authentication list for dot1x security.
Step 16	security web-auth parameter-map <i>parameter-map-name</i> Example: Device(config-wlan)# security web-auth parameter-map ISE-Ext-Webauth_IP	Configures the parameter map. Note If parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

	Command or Action	Purpose
Step 17	end Example: Device(config-wlan)# end	Returns to privileged EXEC mode.

Configuring EWA with Multiple Web Servers and/or Ports Different than Default (80/443)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ip access-list extended name Example: Device(config)# ip access-list extended preauth_ISE_Ext_WA	Defines an extended IPv4 access list using a name, and enters access-list configuration mode.
Step 3	access-list-number permit tcp any host external_web_server_ip_address1 eq port-number Example: Device(config)# 10 permit tcp any host 192.168.0.98 eq 8443	Permits access from any host to the external web server port number 8443.
Step 4	access-list-number permit tcp any host external_web_server_ip_address2 eq port-number Example: Device(config)# 10 permit tcp any host 192.168.0.99 eq 8443	Permits access from any host to the external web server port number 8443.
Step 5	access-list-number permit udp any any eq domain Example: Device(config)# 20 permit udp any any eq domain	Permits DNS UDP traffic.
Step 6	access-list-number permit udp any any eq bootpc Example: Device(config)# 30 permit udp any any eq bootpc	Permits DHCP traffic.

	Command or Action	Purpose
Step 7	<p><i>access-list-number</i> permit udp any any eq bootps</p> <p>Example:</p> <pre>Device(config)# 40 permit udp any any eq bootps</pre>	Permits DHCP traffic.
Step 8	<p><i>access-list-number</i> permit tcp host external_web_server_ip_address1 eq port_number any</p> <p>Example:</p> <pre>Device(config)# 50 permit tcp host 192.168.0.98 eq 8443 any</pre>	Permits the access from the external web server port 8443 to any host.
Step 9	<p><i>access-list-number</i> permit tcp host external_web_server_ip_address2 eq port_number any</p> <p>Example:</p> <pre>Device(config)# 50 permit tcp host 192.168.0.99 eq 8443 any</pre>	Permits the access from the external web server port 8443 to any host.
Step 10	<p><i>access-list-number</i> permit tcp any any eq domain</p> <p>Example:</p> <pre>Device(config)# 60 permit tcp any any eq domain</pre>	Permits the DNS TCP traffic.
Step 11	<p><i>access-list-number</i> deny ip any any</p> <p>Example:</p> <pre>Device(config)# 70 deny ip any any</pre>	Denies all the other traffic.
Step 12	<p>wlan wlan-name wlan-id ssid</p> <p>Example:</p> <pre>Device(config)# wlan EWLC3-GUEST 3 EWLC3-GUEST</pre>	Creates the WLAN.
Step 13	<p>ip access-group web name</p> <p>Example:</p> <pre>Device(config-wlan)# ip access-group web preauth_ISE_Ext_WA</pre>	Configures the IPv4 WLAN web ACL. The variable <i>name</i> specifies the user-defined IPv4 ACL name.
Step 14	<p>end</p> <p>Example:</p> <pre>Device(config-wlan)# end</pre>	Returns to privileged EXEC mode.

Configuring Wired Guest EWA with Multiple Web Servers and/or Ports Different than Default (80/443)

Before you begin

You cannot assign a manual ACL to a wired guest LAN configuration. The workaround is to use the bypass ACL in the global parameter map.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	ip access-list extended <i>name</i> Example: Device(config)# ip access-list extended BYPASS_ACL	Defines an extended IPv4 access list using a name, and enters access-list configuration mode.
Step 3	<i>access-list-number</i> deny ip any host <i>hostname</i> Example: Device(config)# 10 deny ip any host 192.168.0.45	Allows the traffic to switch centrally.
Step 4	<i>access-list-number</i> deny ip any host <i>hostname</i> Example: Device(config)# 20 deny ip any host 4.0.0.1	Allows the traffic to switch centrally.
Step 5	parameter-map type webauth global Example: Device(config)# parameter-map type webauth global	Creates a parameter map and enters parameter-map webauth configuration mode.
Step 6	webauth-bypass-intercept <i>name</i> Example: Device(config-params-parameter-map)# webauth-bypass-intercept BYPASS_ACL	Creates a WebAuth bypass intercept using the ACL name. Note You cannot apply a manual ACL to the wired guest profile and configure an external web authentication with multiple IP addresses or different ports. The workaround is to use the bypass ACL for wired guest profile.
Step 7	end Example:	Returns to privileged EXEC mode.

	Command or Action	Purpose
	Device (config-params-parameter-map) # end	

Authentication for Sleeping Clients

Information About Authenticating Sleeping Clients

Clients with guest access that have had successful web authentication are allowed to sleep and wake up without having to go through another authentication process through the login page. You can configure the duration for which sleeping clients should be remembered for before reauthentication becomes necessary. The valid range is 10 minutes to 43200 minutes, with the default being 720 minutes. You can also configure this duration on WebAuth parameter map that is mapped to a WLAN. Note that the sleeping client timer comes into effect due to instances such as idle timeout, session timeout, disabling of the WLAN, and the AP being nonoperational.

This feature is supported in the following FlexConnect scenario: local switching and central authentication.

Caution If the MAC address of a client that goes to sleep mode is spoofed, the fake device such as a laptop can be authenticated.

Mobility Scenarios

Following are some guidelines in a mobility scenario:

- L2 roaming in the same subnet is supported.
- Anchor sleeping timer is applicable.
- The sleeping client information is shared between multiple autoanchors when a sleeping client moves from one anchor to another.

A sleeping client does not require reauthentication in the following scenarios:

- Suppose there are two controller s in a mobility group. A client that is associated with one controller goes to sleep and then wakes up and gets associated with the other controller .
- Suppose there are three controller s in a mobility group. A client that is associated with the second controller that is anchored to the first controller goes to sleep, wakes up, and gets associated with the third controller .
- A client sleeps, wakes up and gets associated with the same or different export foreign controller that is anchored to the export anchor.

Restrictions on Authenticating Sleeping Clients

- The sleep client feature works only for WLAN configured with WebAuth security.
- You can configure the sleeping clients only on a per WebAuth parameter-map basis.

- The authentication of sleeping clients feature is supported only on WLANs that have Layer 3 security enabled.
- With Layer 3 security, the Authentication, Passthrough, and On MAC Filter failure web policies are supported. The Conditional Web Redirect and Splash Page Web Redirect web policies are not supported.
- The central web authentication of sleeping clients is not supported.
- The authentication of sleeping clients feature is not supported on guest LANs and remote LANs.
- A guest access sleeping client that has a local user policy is not supported. In this case, the WLAN-specific timer is applied.

Configuring Authentication for Sleeping Clients (GUI)

Procedure

-
- Step 1** Choose **Configuration > Security > Web Auth**.
- Step 2** In the **Webauth Parameter Map** tab, click the parameter map name. The **Edit WebAuth Parameter** window is displayed.
- Step 3** Select **Sleeping Client Status** check box.
- Step 4** Click **Update & Apply to Device**.
-

Configuring Authentication for Sleeping Clients (CLI)

Procedure

	Command or Action	Purpose
Step 1	<pre>[no] parameter-map type webauth {parameter-map-name global} Example: Device(config)# parameter-map type webauth global</pre>	Creates a parameter map and enters parameter-map webauth configuration mode.
Step 2	<pre>sleeping-client [timeout time] Example: Device(config-params-parameter-map) # sleeping-client timeout 100</pre>	<p>Configures the sleeping client timeout to 100 minutes. Valid range is between 10 minutes and 43200 minutes.</p> <p>Note If you do not use the timeout keyword, the sleeping client is configured with the default timeout value of 720 minutes.</p>
Step 3	<pre>end</pre>	Exits parameter-map webauth configuration mode and returns to privileged EXEC mode.

	Command or Action	Purpose
Step 4	(Optional) show wireless client sleeping-client Example: Device# <code>show wireless client sleeping-client</code>	Shows the MAC address of the clients and the time remaining in their respective sessions.
Step 5	(Optional) clear wireless client sleeping-client [mac-address mac-addr] Example: Device# <code>clear wireless client sleeping-client mac-address 00e1.e1e1.0001</code>	<ul style="list-style-type: none"> • clear wireless client sleeping-client—Deletes all sleeping client entries from the sleeping client cache. • clear wireless client sleeping-client mac-address mac-addr—Deletes the specific MAC entry from the sleeping client cache.

Sleeping Clients with Multiple Authentications

Mobility Support for Sleeping Clients

From Release 17.1.1 onwards, mobility support for guest and nonguest sleeping clients.

Supported Combinations of Multiple Authentications

Multiple authentication feature supports sleeping clients configured in the WLAN profile.

