ARGUMENT	DESCRIPTION
R	Reserved bit
M	More Fragments bit
D	Don't Fragment bit

To further refine a rule using the `fragbits` keyword, you can specify any operator described in the Fragbit Operators table after the argument value in the rule.

Fragbit Operators

OPERATOR	DESCRIPTION
plus sign (**+**)	The packet must match against all specified bits.
asterisk (*****)	The packet can match against any of the specified bits.
exclamation point (**!**)	The packet meets the criteria if none of the specified bits are set.

For example, to generate an event against packets that have the Reserved Bit set (and possibly any other bits), use `R+` as the `fragbits` value.

Inspecting the IP Header Identification Value

LICENSE: Protection

The `id` keyword tests the IP header fragment identification field against the value you specify in the keyword's argument. Some denial-of-service tools and scanners set this field to a specific number that is easy to detect. For example, in SID 630, which detects a Synscan portscan, the `id` value is set to `39426`, the static value used as the ID number in packets transmitted by the scanner.

IMPORTANT! `id` argument values must be numeric.

Identifying Specified IP Options

LICENSE: Protection

The `IPopts` keyword allows you to search packets for specified IP header options. The IPoption Arguments table lists the available argument values.

IPoption Arguments

ARGUMENT	DESCRIPTION
rr	record route
eol	end of list
nop	no operation
ts	time stamp
sec	IP security option
lsrr	loose source routing
ssrr	strict source routing
satid	stream identifier

Analysts most frequently watch for strict and loose source routing because these options may be an indication of a spoofed source IP address.

Identifying Specified IP Protocol Numbers

LICENSE: Protection

The `ip_proto` keyword allows you to identify packets with the IP protocol specified as the keyword's value. You can specify the IP protocols as a number, 0 through 255. You can find the complete list of protocol numbers at http://www.iana.org/assignments/protocol-numbers. You can combine these numbers with the following operators: `<`, `>`, or `!`. For example, to inspect traffic with any protocol that is not ICMP, use `!1` as a value to the `ip_proto` keyword. You can also use the `ip_proto` keyword multiple times in a single rule; note, however, that the rules engine interprets multiple instances of the keyword as having a Boolean AND relationship. For example, if you create a rule containing `ip_proto:!3; ip_proto:!6`, the rule ignores traffic using the GGP protocol AND the TCP protocol.

Inspecting a Packet's Type of Service

LICENSE: Protection

Some networks use the type of service (ToS) value to set precedence for packets traveling on that network. The `tos` keyword allows you to test the packet's IP header ToS value against the value you specify as the keyword's argument. Rules using the `tos` keyword will trigger on packets whose ToS is set to the specified value and that meet the rest of the criteria set forth in the rule.

IMPORTANT! Argument values for `tos` must be numeric.

The ToS field has been deprecated in the IP header protocol and replaced with the Differentiated Services Code Point (DSCP) field.

Inspecting a Packet's Time-To-Live Value

LICENSE: Protection

A packet's time-to-live (ttl) value indicates how many hops it can make before it is dropped. You can use the `ttl` keyword to test the packet's IP header ttl value against the value, or range of values, you specify as the keyword's argument. It may be helpful to set the `ttl` keyword parameter to a low value such as 0 or 1, as low time-to-live values are sometimes indicative of a traceroute or intrusion evasion attempt. (Note, though, that the appropriate value for this keyword depends on your managed device placement and network topology.) Use syntax as follows:

- Use an integer from 0 to 255 to set a specific value for the TTL value. You can also precede the value with an equal (=) sign (for example, you can specify `5` or `=5`).
- Use a hyphen (-) to specify a range of TTL values (for example, `0-2` specifies all values 0 through 2, `-5` specifies all values 0 through 5, and `5-` specifies all values 5 through 255).
- Use the greater than (>) sign to specify TTL values greater than a specific value (for example, `>3` specifies all values greater than 3).
- Use the greater than and equal to signs (>=) to specify TTL values greater than or equal to a specific value (for example, `>=3` specifies all values greater than or equal to 3).
- Use the less than (<) sign to specify TTL values less than a specific value (for example, `<3` specifies all values less than 3).
- Use the less than and equal to signs (<=) to specify TTL values less than or equal to a specific value (for example, `<=3` specifies all values less than or equal to 3).

Inspecting ICMP Header Values

LICENSE: Protection

The Sourcefire 3D System supports keywords that you can use to identify attacks and security policy violations in the headers of ICMP packets. Note, however, that predefined rules exist that detect most ICMP types and codes. Consider enabling an existing rule or creating a local rule based on an existing rule; you may be able to find a rule that meets your needs more quickly than if you build an ICMP rule from scratch.

See the following sections for more information about ICMP-specific keywords:

- Identifying Static ICMP ID and Sequence Values on page 1134
- Inspecting the ICMP Message Type on page 1134
- Inspecting the ICMP Message Code on page 1135

Identifying Static ICMP ID and Sequence Values

LICENSE: Protection

The ICMP identification and sequence numbers help associate ICMP replies with ICMP requests. In normal traffic, these values are dynamically assigned to packets. Some covert channel and Distributed Denial of Server (DDoS) programs use static ICMP ID and sequence values. The following keywords allow you to identify ICMP packets with static values.

icmp_id

The `icmp_id` keyword inspects an ICMP echo request or reply packet's ICMP ID number. Use a numeric value that corresponds with the ICMP ID number as the argument for the `icmp_id` keyword.

icmp_seq

The `icmp_seq` keyword inspects an ICMP echo request or reply packet's ICMP sequence. Use a numeric value that corresponds with the ICMP sequence number as the argument for the `icmp_seq` keyword.

Inspecting the ICMP Message Type

LICENSE: Protection

Use the `itype` keyword to look for packets with specific ICMP message type values. You can specify either a valid ICMP type value (see http://www.iana.org/assignments/icmp-parameters or http://www.faqs.org/rfcs/rfc792.html for a full list of ICMP type numbers) or an invalid ICMP type value to test for different types of traffic. For example, attackers may set ICMP type values out of range to cause denial of service and flooding attacks.

You can specify a range for the `itype` argument value using less than (<) and greater than (>).

For example:

- <35
- >36
- 3<>55

TIP! See http://www.iana.org/assignments/icmp-parameters or http://www.faqs.org/rfcs/rfc792.html for a full list of ICMP type numbers.

Inspecting the ICMP Message Code

LICENSE: Protection

ICMP messages sometimes include a code value that provides details when a destination is unreachable. (See the second section in http://www.iana.org/assignments/icmp-parameters for a full list of ICMP message codes correlated with the message types for which they can be used.)

You can use the `icode` keyword to identify packets with specific ICMP code values. You can choose to specify either a valid ICMP code value or an invalid ICMP code value to test for different types of traffic.

You can specify a range for the `icode` argument value using less than (<) and greater than (>).

For example:

- to find values less than 35, specify `<35.`
- to find values greater than 36, specify `>36.`
- to find values between 3 and 55, specify `3<>55.`

TIP! You can use the `icode` and `itype` keywords together to identify traffic that matches both. For example, to identify ICMP traffic that contains an ICMP Destination Unreachable code type with an ICMP Port Unreachable code type, specify an `itype` keyword with a value of 3 (for Destination Unreachable) and an `icode` keyword with a value of 3 (for Port Unreachable).

Inspecting TCP Header Values and Stream Size

LICENSE: Protection

The Sourcefire 3D System supports keywords that are designed to identify attacks attempted using TCP headers of packets and TCP stream size. See the following sections for more information about TCP-specific keywords:

- Inspecting the TCP Acknowledgement Value on page 1136
- Inspecting TCP Flag Combinations on page 1136
- Applying Rules to a TCP or UDP Client or Server Flow on page 1138
- Identifying Static TCP Sequence Numbers on page 1140
- Identifying TCP Windows of a Given Size on page 1140
- Identifying TCP Streams of a Given Size on page 1140

Inspecting the TCP Acknowledgement Value

LICENSE: Protection

You can use the `ack` keyword to compare a value against a packet's TCP acknowledgement number. The rule triggers if a packet's TCP acknowledgement number matches the value specified for the `ack` keyword.

Argument values for `ack` must be numeric.

Inspecting TCP Flag Combinations

LICENSE: Protection

You can use the `flags` keyword to specify any combination of TCP flags that, when set in an inspected packet, cause the rule to trigger.

IMPORTANT! In situations where you would traditionally use `A+` as the value for `flags`, you should instead use the `flow` keyword with a value of `established`. Generally, you should use the `flow` keyword with a value of `stateless` when using flags to ensure that all combinations of flags are detected. See Applying Rules to a TCP or UDP Client or Server Flow on page 1138 for more information about the `flow` keyword.

You can specify the values described in the flag Arguments table for the `flag` keyword.

flag Arguments

ARGUMENT	TCP FLAG
Ack	Acknowledges data.
Psh	Data should be sent in this packet.
Syn	A new connection.
Urg	Packet contains urgent data.
Fin	A closed connection.
Rst	An aborted connection.
CWR	An ECN congestion window has been reduced. This was formerly the R1 argument, which is still supported for backward compatibility.
ECE	ECN echo. This was formerly the R2 argument, which is still supported for backward compatibility.

TIP! For more information on Explicit Congestion Notification (ECN), see the information provided at: http://www.faqs.org/rfcs/rfc3168.html.

When using the `flags` keyword, you can use an operator to indicate how the system performs matches against multiple flags. The Operators Used with flags table describes these operators.

Operators Used with flags

OPERATOR	DESCRIPTION	EXAMPLE
all	The packet must contain all specified flags.	Select `Urg` and `all` to specify that a packet must contain the Urgent flag and may contain any other flags.
any	The packet can contain any of the specified flags.	Select `Ack`, `Psh`, and `any` to specify that either or both the `Ack` and `Psh` flags must be set to trigger the rule, and that other flags may also be set on a packet.
not	The packet must **not** contain the specified flag set.	Select `Urg` and `not` to specify that the Urgent flag is **not** set on packets that trigger this rule.

Applying Rules to a TCP or UDP Client or Server Flow

LICENSE: Protection

You can use the `flow` keyword to select packets for inspection by a rule based on session characteristics. The `flow` keyword allows you to specify the direction of the traffic flow to which a rule applies, applying rules to either the client flow or server flow. To specify how the `flow` keyword inspects your packets, you can set the direction of traffic you want analyzed, the state of packets inspected, and whether the packets are part of a rebuilt stream.

Stateful inspection of packets occurs when rules are processed. If you want a TCP rule to ignore stateless traffic (traffic without an established session context), you must add the `flow` keyword to the rule and select the **Established** argument for the keyword. If you want a UDP rule to ignore stateless traffic, you must add the `flow` keyword to the rule and select either the **Established** argument or a directional argument, or both. This causes the TCP or UDP rule to perform stateful inspection of a packet.

When you add a directional argument, the rules engine inspects only those packets that have an established state with a flow that matches the direction specified. For example, if you add the `flow` keyword with the `established` argument and the `From Client` argument to a rule that triggers when a TCP or UDP connection is detected, the rules engine only inspects packets that are sent from the client.

TIP! For maximum performance, always include a `flow` keyword in a TCP rule or a UDP session rule.

To specify flow, select the `flow` keyword from the **Detection Options** list on the Create Rule page and click **Add Option**. Next, select the arguments from the list provided for each field.

The State-Related flow Arguments table describes the stream-related arguments you can specify for the `flow` keyword:

State-Related flow Arguments

ARGUMENT	DESCRIPTION
Established	Triggers on established connections.
Stateless	Triggers regardless of the state of the stream processor.

The flow Directional Arguments table describes the directional options you can specify for the `flow` keyword:

flow Directional Arguments

ARGUMENT	DESCRIPTION
To Client	Triggers on server responses.
To Server	Triggers on client responses.
From Client	Triggers on client responses.
From Server	Triggers on server responses.

Notice that `From Server` and `To Client` perform the same function, as do `To Server` and `From Client`. These options exist to add context and readability to the rule. For example, if you create a rule designed to detect an attack from a server to a client, use `From Server`. But, if you create a rule designed to detect an attack from the client to the server, use `From Client`.

The Stream-Related flow Arguments table describes the stream-related arguments you can specify for the `flow` keyword:

Stream-Related flow Arguments

ARGUMENT	DESCRIPTION
Ignore Stream Traffic	Does not trigger on rebuilt stream packets.
Only Stream Traffic	Triggers only on rebuilt stream packets.

To use the `Established` and `Only Stream traffic` arguments in TCP or UDP stream preprocessing rules, TCP or UDP stream preprocessing must be enabled as needed. When the required preprocessor is disabled and you enable rules that include these arguments, you are prompted whether to enable the required TCP or UDP preprocessor when you save the policy. See Using TCP Stream Preprocessing on page 966 and Reassembling TCP Streams on page 975 for information about using TCP stream preprocessing. See Using UDP Stream Preprocessing on page 982 for information about using UDP stream preprocessing. See Automatically Enabling Advanced Settings on page 813 for more information on automatically enabling processors.

For example, you can use `To Server, Established, Only Stream Traffic` as the value for the `flow` keyword to detect traffic, traveling from a client to the

server in an established session, that has been reassembled by the stream preprocessor.

Identifying Static TCP Sequence Numbers

LICENSE: Protection

The `seq` keyword allows you to specify a static sequence number value. Packets whose sequence number matches the specified argument trigger the rule containing the keyword. While this keyword is used rarely, it is helpful in identifying attacks and network scans that use generated packets with static sequence numbers.

Identifying TCP Windows of a Given Size

LICENSE: Protection

You can use the `window` keyword to specify the TCP window size you are interested in. A rule containing this keyword triggers whenever it encounters a packet with the specified TCP window size. While this keyword is used rarely, it is helpful in identifying attacks and network scans that use generated packets with static TCP window sizes.

Identifying TCP Streams of a Given Size

LICENSE: Protection

You can use the `stream_size` keyword in conjunction with the stream preprocessor to determine the size in bytes of a TCP stream, using the format:

`direction`,*`operator`*,*`bytes`*

where *`bytes`* is number of bytes.

Note that you must separate each option in the argument with a comma (,).

TCP stream preprocessing must be enabled to use the `stream_size` keyword in a rule. See Using TCP Stream Preprocessing on page 966 for more information. When TCP stream preprocessing is disabled and you enable rules that use this keyword, you are prompted whether to enable TCP stream preprocessing when you save the policy. See Automatically Enabling Advanced Settings on page 813 for more information.

The stream_size Keyword Directional Arguments table describes the case-insensitive directional options you can specify for the `stream_size` keyword:

stream_size Keyword Directional Arguments

Argument	Description
client	triggers on a stream from the client matching the specified stream size.
server	triggers on a stream from the server matching the specified stream size.
both	triggers on traffic from the client and traffic from the server both matching the specified stream size. For example, the argument `both, >, 200` would trigger when traffic from the client is greater than 200 bytes AND traffic from the server is greater than 200 bytes.
either	triggers on traffic from either the client or the server matching the specified stream size, whichever occurs first. For example, the argument `either, >, 200` would trigger when traffic from the client is greater than 200 bytes OR traffic from the server is greater than 200 bytes.

The stream_size Keyword Argument Operators table describes the operators you can use with the `stream_size` keyword:

stream_size Keyword Argument Operators

Operator	Description
=	equal to
!=	not equal to
>	greater than
<	less than
>=	greater than or equal to
<=	less than or equal to

For example, you could use `client, >=, 5001216` as the argument for the `stream_size` keyword to detect a TCP stream traveling from a client to a server and greater than or equal to 5001216 bytes.

Enabling and Disabling TCP Stream Reassembly

LICENSE: Protection

You can use the `stream_reassemble` keyword to enable or disable TCP stream reassembly for a single connection when inspected traffic on the connection matches the conditions of the rule. Optionally, you can use this keyword multiple times in a rule.

Use the following syntax to enable or disable stream reassembly:

```
enable|disable, server|client|both, option, option
```

The stream_reassemble Optional Arguments table describes the optional arguments you can use with the `stream_reassemble` keyword.

stream_reassemble Optional Arguments

ARGUMENT	DESCRIPTION
noalert	Generate no events regardless of any other detection options specified in the rule.
fastpath	Ignore the rest of the connection traffic when there is a match.

For example, the following rule disables TCP client-side stream reassembly without generating an event on the connection where a 200 OK status code is detected in an HTTP response:

```
alert tcp any 80 -> any any (flow:to_client, established;
content: “200 OK”; stream_reassemble:disable, client,
noalert
```

Note that the TCP stream preprocessor must be enabled to allow processing of rules using the `stream_reassemble` keyword. When the TCP stream preprocessor is disabled and you enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

To use stream_reassemble:

Access: Admin/Intrusion Admin

▶ On the Create Rule page, select `stream_reassemble` in the drop-down list and click **Add Option**.

The `stream_reassemble` section appears.

Extracting SSL Information from a Session

License: Protection

You can use SSL rule keywords to invoke the Secure Sockets Layer (SSL) preprocessor and extract information about SSL version and session state from packets in an encrypted session.

When a client and server communicate to establish an encrypted session using SSL or Transport Layer Security (TLS), they exchange handshake messages. Although the data transmitted in the session is encrypted, the handshake messages are not.

The SSL preprocessor extracts state and version information from specific handshake fields. Two fields within the handshake indicate the version of SSL or TLS used to encrypt the session and the stage of the handshake.

For more information, see the following sections:

- ssl_state on page 1143
- ssl_version on page 1144

ssl_state

License: Protection

The `ssl_state` keyword can be used to match against state information for an encrypted session. To check for two or more SSL versions used simultaneously, use multiple `ssl_version` keywords in a rule.