The following table outlines the supported combination of multiple authentications:

Table 81: Supported Combinations of Multiple Authentications

Layer 2	Layer 3	Supported
MAB	LWA	Yes
MAB Failure	LWA	Yes
Dot1x	LWA	Yes
PSK	LWA	Yes

Configuring Sleeping Clients with Multiple Authentications

Configuring WLAN for Dot1x and Local Web Authentication

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wlan profile-name wlan-id SSID_name Example: Device(config)# <code>wlan wlan-test 3 ssid-test</code>	Enters WLAN configuration submode. <ul style="list-style-type: none"> • <i>profile-name</i> - Profile name of the configured WLAN. • <i>wlan-id</i> - Wireless LAN identifier. Range is from 1 to 512. • <i>SSID_Name</i> - SSID, which can contain up to 32 alphanumeric characters.
Step 3	security dot1x authentication-list auth-list-name Example: Device(config-wlan)# <code>security dot1x authentication-list default</code>	Enables security authentication list for dot1x security. The configuration is similar for all dot1x security WLANs.
Step 4	security web-auth Example: Device(config-wlan)# <code>security web-auth</code>	Configures web authentication.
Step 5	security web-auth authentication-list authenticate-list-name Example: Device(config-wlan)# <code>security web-auth authentication-list default</code>	Enables authentication list for dot1x security.
Step 6	security web-auth parameter-map parameter-map-name Example: Device(config-wlan)# <code>security web-auth parameter-map global</code>	Maps the parameter map. Note: If the parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.
Step 7	no shutdown Example:	Enables WLAN.

	Command or Action	Purpose
	Device(config-wlan)# no shutdown	

Configuring a WLAN for MAC Authentication Bypass and Local Web Authentication

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan profile-name wlan-id SSID_name Example: Device(config)# wlan wlan-test 3 ssid-test	Enters WLAN configuration submenu. <ul style="list-style-type: none"> • <i>profile-name</i> - Profile name of the configured WLAN. • <i>wlan-id</i> - Wireless LAN identifier. Range is from 1 to 512. • <i>SSID_Name</i> - SSID, which can contain up to 32 alphanumeric characters.
Step 3	mac-filtering list-name Example: Device(config-wlan)# mac-filtering cat-radius	Sets the MAC filtering parameters.
Step 4	no security wpa akm dot1x Example: Device(config-wlan)# no security wpa akm dot1x	Disables security AKM for dot1x.
Step 5	no security wpa wpa2 ciphers aes Example: Device(config-wlan)# no security wpa wpa2 ciphers aes	Disables the WPA2 cipher. aes —Encryption type that specifies WPA/AES support.
Step 6	security web-auth parameter-map parameter-map-name Example: Device(config-wlan)# security web-auth parameter-map global	Maps the parameter map. Note: If parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.
Step 7	no shutdown Example:	Enables WLAN.

	Command or Action	Purpose
	Device(config-wlan) # <code>no shutdown</code>	

Configuring a WLAN for Local Web Authentication and MAC Filtering

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wlan profile-name wlan-id SSID_name Example: Device(config) # <code>wlan wlan-test 3 ssid-test</code>	Enters WLAN configuration submode. <ul style="list-style-type: none"> • <i>profile-name</i> - Profile name of the configured WLAN. • <i>wlan-id</i> - Wireless LAN identifier. Range is from 1 to 512. • <i>SSID_Name</i> - SSID, which can contain up to 32 alphanumeric characters.
Step 3	mac-filtering list-name Example: Device(config-wlan) # <code>mac-filtering cat-radius</code>	Sets the MAC filtering parameters.
Step 4	no security wpa akm dot1x Example: Device(config-wlan) # <code>no security wpa akm dot1x</code>	Disables security Authenticated Key Management (AKM) for dot1x.
Step 5	no security wpa wpa2 ciphers aes Example: Device(config-wlan) # <code>no security wpa wpa2 ciphers aes</code>	Disables the WPA2 cipher. aes: Encryption type that specifies WPA/AES support.
Step 6	security web-auth on-macfilter-failure Example: Device(config-wlan) # <code>security web-auth on-macfilter-failure wlan-id</code>	Configures the fallback policy with MAC filtering and web authentication.
Step 7	security web-auth parameter-map parameter-map-name	Maps the parameter map.

	Command or Action	Purpose
	Example: Device(config-wlan)# security web-auth parameter-map global	Note: If the parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.
Step 8	no shutdown Example: Device(config-wlan)# no shutdown	Enables WLAN.

Configuring a PSK + LWA in a WLAN

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan profile-name wlan-id SSID_name Example: Device(config)# wlan wlan-test 3 ssid-test	Enters WLAN configuration submenu. <ul style="list-style-type: none"> • <i>profile-name</i> - Profile name of the configured WLAN. • <i>wlan-id</i> - Wireless LAN identifier. Range is from 1 to 512. • <i>SSID_Name</i> - SSID, which can contain up to 32 alphanumeric characters.
Step 3	no security wpa akm dot1x Example: Device(config-wlan)# no security wpa akm dot1x	Disables security AKM for dot1x.
Step 4	security web-auth Example: Device(config-wlan)# security web-auth	Enables web authentication for a WLAN.
Step 5	no security wpa wpa2 ciphers aes Example: Device(config-wlan)# no security wpa wpa2 ciphers aes	Disables the WPA2 cipher. aes: Encryption type that specifies WPA/AES support.
Step 6	security wpa psk set-key ascii ascii/hex key Example: Device(config-wlan)# security wpa psk set-key ascii 0 1234567	Configures the preshared key on a WLAN.

	Command or Action	Purpose
Step 7	security wpa akm psk Example: Device(config-wlan) # security wpa akm psk	Configures PSK support.
Step 8	security web-auth authentication-list <i>authenticate-list-name</i> Example: Device(config-wlan) # security web-auth authentication-list default	Enables the authentication list for dot1x security.
Step 9	security web-auth parameter-map <i>parameter-map-name</i> Example: Device(config-wlan) # security web-auth parameter-map global	Maps the parameter map. Note: If the parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

Configuring a Sleeping Client

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	parameter-map type webauth <i>{parameter-map-name global}</i> Example: Device(config) # parameter-map type webauth MAP-2	Creates a parameter map and enters <i>parameter-map-name</i> configuration mode. The specific configuration commands supported for a global parameter map defined with the global keyword differ from the commands supported for a named parameter map defined with the <i>parameter-map-name</i> argument.
Step 3	sleeping client [timeout time] Example: Device(config-params-parameter-map) # sleeping-client timeout 60	Configures the sleeping client timeout, in minutes. The available range for the <i>time</i> argument is from 10 to 43200. Note: If you do not use the timeout keyword, the sleeping client is configured with the default timeout value of 720 minutes.

Verifying a Sleeping Client Configuration

To verify a sleeping client configuration, use the following command:

```
Device# show wireless client sleeping-client
Total number of sleeping-client entries: 1

MAC Address                               Remaining time (mm:ss)
-----
2477.031b.aa18                             59:56
```

Multi Authentication Combination with 802.1X Authentication and Local Web Authentication

Feature History for Multiauthentication Combination of 802.1X and Local Web Authentication

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 82: Feature History for Multiauthentication Combination of 802.1X and Local Web Authentication

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.11.1	Multiauthentication Combination of 802.1X and Local Web Authentication	This feature supports the merging of applied policies during multiauthentication of 802.1X or MAC authentication bypass (MAB) and local web authentication (LWA).

Information About Multiauthentication Combination with 802.1X Authentication and Local Web Authentication

In a wireless setup, for example, in a university, clients authenticate through 802.1X authentication. Because the 802.1X (dot1X) authentication process is secure and does not require user intervention, the end-users are unaware of the network that their devices are connected to. This could lead to serious concerns if they connect to the university's wireless network and post inappropriate content or access restricted content.

To avoid this situation, web authentication (webauth) and 802.1X authentication are configured in the network. End-user consent is used as a part of webauth to inform users that they are connected to the university's Wi-Fi network.

When the end-users accept the credentials for consent, AAA policies are not applied. The AAA policies that were applied earlier are deleted, resulting in a VLAN change and client disconnection.

A new command is introduced in Cisco IOS XE Dublin 17.11.1 to fix this issue. When you run the **consent activation-mode merge** command, the policy that is applied through consent is merged with the policy applied

for 802.1X or MAC Authentication Bypass (MAB) authentication, thereby allowing clients to access the network. This command is available in parameter-map mode, which is configured with **type consent** command.

Limitations for Multi Authentication Combination of 802.1X and Local Web Authentication

The following are the limitations for multiauthentication combination of 802.1X authentication and LWA:

- It is not possible to configure this feature on the controller GUI.
- SNMP is not supported.
- When the **consent activation-mode merge** command is not configured on the webauth parameter map, the default activation mode is Replace. This means that the user profile for consent replaces all the user profile policies that were previously applied.

Enabling the Multiauthentication Combination of 802.1X Authentication and Local Web Authentication (CLI)

Before you begin

Ensure that you have working knowledge of multiauthentication concepts, LWA (consent), and AAA override.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enter global configuration mode.
Step 2	parameter-map type webauth <i>parameter-map-name</i> Example: Device(config)# <code>parameter-map type webauth parameter-map1</code>	Configures the webauth type parameter. Enters the parameter map configuration mode.
Step 3	type consent Example: Device(config-params-parameter-map)# <code>type consent</code>	Configures the type as consent .
Step 4	[no] consent {activation-mode merge email} Example: Device(config-params-parameter-map)# <code>consent activation-mode merge</code>	Enables policy activation mode and merges the previous policy. Run the no form of this command to disable the feature.