When a rule uses the `ssl_state` keyword, the rules engine invokes the SSL preprocessor to check traffic for SSL state information.

For example, to detect an attacker's attempt to cause a buffer overflow on a server by sending a `ClientHello` message with an overly long challenge length and too much data, you could use the `ssl_state` keyword with `client_hello` as an argument then check for abnormally large packets.

Use a comma-separated list to specify multiple arguments for the SSL state. When you list multiple arguments, the system evaluates them using the OR operator. For example, if you specify `client_hello` and `server_hello` as arguments, the system evaluates the rule against traffic that has a `client_hello` OR a `server_hello`.

You can also negate any argument; for example:

```
!client_hello, !unknown
```

To ensure the connection has reached each of a set of states, multiple rules using the ssl_state rule option should be used.

Note that the SSL preprocessor must be enabled to allow processing of rules using the `ssl_state` keyword. When the SSL preprocessor is disabled and you enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

The `ssl_state` keyword takes the following identifiers as arguments:

`ssl_state` Arguments

Argument	Purpose
`client_hello`	Matches against a handshake message with `ClientHello` as the message type, where the client requests an encrypted session.
`server_hello`	Matches against a handshake message with `ServerHello` as the message type, where the server responds to the client's request for an encrypted session.
`client_keyx`	Matches against a handshake message with `ClientKeyExchange` as the message type, where the client transmits a key to the server to confirm receipt of a key from the server.
`server_keyx`	Matches against a handshake message with `ServerKeyExchange` as the message type, where the client transmits a key to the server to confirm receipt of a key from the server.
`unknown`	Matches against any handshake message type.

ssl_version

License: Protection

The `ssl_version` keyword can be used to match against version information for an encrypted session. When a rule uses the `ssl_version` keyword, the rules engine invokes the SSL preprocessor to check traffic for SSL version information.

For example, if you know there is a buffer overflow vulnerability in SSL version 2, you could use the `ssl_version` keyword with the `sslv2` argument to identify traffic using that version of SSL.

Use a comma-separated list to specify multiple arguments for the SSL version. When you list multiple arguments, the system evaluates them using the OR operator. For example, if you wanted to identify any encrypted traffic that was not

using SSLv2, you could add `ssl_version:ssl_v3,tls1.0,tls1.1,tls1.2` to a rule. The rule would evaluate any traffic using SSL Version 3, TLS Version 1.0, TLS Version 1.1, or TLS Version 1.2.

Note that the SSL preprocessor must be enabled to allow processing of rules using the `ssl_version` keyword. When the SSL preprocessor is disabled and you enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

The `ssl_version` keyword takes the following SSL/TLS version identifiers as arguments:

`ssl_version` Arguments

Argument	Purpose
`sslv2`	Matches against traffic encoded using Secure Sockets Layer (SSL) Version 2.
`sslv3`	Matches against traffic encoded using Secure Sockets Layer (SSL) Version 3.
`tls1.0`	Matches against traffic encoded using Transport Layer Security (TLS) Version 1.0.
`tls1.1`	Matches against traffic encoded using Transport Layer Security (TLS) Version 1.1.
`tls1.2`	Matches against traffic encoded using Transport Layer Security (TLS) Version 1.2.

Inspecting Application Layer Protocol Values

License: Protection

Although preprocessors perform most of the normalization and inspection of application layer protocol values, you can continue to inspect application layer values using the keywords described in the following sections:

- RPC on page 1146
- ASN.1 on page 1146
- urilen on page 1148
- DCE/RPC Keywords on page 1149
- SIP Keywords on page 1154
- GTP Keywords on page 1157
- Modbus Keywords on page 1174
- DNP3 Keywords on page 1177

RPC

LICENSE: Protection

The `rpc` keyword identifies Open Network Computing Remote Procedure Call (ONC RPC) services in TCP or UDP packets. This allows you to detect attempts to identify the RPC programs on a host. Intruders can use an RPC portmapper to determine if any of the RPC services running on your network can be exploited. They can also attempt to access other ports running RPC without using portmapper. The rpc Keyword Arguments table lists the arguments that the `rpc` keyword accepts.

rpc Keyword Arguments

ARGUMENT	DESCRIPTION
application	The RPC application number
procedure	The RPC procedure invoked
version	The RPC version

To specify the arguments for the `rpc` keyword, use the following syntax:

`application``,`*`procedure`*`,`*`version`*

where *`application`* is the RPC application number, *`procedure`* is the RPC procedure number, and *`version`* is the RPC version number. You must specify all arguments for the `rpc` keyword — if you are not able to specify one of the arguments, replace it with an asterisk (`*`).

For example, to search for RPC portmapper (which is the RPC application indicated by the number 100000), with any procedure or version, use `100000,*,*` as the arguments.

ASN.1

LICENSE: Protection

The `asn1` keyword allows you to decode a packet or a portion of a packet, looking for various malicious encodings.

The asn.1 Keyword Arguments table describes the arguments for the `asn1` keyword.

asn.1 Keyword Arguments

Argument	Description
Bitstring Overflow	Detects invalid, remotely exploitable bitstring encodings.
Double Overflow	Detects a double ASCII encoding that is larger than a standard buffer. This is known to be an exploitable function in Microsoft Windows, but it is unknown at this time which services may be exploitable.
Oversize Length	Detects ASN.1 type lengths greater than the supplied argument. For example, if you set the Oversize Length to 500, any ASN.1 type greater than 500 triggers the rule.
Absolute Offset	Sets an absolute offset from the beginning of the packet payload. (Remember that the offset counter starts at byte 0.) For example, if you want to decode SNMP packets, set Absolute Offset to 0 and do not set a Relative Offset. Absolute Offset may be positive or negative.
Relative Offset	This is the relative offset from the last successful content match, `pcre`, or `byte_jump`. To decode an ASN.1 sequence right after the content "foo", set Relative Offset to 0, and do not set an Absolute Offset. Relative Offset may be positive or negative. (Remember that the offset counter starts at 0.)

For example, there is a known vulnerability in the Microsoft ASN.1 Library that creates a buffer overflow, allowing an attacker to exploit the condition with a specially crafted authentication packet. When the system decodes the asn.1 data, exploit code in the packet could execute on the host with system-level privileges or could cause a DoS condition. The following rule uses the `asn1` keyword to detect attempts to exploit this vulnerability:

```
alert tcp $EXTERNAL_NET any -> $HOME_NET 445
(flow:to_server, established; content:"|FF|SMB|73|"; nocase;
offset:4; depth:5;
asn1:bitstring_overflow,double_overflow,oversize_length
100,relative_offset 54;)
```

The above rule generates an event against TCP traffic traveling from any IP address defined in the $EXTERNAL_NET variable, from any port, to any IP address defined in the $HOME_NET variable using port 445. In addition, it only executes the rule on established TCP connections to servers. The rule then tests for specific content in specific locations. Finally, the rule uses the `asn1` keyword

to detect bitstring encodings and double ASCII encodings and to identify asn.1 type lengths over 100 bytes in length starting 55 bytes from the end of the last successful content match. (Remember that the `offset` counter starts at byte 0.)

urilen

LICENSE: Protection

You can use the `urilen` keyword in conjunction with the HTTP Inspect preprocessor to inspect HTTP traffic for URIs of a specific length, less than a maximum length, greater than a minimum length, or within a specified range.

After the HTTP Inspect preprocessor normalizes and inspects the packet, the rules engine evaluates the packet against the rule and determines whether the URI matches the length condition specified by the `urilen` keyword. You can use this keyword to detect exploits that attempt to take advantage of URI length vulnerabilities, for example, by creating a buffer overflow that allows the attacker to cause a DoS condition or execute code on the host with system-level privileges.

Note the following when using the `urilen` keyword in a rule:

- In practice, you always use the `urilen` keyword in combination with the `flow:established` keyword and one or more other keywords.
- TCP stream preprocessing must be enabled. See Using TCP Stream Preprocessing on page 966 for more information.
- The HTTP preprocessor must be enabled to allow processing of rules using the `urilen` keyword. When the HTTP preprocessor is disabled and you enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.
- The rule protocol is always TCP. See Specifying Protocols on page 1078 for more information.
- Target ports are always HTTP ports. See Defining Ports in Intrusion Rules on page 1082 and Optimizing Predefined Default Variables on page 197 for more information.

You specify the URI length using a decimal number of bytes, less than (<) and greater than (>).

For example:

- specify `5` to detect a URI 5 bytes long.
- specify `< 5` (separated by one space character) to detect a URI less than 5 bytes long.
- specify `> 5` (separated by one space character) to detect a URI greater than 5 bytes long.
- specify `3 <> 5` (with one space character before and after <>) to detect a URI between 3 and 5 bytes long.

For example, there is a known vulnerability in Novell's server monitoring and diagnostics utility iMonitor version 2.4, which comes with eDirectory version 8.8. A packet containing an excessively long URI creates a buffer overflow, allowing an attacker to exploit the condition with a specially crafted packet that could execute on the host with system-level privileges or could cause a DoS condition. The following rule uses the `urilen` keyword to detect attempts to exploit this vulnerability:

```
alert tcp $EXTERNAL_NET any -> $HOME_NET $HTTP_PORTS
(msg:"EXPLOIT eDirectory 8.8 Long URI iMonitor buffer
overflow attempt";flow:to_server,established;
urilen:> 8192; uricontent:"/nds/"; nocase;
classtype:attempted-admin; sid:x; rev:1;)
```

The above rule generates an event against TCP traffic traveling from any IP address defined in the $EXTERNAL_NET variable, from any port, to any IP address defined in the $HOME_NET variable using the ports defined in the $HTTP_PORTS variable. In addition, packets are evaluated against the rule only on established TCP connections to servers. The rule uses the `urilen` keyword to detect any URI over 8192 bytes in length. Finally, the rule searches the URI for the specific case-insensitive content `/nds/`.

DCE/RPC Keywords

LICENSE: Protection

The three DCE/RPC keywords described in the DCE/RPC Keywords table allow you to monitor DCE/RPC session traffic for exploits. When the system processes rules with these keywords, it invokes the DCE/RPC preprocessor. See Decoding DCE/RPC Traffic on page 836 for more information.

The DCE/RPC preprocessor must be enabled to allow processing of rules that include these keywords. When the DCE/RPC preprocessor is disabled and you enable rules that use these keywords, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

DCE/RPC Keywords

USE THIS KEYWORD...	IN THIS WAY...	TO DETECT...
`dce_iface`	alone	packets identifying a specific DCE/RPC service
`dce_opnum`	preceded by `dce_iface`	packets identifying specific DCE/RPC service operations
`dce_stub_data`	preceded by `dce_iface` + `dce_opnum`	stub data defining a specific operation request or response

Note in the table that you should always precede `dce_opnum` with `dce_iface`, and you should always precede `dce_stub_data` with `dce_iface` + `dce_opnum`.

You can also use these DCE/RPC keywords in combination with other rule keywords. Note that for DCE/RPC rules, you use the `byte_jump`, `byte_test`, and `byte_extract` keywords with their **DCE/RPC** arguments selected. For more information, see Using Byte_Jump and Byte_Test on page 1109 and Reading Packet Data into Keyword Arguments on page 1185.

Sourcefire recommends that you include at least one `content` keyword in rules that include DCE/RPC keywords to ensure that the rules engine uses the fast pattern matcher, which increases processing speed and improves performance. Note that the rules engine uses the fast pattern matcher when a rule includes at least one `content` keyword, regardless of whether you enable the `content` keyword **Use Fast Pattern Matcher** argument. See Searching for Content Matches on page 1093 and Use Fast Pattern Matcher on page 1104 for more information.

You can use the DCE/RPC version and adjoining header information as the matching content in the following cases:

- the rule does not include another `content` keyword
- the rule contains another `content` keyword, but the DCE/RPC version and adjoining information represent a more unique pattern than the other content

  For example, the DCE/RPC version and adjoining information are more likely to be unique than a single byte of content.

You should end qualifying rules with one of the following version and adjoining information content matches:

- For connection-oriented DCE/RPC rules, use the content `|05 00 00|` (for major version 05, minor version 00, and the request PDU (protocol data unit) type 00).
- For connectionless DCE/RPC rules, use the content `|04 00|` (for version 04, and the request PDU type 00).

In either case, position the `content` keyword for version and adjoining information as the last keyword in the rule to invoke the fast pattern matcher without repeating processing already completed by the DCE/RPC preprocessor. Note that placing the `content` keyword at the end of the rule applies to version content used as a device to invoke the fast pattern matcher, and not necessarily to other content matches in the rule.

See the following sections for more information:

- dce_iface on page 1151
- dce_opnum on page 1152
- dce_stub_data on page 1153

dce_iface

LICENSE: Protection

You can use the `dce_iface` keyword to identify a specific DCE/RPC service.

Optionally, you can also use `dce_iface` in combination with the `dce_opnum` and `dce_stub_data` keywords to further limit the DCE/RPC traffic to inspect. See dce_opnum on page 1152 and dce_stub_data on page 1153 for more information.

Note that the DCE/RPC preprocessor must be enabled to allow processing of rules using the `dce_iface` keyword. When the DCE/RPC preprocessor is disabled and you enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

A fixed, sixteen-byte Universally Unique Identifier (UUID) identifies the application interface assigned to each DCE/RPC service. For example, the UUID 4b324fc8-670-01d3-1278-5a47bf6ee188 identifies the DCE/RPC lanmanserver service, also known as the srvsvc service, which provides numerous management functions for sharing peer-to-peer printers, files, and SMB named pipes. The DCE/RPC preprocessor uses the UUID and associated header values to track DCE/RPC sessions.

The interface UUID is comprised of five hexadecimal strings separated by hyphens:

```
<4hexbytes>-<2hexbytes>-<2hexbytes>-<2hexbytes>-<6hexbytes>
```

You specify the interface by entering the entire UUID including hyphens, as seen in the following UUID for the netlogon interface:

```
12345678-1234-abcd-ef00-01234567cffb
```

Note that you must specify the first three strings in the UUID in big endian byte order. Although published interface listings and protocol analyzers typically display UUIDs in the correct byte order, you might encounter a need to rearrange the UUID byte order before entering it. Consider the following messenger service UUID shown as it might sometimes be displayed in raw ASCII text with the first three strings in little endian byte order:

```
f8 91 7b 5a 00 ff d0 11 a9 b2 00 c0 4f b6 e6 fc
```

You would specify the same UUID for the `dce_iface` keyword by inserting hyphens and putting the first three strings in big endian byte order as follows:

```
5a7b91f8-ff00-11d0-a9b2-00c04fb6e6fc
```

Although a DCE/RPC session can include requests to multiple interfaces, you should include only one `dce_iface` keyword in a rule. Create additional rules to detect additional interfaces.

DCE/RPC application interfaces also have interface version numbers. You can optionally specify an interface version with an operator indicating that the version equals, does not equal, is less than, or greater than the specified value.

Both connection-oriented and connectionless DCE/RPC can be fragmented in addition to any TCP segmentation or IP fragmentation. Typically, it is not useful to associate any DCE/RPC fragment other than the first with the specified interface, and doing so may result in a large number of false positives. However, for flexibility you can optionally evaluate all fragments against the specified interface.

The dce_iface Arguments table summarizes the dce_iface keyword arguments.

dce_iface Arguments

Argument	Description
Interface UUID	The UUID, including hyphens, that identifies the application interface of the specific service that you want to detect in DCE/RPC traffic. Any request associated with the specified interface would match the interface UUID.
Version	Optionally, the application interface version number 0 to 65535 and an operator indicating whether to detect a version greater than (>), less than (<), equal to (=), or not equal to (!) the specified value.
All Fragments	Optionally, enable to match against the interface in all associated DCE/RPC fragments and, if specified, on the interface version. This argument is disabled by default, indicating that the keyword matches only if the first fragment or the entire unfragmented packet is associated with the specified interface. Note that enabling this argument may result in false positives.

dce_opnum

License: Protection

You can use the dce_opnum keyword in conjunction with the DCE/RPC preprocessor to detect packets that identify one or more specific operations that a DCE/RPC service provides.

Note that the DCE/RPC preprocessor must be enabled to allow processing of rules using the dce_opnum keyword. When the DCE/RPC preprocessor is disabled and you enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

Client function calls request specific service functions, which are referred to in DCE/RPC specifications as *operations*. An operation number (opnum) identifies a specific operation in the DCE/RPC header. It is likely that an exploit would target a specific operation.

For example, the UUID 12345678-1234-abcd-ef00-01234567cffb identifies the interface for the netlogon service, which provides several dozen different operations. One of these is operation 6, the NetrServerPasswordSet operation.

You should precede a **dce_opnum** keyword with a **dce_iface** keyword to identify the service for the operation, as shown in the following example. See dce_iface on page 1151 for more information.

You can specify a single decimal value 0 to 65535 for a specific operation, a range of operations separated by a hyphen, or a comma-separated list of operations and ranges in any order.

Any of the following examples would specify valid netlogon operation numbers:

```
15
15-18
15, 18-20
15, 20-22, 17
15, 18-20, 22, 24-26
```

dce_stub_data

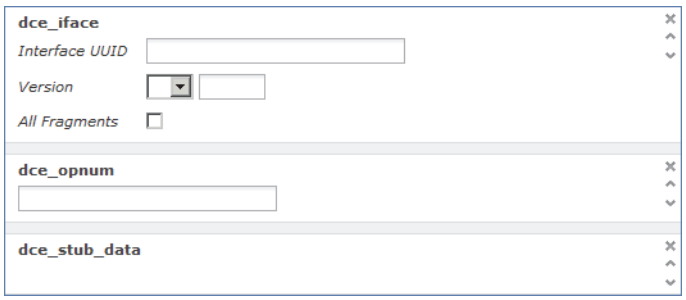
LICENSE: Protection

You can use the **dce_stub_data** keyword in conjunction with the DCE/RPC preprocessor to specify that the rules engine should start inspection at the beginning of the stub data, regardless of any other rule options. Packet payload rule options that follow the **dce_stub_data** keyword are applied relative to the stub data buffer.

Note that the DCE/RPC preprocessor must be enabled to allow processing of rules using the **dce_stub_data** keyword. When the DCE/RPC preprocessor is disabled and you enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

DCE/RPC stub data provides the interface between a client procedure call and the DCE/RPC run-time system, the mechanism that provides the routines and services central to DCE/RPC. DCE/RPC exploits are identified in the stub data portion of the DCE/RPC packet. Because stub data is associated with a specific operation or function call, you should always precede **dce_stub_data** with **dce_**

`iface` and `dce_opnum` to identify the related service and operation, as shown in the following example.



The `dce_stub_data` keyword has no arguments. See dce_iface on page 1151 and dce_opnum on page 1152 for more information.

SIP Keywords

LICENSE: Protection

Four SIP keywords allow you to monitor SIP session traffic for exploits.

Note that the SIP protocol is vulnerable to denial of service (DoS) attacks. Rules addressing these attacks can benefit from rate-based attack prevention. See Adding Dynamic Rule States on page 783 and Preventing Rate-Based Attacks on page 997 for more information.

See the following sections for more information:

- sip_header on page 1154
- sip_body on page 1155
- sip_method on page 1155
- sip_stat_code on page 1156

sip_header

LICENSE: Protection

You can use the `sip_header` keyword to start inspection at the beginning of the extracted SIP request or response header and restrict inspection to header fields.

The `sip_header` keyword has no arguments. See sip_method on page 1155 and sip_stat_code on page 1156 for more information.

The following example rule fragment points to the SIP header and matches the CSeq header field:

```
alert udp any any -> any 5060 ( sip_header;
content:"CSeq"; )
```

Note that the SIP preprocessor must be enabled to allow processing of rules using the `sip_header` keyword. When the SIP preprocessor is disabled and you

enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

sip_body

LICENSE: Protection

You can use the `sip_body` keyword to start inspection at the beginning of the extracted SIP request or response message body and restrict inspection to the message body.

The `sip_body` keyword has no arguments.

The following example rule fragment points to the SIP message body and matches a specific IP address in the c (connection information) field in extracted SDP data:

```
alert udp any any -> any 5060 ( sip_body;
content:"c=IN 192.168.12.14"; )
```

Note that rules are not limited to searching for SDP content. The SIP preprocessor extracts the entire message body and makes it available to the rules engine.

Note also that the SIP preprocessor must be enabled to allow processing of rules using the `sip_body` keyword. When the SIP preprocessor is disabled and you enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

sip_method

LICENSE: Protection

A *method* field in each SIP request identifies the purpose of the request. You can use the `sip_method` keyword to test SIP requests for specific methods. Separate multiple methods with commas.

You can specify any of the following currently defined SIP methods:

```
ack, benotify, bye, cancel, do, info, invite, join, message,
notify, options, prack, publish, quath, refer, register,
service, sprack, subscribe, unsubscribe, update
```

Methods are case-insensitive. You can separate multiple methods with commas.

Because new SIP methods might be defined in the future, you can also specify a custom method, that is, a method that is not a currently defined SIP method. Accepted field values are defined in RFC 2616, which allows all characters except control characters and separators such as `=`, `(`, and `}`. See RFC 2616 for the

complete list of excluded separators. When the system encounters a specified custom method in traffic, it will inspect the packet header but not the message.

The system supports up to 32 methods, including the 21 currently defined methods and an additional 11 methods. The system ignores any undefined methods that you might configure. Note that the 32 total methods includes methods specified using the **Methods to Check** SIP preprocessor option. See Selecting SIP Preprocessor Options on page 899 for more information.

You can specify only one method when you use negation. For example:

```
!invite
```

Note, however, that multiple `sip_method` keywords in a rule are linked with an **AND** operation. For example, to test for all extracted methods except `invite` and `cancel`, you would use two negated `sip_method` keywords:

```
sip_method: !invite
sip_method: !cancel
```

The SIP preprocessor must be enabled to allow processing of rules using the `sip_method` keyword. When the SIP preprocessor is disabled and you enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

Sourcefire recommends that you include at least one `content` keyword in rules that include the `sip_method` keyword to ensure that the rules engine uses the fast pattern matcher, which increases processing speed and improves performance. Note that the rules engine uses the fast pattern matcher when a rule includes at least one `content` keyword, regardless of whether you enable the `content` keyword **Use Fast Pattern Matcher** argument. See Searching for Content Matches on page 1093 and Use Fast Pattern Matcher on page 1104 for more information.

sip_stat_code

LICENSE: Protection

A three-digit status code in each SIP response indicates the outcome of the requested action. You can use the `sip_stat_code` keyword to test SIP responses for specific status codes.

You can specify a one-digit response-type number 1-9, a specific three-digit number 100-999, or a comma-separated list of any combination of either. A list matches if any single number in the list matches the code in the SIP response.

The following table describes the SIP status code values you can specify.

`sip_stat_code` Values

TO DETECT...	SPECIFY...	FOR EXAMPLE...	DETECTS...
a specific status code	the three-digit status code	189	189
any three-digit code that begins with a specified single digit	the single digit	1	1xx; that is, 100, 101, 102, and so on
a list of values	any comma-separated combination of specific codes and single digits	222, 3	222 plus 300, 301, 302, and so on

Note that the SIP preprocessor must be enabled to allow processing of rules using the **`sip_stat_code`** keyword. When the SIP preprocessor is disabled and you enable rules that use this keyword, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

Note also that the rules engine does not use the fast pattern matcher to search for the value specify using the **`sip_stat_code`** keyword, regardless of whether your rule includes a **`content`** keyword.

GTP Keywords

LICENSE: Protection

Three GSRP Tunneling Protocol (GTP) keywords allow you to inspect the GTP command channel for GTP version, message type, and information elements. You cannot use GTP keywords in combination with other intrusion rule keywords such as **`content`** or **`byte_jump`**. You must use the **`gtp_version`** keyword in each rule that uses the **`gtp_info`** or **`gtp_type`** keyword.

The GTP preprocessor must be enabled to allow processing of rules using GTP keywords. When the GTP preprocessor is disabled and you enable rules that use these keywords, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

See the following sections for more information:

- gtp_version on page 1158
- gtp_type on page 1158
- gtp_info on page 1166

gtp_version

You can use the `gtp_version` keyword to inspect GTP control messages for GTP version 0, 1, or 2.

Because different GTP versions define different message types and information elements, you must use this keyword when you use the `gtp_type` or `gtp_info` keyword. You can specify the value 0, 1, or 2.

To specify the GTP version:

Access: Admin/Intrusion Admin

1. On the Create Rule page, select **gtp_version** in the drop-down list and click **Add Option.**

   The `gtp_version` keyword appears.

2. Specify `0`, `1`, or `2` to identify the GTP version.

gtp_type

Each GTP message is identified by a message type, which is comprised of both a numeric value and a string. You can use the `gtp_type` keyword in combination with the `gtp_version` keyword to inspect traffic for specific GTP message types.

You can specify a defined decimal value for a message type, a defined string, or a comma-separated list of either or both in any combination, as seen in the following example:

```
10, 11, echo_request
```

The system uses an OR operation to match each value or string that you list. The order in which you list values and strings does not matter. Any single value or string in the list matches the keyword. You receive an error if you attempt to save a rule that includes an unrecognized string or an out-of-range value.

Note in the table that different GTP versions sometimes use different values for the same message type. For example, the `sgsn_context_request` message type has a value of 50 in GTPv0 and GTPv1, but a value of 130 in GTPv2.

The `gtp_type` keyword matches different values depending on the version number in the packet. In the example above, the keyword matches the message type value 50 in a GTPv0 or GTPv1 packet and the value 130 in a GTPv2 packet. The keyword does not match a packet when the message type value in the packet is not a known value for the version specified in the packet.

If you specify an integer for the message type, the keyword matches if the message type in the keyword matches the value in the GTP packet, regardless of the version specified in the packet.

The following table lists the defined values and strings recognized by the system for each GTP message type.

GTP Message Types

VALUE	VERSION 0	VERSION 1	VERSION 2
1	echo_request	echo_request	echo_request
2	echo_response	echo_response	echo_response
3	version_not_supported	version_not_supported	version_not_supported

To specify GTP message types:

Access: Admin/Intrusion Admin

1. On the Create Rule page, select **gtp_type** in the drop-down list and click **Add Option.**

   The `gtp_type` keyword appears.

2. Specify a defined decimal value 0 to 255 for the message type, a defined string, or a comma-separated list of either or both in any combination. See the GTP Message Types table on page 1159 for values and strings recognized by the system.

gtp_info

A GTP message can include multiple information elements, each of which is identified by both a defined numeric value and a defined string. You can use the `gtp_info` keyword in combination with the `gtp_version` keyword to start inspection at the beginning of a specified information element and restrict inspection to the specified information element.

You can specify either the defined decimal value or the defined string for an information element. You can specify a single value or string, and you can use multiple `gtp_info` keywords in a rule to inspect multiple information elements.

When a message includes multiple information elements of the same type, all are inspected for a match. When information elements occur in an invalid order, only the last instance is inspected.

Note that different GTP versions sometimes use different values for the same information element. For example, the `cause` information element has a value of 1 in GTPv0 and GTPv1, but a value of 2 in GTPv2.

The `gtp_info` keyword matches different values depending on the version number in the packet. In the example above, the keyword matches the information element value 1 in a GTPv0 or GTPv1 packet and the value 2 in a GTPv2 packet. The keyword does not match a packet when the information element value in the packet is not a known value for the version specified in the packet.

If you specify an integer for the information element, the keyword matches if the message type in the keyword matches the value in the GTP packet, regardless of the version specified in the packet.

The following table lists the values and strings recognized by the system for each GTP information element.

GTP Information Elements

VALUE	VERSION 0	VERSION 1	VERSION 2
1	cause	cause	imsi
2	imsi	imsi	cause
3	rai	rai	recovery
4	tlli	tlli	N/A

You can use the following procedure to specify a GTP information element.

To specify a GTP information element:

ACCESS: Admin/Intrusion Admin

1. On the Create Rule page, select **gtp_info** in the drop-down list and click **Add Option.**

   The `gtp_info` keyword appears.

2. Specify a single defined decimal value 0 to 255 for the information element, or a single defined string. See the GTP Information Elements table on page 1167 for values and strings recognized by the system.

Modbus Keywords

LICENSE: Protection

You can use Modbus keywords to point to the beginning of the Data field in a Modbus request or response, to match against the Modbus Function Code, and to match against a Modbus Unit ID. You can use Modbus keywords alone or in combination with other keywords such as `content` and `byte_jump`.

See the following sections for more information:

- modbus_data on page 1175
- modbus_func on page 1175
- modbus_unit on page 1176

modbus_data

You can use the `modbus_data` keyword to point to the beginning of the Data field in a Modbus request or response.

To point to the beginning of the modbus Data field:

Access: Admin/Intrusion Admin

- On the Create Rule page, select **modbus_data** from the drop-down list and click **Add Option.**

  The `modbus_data` keyword appears.

  The `modbus_data` keyword has no arguments.

modbus_func

You can use the `modbus_func` keyword to match against the Function Code field in a Modbus application layer request or response header. You can specify either a single defined decimal value or a single defined string for a Modbus function code.

The following table lists the defined values and strings recognized by the system for Modbus function codes.

Modbus Function Codes

Value	String
1	read_coils
2	read_discrete_inputs
3	read_holding_registers
4	read_input_registers
5	write_single_coil
6	write_single_register
7	read_exception_status
8	diagnostics
11	get_comm_event_counter
12	get_comm_event_log

Modbus Function Codes (Continued)

VALUE	STRING
15	write_multiple_coils
16	write_multiple_registers
17	report_slave_id
20	read_file_record
21	write_file_record
22	mask_write_register
23	read_write_multiple_registers
24	read_fifo_queue
43	encapsulated_interface_transport

To specify a Modbus function code:

ACCESS: Admin/Intrusion Admin

1. On the Create Rule page, select **modbus_func** in the drop-down list and click **Add Option.**

   The `modbus_func` keyword appears.

2. Specify a single defined decimal value 0 to 255 for the function code, or a single defined string. See the Modbus Function Codes table on page 1175 for values and strings recognized by the system.

modbus_unit

You can use the `modbus_unit` keyword to match a single decimal value against the Unit ID field in a Modbus request or response header.

To specify a Modbus unit ID:

Access: Admin/Intrusion Admin

1. On the Create Rule page, select **modbus_unit** in the drop-down list and click **Add Option.**

   The `modbus_unit` keyword appears.

2. Specify a decimal value 0 through 255.

DNP3 Keywords

License: Protection

You can use DNP3 keywords to point to the beginning of application layer fragments, to match against DNP3 function codes and objects in DNP3 responses and requests, and to match against internal indication flags in DNP3 responses. You can use DNP3 keywords alone or in combination with other keywords such as `content` and `byte_jump`.

See the following sections for more information:

- dnp3_data on page 1177
- dnp3_func on page 1178
- dnp3_ind on page 1180
- dnp3_obj on page 1181

dnp3_data

You can use the `dnp3_data` keyword to point to the beginning of reassembled DNP3 application layer fragments.

The DNP3 preprocessor reassembles link layer frames into application layer fragments. The `dnp3_data` keyword points to the beginning of each application layer fragment; other rule options can match against the reassembled data within fragments without separating the data and adding checksums every 16 bytes.

To point to the beginning of reassembled DNP3 fragments:

Access: Admin/Intrusion Admin

▶ On the Create Rule page, select **modbus_data** from the drop-down list and click **Add Option.**

The `dnp3_data` keyword appears.

The `dnp3_data` keyword has no arguments.

dnp3_func

You can use the `dnp3_func` keyword to match against the Function Code field in a DNP3 application layer request or response header. You can specify either a single defined decimal value or a single defined string for a DNP3 function code.

The following table lists the defined values and strings recognized by the system for DNP3 function codes.

DNP3 Function Codes

VALUE	STRING
0	confirm
1	read
2	write
3	select
4	operate
5	direct_operate
6	direct_operate_nr
7	immed_freeze
8	immed_freeze_nr
9	freeze_clear
10	freeze_clear_nr
11	freeze_at_time
12	freeze_at_time_nr
13	cold_restart
14	warm_restart
15	initialize_data
16	initialize_appl
17	start_appl

DNP3 Function Codes (Continued)

VALUE	STRING
18	stop_appl
19	save_config
20	enable_unsolicited
21	disable_unsolicited
22	assign_class
23	delay_measure
24	record_current_time
25	open_file
26	close_file
27	delete_file
28	get_file_info
29	authenticate_file
30	abort_file
31	activate_config
32	authenticate_req
33	authenticate_err
129	response
130	unsolicited_response
131	authenticate_resp

To specify DNP3 function codes:

Access: Admin/Intrusion Admin

1. On the Create Rule page, select **dnp3_func** in the drop-down list and click **Add Option.**

   The `dnp3_func` keyword appears.

2. Specify a single defined decimal value 0 to 255 for the function code, or a single defined string. See the DNP3 Function Codes table on page 1178 for values and strings recognized by the system.

dnp3_ind

You can use the `dnp3_ind` keyword to match against flags in the Internal Indications field in a DNP3 application layer response header.

You can specify the string for a single known flag or a comma-separated list of flags, as seen in the following example:

```
class_1_events, class_2_events
```

When you specify multiple flags, the keyword matches against any flag in the list. To detect a combination of flags, use the `dnp3_ind` keyword multiple times in a rule.

The following list provides the string syntax recognized by the system for defined DNP3 internal indications flags:

```
class_1_events
class_2_events
class_3_events
need_time
local_control
device_trouble
device_restart
no_func_code_support
object_unknown
parameter_error
event_buffer_overflow
already_executing
config_corrupt
reserved_2
reserved_1
```

To specify DNP3 internal indications flags:

Access: Admin/Intrusion Admin

1. On the Create Rule page, select **dnp3_ind** in the drop-down list and click **Add Option.**

   The `dnp3_ind` keyword appears.

2. You can specify the string for a single known flag or a comma-separated list of flags.

dnp3_obj

You can use the `dnp3_obj` keyword to match against DNP3 object headers in a request or response.

DNP3 data is comprised of a series of DNP3 objects of different types such as analog input, binary input, and so on. Each type is identified with a *group* such as analog input group, binary input group, and so on, each of which can be identified by a decimal value. The objects in each group are further identified by an *object variation* such as 16-bit integers, 32-bit integers, short floating point, and so on, each of which specifies the data format of the object. Each type of object variation can also be identified by a decimal value.

You identify object headers by specifying the decimal number for the type of object header group and the decimal number for the type of object variation. The combination of the two defines a specific type of DNP3 object.

To specify a DNP3 object:

Access: Admin/Intrusion Admin

1. On the Create Rule page, select **dnp3_obj** in the drop-down list and click **Add Option.**

   The `dnp3_obj` keyword appears.

2. Specify a decimal value 0 through 255 to identify a known object group, and another decimal value 0 through 255 to identify a known object variation type.