Verifying Multiauthentication Combination with 802.1X Authentication and Local Web Authentication

To verify the multiauthentication combination with 802.1X authentication and LWA, run the following command:

```
Device# show parameter-map type webauth lwa-consent
Parameter Map Name      : lwa_consent
Banner Title            : Consent Title
Banner Text             : Please accept the consent
Type                   : consent
Auth-proxy Init State time : 300 sec
Webauth max-http connection : 200
Webauth logout-window   : Enabled
Webauth success-window  : Enabled
Consent Email           : Disabled
Activation Mode         : Merge
Sleeping-Client         : Disabled
Webauth login-auth-bypass:
```

CHAPTER 98

Central Web Authentication

- [Information About Central Web Authentication, on page 1089](#)
- [How to Configure ISE, on page 1090](#)
- [How to Configure Central Web Authentication on the Controller, on page 1092](#)
- [Authentication for Sleeping Clients, on page 1100](#)
- [Sleeping Clients with Multiple Authentications, on page 1102](#)

Information About Central Web Authentication

Central web authentication offers the possibility to have a central device that acts as a web portal (in this example, the ISE). The major difference compared to the usual local web authentication is that it is shifted to Layer 2 along with MAC filtering or dot1x authentication. The concept also differs in that the radius server (ISE in this example) returns special attributes that indicate to the switch that a web redirection must occur. This solution eliminates any delay to start the web authentication.

The following are the different types of web authentication methods:

- **Local Web Authentication (LWA):** Configured as Layer 3 security on the controller, the web authentication page and the pre-authentication ACL are locally configured on the controller. The controller intercepts http(s) traffic and redirects the client to the internal web page for authentication. The credentials entered by the client on the login page is authenticated by the controller locally or through a RADIUS or LDAP server.
- **External Web Authentication (EWA):** Configured as Layer 3 security on the controller, the controller intercepts http(s) traffic and redirects the client to the login page hosted on the external web server. The credentials entered by the client on the login page is authenticated by the controller locally or through a RADIUS or LDAP server. The pre-authentication ACL is configured statically on the controller.
- **Central Web Authentication (CWA):** Configured mostly as Layer 2 security on the controller, the redirection URL and the pre-authentication ACL reside on ISE and are pushed during layer 2 authentication to the controller. The controller redirects all web traffic from the client to the ISE login page. ISE validates the credentials entered by the client through HTTPS and authenticates the user.

Globally, if the MAC address of the client station is not known by the radius server (but other criteria can also be used), the server returns the redirection attributes, and the controller authorizes the station (using the MAC filtering) but places an access list to redirect the web traffic to the portal.

Once the user logs into the guest portal, it is possible to re-authenticate the client so that a new Layer 2 MAC filtering occurs using the Change of Authorization (CoA). This way, the ISE remembers that it was a webauth user and pushes the necessary authorization attributes to the controller for accessing the network.

**Note**

- In Central Web Authentication (CWA) with dual VLAN posture scenario, Cisco AireOS and IOS-XE controller performs 2 and 3 EAPOL handshakes respectively. If a client is stuck in a quarantine VLAN because of any break in EAPOL handshake due to client or network issue, you need to analyze the client or network issue.
- However, you can manually disconnect or reconnect the client to come out of the quarantine loop (or) click the Scan Again on AnyConnect (Or) enable posture lease (Or) use the ISE posture sync feature.
- If the controller has no switch virtual interface (SVI) in the client subnet or VLAN, the controller has to use any of the other SVIs and send traffic as defined in the routing table. This means that the traffic is sent to another gateway in the core of the network; this traffic then reaches the client subnet. Firewalls typically block traffic from and to the same switch, as seen in this scenario, so redirection might not work properly. Workarounds are to allow this behavior on the firewall.

Prerequisites for Central Web Authentication

- Cisco Identity Services Engine (ISE)

How to Configure ISE

To configure ISE, proceed as follows:

1. Create an authorization profile.
2. Create an authentication rule.
3. Create an authorization rule.

Creating an Authorization Profile

Procedure

-
- Step 1** Click **Policy**, and click **Policy Elements**.
 - Step 2** Click **Results**.
 - Step 3** Expand **Authorization**, and click **Authorization Profiles**.
 - Step 4** Click **Add** to create a new authorization profile for central webauth.
 - Step 5** In the **Name** field, enter a name for the profile. For example, CentralWebauth.
 - Step 6** Choose **ACCESS_ACCEPT** from the Access Type drop-down list.

- Step 7** Check the **Web Redirection (CWA, MDM, NSP, CPP)** check box, and choose **Centralized Web Auth** from the drop-down list.
- Step 8** In the **ACL** field, enter the name of the ACL that defines the traffic to be redirected. For example, redirect.
- Step 9** In the **Value** field, choose the default or customized values.
The Value attribute defines whether the ISE sees the default or a custom web portal that the ISE admin created.
- Step 10** Click **Save**.
-

Creating an Authentication Rule

Follow the procedure given below to use the authentication profile and create the authentication rule:

Procedure

- Step 1** In the **Policy > Authentication** page, click **Authentication**.
- Step 2** Enter a name for your authentication rule. For example, MAB.
- Step 3** In the If condition field, select the plus (+) icon.
- Step 4** Choose **Compound condition**, and choose **Wireless_MAB**.
- Step 5** Click the arrow located next to **and ...** in order to expand the rule further.
- Step 6** Click the + icon in the Identity Source field, and choose **Internal endpoints**.
- Step 7** Choose **Continue** from the 'If user not found' drop-down list.
This option allows a device to be authenticated even if its MAC address is not known.
- Step 8** Click **Save**.
-

Creating an Authorization Rule

You can configure many rules in the authorization policy. The *MAC not known* rule is configured in this section:

Procedure

- Step 1** Click **Policy > Authorization**.
- Step 2** In the Rule Name field, enter a name. For example: *Mac not known*.
- Step 3** In the Conditions field, click the plus (+) icon.
- Step 4** Choose **Compound Conditions**, and choose **Wireless_MAB**.
- Step 5** From the settings icon, select **Add Attribute/Value** from the options.
- Step 6** In the Description field, choose **Network Access > AuthenticationStatus** as the attribute from the drop-down list.
- Step 7** Choose the **Equals** operator.

- Step 8** From the right-hand field, choose **UnknownUser**.
- Step 9** In the Permissions field, choose the authorization profile name that you had created earlier.
- The ISE continues even though the user (or MAC) is not known.
- Unknown users are now presented with the Login page. However, once they enter their credentials, they are presented again with an authentication request on the ISE; therefore, another rule must be configured with a condition that is met if the user is a guest user. For example, if `UseridentityGroup Equals Guest` is used then it is assumed that all guests belong to this group.
- Step 10** In the Conditions field, click the plus (+) icon.
- Step 11** Choose **Compound Conditions**, and choose to create a new condition.
- The new rule must come before the *MAC not known* rule.
- Step 12** From the settings icon, select **Add Attribute/Value** from the options.
- Step 13** In the Description field, choose **Network Access > UseCase** as the attribute from the drop-down list.
- Step 14** Choose the **Equals** operator.
- Step 15** From the right-hand field, choose **GuestFlow**.
- Step 16** In the Permissions field, click the plus (+) icon to select a result for your rule.
- You can choose **Standard > PermitAccess** option or create a custom profile to return the attributes that you like.
- When the user is authorized on the login page, the ISE triggers a COA that results in the restart of Layer 2 authentication. When the user is identified as a guest user, the user is authorized.
-

How to Configure Central Web Authentication on the Controller

To configure central web authentication on the controller, proceed as follows:

1. Configure WLAN.
2. Configure policy profile.
3. Configure redirect ACL.
4. Configure AAA for central web authentication.
5. Configure redirect ACL in Flex profile.

Configuring WLAN (GUI)

Before you begin

You need to enable MAC filtering for Layer 2 authentication to download the redirect URL and ACL.

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > WLANs**.
- Step 2** In the **WLANs** window, click the name of the **WLAN** or click **Add** to create a new one.
- Step 3** In the **Add/Edit WLAN** window that is displayed, click the **General** tab to configure the following parameters.
- In the **Profile Name** field, enter or edit the name of the profile.
 - In the **SSID** field, enter or edit the SSID name.
The SSID name can be alphanumeric, and up to 32 characters in length.
 - In the **WLAN ID** field, enter or edit the ID number. The valid range is between 1 and 512.
 - From the **Radio Policy** drop-down list, choose the **802.11** radio band.
 - Using the **Broadcast SSID** toggle button, change the status to either **Enabled** or **Disabled** .
 - Using the **Status** toggle button, change the status to either **Enabled** or **Disabled** .
- Step 4** Click the **Security** tab, and then **Layer 2** tab to configure the following parameters:
- From the **Layer 2 Security Mode** drop-down list, choose **None** . This setting disables Layer 2 security.
 - Enter the **Reassociation Timeout** value, in seconds. This is the time after which a fast transition reassociation times out.
 - Check the **Over the DS** check box to enable Fast Transition over a distributed system.
 - Choose OWE, Opportunistic Wireless Encryption (OWE) provides data confidentiality with encryption over the air between an AP radio and a wireless client. OWE Transition Mode is meant to provide a sort of backwards compatibility.
 - Choose Fast Transition, 802.11r which is the IEEE standard for fast roaming, introduces a new concept of roaming where the initial handshake with a new AP is done even before the corresponding client roams to the target access point. This concept is called Fast Transition.
 - Check the check box to enable MAC filtering in the WLAN.
 - Check the **Lobby Admin Access** check box to enable Lobby Admin access.
- Step 5** Click **Save & Apply to Device**.
-

Configuring WLAN (CLI)

Configure WLAN using commands.

Note You need to enable MAC filtering for Layer 2 authentication to download the redirect URL and ACL.

After completing the WLAN configuration, if the changes are not pushed to all the APs, the following syslog message appears:

```
2021/01/06 16:20:00.597927186 {wncd_x_R0-4}{1}: [wlanmgr-db] [20583]: UUID: 0, ra: 0, TID: 0 (note):
Unable to push WLAN config changes to all APs, cleanup required for WlanId: 2, profile: wlan1 state: Delete
pending
```

If the above mentioned syslog message appears for more than six minutes, reload the controller.

If the controller does not reload and still the syslog message appears, then collect the archive logs, wncd core file, and raise a case by clicking the following link: [Support Case Manager](#).

Procedure

	Command or Action	Purpose
Step 1	wlan wlan-name wlan-id SSID-name Example: <pre>Device(config)# wlan wlanProfileName 1 ngwcSSID</pre>	Enters the WLAN configuration sub-mode. wlan-name is the name of the configured WLAN. wlan-id is the wireless LAN identifier. The range is 1 to 512. SSID-name is the SSID name which can contain 32 alphanumeric characters. Note If you have already configured this command, enter wlan wlan-name command.
Step 2	mac-filtering [name] Example: <pre>Device(config-wlan)# mac-filtering name</pre>	Enables MAC filtering on a WLAN. Note While configuring mac-filtering the default authentication list is considered, if the authentication list is not configured earlier.
Step 3	no security wpa Example: <pre>Device(config-wlan)# no security wpa</pre>	Disable WPA security.
Step 4	no shutdown Example: <pre>Device(config-wlan)# no shutdown</pre>	Enables the WLAN.
Step 5	end Example: <pre>Device(config-wlan)# end</pre>	Returns to privileged EXEC mode.

Example

```
Device# config terminal
Device(config)# wlan wlanProfileName 1 ngwcSSID
Device(config-wlan)# mac-filtering default
Device(config-wlan)# no security wpa
Device(config-wlan)# no shutdown
Device(config-wlan)# end
```

Configuring Policy Profile (CLI)

Configure Policy Profile using commands.

- Note** You need a AAA override to apply policies coming from the AAA or ISE servers. When a redirect URL and redirect ACL is received from the ISE server, NAC is used to trigger the Central Web Authentication (CWA). Both NAC and AAA override must be available in the policy profile to which the client is being associated. The default policy profile is associated to an AP, if the AP is not associated to any other policy profiles.

Procedure

	Command or Action	Purpose
Step 1	wireless profile policy default-policy-profile Example: Device(config)# wireless profile policy default-policy-profile	Sets the policy profile.
Step 2	vlan vlan-id Example: Device(config-wireless-policy)# vlan 41	Maps the VLAN to a policy profile. If vlan-id is not specified, the default native vlan 1 is applied. The valid range for vlan-id is 1 to 4096. Management VLAN is applied if no VLAN is configured on the policy profile.
Step 3	aaa-override Example: Device(config-wireless-policy)# aaa-override	Configures AAA override to apply policies coming from the AAA or ISE servers.
Step 4	nac Example: Device(config-wireless-policy)# nac	Configures Network Access Control in the policy profile. NAC is used to trigger the Central Web Authentication (CWA).
Step 5	no shutdown Example: Device(config-wireless-policy)# no shutdown	Enables the WLAN.

	Command or Action	Purpose
Step 6	end Example: Device(config-wireless-policy)# end	Returns to privileged EXEC mode.

Example

```

Device# configure terminal
Device(config)# wireless profile policy default-policy-profile
Device(config-wireless-policy)# vlan 41
Device(config-wireless-policy)# aaa-override
Device(config-wireless-policy)# nac
Device(config-wireless-policy)# no shutdown
Device(config-wireless-policy)# end

```

Configuring a Policy Profile (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Policy**.
- Step 2** On the **Policy Profile** page, click **Add**.
- Step 3** In the **Add Policy Profile** window, in General Tab, enter a name and description for the policy profile.
- Step 4** To enable the policy profile, set **Status** as Enabled.
- Step 5** Use the slider to enable or disable **Passive Client** and **Encrypted Traffic Analytics**.
- Step 6** (Optional) In the **CTS Policy** section, choose the appropriate status for the following:
- Inline Tagging—a transport mechanism using which a controller embedded wireless controller or access point understands the source SGT.
 - SGACL Enforcement
- Step 7** Specify a default **SGT**. The valid range is from 2 to 65519.
- Step 8** In the WLAN Switching Policy section, choose the following, as required:
- Central Switching
 - Central Authentication
 - Central DHCP
 - Central Association Enable
 - Flex NAT/PAT
- Step 9** Click **Save & Apply to Device**.
-

Creating Redirect ACL

The redirect ACL is a punt ACL that needs to be predefined on the controller (or the AP in case of FlexConnect local switching): the AAA server returns the name of the ACL and not its definition. The redirect ACL defines traffic (matching “deny” statements, as it denies redirection for it) that will be allowed through on the data plane and traffic (matching “permit” statements) that will be sent to the control plane towards the CPU for further processing (that is, the web interception and redirection in this case). The ACL has implicit (that is, the invisible) statements allowing DHCP and DNS traffic towards all IPs, just like it is the case with LWA. It also ends with a statement that a security ACL implicit deny.

Procedure

	Command or Action	Purpose
Step 1	ip access-list extended redirect Example: Device(config)# ip access-list extended redirect	The HTTP and HTTPS browsing does not work without authentication (per the other ACL) as ISE is configured to use a redirect ACL (named redirect).
Step 2	deny ip any host ISE-IP-add Example: Device(config)# deny ip any host 123.123.134.112	Allows traffic to ISE and all other traffic is blocked.
Step 3	deny ip host ISE-IP-add any Example: Device(config)# deny ip host 123.123.134.112 any	Allows traffic to ISE and all other traffic is blocked. Note This ACL is applicable for both local and flex mode.
Step 4	permit TCP any any eq web address/port-number Example: In case of HTTP: Device(config)# permit TCP any any eq www Device(config)# permit TCP any any eq 80 Example: In case of HTTPS: Device(config)# permit TCP any any eq 443	Redirects all HTTP or HTTPS access to the ISE login page. port-number 80 is used for HTTP and port-number 443 is used for HTTPS. For the ACE to allow traffic to ISE, ISE should be configured above the HTTP/HTTPS ACE.
Step 5	end Example: Device(config)# end	Returns to privileged EXEC mode.

Configuring AAA for Central Web Authentication

Procedure

	Command or Action	Purpose
Step 1	aaa server radius dynamic-author Example: Device(config)# aaa server radius dynamic-author	Configures the Change of Authorization (CoA) on the controller.
Step 2	client ISE-IP-add server-key radius-shared-secret Example: Device(config-locsvr-da-radius)# client 123.123.134.112 server-key 0 SECRET	Specifies a RADIUS client and the RADIUS key to be shared between a device and a RADIUS client. ISE-IP-add is the IP address of the RADIUS client. server-key is the radius client server-key. radius-shared-secret covers the following: <ul style="list-style-type: none"> • 0—Specifies unencrypted key. • 6—Specifies encrypted key. • 7—Specifies HIDDEN key. • Word—Unencrypted (cleartext) server key. The RADIUS shared secret should not exceed 240 characters while configuring WSMA data in GUI. Note All these steps work only if the AAA configuration is in place. See the <i>Configuring AAA Authentication</i> for details.

Example

```
Device# config terminal
Device(config)# aaa server radius dynamic-author
Device(config-locsvr-da-radius)# client 123.123.134.112 server-key 0 SECRET
Device(config-locsvr-da-radius)# end
```

Configuring Redirect ACL in Flex Profile (GUI)

The redirect ACL definition must be sent to the access point in the FlexConnect profile. For this, the redirect ACL associated with an AP must be configured in the FlexConnect profile where the client is hosted. If an

access point is not configured with any of the FlexConnect profiles, the default FlexConnect profile is associated with it.