Inspecting Packet Characteristics

LICENSE: Protection

You can write rules that only generate events against packets with specific packet characteristics. The Sourcefire 3D System provides the following keywords to evaluate packet characteristics:

- dsize on page 1182
- isdataat on page 1182
- sameip on page 1184
- fragoffset on page 1184
- cvs on page 1184

dsize

LICENSE: Protection

The `dsize` keyword tests the packet payload size. With it, you can use the greater than and less than operators (< and >) to specify a range of values. You can use the following syntax to specify ranges:

```
>number_of_bytes
<number_of_bytes
number_of_bytes<>number_of_bytes
```

For example, to indicate a packet size greater than 400 bytes, use `>400` as the `dtype` value. To indicate a packet size of less than 500 bytes, use `<500`. To specify that the rule trigger against any packet between 400 and 500 bytes, use `400<>500`.

WARNING! The `dsize` keyword tests packets before they are decoded by any preprocessors.

isdataat

LICENSE: Protection

The `isdataat` keyword instructs the rules engine to verify that data resides at a specific location in the payload.

The isdataat Arguments table lists the arguments you can use with the `isdataat` keyword.

isdataat Arguments

ARGUMENT	TYPE	DESCRIPTION
Offset	Required	The specific location in the payload. For example, to test that data appears at byte 50 in the packet payload, you would specify `50` as the offset value. A `!` modifier negates the results of the `isdataat` test; it alerts if a certain amount of data is not present within the payload. You can also use an existing `byte_extract` variable to specify the value for this argument. See Reading Packet Data into Keyword Arguments on page 1185 for more information.
Relative	Optional	Makes the location relative to the last successful content match. If you specify a relative location, note that the counter starts at byte 0, so calculate the location by subtracting 1 from the number of bytes you want to move forward from the last successful content match. For example, to specify that the data must appear at the ninth byte after the last successful content match, you would specify a relative offset of `8`.
Raw Data	Optional	Specifies that the data is located in the original packet payload before decoding or application layer normalization by any Sourcefire 3D System preprocessor. You can use this argument with **Relative** if the previous content match was in the raw packet data.

For example, in a rule searching for the content `foo`, if the value for `isdataat` is specified as the following:

- Offset = !10
- Relative = enabled

The system alerts if the rules engine does not detect 10 bytes after `foo` before the payload ends.

To use isdataat:

Access: Admin/Intrusion Admin

- On the Create Rule page, select `isdataat` in the drop-down list and click **Add Option**.

  The `isdataat` section appears.

sameip

License: Protection

The `sameip` keyword tests that a packet's source and destination IP addresses are the same. It does not take an argument.

fragoffset

License: Protection

The `fragoffset` keyword tests the offset of a fragmented packet. This is useful because some exploits (such as WinNuke denial-of-service attacks) use hand-generated packet fragments that have specific offsets.

For example, to test whether the offset of a fragmented packet is 31337 bytes, specify `31337` as the `fragoffset` value.

You can use the following operators when specifying arguments for the `fragoffset` keyword.

fragoffset Keyword Argument Operators

Operator	Description
!	not
>	greater than
<	less than

Note that you cannot use the not (`!`) operator in combination with < or >.

cvs

License: Protection

The `cvs` keyword tests Concurrent Versions System (CVS) traffic for malformed CVS entries. An attacker can use a malformed entry to force a heap overflow and execute malicious code on the CVS server. This keyword can be used to identify

attacks against two known CVS vulnerabilities: CVE-2004-0396 (CVS 1.11.x up to 1.11.15, and 1.12.x up to 1.12.7) and CVS-2004-0414 (CVS 1.12.x through 1.12.8, and 1.11.x through 1.11.16). The `cvs` keyword checks for a well-formed entry, and generates alerts when a malformed entry is detected.

Your rule should include the ports where CVS runs. In addition, any ports where traffic may occur should be added to the list of ports for stream reassembly in your TCP policies so state can be maintained for CVS sessions. The TCP ports 2401 (`pserver`) and 514 (`rsh`) are included in the list of client ports where stream reassembly occurs. However, note that if your server runs as an `xinetd` server (i.e., pserver), it can run on any TCP port. Add any non-standard ports to the stream reassembly **Client Ports** list. For more information, see Selecting Stream Reassembly Options on page 976.

To detect malformed CVS entries:

ACCESS: Admin/Intrusion Admin

- Add the `cvs` option to a rule and type `invalid-entry` as the keyword argument.

Reading Packet Data into Keyword Arguments

LICENSE: Protection

You can use the `byte_extract` keyword to read a specified number of bytes from a packet into a variable. You can then use the variable later in the same rule as the value for specific arguments in certain other detection keywords.

This is useful, for example, for extracting data size from packets where a specific segment of bytes describes the number of bytes included in data within the packet. For example, a specific segment of bytes might say that subsequent data is comprised of four bytes; you can extract the data size of four bytes to use as your variable value.

You can use `byte_extract` to create up to two separate variables in a rule concurrently. You can redefine a `byte_extract` variable any number of times; entering a new `byte_extract` keyword with the same variable name and a different variable definition overwrites the previous definition of that variable.

The Required byte_extract Arguments table describes the arguments required by the `byte_extract` keyword.

Required byte_extract Arguments

ARGUMENT	DESCRIPTION
Bytes to Extract	The number of bytes to extract from the packet. You can specify 1, 2, 3, or 4 bytes.
Offset	The number of bytes into the payload to begin extracting data. You can specify -65534 to 65535 bytes. The offset counter starts at byte 0, so calculate the offset value by subtracting 1 from the number of bytes you want to count forward. For example, specify 7 to count forward 8 bytes. The rules engine counts forward from the beginning of the packet payload or, if you also specify **Relative**, after the last successful content match. Note that you can specify negative numbers only when you also specify **Relative**; see the Additional Optional byte_extract Arguments table on page 1186 for more information.
Variable Name	The variable name to use in arguments for other detection keywords. You can specify an alphanumeric string that must begin with a letter.

To further define how the system locates the data to extract, you can use the arguments described in the Additional Optional byte_extract Arguments table.

Additional Optional byte_extract Arguments

ARGUMENT	DESCRIPTION
Multiplier	A multiplier for the value extracted from the packet. You can specify 0 to 65535. If you do not specify a multiplier, the default value is 1.
Align	Rounds the extracted value to the nearest 2-byte or 4-byte boundary. When you also select **Multiplier**, the system applies the multiplier before the alignment.
Relative	Makes **Offset** relative to the end of the last successful content match instead of the beginning of the payload. See the Required byte_extract Arguments table on page 1186 for more information.

You can specify only one of **DCE/RPC**, **Endian**, or **Number Type**.

To define how the `byte_extract` keyword calculates the bytes it tests, you can choose from the arguments in the Endianness byte_extract Arguments table. The rules engine uses big endian byte order if you do not select either argument.

Endianness byte_extract Arguments

Argument	Description
Big Endian	Processes data in big endian byte order, which is the default network byte order.
Little Endian	Processes data in little endian byte order.
DCE/RPC	Specifies a `byte_extract` keyword for traffic processed by the DCE/RPC preprocessor. See Decoding DCE/RPC Traffic on page 836 for more information. The DCE/RPC preprocessor determines big endian or little endian byte order, and the **Number Type** and **Endian** arguments do not apply. When you enable this argument, you can also use `byte_extract` in conjunction with other specific DCE/RPC keywords. See DCE/RPC Keywords on page 1149 for more information. The DCE/RPC preprocessor must be enabled to allow processing of rules that include this option. When the DCE/RPC preprocessor is disabled and you enable rules that use this option, you are prompted whether to enable the preprocessor when you save the policy. See Automatically Enabling Advanced Settings on page 813.

You can specify a number type to read data as an ASCII string. To define how the system views string data in a packet, you can select one of the arguments in the Number Type byte_extract arguments table.

Number Type byte_extract arguments

Argument	Description
Hexadecimal String	Reads extracted string data in hexadecimal format.
Decimal String	Reads extracted string data in decimal format.
Octal String	Reads extracted string data in octal format.

For example, if the value for `byte_extract` is specified as the following:

- Bytes to Extract = 4
- Variable Name = var
- Offset = 8
- Relative = enabled

the rules engine reads the number described in the four bytes that appear 9 bytes away from (relative to) the last successful content match into a variable named `var`, which you can specify later in the rule as the value for certain keyword arguments.

The Arguments Accepting a byte_extract Variable table lists the keyword arguments where you can specify a variable defined in the `byte_extract` keyword.

Arguments Accepting a byte_extract Variable

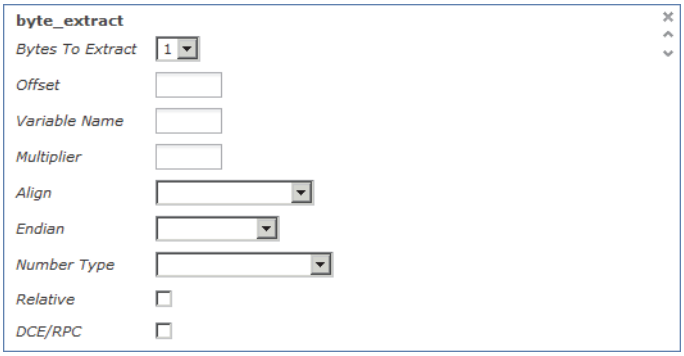
KEYWORD	ARGUMENT
content	Depth, Offset, Distance, Within See Constraining Content Matches on page 1095 for more information.
byte_jump	Offset See byte_jump on page 1110 for more information.
byte_test	Offset, Value See byte_test on page 1114 for more information.
isdataat	Offset See isdataat on page 1182 for more information.

To use byte_extract:

ACCESS: Admin/Intrusion Admin

▶ On the Create Rule page, select t `byte_extract` in the drop-down list and click **Add Option**.

The `byte_extract` section appears beneath the last keyword you selected.



Initiating Active Responses with Rule Keywords

LICENSE: Protection

The system can initiate active responses to close TCP connections in response to triggered TCP rules or UDP sessions in response to triggered UDP rules. Two keywords provide you with separate approaches to initiating active responses. When a packet triggers a rule containing either of the keywords, the system initiates a single active response. You can also use the `config response` command to configure the active response interface to use and the number of TCP resets to attempt in a passive deployment.

Active responses are most effective in inline deployments because resets are more likely to arrive in time to affect the connection or session. For example, in response to the `react` keyword in an inline deployment, the system inserts a TCP reset (RST) packet directly into the traffic for each end of the connection, which normally should close the connection.

Active responses are not intended to take the place of a firewall for a number of reasons, including that the system cannot insert packets in passive deployments and an attacker may have chosen to ignore or circumvent active responses.

Because active responses can be routed back, the system does not allow TCP resets to initiate TCP resets; this prevents an unending sequence of active responses. the system also does not allow ICMP unreachable packets to initiate ICMP unreachable packets in keeping with standard practice.

You can configure the TCP stream preprocessor to detect additional traffic on a connection or session after an intrusion rule has triggered an active response. When the preprocessor detects additional traffic, it sends additional active responses up to a specified maximum to both ends of the connection or session. See Initiating Active Responses with Drop Rules on page 967 for more

information.

Note that to initiate additional TCP resets you must ensure that TCP Stream Configuration is enabled, and to initiate additional ICMP unreachable packets you must ensure that UDP Stream Configuration is enabled. See Modifying Advanced Settings on page 800 for more information. Note also that initial active responses do not require that you enable either TCP or UDP Stream Configuration.

See the following sections for information specific to the keywords you can use to initiate active responses:

- Initiating Active Responses by Type and Direction on page 1190
- Sending an HTML Page Before a TCP Reset on page 1191
- Setting the Active Response Reset Attempts and Interface on page 1193

Initiating Active Responses by Type and Direction

LICENSE: Protection

You can use the `resp` keyword to actively respond to TCP connections or UDP sessions, depending on whether you specify the TCP or UDP protocol in the rule header. See Specifying Protocols on page 1078 for more information.

Keyword arguments allow you to specify the packet direction and whether to use TCP reset (RST) packets or ICMP unreachable packets as active responses.

You can use any of the TCP reset or ICMP unreachable arguments to close TCP connections. You should use only ICMP unreachable arguments to close UDP sessions.

Different TCP reset arguments also allow you to target active responses to the packet source, destination, or both. All ICMP unreachable arguments target the packet source and allow you to specify whether to use an ICMP network, host, or port unreachable packet, or all three.

The resp Arguments table lists the arguments you can use with the `resp` keyword to specify exactly what you want the Sourcefire 3D System to do when the rule triggers.

resp Arguments

ARGUMENT	DESCRIPTION
reset_source	Directs a TCP reset packet to the endpoint that sent the packet that triggered the rule. Alternatively, you can specify `rst_snd`, which is supported for backward compatibility.
reset_dest	Directs a TCP reset packet to the intended destination endpoint of the packet that triggered the rule. Alternatively, you can specify `rst_rcv`, which is supported for backward compatibility.

resp Arguments (Continued)

Argument	Description
reset_both	Directs a TCP reset packet to both the sending and receiving endpoints. Alternatively, you can specify `rst_all`, which is supported for backward compatibility.
icmp_net	Directs an ICMP network unreachable message to the sender.
icmp_host	Directs an ICMP host unreachable message to the sender.
icmp_port	Directs an ICMP port unreachable message to the sender. This argument is used to terminate UDP traffic.
icmp_all	Directs the following ICMP messages to the sender: • network unreachable • host unreachable • port unreachable

For example, to configure a rule to reset both sides of a connection when a rule is triggered, use `reset_both` as the value for the `resp` keyword.

You can use a comma-separated list to specify multiple arguments as follows:

`argument,argument,argument`

See Setting the Active Response Reset Attempts and Interface on page 1193 for information on using the `config response` command to configure the active response interface to use and the number of TCP resets to attempt in a passive deployment.

To specify active responses:

Access: Admin/Intrusion Admin

1. On the Create Rule page, select **resp** in the drop-down list and click **Add Option.**

   The `resp` keyword appears.

2. Specify any of the arguments in the resp Arguments table on page 1190 in the **resp** field; use a comma-separated list to specify multiple arguments.

Sending an HTML Page Before a TCP Reset

License: Protection

You can use the `react` keyword to send a default HTML page to the TCP connection client when a packet triggers the rule; after sending the HTML page, the system uses TCP reset packets to initiate active responses to both ends of

the connection. The `react` keyword does not trigger active responses for UDP traffic.

Optionally, you can specify the following argument:

`msg`

When a packet triggers a `react` rule that uses the `msg` argument, the HTML page includes the rule event message. See Understanding Rule Anatomy on page 1074 for a description of the event message field.

If you do not specify the `msg` argument, the HTML page includes the following message:

```
You are attempting to access a forbidden site.
Consult your system administrator for details.
```

IMPORTANT! Because active responses can be routed back, ensure that the HTML response page does not trigger a `react` rule; this could result in an unending sequence of active responses. Sourcefire recommends that you test `react` rules extensively before activating them in a production environment.

See Setting the Active Response Reset Attempts and Interface on page 1193 for information on using the `config response` command to configure the active response interface to use and the number of TCP resets to attempt in a passive deployment.

To send an HTML page before initiating an active responses:

Access: Admin/Intrusion Admin

1. On the Create Rule page, select **react** in the drop-down list and click **Add Option.**

   The `react` keyword appears.

2. You have two choices:
   - To send an HTML page that includes the event message configured for the rule to the client before closing a connection, type `msg` in the **react** field.
   - To send an HTML page that includes the following default message to the client before closing a connection, leave the **react** field blank:

     ```
     You are attempting to access a forbidden site.
     Consult your system administrator for details
     ```

Setting the Active Response Reset Attempts and Interface

LICENSE: Protection

You can use the **config response** command to further configure the behavior of TCP resets initiated by `resp` and `react` rules. This command also affects the behavior of active responses initiated by drop rules; see Initiating Active Responses with Drop Rules on page 967 for more information.

You use the **config response** command by inserting it on a separate line in the USER_CONF advanced variable. See Understanding Advanced Variables on page 217 for information on using a USER_CONF variable.

WARNING! Do **not** use the `USER_CONF` advanced variable to configure an intrusion policy feature unless you are instructed to do so in the feature description or by Sourcefire Support. Conflicting or duplicate configurations will halt the system.

To specify active response reset attempts, the active response interface, or both:

ACCESS: Admin/Intrusion Admin

- Depending on whether you want to specify only the number of active responses, only the active response interface, or both, insert a form of the `config response` command on a separate line in the USER_CONF advanced variable. You have the following choices:
  - To specify only the number of active response attempts, insert the command:
    `config response: attempts` *`att`*

    For example: `config response: attempts 10`
  - To specify only the active response interface, insert the command:
    `config response: device` *`dev`*

    For example: `config response: device eth0`
  - To specify both the number of active response attempts and the active response interface, insert the command:
    `config response: attempts` *`att`*`, device` *`dev`*

    For example: `config response: attempts 10, device eth0`

    where:

    `att` is the number 1 to 20 of attempts to land each TCP reset packet within the current connection window so the receiving host accepts the packet. This sequence *strafing* is useful only in passive deployments; in inline deployments, the system inserts reset packets directly into the stream in place of triggering packets. the system sends only 1 ICMP reachable active response.

    `dev` is an alternate interface where you want the system to send active responses in a passive deployment or insert active responses in an inline deployment.

Filtering Events

LICENSE: Protection

You can use the `detection_filter` keyword to prevent a rule from generating events unless a specified number of packets trigger the rule within a specified time. This can stop the rule from prematurely generating events. For example, two or three failed login attempts within a few seconds could be expected behavior, but a large number of attempts within the same time could indicate a brute force attack.

The `detection_filter` keyword requires arguments that define whether the system tracks the source or destination IP address, the number of times the detection criteria must be met before triggering an event, and how long to continue the count.