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > Flex**.
 - Step 2** On the **Flex Profile** page, click the name of the FlexConnect profile or click **Add** to create a new FlexConnect profile.
 - Step 3** In the **Add/Edit Flex Profile** window that is displayed, click the **Policy ACL** tab.
 - Step 4** Click **Add** to map an ACL to the FlexConnect profile.
 - Step 5** Choose the ACL name, enable central web authentication, and specify the preauthentication URL filter.
 - Step 6** Click **Save**.
 - Step 7** Click **Update & Apply to Device**.
-

Configuring Redirect ACL in Flex Profile (CLI)

The redirect ACL definition must be sent to the access point in the Flex profile. For this, the redirect ACL associated to an AP must be configured in the Flex profile where the client is being hosted. If an access point is not configured with any of the Flex profiles, the default Flex profile is associated with it.

Note When the ACL is pushed down to the APs, the permission must change from **deny** to **permit** or vice-versa. This change does not occur if the ACL contains an object group, causing the ACL not to be fully translated, which may cause the redirection to fail.

Procedure

	Command or Action	Purpose
Step 1	wireless profile flex default-flex-profile Example: Device(config)# wireless profile flex default-flex-profile	Creates a new flex policy. The default flex profile name is default-flex-profile .
Step 2	acl-policy <i>acl policy name</i> Example: Device(config-wireless-flex-profile)# acl-policy acl1	Configures ACL policy.
Step 3	central-webauth Example: Device (config-wireless-flex-profile-acl)# central-webauth	Configures central web authentication.

	Command or Action	Purpose
Step 4	end Example: Device (config-wireless-flex-profile-acl) # end	Returns to privileged EXEC mode.

Troubleshooting Central Web Authentication

Init-State timer running out

Problem Issue: The client devices are deauthenticated by the controller if users fail to enter their credentials in a limited time interval. The clients are deauthenticated after three times the time configured for the init-state timeout in the controller.

Problem Explanation: This is the expected functionality as the init-state timeout is not directly applicable for central web authentication; instead, it is the reap timer's value which is three times the init-state time plus five seconds ($3 * \text{init-state timeout} + 5$) that determines the time interval in seconds for client deauthentication. For example, if you have configured the init-state timeout as 10 seconds, then the client devices are deauthenticated if users fail to enter their credentials after 35 seconds; that is $(3 * 10 + 5) = 35$ seconds.

Authentication for Sleeping Clients

Information About Authenticating Sleeping Clients

Clients with guest access that have had successful web authentication are allowed to sleep and wake up without having to go through another authentication process through the login page. You can configure the duration for which sleeping clients should be remembered for before reauthentication becomes necessary. The valid range is 10 minutes to 43200 minutes, with the default being 720 minutes. You can also configure this duration on WebAuth parameter map that is mapped to a WLAN. Note that the sleeping client timer comes into effect due to instances such as idle timeout, session timeout, disabling of the WLAN, and the AP being nonoperational.

This feature is supported in the following FlexConnect scenario: local switching and central authentication.

Caution If the MAC address of a client that goes to sleep mode is spoofed, the fake device such as a laptop can be authenticated.

Mobility Scenarios

Following are some guidelines in a mobility scenario:

- L2 roaming in the same subnet is supported.
- Anchor sleeping timer is applicable.
- The sleeping client information is shared between multiple autoanchors when a sleeping client moves from one anchor to another.

A sleeping client does not require reauthentication in the following scenarios:

- Suppose there are two controller s in a mobility group. A client that is associated with one controller goes to sleep and then wakes up and gets associated with the other controller .
- Suppose there are three controller s in a mobility group. A client that is associated with the second controller that is anchored to the first controller goes to sleep, wakes up, and gets associated with the third controller .
- A client sleeps, wakes up and gets associated with the same or different export foreign controller that is anchored to the export anchor.

Restrictions on Authenticating Sleeping Clients

- The sleep client feature works only for WLAN configured with WebAuth security.
- You can configure the sleeping clients only on a per WebAuth parameter-map basis.
- The authentication of sleeping clients feature is supported only on WLANs that have Layer 3 security enabled.
- With Layer 3 security, the Authentication, Passthrough, and On MAC Filter failure web policies are supported. The Conditional Web Redirect and Splash Page Web Redirect web policies are not supported.
- The central web authentication of sleeping clients is not supported.
- The authentication of sleeping clients feature is not supported on guest LANs and remote LANs.
- A guest access sleeping client that has a local user policy is not supported. In this case, the WLAN-specific timer is applied.

Configuring Authentication for Sleeping Clients (GUI)

Procedure

- Step 1** Choose **Configuration > Security > Web Auth**.
- Step 2** In the **Webauth Parameter Map** tab, click the parameter map name. The **Edit WebAuth Parameter** window is displayed.
- Step 3** Select **Sleeping Client Status** check box.
- Step 4** Click **Update & Apply to Device**.
-

Configuring Authentication for Sleeping Clients (CLI)

Procedure

	Command or Action	Purpose
Step 1	<p>[no] parameter-map type webauth {<i>parameter-map-name</i> global}</p> <p>Example:</p> <pre>Device(config)# parameter-map type webauth global</pre>	Creates a parameter map and enters parameter-map webauth configuration mode.
Step 2	<p>sleeping-client [timeout <i>time</i>]</p> <p>Example:</p> <pre>Device(config-params-parameter-map)# sleeping-client timeout 100</pre>	<p>Configures the sleeping client timeout to 100 minutes. Valid range is between 10 minutes and 43200 minutes.</p> <p>Note If you do not use the timeout keyword, the sleeping client is configured with the default timeout value of 720 minutes.</p>
Step 3	end	Exits parameter-map webauth configuration mode and returns to privileged EXEC mode.
Step 4	<p>(Optional) show wireless client sleeping-client</p> <p>Example:</p> <pre>Device# show wireless client sleeping-client</pre>	Shows the MAC address of the clients and the time remaining in their respective sessions.
Step 5	<p>(Optional) clear wireless client sleeping-client [mac-address <i>mac-addr</i>]</p> <p>Example:</p> <pre>Device# clear wireless client sleeping-client mac-address 00e1.e1e1.0001</pre>	<ul style="list-style-type: none"> • clear wireless client sleeping-client—Deletes all sleeping client entries from the sleeping client cache. • clear wireless client sleeping-client mac-address <i>mac-addr</i>—Deletes the specific MAC entry from the sleeping client cache.

Sleeping Clients with Multiple Authentications

Mobility Support for Sleeping Clients

From Release 17.1.1 onwards, mobility support for guest and nonguest sleeping clients.

Supported Combinations of Multiple Authentications

Multiple authentication feature supports sleeping clients configured in the WLAN profile.

The following table outlines the supported combination of multiple authentications:

Table 83: Supported Combinations of Multiple Authentications

Layer 2	Layer 3	Supported
MAB	LWA	Yes
MAB Failure	LWA	Yes
Dot1x	LWA	Yes
PSK	LWA	Yes

Configuring Sleeping Clients with Multiple Authentications

Configuring WLAN for Dot1x and Local Web Authentication

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan profile-name wlan-id SSID_name Example: Device(config)# wlan wlan-test 3 ssid-test	Enters WLAN configuration submenu. <ul style="list-style-type: none"> • <i>profile-name</i> - Profile name of the configured WLAN. • <i>wlan-id</i> - Wireless LAN identifier. Range is from 1 to 512. • <i>SSID_Name</i> - SSID, which can contain up to 32 alphanumeric characters.
Step 3	security dot1x authentication-list auth-list-name Example: Device(config-wlan)# security dot1x authentication-list default	Enables security authentication list for dot1x security. The configuration is similar for all dot1x security WLANs.
Step 4	security web-auth Example: Device(config-wlan)# security web-auth	Configures web authentication.

	Command or Action	Purpose
Step 5	security web-auth authentication-list <i>authenticate-list-name</i> Example: Device(config-wlan)# security web-auth authentication-list default	Enables authentication list for dot1x security.
Step 6	security web-auth parameter-map <i>parameter-map-name</i> Example: Device(config-wlan)# security web-auth parameter-map global	Maps the parameter map. Note: If the parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.
Step 7	no shutdown Example: Device(config-wlan)# no shutdown	Enables WLAN.

Configuring a WLAN for MAC Authentication Bypass and Local Web Authentication

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan profile-name wlan-id SSID_name Example: Device(config)# wlan wlan-test 3 ssid-test	Enters WLAN configuration submenu. <ul style="list-style-type: none"> • <i>profile-name</i> - Profile name of the configured WLAN. • <i>wlan-id</i> - Wireless LAN identifier. Range is from 1 to 512. • <i>SSID_Name</i> - SSID, which can contain up to 32 alphanumeric characters.
Step 3	mac-filtering list-name Example: Device(config-wlan)# mac-filtering cat-radius	Sets the MAC filtering parameters.
Step 4	no security wpa akm dot1x Example:	Disables security AKM for dot1x.

	Command or Action	Purpose
	Device(config-wlan) # no security wpa akm dot1x	
Step 5	no security wpa wpa2 ciphers aes Example: Device(config-wlan) # no security wpa wpa2 ciphers aes	Disables the WPA2 cipher. aes —Encryption type that specifies WPA/AES support.
Step 6	security web-auth parameter-map parameter-map-name Example: Device(config-wlan) # security web-auth parameter-map global	Maps the parameter map. Note: If parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.
Step 7	no shutdown Example: Device(config-wlan) # no shutdown	Enables WLAN.

Configuring a WLAN for Local Web Authentication and MAC Filtering

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan profile-name wlan-id SSID_name Example: Device(config) # wlan wlan-test 3 ssid-test	Enters WLAN configuration submode. <ul style="list-style-type: none"> • <i>profile-name</i> - Profile name of the configured WLAN. • <i>wlan-id</i> - Wireless LAN identifier. Range is from 1 to 512. • <i>SSID_Name</i> - SSID, which can contain up to 32 alphanumeric characters.
Step 3	mac-filtering list-name Example: Device(config-wlan) # mac-filtering cat-radius	Sets the MAC filtering parameters.
Step 4	no security wpa akm dot1x Example:	Disables security Authenticated Key Management (AKM) for dot1x.

	Command or Action	Purpose
	Device(config-wlan)# no security wpa akm dot1x	
Step 5	no security wpa wpa2 ciphers aes Example: Device(config-wlan)# no security wpa wpa2 ciphers aes	Disables the WPA2 cipher. aes: Excrption type that specifies WPA/AES support.
Step 6	security web-auth on-macfilter-failure Example: Device(config-wlan)# security web-auth on-macfilter-failure wlan-id	Configures the fallback policy with MAC filtering and web authentication.
Step 7	security web-auth parameter-map parameter-map-name Example: Device(config-wlan)# security web-auth parameter-map global	Maps the parameter map. Note: If the parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.
Step 8	no shutdown Example: Device(config-wlan)# no shutdown	Enables WLAN.

Configuring a PSK + LWA in a WLAN

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan profile-name wlan-id SSID_name Example: Device(config)# wlan wlan-test 3 ssid-test	Enters WLAN configuration submode. <ul style="list-style-type: none"> • <i>profile-name</i> - Profile name of the configured WLAN. • <i>wlan-id</i> - Wireless LAN identifier. Range is from 1 to 512. • <i>SSID_Name</i> - SSID, which can contain up to 32 alphanumeric characters.
Step 3	no security wpa akm dot1x Example: Device(config-wlan)# no security wpa akm dot1x	Disables security AKM for dot1x.

	Command or Action	Purpose
Step 4	security web-auth Example: Device(config-wlan)# security web-auth	Enables web authentication for a WLAN.
Step 5	no security wpa wpa2 ciphers aes Example: Device(config-wlan)# no security wpa wpa2 ciphers aes	Disables the WPA2 cipher. aes: Exryption type that specifies WPA/AES support.
Step 6	security wpa psk set-key ascii <i>ascii/hex key</i> Example: Device(config-wlan)# security wpa psk set-key ascii 0 1234567	Configures the preshared key on a WLAN.
Step 7	security wpa akm psk Example: Device(config-wlan)# security wpa akm psk	Configures PSK support.
Step 8	security web-auth authentication-list <i>authenticate-list-name</i> Example: Device(config-wlan)# security web-auth authentication-list default	Enables the authentication list for dot1x security.
Step 9	security web-auth parameter-map <i>parameter-map-name</i> Example: Device(config-wlan)# security web-auth parameter-map global	Maps the parameter map. Note: If the parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

Configuring a Sleeping Client

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	parameter-map type webauth <i>{parameter-map-name global}</i> Example:	Creates a parameter map and enters <i>parameter-map-name</i> configuration mode.

	Command or Action	Purpose
	Device(config)# parameter-map type webauth MAP-2	The specific configuration commands supported for a global parameter map defined with the global keyword differ from the commands supported for a named parameter map defined with the <i>parameter-map-name</i> argument.
Step 3	sleeping client [timeout time] Example: Device(config-params-parameter-map)# sleeping-client timeout 60	Configures the sleeping client timeout, in minutes. The available range for the <i>time</i> argument is from 10 to 43200. Note: If you do not use the timeout keyword, the sleeping client is configured with the default timeout value of 720 minutes.

Verifying a Sleeping Client Configuration

To verify a sleeping client configuration, use the following command:

```
Device# show wireless client sleeping-client
Total number of sleeping-client entries: 1
```

```
MAC Address                               Remaining time (mm:ss)
-----
2477.031b.aa18                            59:56
```

CHAPTER 99

Private Shared Key

- [Information About Private Preshared Key, on page 1109](#)
- [Configuring a PSK in a WLAN \(CLI\), on page 1110](#)
- [Configuring a PSK in a WLAN \(GUI\), on page 1111](#)
- [Applying a Policy Profile to a WLAN \(GUI\), on page 1112](#)
- [Applying a Policy Profile to a WLAN \(CLI\), on page 1112](#)
- [Verifying a Private PSK, on page 1113](#)

Information About Private Preshared Key

With the advent of Internet of Things (IoT), the number of devices that connect to the internet has increased manifold. Not all of these devices support the 802.1x supplicant and need an alternate mechanism to connect to the internet. One of the security mechanisms, WPA-PSK, could be considered as an alternative. With the current configuration, the PSK is the same for all the clients that connect to the same WLAN. In certain deployments, such as educational institutions, this results in the key being shared to unauthorized users leading to security breach. This necessitates the need to provision unique PSKs for different clients on a large scale.

Identity PSKs are unique PSKs created for individuals or groups of users on the same SSID. No complex configuration is required for the clients. It provides the same simplicity of PSK, making it ideal for IoT, Bring your own device (BYOD), and guest deployments.

Identity PSKs are supported on most devices, in which 802.1X is not, enabling stronger security for IoT. It is possible to easily revoke access, for a single device or individual without affecting everyone else. Thousands of keys can easily be managed and distributed through the AAA server.

Note Special characters, such as '<' and '>' are supported in SSID Preshared key.

Note PSK supports whitespace in passwords (before or after or in-between) within double quotes only; single quotes for whitespaces are not supported.

IPSK Solution

During client authentication, the AAA server authorizes the client MAC address and sends the passphrase (if configured) as part of the Cisco-AV pair list. The Cisco Wireless Controller (WLC) receives this as part of the RADIUS response and processes this further for the computation of PSKs.

When a client sends an association request to the SSID broadcast by the corresponding access point, the controller forms the RADIUS request packet with the particular mac address of the client and relays to the RADIUS server.

The RADIUS server performs the authentication and checks whether the client is allowed or not and sends either ACCESS-ACCEPT or ACCESS-REJECT as response to the WLC.

To support Identity PSKs, in addition to sending the authentication response, the authentication server also provides the AV pair passphrase for this specific client. This is used for the computation of the PMK.

The RADIUS server might also provide additional parameters, such as username, VLAN, Quality of Service (QoS), and so on, in the response, that is specific to this client. For multiple devices owned by a single user, the passphrase can remain the same.

Note When the PSK length is less than 15 characters in Federal Information Processing Standard (FIPS), the controller allows the WLAN configuration but displays the following error message on the console:

"AP is allowed to join but corresponding WLAN will not be pushed to the access point"

Configuring a PSK in a WLAN (CLI)

Follow the procedure given below to configure a PSK in a WLAN:

Before you begin

- Security should be configured for a pre-shared key (PSK) in a WLAN.
- If there is no override from the AAA server, the value on the corresponding WLAN is considered for authentication.
- In Federal Information Processing Standard (FIPS) and common criteria mode, ensure that the PSK WLAN has a minimum of 15 ASCII characters, else APs won't join the controller.

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wlan wlan-name wlan-id ssid Example: Device(config)# wlan test-profile 4 abc	Configures the WLAN and SSID.

	Command or Action	Purpose
Step 3	no security wpa akm dot1x Example: Device(config-wlan)# no security wpa akm dot1x	Disables security AKM for dot1x.
Step 4	security wpa akm psk Example: Device(config-wlan)# security wpa akm psk	Configures the security type PSK.
Step 5	security wpa akm psk set-key ascii/hex key Example: Device(config-wlan)# security wpa akm psk set-key ascii 0	Configures the PSK authenticated key management (AKM) shared key. Note You must set the psk set-key before configuring AKM PSK.
Step 6	security wpa akm psk Example: Device(config-wlan)# security wpa akm psk	Configures PSK support.
Step 7	security wpa wpa2 mpsk Example: Device(config-wlan)# security wpa wpa2 mpsk	Configures multi-preshared key (MPSK) support. Note AKM PSK should be enabled for MPSK to work.
Step 8	mac-filtering auth-list-name Example: Device(config-wlan)# mac-filtering test1	Specifies MAC filtering in a WLAN.

Configuring a PSK in a WLAN (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > WLANs**.
- Step 2** On the **Wireless Networks** page, click **Security** tab.
- Step 3** In the **Layer 2** window that is displayed, go to the **WPA Parameters** section.
- Step 4** From the **Auth Key Mgmt** drop-down, select the PSK format and type.
- Step 5** Enter the Pre-Shared Key in hexadecimal characters.
- If you selected the PSK format as HEX, the key length must be exactly 64 characters.
 - If you selected the PSK format as ASCII, the key length must be in the range of 8-63 characters.

Note that once you have configured the key, these details are not visible even if you click on the eye icon next to the preshared key box, due to security reasons.