Use the following syntax to delay the triggering of events:

```
track by_src/by_dst, count count, seconds number_of_seconds
```

The `track` argument specifies whether to use the packet's source or destination IP address when counting the number of packets that meet the rule's detection criteria. Select from the argument values described in the detection_filter Track Arguments table to specify how the system tracks event instances.

detection_filter Track Arguments

ARGUMENT	DESCRIPTION
by_src	Detection criteria count by source IP address.
by_dst	Detection criteria count by destination IP address.

The `count` argument specifies the number of packets that must trigger the rule for the specified IP address within the specified time before the rule generates an event.

The `seconds` argument specifies the number of seconds within which the specified number of packets must trigger the rule before the rule generates an event.

Consider the case of a rule that searches packets for the content `foo` and uses the `detection_filter` keyword with the following arguments:

```
track by_src, count 10, seconds 20
```

In the example, the rule will not generate an event until it has detected `foo` in 10 packets within 20 seconds from a given source IP address. If the system detects only 7 packets containing `foo` within the first 20 seconds, no event is generated. However, if `foo` occurs 40 times in the first 20 seconds, the rule generates 30 events and the count begins again when 20 seconds have elapsed.

Comparing the threshold and detection_filter Keywords

The `detection_filter` keyword replaces the deprecated `threshold` keyword. The `threshold` keyword is still supported for backward compatibility and operates the same as thresholds that you set within an intrusion policy.

The `detection_filter` keyword is a detection feature that is applied before a packet triggers a rule. The rule does not generate an event for triggering packets detected before the specified packet count and, in an inline deployment, does not drop those packets if the rule is set to drop packets. Conversely, the rule does generate events for packets that trigger the rule and occur after the specified packet count and, in an inline deployment, drops those packets if the rule is set to drop packets.

Thresholding is an event notification feature that does not result in a detection action. It is applied after a packet triggers an event. In an inline deployment, a rule that is set to drop packets drops all packets that trigger the rule, independent of the rule threshold.

Note that you can use the `detection_filter` keyword in any combination with the intrusion event thresholding, intrusion event suppression, and rate-based attack prevention features in an intrusion policy. Note also that policy validation fails if you enable an imported local rule that uses the deprecated `threshold` keyword in combination with the intrusion event thresholding feature in an intrusion policy. See Configuring Event Thresholding on page 774, Configuring Suppression Per Intrusion Policy on page 780, Setting a Dynamic Rule State on page 785, and Importing Local Rule Files on page 2162 for more information.

Evaluating Post-Attack Traffic

LICENSE: Protection

Use the `tag` keyword to tell the system to log additional traffic for the host or session. Use the following syntax when specifying the type and amount of traffic you want to capture using the `tag` keyword:

`tagging_type, count, metric, optional_direction`

The Tag Arguments table, Count Argument table and Logging Metrics Arguments table describe the other available arguments.

You can choose from two types of tagging. The Tag Arguments table describes the two types of tagging. Note that the session tag argument type causes the system to log packets from the same session as if they came from different sessions if you configure only rule header options in the intrusion rule. To group

packets from the same session together, configure one or more rule options (such as a flag keyword or content keyword) within the same intrusion rule.

Tag Arguments

ARGUMENT	DESCRIPTION
session	Logs packets in the session that triggered the rule.
host	Logs packets from the host that sent the packet that triggered the rule. You can add a directional modifier to log only the traffic coming from the host (`src`) or going to the host (`dst`).

To indicate how much traffic you want to log, use the following argument:

Count Argument

ARGUMENT	DESCRIPTION
count	The number of packets or seconds you want to log after the rule triggers. This unit of measure is specified with the metric argument, which follows the count argument.

Select the metric you want to use to log by time or volume of traffic from those described in the Logging Metrics Arguments table.

WARNING! High-bandwidth networks can see thousands of packets per second, and tagging a large number of packets may seriously affect performance, so make sure you tune this setting for your network environment.

Logging Metrics Arguments

ARGUMENT	DESCRIPTION
packets	Logs the number of packets specified by the count after the rule triggers.
seconds	Logs traffic for the number of seconds specified by the count after the rule triggers.

For example, when a rule with the following `tag` keyword value triggers:

```
host, 30, seconds, dst
```

all packets that are transmitted from the client to the host for the next 30 seconds are logged.

Detecting Attacks That Span Multiple Packets

LICENSE: Protection

Use the `flowbits` keyword to assign state names to sessions. By analyzing subsequent packets in a session according to the previously named state, the system can detect and alert on exploits that span multiple packets in a single session.

The `flowbits` state name is a user-defined label assigned to packets in a specific part of a session. You can label packets with state names based on packet content to help distinguish malicious packets from those you do not want to alert on. You can define up to 1024 state names per managed device. For example, if you want to alert on malicious packets that you know only occur after a successful login, you can use the `flowbits` keyword to filter out the packets that constitute an initial login attempt so you can focus only on the malicious packets. You can do this by first creating a rule that labels all packets in the session that have an established login with a `logged_in` state, then creating a second rule where `flowbits` checks for packets with the state you set in the first rule and acts only on those packets. See flowbits Example Using state_name on page 1200 for an example that uses `flowbits` to determine if a user is logged in.

An optional *group name* allows you to include a state name in a group of states. A state name can belong to several groups. States not associated with a group are not mutually exclusive, so a rule that triggers and sets a state that is not associated with a group does not affect other currently set states. See flowbits Example Resulting in a False Positive on page 1201 for an example that illustrates how including a state name in a group can prevent false positives by unsetting another state in the same group.

The flowbits Options table describes the various combinations of operators, states, and groups available to the `flowbits` keyword. Note that state names can contain alphanumeric characters, periods (.), underscores (_), and dashes (-).

flowbits Options

Operator	State Option	Group	Description
`set`	`state_name`	optional	Sets the specified state for a packet. Sets the state in the specified group if a group is defined.
	`state_name&state_name`	optional	Sets the specified states for a packet. Sets the states in the specified group if a group is defined.
`setx`	`state_name`	mandatory	Sets the specified state in the specified group for a packet, and unsets all other states in the group.
	`state_name&state_name`	mandatory	Sets the specified states in the specified group for a packet, and unsets all other states in the group.
`unset`	`state_name`	no group	Unsets the specified state for a packet.
	`state_name&state_name`	no group	Unsets the specified states for a packet.
	`all`	mandatory	Unsets all the states in the specified group.
`toggle`	`state_name`	no group	Unsets the specified state if it is set, and sets the specified state if it is unset.
	`state_name&state_name`	no group	Unsets the specified states if they are set, and sets the specified states if they are unset.
	`all`	mandatory	Unsets all states set in the specified group, and sets all states unset in the specified group.

flowbits Options (Continued)

Operator	State Option	Group	Description
`isset`	`state_name`	no group	Determines if the specified state is set in the packet.
	`state_name&state_name`	no group	Determines if the specified states are set in the packet.
	`state_name|state_name`	no group	Determines if any of the specified states are set in the packet.
	`any`	mandatory	Determines if any state is set in the specified group.
	`all`	mandatory	Determines if all states are set in the specified group.
`isnotset`	`state_name`	no group	Determines if the specified state is not set in the packet.
	`state_name&state_name`	no group	Determines if the specified states are not set in the packet.
	`state_name|state_name`	no group	Determines if any of the specified states is not set in the packet.
	`any`	mandatory	Determines if any state is not set in the packet.
	`all`	mandatory	Determines if all states are not set in the packet.
`reset`	(no state)	optional	Unsets all states for all packets. Unsets all states in a group if a group is specified.
`noalert`	(no state)	no group	Use this in conjunction with any other operator to suppress event generation.

Note the following when using the `flowbits` keyword:

- When using the `setx` operator, the specified state can only belong to the specified group, and not to any other group.
- You can define the `setx` operator multiple times, specifying different states and the same group with each instance.

- When you use the `setx` operator and specify a group, you cannot use the `set`, `toggle`, or `unset` operators on that specified group.
- The `isset` and `isnotset` operators evaluate for the specified state regardless of whether the state is in a group.
- During intrusion policy saves, intrusion policy reapplies, and access control policy applies (regardless of whether the access control policy references one intrusion policy or multiple intrusion policies), if you enable a rule that contains the isset or isnotset operator **without** a specified group, and you do not enable at least one rule that affects `flowbits` assignment (`set, setx, unset, toggle`) for the corresponding state name and protocol, all rules that affect `flowbits` assignment for the corresponding state name are enabled.
- During intrusion policy saves, intrusion policy reapplies, and access control policy applies (regardless of whether the access control policy references one intrusion policy or multiple intrusion policies), if you enable a rule that contains the `isset` or `isnotset` operator **with** a specified group, all rules that affect `flowbits` assignment (`set, setx, unset, toggle`) and define a corresponding group name are also enabled.
- Stream preprocessing must be enabled for the TCP or UDP protocol specified in rules using the `flowbits` keyword. If you enable a rule using the `flowbits` keyword in an intrusion policy where the necessary TCP or UDP stream preprocessing is disabled, you are prompted when you try to save your changes whether to allow the system to automatically enable the required TCP or UDP stream preprocessing. See Automatically Enabling Advanced Settings on page 813 for more information.

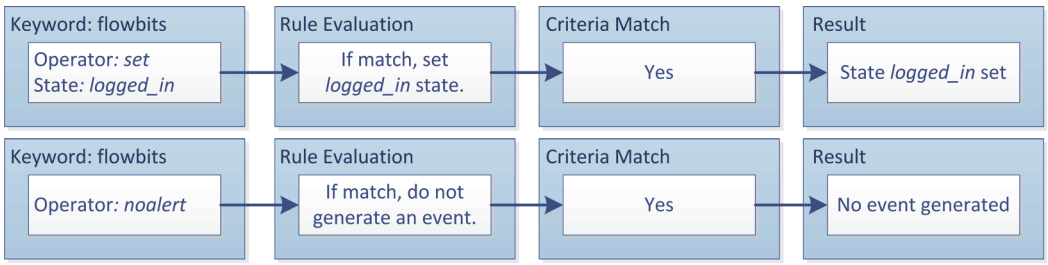
flowbits Example Using state_name

Consider the IMAP vulnerability described in Bugtraq ID #1110. This vulnerability exists in an implementation of IMAP, specifically in the LIST, LSUB, RENAME, FIND, and COPY commands. However, to take advantage of the vulnerability, the attacker must be logged into the IMAP server. Because the LOGIN confirmation from the IMAP server and the exploit that follows are necessarily in different packets, it is difficult to construct non-flow-based rules that catch this exploit. Using the `flowbits` keyword, you can construct a series of rules that track whether the user is logged into the IMAP server and, if so, generate an event if one of the attacks is detected. If the user is not logged in, the attack cannot exploit the vulnerability and no event is generated.

The two rule fragments that follow illustrate this example. The first rule fragment looks for an IMAP login confirmation from the IMAP server:

```
alert tcp any 143 -> any any (msg:"IMAP login"; content:"OK
LOGIN"; flowbits:set,logged_in; flowbits:noalert;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

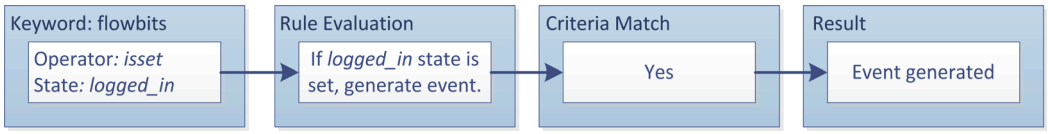


Note that `flowbits:set` sets a state of `logged_in`, while `flowbits:noalert` suppresses the alert because you are likely to see many innocuous login sessions on an IMAP server.

The next rule fragment looks for a LIST string, but does not generate an event unless the logged_in state has been set as a result of some previous packet in the session:

```
alert tcp any any -> any 143 (msg:"IMAP LIST";
content:"LIST"; flowbits:isset,logged_in;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:



In this case, if a previous packet has caused a rule containing the first fragment to trigger, then a rule containing the second fragment triggers and generates an event.

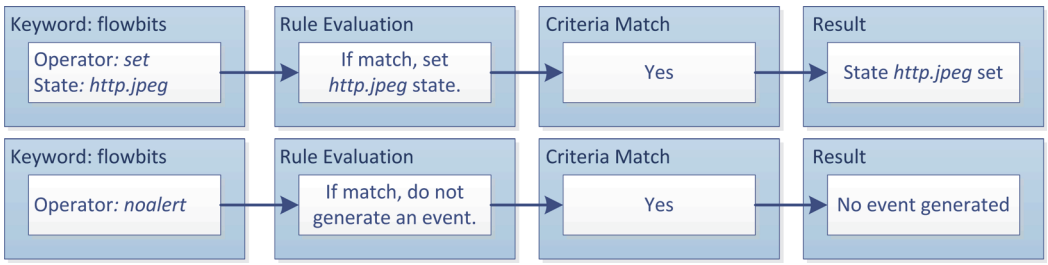
flowbits Example Resulting in a False Positive

Including different state names that are set in different rules in a group can prevent false positive events that might otherwise occur when content in a subsequent packet matches a rule whose state is no longer valid. The following example illustrates how you can get false positives when you do not include multiple state names in a group.

Consider the case where the following three rule fragments trigger in the order shown during a single session:

```
(msg:"JPEG transfer"; content:"image/";pcre:"/^Content-
Type\x3a(\s*|\s*\r?\n\s+)image\x2fp?jpe?g/smi";
flowbits:set,http.jpeg; flowbits:noalert;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

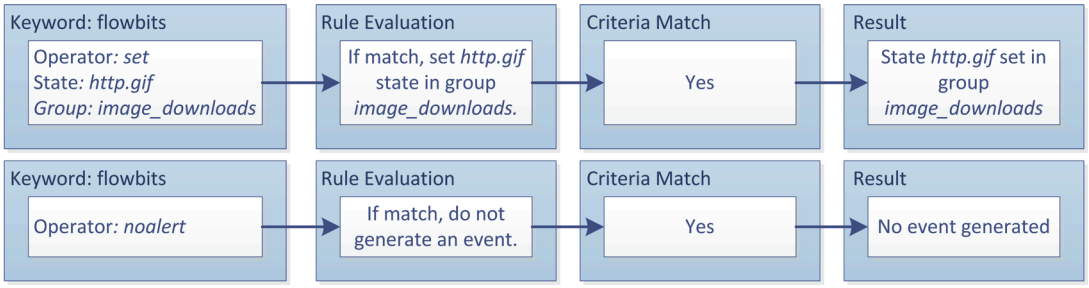


The `content` and `pcre` keywords in the first rule fragment match a JPEG file download, `flowbits:set,http.jpeg` sets the `http.jpeg` `flowbits` state, and `flowbits:noalert` stops the rule from generating events. No event is generated because the rule's purpose is to detect the file download and set the `flowbits` state so one or more companion rules can test for the state name in combination with malicious content and generate events when malicious content is detected.

The next rule fragment detects a GIF file download subsequent to the JPEG file download above:

```
(msg:"GIF transfer"; content:"image/"; pcre:"/^Content-
Type\x3a(\s*|\s*\r?\n\s+)image\x2fgif/smi";
flowbits:set,http.gif,image_downloads; flowbits:noalert;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

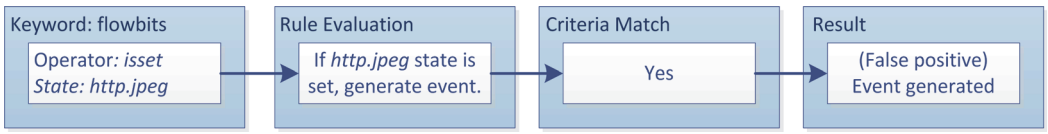


The `content` and `pcre` keywords in the second rule match the GIF file download, `flowbits:set,http.gif` sets the `http.gif` flowbit state, and `flowbits:noalert` stops the rule from generating an event. Note that the `http.jpeg` state set by the first rule fragment is still set even though it is no longer needed; this is because the JPEG download must have ended if a subsequent GIF download has been detected.

The third rule fragment is a companion to the first rule fragment:

```
(msg:"JPEG exploit";
flowbits:isset,http.jpeg;content:"|FF|"; pcre:"
/\xFF[\xE1\xE2\xED\xFE]\x00[\x00\x01]/";)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:



In the third rule fragment, `flowbits:isset,http.jpeg` determines that the now-irrelevant `http.jpeg` state is set, and `content` and `pcre` match content that would be malicious in a JPEG file but not in a GIF file. The third rule fragment results in a false positive event for a nonexistent exploit in a JPEG file.

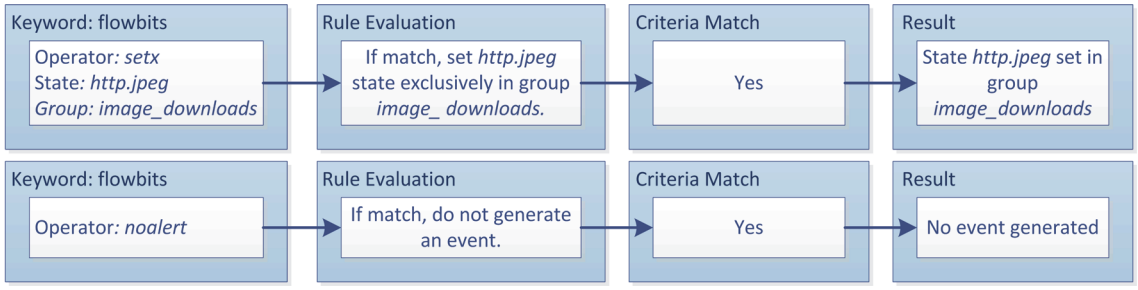
flowbits Example for Preventing False Positives

The following example illustrates how including state names in a group and using the `setx` operator can prevent false positives.

Consider the same case as the previous example, except that the first two rules now include their two different state names in the same state group.