Step 6 Click **Save & Apply to Device**.

Applying a Policy Profile to a WLAN (GUI)

Procedure

- Step 1** Choose **Configuration > Tags & Profiles > Tags**.
- Step 2** On the **Manage Tags** page, click **Policy** tab.
- Step 3** Click **Add** to view the **Add Policy Tag** window.
- Step 4** Enter a name and description for the policy tag.
- Step 5** Click **Add** to map WLAN and policy.
- Step 6** Choose the WLAN profile to map with the appropriate policy profile, and click the tick icon.
- Step 7** Click **Save & Apply to Device**.

Applying a Policy Profile to a WLAN (CLI)

Follow the procedure given below to a apply policy profile to a WLAN:

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 2	wireless profile policy <i>policy-profile-name</i> Example: Device(config)# wireless profile policy policy-iot	Configures the default policy profile.
Step 3	aaa-override Example: Device(config-wireless-policy)# aaa-override	Configures AAA override to apply policies coming from the AAA server or ISE the Cisco Identify Services Engine (ISE) server.

Verifying a Private PSK

Use the following **show** commands to verify the configuration of a WLAN and a client:

```
Device# show wlan id 2
```

```
WLAN Profile Name      : test_ppsk
=====

CHAPTER 100

Multi-Preshared Key

- [Information About Multi-Preshared Key, on page 1117](#)
- [Restrictions on Multi-PSK, on page 1118](#)
- [Configuring Multi-Preshared Key \(GUI\), on page 1118](#)
- [Configuring Multi-Preshared Key \(CLI\), on page 1121](#)
- [Verifying Multi-PSK Configurations, on page 1122](#)

Information About Multi-Preshared Key

Multi-PSK feature supports multiple PSKs simultaneously on a single SSID. You can use any of the configured PSKs to join the network. This is different from the Identity PSK (iPSK), wherein unique PSKs are created for individuals or groups of users on the same SSID.

From 16.10 onwards, each SSID supports five PSKs, which can be extended

In a traditional PSK, all the clients joining the network use the same password as shown in the below figure.

Figure 30: Traditional PSK

But with multi-PSK, client can use any of the configured pre-shared keys to connect to the network as shown in the below figure.

Figure 31: Multi-PSK

In Multi-PSK, two passwords are configured (deadbeef and beefdead) for the same SSID. In this scenario, clients can connect to the network using either of the passwords.

Restrictions on Multi-PSK

- Central authentication is supported in local, flex, and fabric modes only.
- In central authentication flex mode, the standalone AP allows client join with the highest priority PSK (*priority 0* key). New clients that do not use the highest priority PSK are rejected during the standalone mode.
- Multi-PSK does not support local authentication.

Configuring Multi-Preshared Key (GUI)

Procedure

-
- Step 1** Choose **Configuration** > **Tags & Profiles** > **WLANs**.
 - Step 2** On the **Wireless Networks** page, click the name of the WLAN.
 - Step 3** In the **Edit WLAN** window, click the **Security** tab.
 - Step 4** In the **Layer2** tab, choose the **Layer2 Security Mode** from the following options:
 - None: No Layer 2 security
 - 802.1X: WEP 802.1X data encryption type
 - WPA + WPA2: Wi-Fi Protected Access
 - Static WEP: Static WEP encryption parameters
 - Static WEP+802.1X: Both Static WEP and 802.1X parameters

Parameters	Description
802.1X	
WEP Key Size	Choose the key size. The available values are <i>None</i> , <i>40 bits</i> , and <i>104 bits</i> .
WPA + WPA2	
Protected Management Frame	Choose from the following options: <ul style="list-style-type: none"> • Disabled • Optional • Required
WPA Policy	Check the check box to enable WPA policy.
WPA Encryption	Choose the WPA encryption standard. A WPA encryption standard must be specified if you have enabled WPA policy.
WPA2 Policy	Check the check box to enable WPA2 policy.
WPA2 Encryption	Choose the WPA2 encryption standard. A WPA encryption standard must be specified if you have enabled WPA policy.
Auth Key Mgmt	Choose the rekeying mechanism from the following options: <ul style="list-style-type: none"> • 802.1X • FT + 802.1X • PSK: You must specify the PSK format and a preshared key • Cisco Centralized Key Management: You must specify a Cisco Centralized Key Management Timestamp Tolerance value • 802.1X + Cisco Centralized Key Management: You must specify a Cisco Centralized Key Management Timestamp Tolerance value • FT + 802.1X + Cisco Centralized Key Management: You must specify a Cisco Centralized Key Management Timestamp Tolerance value
Static WEP	

Parameters	Description
Key Size	Choose the key size from the following options: <ul style="list-style-type: none"> • 40 bits • 104 bits
Key Index	Choose a key index from 1 to 4. One unique WEP key index can be applied to each WLAN. As there are only four WEP key indexes, only four WLANs can be configured for static WEP Layer2 encryption.
Key Format	Choose the encryption key format as either ASCII or HEX.
Encryption Key	Enter an encryption key that is 13 characters long.
Static WEP + 802.1X	
Key Size	Choose the key size from the following options: <ul style="list-style-type: none"> • 40 bits • 104 bits
Key Index	Choose a key index from 1 to 4. One unique WEP key index can be applied to each WLAN. As there are only four WEP key indexes, only four WLANs can be configured for static WEP Layer2 encryption.
Key Format	Choose the encryption key format as either ASCII or HEX.
Encryption Key	Enter an encryption key that is 13 characters long.
WEP Key Size	Choose from the following options: <ul style="list-style-type: none"> • None • 40 bits • 104 bits

Step 5 Click **Save & Apply to Device**.

Configuring Multi-Preshared Key (CLI)

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wlan wlan-name wlan-id ssid Example: Device(config)# <code>wlan mywlan 1 SSID_name</code>	Configures WLAN and SSID.
Step 3	no security wpa akm dot1x Example: Device(config-wlan)# <code>no security wpa akm dot1x</code>	Disables security AKM for dot1x.
Step 4	security wpa akm psk Example: Device(config-wlan)# <code>security wpa akm psk</code>	Configures PSK.
Step 5	security wpa wpa2 mpsk Example: Device(config-wlan)# <code>security wpa wpa2 mpsk</code>	Configures multi-PSK.
Step 6	priority priority_value set-key {ascii [0 8] pre-shared-key hex [0 8] pre-shared-key} Example: Device(config-mpsk)# <code>priority 0 set-key ascii 0 deadbeef</code>	Configures PSK priority and all its related passwords. The <i>priority_value</i> ranges from 0 to 4. Note You need to configure priority 0 key for multi-PSK.
Step 7	no shutdown Example: Device(config-mpsk)# <code>no shutdown</code>	Enables WLAN.
Step 8	exit Example: Device(config-wlan)# <code>exit</code>	Exits WLAN configuration mode and returns to configuration mode.

	Command or Action	Purpose
Step 9	end Example: Device(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Verifying Multi-PSK Configurations

To verify the configuration of a WLAN and a client, use the following command:

```
Device# show wlan id 8
WLAN Profile Name      : wlan_8
=====
Identifier              : 8
Network Name (SSID)    : ssid_8
Status                  : Enabled
Broadcast SSID         : Enabled
Universal AP Admin     : Disabled
Max Associated Clients per WLAN : 0
Max Associated Clients per AP per WLAN : 0
Max Associated Clients per AP Radio per WLAN : 200

CHAPTER 101

Multiple Authentications for a Client

- [Information About Multiple Authentications for a Client](#), on page 1125
- [Configuring Multiple Authentications for a Client](#), on page 1127
- [Configure WLAN for Web Authentication on MAC Authentication Bypass Failure with Pre-Shared Key \(CLI\)](#), on page 1133
- [Configure WLAN for Web Authentication on MAC Authentication Bypass Failure with OWE \(CLI\)](#), on page 1135
- [Configure WLAN for Web Authentication on MAC Authentication Bypass Failure with Secure Agile Exchange \(CLI\)](#), on page 1137
- [Configuring 802.1x and Central Web Authentication on Controller \(CLIs\)](#), on page 1138
- [Configuring ISE for Central Web Authentication with Dot1x \(GUI\)](#), on page 1145
- [Verifying Multiple Authentication Configurations](#), on page 1147

Information About Multiple Authentications for a Client

Multiple Authentication feature is an extension of Layer 2 and Layer 3 security types supported for client join.

Note You can enable both L2 and L3 authentication for a given SSID.

Note The Multiple Authentication feature is applicable for regular clients only.

Information About Supported Combination of Authentications for a Client

The Multiple Authentications for a Client feature supports multiple combination of authentications for a given client configured in the WLAN profile.

The following table outlines the supported combination of authentications:

Layer 2	Layer 3	Supported
MAB	CWA	Yes

MAB	LWA	Yes
MAB + PSK	-	Yes
MAB + 802.1X	-	Yes
MAB Failure	LWA	Yes
802.1X	CWA	Yes
802.1X	LWA	Yes
PSK	-	Yes
PSK	LWA	Yes
PSK	CWA	Yes
iPSK	-	Yes
iPSK	CWA	Yes
iPSK + MAB	CWA	Yes
iPSK	LWA	No
MAB Failure + PSK	LWA	Yes
MAB Failure + PSK	CWA	No
MAB Failure + OWE	LWA	Yes
MAB Failure + SAE	LWA	Yes

From 16.10.1 onwards, 802.1X configurations on WLAN support web authentication configurations with WPA or WPA2 configuration.

The feature also supports the following AP modes:

- Local
- FlexConnect
- Fabric

Jumbo Frame Support for RADIUS Packets

This document describes how to configure IP Maximum Transmission Unit (MTU) size for RADIUS server. RADIUS packets will get fragmented based on IP MTU, if source interface is attached to RADIUS group. With the new design, the RADIUS packets get fragmented at interface IP MTU configured value.

Note Fragmentation size is fixed.

Combination of Authentications on MAC Failure Not Supported on a Client

The following table outlines the combination of authentications on MAC failure that are not supported on a given client:

Authentication Types	Foreign	Anchor	Supported
WPA3-OWE+LWA	Cisco AireOS	Cisco Catalyst 9800 Controller	No
WPA3-SAE+LWA	Cisco AireOS	Cisco Catalyst 9800 Controller	No

Configuring Multiple Authentications for a Client

Configuring WLAN for 802.1X and Local Web Authentication (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > WLANs**.
 - Step 2** Select the required WLAN from the list of WLANs displayed.
 - Step 3** Choose **Security > Layer2** tab.
 - Step 4** Select the security method from the **Layer 2 Security Mode** drop-down list.
 - Step 5** In the **Auth Key Mgmt**, check the **802.1x** check box.
 - Step 6** Check the **MAC Filtering** check box to enable the feature.
 - Step 7** After MAC Filtering is enabled, from the **Authorization List** drop-down list, choose an option.
 - Step 8** Choose **Security > Layer3** tab.
 - Step 9** Check the **Web Policy** check box to enable web authentication policy.
 - Step 10** From the **Web Auth Parameter Map** and the **Authentication List** drop-down lists, choose an option.
 - Step 11** Click **Update & Apply to Device**.
-

Configuring WLAN for 802.1X and Local Web Authentication (CLI)

Procedure

	Command or Action	Purpose
Step 1	<code>configure terminal</code> Example: <code>Device# configure terminal</code>	Enters global configuration mode.
Step 2	<code>wlan profile-name wlan-id SSID_Name</code>	Enters WLAN configuration sub-mode.

	Command or Action	Purpose
	<p>Example:</p> <pre>Device(config)# wlan wlan-test 3 ssid-test</pre>	<ul style="list-style-type: none"> • <i>profile-name</i>: Profile name of the configured WLAN. • <i>wlan-id</i>: Wireless LAN identifier. Range is from 1 to 512. • <i>SSID_Name</i>: SSID that can contain 32 alphanumeric characters. <p>Note If you have already configured this command, enter the wlan profile-name command.</p>
Step 3	<p>security dot1x authentication-list <i>auth-list-name</i></p> <p>Example:</p> <pre>Device(config-wlan)# security dot1x authentication-list default</pre>	<p>Enables security authentication list for dot1x security.</p> <p>The configuration is similar for all dot1x security WLANs.</p>
Step 4	<p>security web-auth</p> <p>Example:</p> <pre>Device(config-wlan)# security web-auth</pre>	<p>Enables web authentication.</p>
Step 5	<p>security web-auth authentication-list <i>authenticate-list-name</i></p> <p>Example:</p> <pre>Device(config-wlan)# security web-auth authentication-list default</pre>	<p>Enables authentication list for dot1x security.</p>
Step 6	<p>security web-auth parameter-map <i>parameter-map-name</i></p> <p>Example:</p> <pre>Device(config-wlan)# security web-auth parameter-map WLAN1_MAP</pre>	<p>Maps the parameter map.</p> <p>Note If a parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.</p>
Step 7	<p>no shutdown</p> <p>Example:</p> <pre>Device(config-wlan)# no shutdown</pre>	<p>Enables the WLAN.</p>

Example

```
wlan wlan-test 3 ssid-test
security dot1x authentication-list default
security web-auth
security web-auth authentication-list default
security web-auth parameter-map WLAN1_MAP
no shutdown
```

Configuring WLAN for Preshared Key (PSK) and Local Web Authentication (GUI)

Procedure

-
- Step 1** Choose **Configuration** > **Tags & Profiles** > **WLANs**.
- Step 2** Select the required WLAN.
- Step 3** Choose **Security** > **Layer2** tab.
- Step 4** Select the security method from the **Layer 2 Security Mode** drop-down list.
- Step 5** In the Auth Key Mgmt, uncheck the **802.1x** check box.
- Step 6** Check the **PSK** check box.
- Step 7** Enter the **Pre-Shared Key** and choose the PSK Format from the **PSK Format** drop-down list and the PSK Type from the **PSK Type** drop-down list.
- Step 8** Choose **Security** > **Layer3** tab.
- Step 9** Check the **Web Policy** checkbox to enable web authentication policy.
- Step 10** Choose the Web Auth Parameter Map from the **Web Auth Parameter Map** drop-down list and the authentication list from the **Authentication List** drop-down list.
- Step 11** Click **Update & Apply to Device**.
-

Configuring WLAN for Preshared Key (PSK) and Local Web Authentication

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wlan profile-name wlan-id SSID_Name Example: Device(config)# <code>wlan wlan-test 3 ssid-test</code>	Enters WLAN configuration sub-mode. <ul style="list-style-type: none"> • <i>profile-name</i> - Is the profile name of the configured WLAN. • <i>wlan-id</i> - Is the wireless LAN identifier. Range is from 1 to 512. • <i>SSID_Name</i> - Is the SSID which can contain 32 alphanumeric characters. <p>Note If you have already configured this command, enter wlan profile-name command.</p>

	Command or Action	Purpose
Step 3	security wpa psk set-key <i>ascii/hex key password</i> Example: Device(config-wlan)# security wpa psk set-key ascii 0 PASSWORD	Configures the PSK shared key.
Step 4	no security wpa akm dot1x Example: Device(config-wlan)# no security wpa akm dot1x	Disables security AKM for dot1x.
Step 5	security wpa akm psk Example: Device(config-wlan)# security wpa akm psk	Configures the PSK support.
Step 6	security web-auth Example: Device(config-wlan)# security web-auth	Enables web authentication for WLAN.
Step 7	security web-auth authentication-list <i>authenticate-list-name</i> Example: Device(config-wlan)# security web-auth authentication-list webauth	Enables authentication list for dot1x security.
Step 8	security web-auth parameter-map <i>parameter-map-name</i> Example: (config-wlan)# security web-auth parameter-map WLAN1_MAP	Configures the parameter map. Note If parameter map is not associated with a WLAN, the configuration is considered from the global parameter map.

Example

```
wlan wlan-test 3 ssid-test
 security wpa psk set-key ascii 0 PASSWORD
 no security wpa akm dot1x
 security wpa akm psk
 security web-auth
 security web-auth authentication-list webauth
 security web-auth parameter-map WLAN1_MAP
```

Configuring WLAN for PSK or Identity Preshared Key (iPSK) and Central Web Authentication (GUI)

Procedure

-
- Step 1** Choose **Configuration > Tags & Profiles > WLANs**.
- Step 2** Select the required WLAN.
- Step 3** Choose **Security > Layer2** tab.
- Step 4** Select the security method from the **Layer 2 Security Mode** drop-down list.
- Step 5** In the **Auth Key Mgmt**, uncheck the **802.1x** check box.
- Step 6** Check the **PSK** check box.
- Step 7** Enter the **Pre-Shared Key** and choose the PSK Format from the **PSK Format** drop-down list and the PSK Type from the **PSK Type** drop-down list.
- Step 8** Check the **MAC Filtering** check box to enable the feature.
- Step 9** With MAC Filtering enabled, choose the Authorization List from the **Authorization List** drop-down list.
- Step 10** Choose **Security > Layer3** tab.
- Step 11** Check the **Web Policy** checkbox to enable web authentication policy.
- Step 12** Choose the Web Auth Parameter Map from the **Web Auth Parameter Map** drop-down list and the authentication list from the **Authentication List** drop-down list.
- Step 13** Click **Update & Apply to Device**.
-

Configuring WLAN for PSK or Identity Preshared Key (iPSK) and Central Web Authentication

Configuring WLAN

Procedure

	Command or Action	Purpose
Step 1	configure terminal Example: Device# <code>configure terminal</code>	Enters global configuration mode.
Step 2	wlan profile-name wlan-id SSID_Name Example: Device(config)# <code>wlan wlan-test 3 ssid-test</code>	Enters WLAN configuration sub-mode. <ul style="list-style-type: none"> • <i>profile-name</i> - Is the profile name of the configured WLAN. • <i>wlan-id</i> - Is the wireless LAN identifier. Range is from 1 to 512.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • <i>SSID_Name</i> - Is the SSID which can contain 32 alphanumeric characters. <p>Note If you have already configured this command, enter wlan profile-name command.</p>