```
(msg:"JPEG transfer"; content:"image/";pcre:"/^Content-
Type\x3a(\s*|\s*\r?\n\s+)image\x2fp?jpe?g/smi";
flowbits:setx,http.jpeg,image_downloads; flowbits:noalert;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

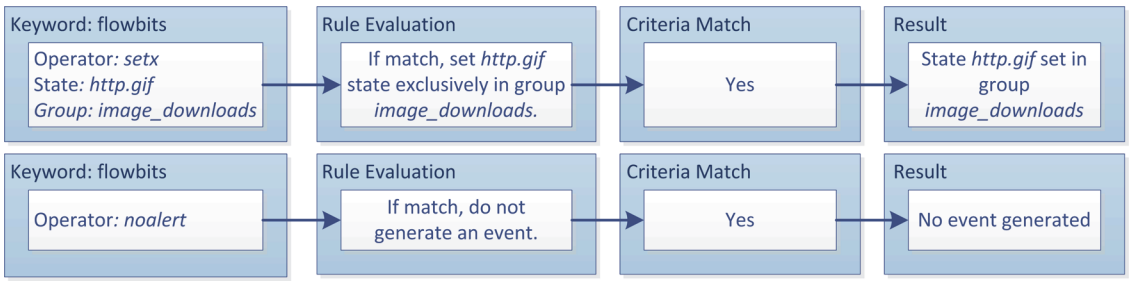


When the first rule fragment detects a JPEG file download, the `flowbits:setx,http.jpeg,image_downloads` keyword sets the `flowbits` state to `http.jpeg` and includes the state in the `image_downloads` group.

The next rule then detects a subsequent GIF file download:

```
(msg:"GIF transfer"; content:"image/"; pcre:"/^Content-
Type\x3a(\s*|\s*\r?\n\s+)image\x2fgif/smi";
flowbits:setx,http.gif,image_downloads; flowbits:noalert;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

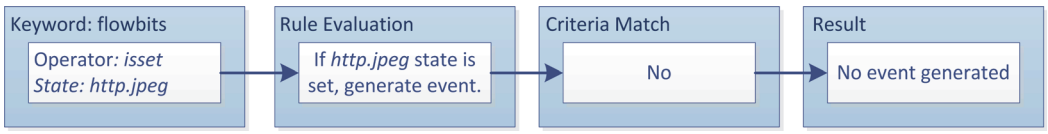


When the second rule fragment matches the GIF download, the `flowbits:setx,http.gif,image_downloads` keyword sets the `http.gif` `flowbits` state and unsets `http.jpeg`, the other state in the group.

The third rule fragment does not result in a false positive:

```
(msg:"JPEG exploit";
flowbits:isset,http.jpeg;content:"|FF|"; pcre:"/
\xFF[\xE1\xE2\xED\xFE]\x00[\x00\x01]/";)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:



Because `flowbits:isset,http.jpeg` is false, the rules engine stops processing the rule and no event is generated, thus avoiding a false positive even in a case where content in the GIF file matches exploit content for a JPEG file.

Generating Events on the HTTP Encoding Type and Location

LICENSE: Protection

You can use the `http_encode` keyword to generate events on the type of encoding in an HTTP request or response before normalization, either in the HTTP URI, in non-cookie data in an HTTP header, in cookies in HTTP requests headers, or set-cookie data in HTTP responses.

The HTTP Inspect preprocessor must be enabled for rules using the `http_encode` keyword to return matches. If you enable those rules in an intrusion policy where the HTTP preprocessor is disabled and try to save the policy, you are prompted whether to allow the system to automatically enable the HTTP preprocessor. For more information on automatically enabling processors and other advanced intrusion policy features, see Automatically Enabling Advanced Settings on page 813.

You must also configure the preprocessor to inspect HTTP responses and HTTP cookies to return matches for these. See Decoding HTTP Traffic on page 876 and

Selecting Server-Level HTTP Normalization Options on page 880 for more information.

Also, you must enable both the decoding and alerting option for each specific encoding type in your HTTP Inspect preprocessor configuration for the **http_encode** keyword in an intrusion rule to trigger events on that encoding type. See Selecting Server-Level HTTP Normalization Encoding Options on page 888 for more information.

Note that the base36 encoding type has been deprecated. For backward compatibility, the base36 argument is allowed in existing rules, but it does not cause the rules engine to inspect base36 traffic.

The http_encode Encoding Types table describes the encoding types this option can generate events for in HTTP URIs, headers, cookies, and set-cookies:

http_encode Encoding Types

Encoding Type	Description
utf8	Detects UTF-8 encoding in the specified location when this encoding type is enabled for decoding by the HTTP Inspect preprocessor.
double_encode	Detects double encoding in the specified location when this encoding type is enabled for decoding by the HTTP Inspect preprocessor.
non_ascii	Detects non-ascii characters in the specified location when non-ASCII characters are detected but the detected encoding type is not enabled.
uencode	Detects Microsoft %u encoding in the specified location when this encoding type is enabled for decoding by the HTTP Inspect preprocessor.
bare_byte	Detects bare byte encoding in the specified location when this encoding type is enabled for decoding by the HTTP Inspect preprocessor.

To identify the HTTP encoding type and location in an intrusion rule:

Access: Admin/Intrusion Admin

1. Add the `http_encode` keyword to a rule.
2. From the **Encoding Location** drop-down list, select whether to search for the specified encoding type in an HTTP URI, header, or cookie, including a set-cookie.

3. Specify one or more encoding types using one of the following formats:

   encode_type

   encode_type|*encode_type*|*encode_type*...

   !encode_type

   where *encode_type* is one of the following:

   utf8, double_encode, non_ascii, uencode, bare_byte

   Note that you cannot use the negation (!) and OR (|) operators together.

4. Optionally, add multiple **http_encode** keywords to the same rule to AND the conditions for each. For example, enter two keywords with the following conditions:

   First **http_encode** keyword:

   - **Encoding Location**: HTTP URl
   - **Encoding Type**: utf8

   Additional **http_encode** keyword:

   - **Encoding Location**: HTTP URI
   - **Encoding Type**: uencode

   The example configuration searches the HTTP URI for UTF-8 AND Microsoft IIS %u encoding.

Pointing to a Specific Payload Type

LICENSE: Protection

The **file_data** keyword provides a pointer that serves as a reference for the positional arguments available for other keywords such as **content**, **byte_jump**, **byte_test**, and **pcre**. The detected traffic determines the type of data the **file_data** keyword points to. You can use the **file_data** keyword to point to the beginning of the following payload types:

- HTTP response body

  To inspect HTTP response packets, the HTTP Inspect preprocessor must be enabled and you must configure the preprocessor to inspect HTTP responses. See Decoding HTTP Traffic on page 876 and **Inspect HTTP Responses** in Selecting Server-Level HTTP Normalization Options on page 880 for more information. The **file_data** keyword matches if the HTTP Inspect preprocessor detects HTTP response body data.

- Uncompressed gzip file data

  To inspect uncompressed gzip files in the HTTP response body, the HTTP Inspect preprocessor must be enabled and you must configure the preprocessor to inspect HTTP responses and to decompress gzip-compressed files in the HTTP response body. For more information, see Decoding HTTP Traffic on page 876, and the **Inspect HTTP Responses** and **Inspect Compressed Data** options in Selecting Server-Level HTTP Normalization Options on page 880. The **file_data** keyword matches if the

HTTP Inspect preprocessor detects uncompressed gzip data in the HTTP response body.

- Normalized Javascript

  To inspect normalized Javascript data, the HTTP Inspect preprocessor must be enabled and you must configure the preprocessor to inspect HTTP responses. See Decoding HTTP Traffic on page 876 and **Inspect HTTP Responses** in Selecting Server-Level HTTP Normalization Options on page 880 for more information. The `file_data` keyword matches if the HTTP Inspect preprocessor detects Javascript in response body data.

- SMTP payload

  To inspect the SMTP payload, the SMTP preprocessor must be enabled. See Configuring SMTP Decoding on page 921 for more information. The `file_data` keyword matches if the SMTP preprocessor detects SMTP data.

- Encoded email attachments in SMTP, POP, or IMAP traffic

  To inspect email attachments in SMTP, POP, or IMAP traffic, the SMTP, POP, or IMAP preprocessor, respectively, must be enabled, alone or in any combination. Then, for each enabled preprocessor, you must ensure that the preprocessor is configured to decode each attachment encoding type that you want decoded. The attachment decoding options that you can configure for each preprocessor are: **Base64 Decoding Depth**, **7-Bit/8-Bit/Binary Decoding Depth**, **Quoted-Printable Decoding Depth**, and **Unix-to-Unix Decoding Depth**. See Decoding IMAP Traffic on page 906, Decoding POP Traffic on page 910, and Decoding SMTP Traffic on page 915 for more information.

  You can use multiple `file_data` keywords in a rule.

To point to the beginning of a specific payload type:

Access: Admin/Intrusion Admin

▶ On the Create Rule page, select **file_data** from the drop-down list and click **Add Option.**

The `file_data` keyword appears.

The `file_data` keyword has no arguments.

Pointing to the Beginning of the Packet Payload

License: Protection

The `pkt_data` keyword provides a pointer that serves as a reference for the positional arguments available for other keywords such as `content`, `byte_jump`, `byte_test`, and `pcre`.

When normalized FTP, telnet, or SMTP traffic is detected, the `pkt_data` keyword points to the beginning of the normalized packet payload. When other traffic is

detected, the `pkt_data` keyword points to the beginning of the raw TCP or UDP payload.

The following normalization options must be enabled for the system to normalize the corresponding traffic for inspection by intrusion rules:

- To normalize FTP traffic for inspection, you must enable the FTP and Telnet preprocessor **Detect Telnet Escape codes within FTP commands** option; see Understanding Server-Level FTP Options on page 865.
- To normalize telnet traffic for inspection, you must enable the FTP & Telnet preprocessor **Normalize** telnet option; see Understanding Telnet Options on page 862.
- To normalize SMTP traffic for inspection, you must enable the SMTP preprocessor **Normalize** option; see Understanding SMTP Decoding on page 916.

You can use multiple `pkt_data` keywords in a rule.

To point to the beginning of the packet payload:

Access: Admin/Intrusion Admin

▶ On the Create Rule page, select **pkt_data** from the drop-down list and click **Add Option.**

The `pkt_data` keyword appears.

The `pkt_data` keyword has no arguments.

Decoding and Inspecting Base64 Data

License: Protection

You can use the `base64_decode` and `base64_data` keywords in combination to instruct the rules engine to decode and inspect specified data as Base64 data. This can be useful, for example, for inspecting Base64-encoded HTTP Authentication request headers and Base64-encoded data in HTTP PUT and POST requests.

These keywords are particularly useful for decoding and inspecting Base64 data in HTTP requests. However, you can also use them with any protocol such as SMTP that uses the space and tab characters the same way HTTP uses these characters to extend a lengthy header line over multiple lines. When this line extension, which is known as folding, is not present in a protocol that uses it, inspection ends at any carriage return or line feed that is not followed with a space or tab.

See the following sections for more information:

- base64_decode on page 1209
- base64_data on page 1210

base64_decode

LICENSE: Protection

The `base64_decode` keyword instructs the rules engine to decode packet data as Base64 data. Optional arguments let you specify the number of bytes to decode and where in the data to begin decoding.

You can use the `base64_decode` keyword once in a rule; it must precede at least one instance of the `base64_data` keyword. See base64_data on page 1210 for more information.

Before decoding Base64 data, the rules engine unfolds lengthy headers that are folded across multiple lines. Decoding ends when the rules engine encounters any the following:

- the end of a header line
- the specified number of bytes to decode
- the end of the packet

The Optional base64_decode Arguments table describes the arguments you can use with the `base64_decode` keyword.

Optional base64_decode Arguments

ARGUMENT	DESCRIPTION
Bytes	Specifies the number of bytes to decode. When not specified, decoding continues to the end of a header line or the end of the packet payload, whichever comes first. You can specify a positive, non-zero value.
Offset	Determines the offset relative to the start of the packet payload or, when you also specify **Relative**, relative to the current inspection location. You can specify a positive, non-zero value.
Relative	Specifies inspection relative to the current inspection location.

To decode Base64 data:

ACCESS: Admin/Intrusion Admin

1. On the Create Rule page, select **base64_decode** from the drop-down list and click **Add Option.**

   The `base64_decode` keyword appears.

2. Optionally, select any of the arguments described in the Optional base64_decode Arguments table on page 1209.

base64_data

LICENSE: Protection

The `base64_data` keyword provides a reference for inspecting Base64 data decoded using the `base64_decode` keyword. The `base64_data` keyword sets inspection to begin at the start of the decoded Base64 data. Optionally, you can then use the positional arguments available for other keywords such as `content` or `byte_test` to further specify the location to inspect.

You must use the `base64_data` keyword at least once after using the `base64_decode` keyword; optionally, you can use `base64_data` multiple times to return to the beginning of the decoded Base64 data.

Note the following when inspecting Base64 data:

- You cannot use the fast pattern matcher; see Use Fast Pattern Matcher on page 1104 for more information.
- If you interrupt Base64 inspection in a rule with an intervening HTTP content argument, you must insert another `base64_data` keyword in the rule before further inspecting Base64 data; see HTTP Content Options on page 1099 for more information.

To inspect decoded Base64 data:

ACCESS: Admin/Intrusion Admin

▶ On the Create Rule page, select **base64_data** from the drop-down list and click **Add Option.**

The `base64_data` keyword appears.

Constructing a Rule

LICENSE: Protection

Just as you can create your own custom standard text rules, you can also modify existing standard text rules and shared object rule provided by Sourcefire and save your changes as a new rule. Note that for shared object rules provided by Sourcefire, you are limited to modifying rule header information such as the source and destination ports and IP addresses. You cannot modify the rule keywords and arguments in a shared object rule.

See the following sections for more information:

- Writing New Rules on page 1211
- Modifying Existing Rules on page 1214
- Adding Comments to Rules on page 1216
- Deleting Custom Rules on page 1217

Writing New Rules

LICENSE: Protection

You can create your own standard text rules.

In a custom standard text rule, you set the rule header settings and the rule keywords and arguments. Optionally, you can use the rule header settings to focus the rule to only match traffic using a specific protocol and traveling to or from specific IP addresses or ports.

After you create a new rule, you can find it again quickly using the rule number, which has the format `GID:SID:Rev`. The rule number for all standard text rules starts with 1. The second part of the rule number, the Snort ID (SID) number, indicates whether the rule is a local rule or a rule provided by Sourcefire. When you create a new rule, the system assigns the rule the next available Snort ID number for a local rule and saves the rule in the local rule category. Snort ID numbers for local rules start at 1,000,000 (although intrusion rules created on the secondary Defense Center in a high availability pair begin with the number 1,000,000,000) and the SID for each new local rule is incremented by one. The last part of the rule number is the revision number. For a new rule, the revision number is one. Each time you modify a custom rule the revision number increments by one.

IMPORTANT! The system assigns a new SID to any custom rule in an intrusion policy that you import. For more information, see Importing and Exporting Configurations on page 2308.

To write a custom standard text rule using the rule editor:

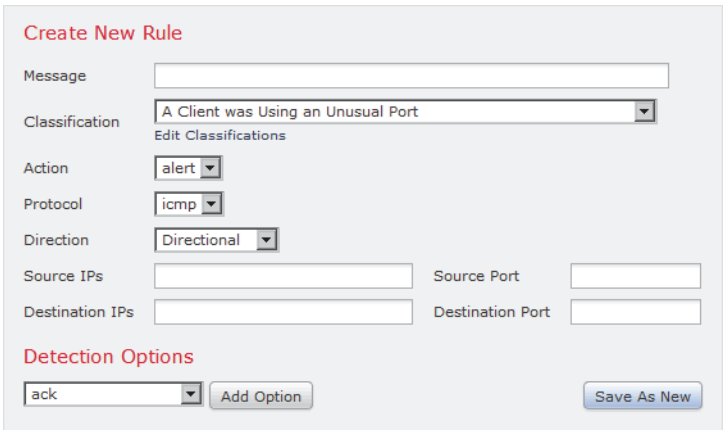
ACCESS: Admin/Intrusion Admin

1. Select **Policies > Intrusion > Rule Editor**.

   The Rule Editor page appears.

2. Click **Create Rule**.

   The Create Rule page appears.



3. In the **Message** field, enter the message you want displayed with the event.

   For details on event messages, see Defining the Event Message on page 1087.

TIP! You must specify a rule message. Also, the message cannot consist of white space only, one or more quotation marks only, one or more apostrophes only, or any combination of just white space, quotation marks, or apostrophes.

4. From the **Classification** list, select a classification to describe the type of event.

   For details on available classifications, see Defining the Intrusion Event Classification on page 1088.

5. From the **Action** list, select the type of rule you would like to create. You can use one of the following:

   - Select **alert** to create a rule that generates an event when traffic triggers the rule.
   - Select **pass** to create a rule that ignores traffic that triggers the rule.

6. From the **Protocol** list, select the traffic protocol (**tcp**, **udp**, **icmp**, or **ip**) of packets you want the rule to inspect.

   For more information about selecting a protocol type, see Specifying Protocols on page 1078.

7. In the **Source IPs** field, enter the originating IP address or address block for traffic that should trigger the rule. In the **Destination IPs** field, enter the destination IP address or address block for traffic that should trigger the rule.

   For more detailed information about the IP address syntax that the rule editor accepts, see Specifying IP Addresses In Intrusion Rules on page 1078.

8. In the **Source Port** field, enter the originating port numbers for traffic that should trigger the rule. In the **Destination Port** field, enter the receiving port numbers for traffic that should trigger the rule.

   IMPORTANT! The system ignores port definitions in an intrusion rule header when the protocol is set to `ip`.

   For more detailed information about the port syntax that the rule editor accepts, see Defining Ports in Intrusion Rules on page 1082.

9. From the **Direction** list, select the operator that indicates which direction of traffic you want to trigger the rule. You can use one of the following:
   - **Directional** to match traffic that moves from the source IP address to the destination IP address
   - **Bidirectional** to match traffic that moves in either direction

10. From the **Detection Options** list, select the keyword that you want to use.

11. Click **Add Option**.

12. Enter any arguments that you want to specify for the keyword you added. For more information about rule keywords and how to use them, see Understanding Keywords and Arguments in Rules on page 1084.

    When adding keywords and arguments, you can also perform the following:
    - To reorder keywords after you add them, click the up or down arrow next to the keyword you want to move.
    - To delete a keyword, click the **X** next to that keyword.

    Repeat steps 10 through 12 for each keyword option you want to add.

13. Click **Save As New** to save the rule.

    The system assigns the rule the next available Snort ID (SID) number in the rule number sequence for local rules and saves it in the local rule category.

    The system does not begin evaluating traffic against new or changed rules until you enable them within the appropriate intrusion policy, and then apply the intrusion policy as part of an access control policy. See Applying an Access Control Policy on page 506 for more information.

Modifying Existing Rules

LICENSE: Protection

You can modify custom standard text rules. You can also modify a standard text rule or shared object rule provided by Sourcefire and create one or more new instances of the rule by saving it.

Creating a rule or modifying a Sourcefire rule copies the new rule or revision to the local rule category and assigns the rule the next available Snort ID (SID) greater than 100000.

You can only modify header information for a shared object rule. You cannot modify the rule keywords used in a shared object rule or their arguments. Modifying header information for a shared object rule and saving your changes creates a new instance of the rule with a generator ID (GID) of 3 and the next available SID for a custom rule. The Rule Editor links the new instance of the shared object rule to the reserved `soid` keyword, which maps the rule you create to the rule created by the Sourcefire Vulnerability Research Team (VRT). You can delete instances of a shared object rule that you create, but you cannot delete shared object rules provided by Sourcefire. See Understanding Rule Headers on page 1076 and Deleting Custom Rules on page 1217 for more information.

IMPORTANT! Do not modify the protocol for a shared object rule; doing so would render the rule ineffective.

To modify a rule:

ACCESS: Admin/Intrusion Admin

1. Select **Policies > Intrusion > Rule Editor**.

   The Rule Editor page appears.

2. Locate the rule or rules you want to modify. You have the following options:
   - To locate rules by browsing rule categories, navigate through the folders to the rule you want and click the edit icon ( ) next to the rule.
   - To locate rules by searching for them, enter the search criteria (most simply, the SID) for the rule or rules you want and click **Search**. Click a rule returned by the search as appropriate. See Searching for Rules on page 1218 for more information.
   - To locate a rule or rules by filtering the rules displayed on the page, enter a rule filter in the text box indicated by the filter icon ( ) at the upper left of the rule list. Navigate to the rule you want and click the edit icon ( ) next to the rule. See Filtering Rules on the Rule Editor Page on page 1221 for more information.

   The rule editor opens, displaying the rule you selected.

   Note that if you select a shared object rule, the rule editor displays only the rule header information. A shared object rule can be identified on the Rule Editor page by a listing that begins with the number 3 (the GID), for example, 3:1000004.

3. Make any modifications to the rule (see Writing New Rules on page 1211 for more information about rule options) and click **Save As New**.

   The rule is saved to the local rule category.

TIP! If you want to use the local modification of the rule instead of the system rule, deactivate the system rule by using the procedures at Setting Rule States on page 770 and activate the local rule.

4. Activate the intrusion policy by applying it as part of an access control policy as described in Applying an Access Control Policy on page 506 to apply your changes.

Adding Comments to Rules

LICENSE: Protection

You can add comments to any intrusion rule. This allows you to provide additional context and information about the rule and the exploit or policy violation it identifies.

To add a comment to a rule:

ACCESS: Admin/Intrusion Admin

1. Select **Policies > Intrusion > Rule Editor**.

   The Rule Editor page appears.

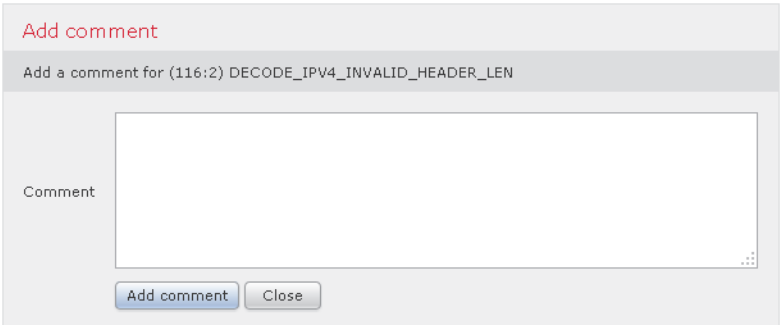
2. Locate the rule you want to annotate. You have the following options:

   - To locate a rule by browsing rule categories, navigate through the folders to the rule you want and click the edit icon ( ) next to the rule.
   - To locate a rule by searching for it, enter the search criteria (most simply, the SID) for the rule you want and click **Search**. Click the rule returned by the search as appropriate. See Searching for Rules on page 1218 for more information.
   - To locate a rule by filtering the rules displayed on the page, enter a rule filter in the text box, which is indicated by the filter icon ( ), at the upper left of the rule list. Navigate to the rule you want and click the edit icon ( ) next to the rule. See Filtering Rules on the Rule Editor Page on page 1221 for more information.

   The rule editor appears.

3. Click **Rule Comment**.

   The Rule Comment page appears.



4. Enter your comment in the text box and click **Add Comment**.

   The comment is saved in the comment text box.

TIP! You can also add and view rule comments in an intrusion event's packet view. For more information, see Viewing Event Information on page 672.

Deleting Custom Rules

LICENSE: Protection

You can delete custom rules that are not currently enabled in an intrusion policy. You cannot delete either standard text rules or shared object rules rules provided by Sourcefire.

The system stores deleted rules in the deleted category, and you can use a deleted rule as the basis for a new rule. See Modifying Existing Rules on page 1214 for information on editing rules.

The Rules page in an intrusion policy does not display the deleted category, so you cannot enable deleted custom rules.

Note that you can also delete all local rules on the Rule Updates page. See, for example, Using One-Time Rule Updates on page 2156.

See the following sections for more information:

- For information on creating custom rules, see Writing New Rules on page 1211.
- For information on importing local rules, see Importing Rule Updates and Local Rule Files on page 2154.
- For information on setting rule states, see Setting Rule States on page 770.

To delete custom rules:

ACCESS: Admin/Intrusion Admin

1. Select **Policies > Intrusion > Rule Editor**.

   The Rule Editor page appears.

2. You have two choices:
   - Click **Delete Local Rules**, then click **OK**.

     All rules not currently enabled in an intrusion policy whose changes you have saved are deleted from the local rule category and moved to the deleted category.
   - Navigate through the folders to the local rule category; click on the local rule category to expand it, then click the delete icon ( ) next to a rule you want to delete.

     The rule is deleted from the local rule category and moved to the deleted category.

     Note that custom standard text rules have a generator ID (GID) of 1 (for example, 1:1000012) and custom shared object rules have a GID of 3 (for example, 3:1000005).

TIP! The system also stores shared object rules that you save with modified header information in the local rule category and lists them with a GID of 3. You can delete your modified version of a shared object rule, but you cannot delete the original shared object rule.

Searching for Rules

LICENSE: Protection

The Sourcefire 3D System provides thousands of standard text rules, and the Sourcefire Vulnerability Research Team continues to add rules as new vulnerabilities and exploits are discovered. You can easily search for specific rules so that you can activate, deactivate, or edit them.

The Rule Search Criteria table describes the available search options:

Rule Search Criteria

OPTION	DESCRIPTION
Signature ID	To search for a single rule based on Snort ID (also called the Signature ID), enter a Snort ID number. To search for multiple rules, enter a comma-separated list of Snort ID numbers. This field has an 80-character limit.
Generator ID	To search for standard text rules, select **1**. To search for shared object rules, select **3**.
Message	To search for a rule with a specific message, enter a single word from the rule message in the **Message** field. For example, to search for DNS exploits, you would enter `DNS`, or to search for buffer overflow exploits, enter `overflow`.

Rule Search Criteria (Continued)

Option	Description
Protocol	To search rules that evaluate traffic of a specific protocol, select the protocol. If you do not select a protocol, search results contain rules for all protocols.
Source Port	To search for rules that inspect packets originating from a specified port, enter a source port number or a port-related variable.
Destination Port	To search for rules that inspect packets destined for a specific port, enter a destination port number or a port-related variable.
Source IP	To search for rules that inspect packets originating from a specified IP address, enter a source IP address or an IP address-related variable.
Destination IP	To search for rules that inspect packets destined for a specified IP address, enter a destination IP address or an IP address-related variable.
Keyword	To search for specific keywords, you can use the keyword search options. You select a keyword and a keyword value for which to search. You can also precede the keyword value with an exclamation point (!) to match any value other than the specified value.
Category	To search for rules in a specific category, select the category from the **Category** list.
Classification	To search for rules that have a specific classification, select the classification name from the **Classification** list.
Rule State	To search for rules within a specific policy and a specific rule state, select the policy from the first **Rule State** list, and choose a state from the second list to search for rules set to **Generate Events**, **Drop and Generate Events**, or **Disabled**.

To search for specific rules:

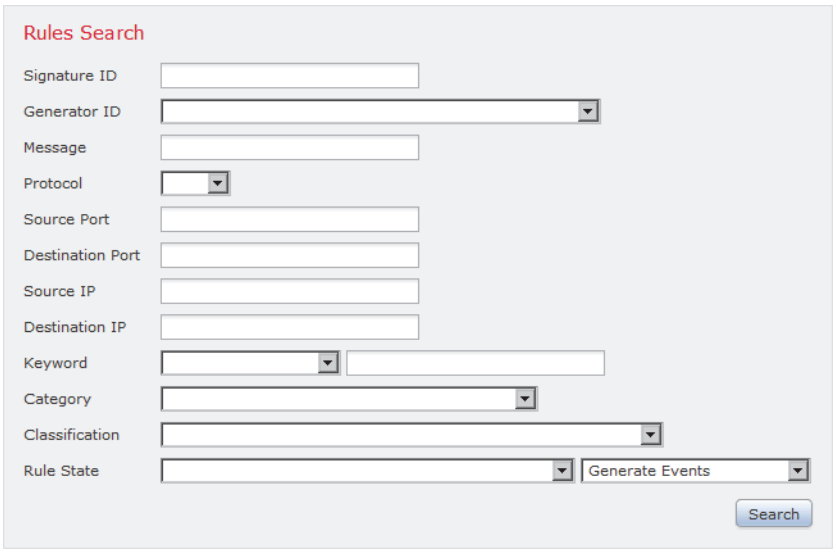
Access: Admin/Intrusion Admin

1. Select **Policies > Intrusion > Rule Editor**.

   The Rule Editor page appears.

2. Click **Search** on the toolbar.

   The Search page appears.



3. Add search criteria using any of the fields described in the Rule Search Criteria table on page 1218.

IMPORTANT! You must specify at least one search criterion to search for rules.

4. Perform the following steps to search for rules that contain specific keywords:
   - From the drop-down list in the **Keyword** section, select the keyword for which to search.

     For a list of each available keyword, see Understanding Keywords and Arguments in Rules on page 1084.
   - In the **Keyword** field, enter the arguments for which you want to search.
5. Click **Search**.

   The page reloads, showing a list of the rules that match your search criteria.
6. To view or edit a rule (or a copy of the rule, if it is a system rule), click the hyperlinked rule message. See Modifying Existing Rules on page 1214 for detailed information about editing rules.

Filtering Rules on the Rule Editor Page

LICENSE: Protection

You can filter the rules on the Rule Editor page to display a subset of rules. This can be useful, for example, when you want to modify a rule or change its state but have difficulty finding it among the thousands of rules available.

When you enter a filter, the page displays any folder that includes at least one matching rule, or a message when no rule matches. Your filter can include special keywords and their arguments, character strings, and literal character strings in quotes, with spaces separating multiple filter conditions. A filter cannot include regular expressions, wild card characters, or any special operator such as a negation character (!), a greater than symbol (>), less than symbol (<), and so on.

All keywords, keyword arguments, and character strings are case-insensitive. Except for the `gid` and `sid` keywords, all arguments and strings are treated as partial strings. Arguments for `gid` and `sid` return only exact matches.

Optionally, you can expand a folder on the original, unfiltered page and the folder remains expanded when the subsequent filter returns matches in that folder. This can be useful when the rule you want to find is in a folder that contains a large number of rules.

You cannot constrain a filter with a subsequent filter. Any filter you enter searches the entire rules database and returns all matching rules. When you enter a filter while the page still displays the result of a previous filter, the page clears and returns the result of the new filter instead.

You can use the same features with rules in a filtered or unfiltered list. For example, you can edit rules in a filtered or unfiltered list on the Rule Editor page. You can also use any of the options in the context menu for the page.

See the following sections for more information:

- Using Keywords in a Rule Filter on page 1221
- Using Character Strings in a Rule Filter on page 1223
- Combining Keywords and Character Strings in a Rule Filter on page 1224
- Filtering Rules on page 1224

Using Keywords in a Rule Filter

LICENSE: Protection

Each rule filter can include one or more keywords in the format:

`keyword``:`*`argument`*

where *`keyword`* is one of the keywords in the Rule Filter Keywords table on page 1222 and *`argument`* is a single, case-insensitive, alphanumeric string to search for in the specific field or fields relevant to the keyword.

Arguments for all keywords except `gid` and `sid` are treated as partial strings. For example, the argument `123` returns `"12345"`, `"41235"`, `"45123"`, and so on. The

arguments for `gid` and `sid` return only exact matches; for example, `sid:3080` returns only SID 3080.

TIP! You can search for a partial SID by filtering with one or more character strings. See Using Character Strings in a Rule Filter on page 1223 for more information.

The Rule Filter Keywords table describes the specific filtering keywords and arguments you can use to filter rules.

Rule Filter Keywords

KEYWORD	DESCRIPTION	EXAMPLE
`arachnids`	Returns one or more rules based on all or part of the Arachnids ID in a rule reference. See Defining the Event Reference on page 1092 for more information.	`arachnids:181`
`bugtraq`	Returns one or more rules based on all or part of the Bugtraq ID in a rule reference. See Defining the Event Reference on page 1092 for more information.	`bugtraq:2120`
`cve`	Returns one or more rules based on all or part of the CVE number in a rule reference. See Defining the Event Reference on page 1092 for more information.	`cve:2003-0109`
`gid`	The argument `1` returns standard text rules. The argument `3` returns shared object rules. See Reading Preprocessor Generator IDs on page 810 and the Rule Types table on page 746 for more information.	`gid:3`
`mcafee`	Returns one or more rules based on all or part of the McAfee ID in a rule reference. See Defining the Event Reference on page 1092 for more information.	`mcafee:10566`
`msg`	Returns one or more rules based on all or part of the rule Message field, also known as the event message. See Defining the Event Message on page 1087 for more information.	`msg:chat`

Rule Filter Keywords (Continued)

KEYWORD	DESCRIPTION	EXAMPLE
`nessus`	Returns one or more rules based on all or part of the Nessus ID in a rule reference. See Defining the Event Reference on page 1092 for more information.	`nessus:10737`
`ref`	Returns one or more rules based on all or part of a single alphanumeric string in a rule reference or in the rule Message field. See Defining the Event Reference on page 1092 and Defining the Event Message on page 1087 for more information.	`ref:MS03-039`
`sid`	Returns the rule with the exact Signature ID. See Reading Preprocessor Generator IDs on page 810 for more information.	`sid:235`
`url`	Returns one or more rules based on all or part of the URL in a rule reference. See Defining the Event Reference on page 1092 for more information.	`url:faqs.org`

Using Character Strings in a Rule Filter

LICENSE: Protection

Each rule filter can include one or more alphanumeric character strings. Character strings search the rule **Message** field, Signature ID, and Generator ID. For example, the string `123` returns the strings `"Lotus123"`, `"123mania"`, and so on in the rule message, and also returns SID 6123, SID 12375, and so on. For information on the rule **Message** field, see Defining the Event Message on page 1087. For information on rule SIDs and GIDs, see Reading Preprocessor Generator IDs on page 810.

All character strings are case-insensitive and are treated as partial strings. For example, any of the strings `ADMIN`, `admin`, or `Admin` return `"admin"`, `"CFADMIN"`, `"Administrator"` and so on.

You can enclose character strings in quotes to return exact matches. For example, the literal string `"overflow attempt"` in quotes returns only that exact string, whereas a filter comprised of the two strings `overflow` and `attempt` without quotes returns `"overflow attempt"`, `"overflow multipacket attempt"`, `"overflow with evasion attempt"`, and so on.

Combining Keywords and Character Strings in a Rule Filter

LICENSE: Protection

You can narrow filter results by entering any combination of keywords, character strings, or both, separated by spaces. The result includes any rule that matches all the filter conditions.

You can enter multiple filter conditions in any order. For example, each of the following filters returns the same rules:

- `url:at login attempt cve:200`
- `login attempt cve:200 url:at`
- `login cve:200 attempt url:at`

Filtering Rules

LICENSE: Protection

You can filter the rules on the Rule Editor page to display a subset of rules so you can more easily find specific rules. You can then use any of the page features, including selecting any of the features available in the context menu.

To filter for specific rules:

ACCESS: Admin/Intrusion Admin

1. Select **Policies > Intrusion > Rule Editor**.

   The Rule Editor page appears.

   Rule filtering can be particularly useful on the Rule Editor page when you want to locate a rule to edit it. See Modifying Existing Rules on page 1214 for more information.

2. Optionally, select a different grouping method from the Group Rules By list.

   TIP! Filtering may take significantly longer when the combined total of rules in all sub-groups is large because rules appear in multiple categories, even when the total number of unique rules is much smaller.

3. Optionally, click the folder next to any group that you want to expand.

   The folder expands to show the rules in that group. Note that some rule groups have sub-groups that you can also expand.

   Note also that expanding a group on the original, unfiltered page can be useful when you expect that a rule might be in that group. The group remains expanded when the subsequent filter results in a match in that folder, and when you return to the original, unfiltered page by clicking on the filter clearing icon (✖).

4. To activate the filter text box, click to the right of the filter icon ( ) that is inside the text box at the upper left of the rule list.
5. Type your filter constraints and press Enter.

   Your filter can include keywords and arguments, character strings with or without quotes, and spaces separating multiple conditions. See Filtering Rules on the Rule Editor Page on page 1221 for more information.

   The page refreshes to display any group that contains at least one matching rule.
6. Optionally, open any folder not already opened to display matching rules. You have the following filtering choices:
   - To enter a new filter, position your cursor inside the filter text box and click to activate it; type your filter and press Enter.
   - To clear the current filtered list and return to the original, pre-filtered page, click the filter clearing icon ( ).
7. Optionally, make any changes to the rule that you would normally make on the page. See Modifying Existing Rules on page 1214.

   To put any changes you make into effect, apply the intrusion policy part of an access control policy as described in Applying an Access Control Policy on page 506.

CHAPTER 31

WORKING WITH MALWARE PROTECTION AND FILE CONTROL

Malicious software, or *malware*, can enter your organization's network via multiple routes. To help you identify and mitigate the effects of malware, the Sourcefire 3D System's file control, network file trajectory, and advanced malware protection components can detect, track, store, analyze, and optionally block the transmission of malware and other types of files in network traffic.

You configure the system to perform malware protection and file control as part of your overall access control configuration. *File policies* that you create and associate with access control rules handle network traffic that matches the rules. You can download files detected in that traffic, then submit them to Sourcefire's malware awareness network (called the *Sourcefire cloud*) for *dynamic analysis* of the file's signatures to determine whether they contain malware.

If your organization has a FireAMP subscription, the Defense Center can also receive endpoint-based malware detection data from the Sourcefire cloud. The Defense Center presents this data alongside the network-based file and malware data generated by the system.

The Context Explorer and the dashboard provide you with different types of high-level views of the files (including malware files) detected in your organization. To further target your analysis, you can use a malware file's *network file trajectory* page to track the spread of an individual threat across hosts over time, allowing you to concentrate outbreak control and prevention efforts where most useful.

Although you can create file policies with any license, certain aspects of malware protection and file control require that you enable specific licensed capabilities on target devices, as described in the following table.

License Requirements for File and Malware Detection

Feature	Description	License
file control	detect and optionally block the transmission of file types in network traffic	Protection
advanced malware protection	detect, store, track, and optionally block the transmission of malware files or specified files in network traffic; submit captured files to the Sourcefire cloud to analyze for malware	Malware
FireAMP integration	receive endpoint-based malware information from the Sourcefire cloud, using your organization's FireAMP subscription; track the transmission of malware files using that information	Any
geolocation	detect source and destination countries and other geographical information associated with file and malware events	FireSIGHT (with GeoDB update for detailed information)

Because you cannot use a Malware license with a DC500, nor enable a Malware license on a Series 2 device, you cannot use those appliances to capture, store, or block individual files, submit files for dynamic analysis, or view file trajectories for files for which you conduct a malware cloud lookup.

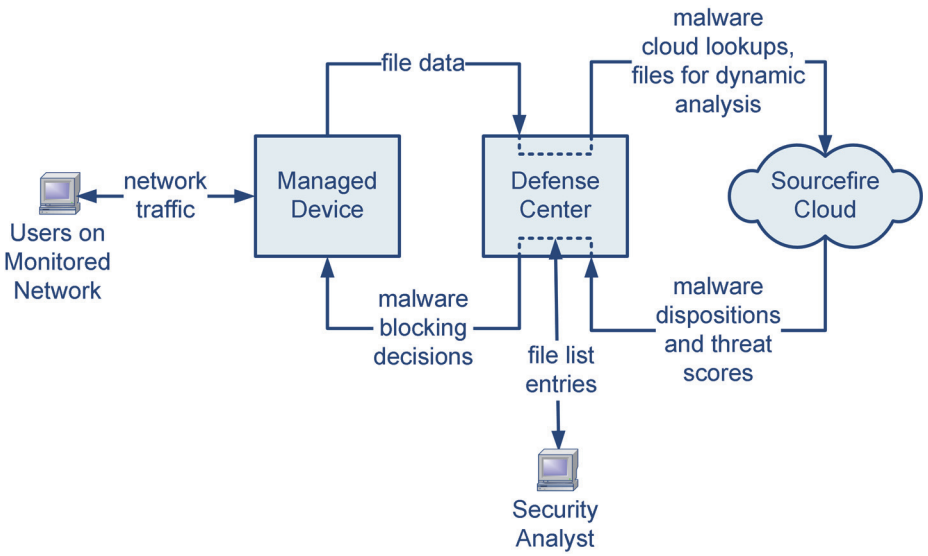
Understanding Malware Protection and File Control

LICENSE: Protection, Malware, or Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

Using the *advanced malware protection* feature, you can configure the Sourcefire 3D System to detect, store, track, analyze, and optionally block malware files being transmitted on your network, as shown in the following diagram.



The system can detect and optionally block malware in many types of files, including PDFs, Microsoft Office documents, and others. Managed devices monitor specific application protocol-based network traffic for transmissions of those file types. When a device detects an eligible file, it can send the file's SHA-256 hash value to the Defense Center, which then performs a *malware cloud lookup* using that information. Based on these results, the Sourcefire cloud returns a file disposition to the Defense Center.

When the system detects a file in network traffic, the *file storage* feature allows a device to store an eligible file to the hard drive or malware storage pack. For executable files with an Unknown disposition, the device can submit the file for *dynamic analysis,* regardless of whether the device stores the file. The cloud returns to the Defense Center:

- a threat score that describes the likelihood a file contains malware, and
- a dynamic analysis summary report that details why the cloud assigned the threat score.

If the file is an eligible executable file, the device can also perform a Spero analysis of the file structure and submit the resulting Spero signature to the cloud. Using this signature to supplement dynamic analysis, the cloud determines whether the file is malware.

If a file has a disposition in the cloud that you know to be incorrect, you can add the file's SHA-256 value to a file list:

- To treat a file as if the cloud assigned a clean disposition, add the file to the *clean list*.
- To treat a file as if the cloud assigned a malware disposition, add the file to the *custom detection list.*

If the system detects a file's SHA-256 value on a file list, it takes the appropriate action without performing a malware lookup or checking the file disposition. Note that you must configure a rule in the file policy with either a **Malware Cloud Lookup** or **Block Malware** action and a matching file type to calculate a file's SHA value. You can enable use of the clean list or custom detection list on a per-file-policy basis. For more information on managing file lists, see Working with File Lists on page 218.

To inspect or block files, you must enable a Protection license on the managed devices where you apply policies. To store files, perform malware cloud lookups on and optionally block malware files, submit files to the cloud for dynamic analysis, or add files to a file list, you must also enable a Malware license for those devices.

Understanding File Dispositions

The system determines file dispositions based on the disposition returned by the Sourcefire cloud. A file can have one of the following file dispositions returned by the Sourcefire cloud, as a result of addition to a file list, or due to threat score:

- `Malware` indicates that the cloud categorized the file as malware, or that the file's threat score exceeded the malware threshold defined in the file policy.
- `Clean` indicates that the cloud categorized the file as clean, or that a user added the file to the clean list.
- `Unknown` indicates that a malware cloud lookup occurred before the cloud assigned a disposition. The cloud has not categorized the file.
- `Custom Detection` indicates that a user added the file to the custom detection list.
- `Unavailable` indicates that the Defense Center could not perform a malware cloud lookup.

TIP! If several recent malware events have the disposition `Unavailable`, check the cloud connection and port configuration. For more information, see Security, Internet Access, and Communication Ports on page 54.

Based on the file disposition, the Defense Center instructs the managed device either to block the file or to allow its upload or download. To improve performance, if the system already knows the disposition for a file based on its SHA-256 value, the Defense Center uses the cached disposition rather than querying the Sourcefire cloud.

Note that file dispositions can change. For example, the cloud can determine that a file that was previously thought to be clean is now identified as malware, or the reverse—that a malware-identified file is actually clean. When the disposition changes for a file for which you performed a malware lookup in the last week, the cloud notifies the Defense Center so the system can take appropriate action the next time it detects that file being transmitted. A changed file disposition is called a *retrospective* disposition.

File dispositions returned from a malware cloud lookup, and any associated threat scores, have a time-to-live (TTL) value. After a file disposition has been held for the duration specified in the TTL value without update, the system purges the cached information. Dispositions and associated threat scores have the following TTL values:

- Clean - 4 hours
- Unknown - 1 hour
- Malware - 1 hour

If a malware cloud lookup against the cache identifies a cached disposition that timed out, the system performs a fresh lookup to determine a file disposition.

Understanding File Control

If your organization wants to block not only the transmission of malware files, but all files of a specific type (regardless of whether the files contain malware), the *file control* feature allows you to cast a wider net. As with malware protection, managed devices monitor network traffic for transmissions of specific file types, then either block or allow the file.

File control is supported for all file types where the system can detect malware, plus many additional file types. These file types are grouped into basic categories, including multimedia (swf, mp3), executables (exe, torrent), and PDFs. Note that file control, unlike malware protection, does not require queries of the Sourcefire cloud.

Using Captured Files, File Events, and Malware Events for Analysis

The system generates malware and file events when files are transferred or blocked. It also collects information on any files captured by a managed device. You can view these events and information using the Defense Center's web interface. Additionally, the Context Explorer and the dashboard provide you with different types of high-level views of the files (including malware files) detected by your organization.

To further target your analysis, the *network file trajectory* feature allows you to track individual files' paths of transmission. A file's trajectory page displays summary information about the file, a graphical map of the file's transmission from host to host (including blocked transmissions), and a list of the malware or file events associated with the detection or blocking of those files.

Note that because you cannot use a Malware license with a DC500, nor enable a Malware license on a Series 2 device, you cannot use those appliances to capture or block individual files, submit files for dynamic analysis, or view file trajectories for files for which you conduct a malware cloud lookup.

For more information, see the following sections:

Configuring Malware Protection and File Control

LICENSE: Protection or Malware
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

You configure malware protection and file control as part of your overall access control configuration by associating file policies with access control rules. This association ensures that before the system passes a file in traffic that matches an access control rule's conditions, it first inspects the file.

A file policy, like its parent access control policy, contains rules that determine how the system handles files that match the conditions of each rule. You can configure separate file rules to take different actions for different file types, application protocols, or directions of transfer.

Once a file matches a rule, the rule can:

- allow or block files based on simple file type matching
- block files based on malware file disposition
- capture files and store them to the device
- submit captured files for dynamic analysis

In addition, the file policy can:

- automatically treat a file as if it is clean or malware based on entries in the clean list or custom detection list
- treat a file as if it is malware if the file's threat score exceeds a configurable threshold

As a simple example, you could implement a file policy that blocks your users from downloading executable files. As another example, you could examine downloaded PDFs for malware and block any instances you find. For detailed information on file policies and associating them with access control rules, see Understanding and Creating File Policies on page 1236 and Performing File and Intrusion Inspection on Allowed Traffic on page 556.

Because you cannot use a Malware license with a DC500, you cannot use that appliance to apply file policies that perform network-based malware protection. Similarly, because you cannot enable a Malware license on a Series 2 device, you cannot apply a file policy that performs network-based malware protection to those appliances.

Logging Events Based on Malware Protection and File Control

LICENSE: Protection or Malware
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

The Defense Center logs records of the system's file inspection and handling as captured files, file events, and malware events:

- *Captured files* represent files that the system captured.
- *File events* represent files that the system detected, and optionally blocked, in network traffic.
- *Malware events* represent malware files detected, and optionally blocked, in network traffic by the system.
- *Retrospective malware events* represent files whose malware file dispositions have changed.

When the system generates a malware event based on detection or blocking of malware in network traffic, it also generates a file event, because to detect malware in a file the system must first detect the file itself. Note that endpoint-based malware events generated by FireAMP Connectors (see Integrating FireAMP with the Sourcefire 3D System on page 1233) do not have corresponding file events. Similarly, when the system captures a file in network traffic, it also generates a file event because the system first detected the file.

You can use the Defense Center to view, manipulate, and analyze captured files, file events, and malware events, then communicate your analysis to others. The Context Explorer, dashboards, event viewer, network file trajectory map, and reporting features can give you a deeper understanding of the files and malware detected, captured, and blocked. You can also use events to trigger correlation policy violations, or alert you via email, SMTP, or syslog. For detailed information on file and malware events, see Working with File Events on page 1265 and Working with Malware Events on page 1274.

Because you cannot use a Malware license with a DC500, nor can you enable a Malware license on a Series 2 device, you cannot use those appliances to generate or analyze captured files, file events, and malware events associated with malware cloud lookups.

Integrating FireAMP with the Sourcefire 3D System

LICENSE: Any

FireAMP is Sourcefire's enterprise-class advanced malware analysis and protection solution that discovers, understands, and blocks advanced malware outbreaks, advanced persistent threats, and targeted attacks.

If your organization has a FireAMP subscription, individual users install *FireAMP Connectors* on *endpoints*: computers and mobile devices. A FireAMP Connector is a lightweight agent that, among other capabilities, can inspect files upon upload, download, execution, open, copy, move, and so on. These connectors communicate with the Sourcefire cloud to determine if inspected files contain malware.

When a file is positively identified as malware, the cloud sends the threat identification to the Defense Center. The cloud can also send other kinds of information to the Defense Center, including data on scans, quarantines, blocked executions, and cloud recalls. The Defense Center logs this information as malware events.

With a FireAMP deployment, you can not only configure Defense Center-initiated remediations and alerts based on malware events, but you can also use the FireAMP portal (http://amp.sourcefire.com/) to help you mitigate the effect of malware. The portal provides a robust, flexible web interface where you control all aspects of your FireAMP deployment and manage all phases of an outbreak. You can:

- configure custom malware detection policies and profiles for your entire organization, as well as perform flash and full scans on all your users' files
- perform malware analysis, including view heat maps, detailed file information, network file trajectory, and threat root causes
- configure multiple aspects of outbreak control, including automatic quarantines, application blocking to stop non-quarantined executables from running, and exclusion lists
- create custom protections, block execution of certain applications based on group policy, and create custom whitelists

For more information, see the following sections:

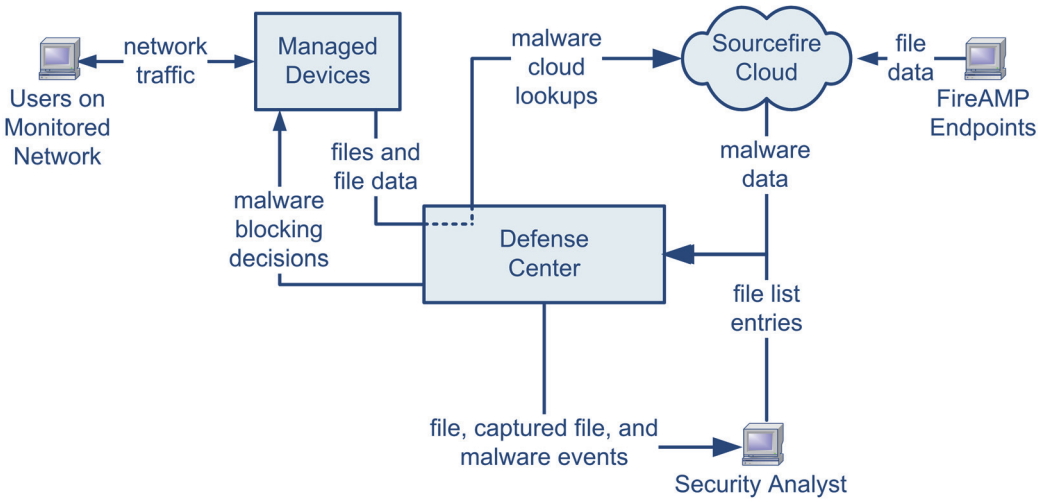
- Network-Based AMP vs Endpoint-Based FireAMP on page 1234 compares the malware protection strategies available in the Sourcefire family of products.
- Working with Sourcefire Cloud Connections for FireAMP on page 1254 explains how to establish communications between the Defense Center and the Sourcefire cloud.

TIP! For detailed information on FireAMP, refer to the online help on the FireAMP portal.

Network-Based AMP vs Endpoint-Based FireAMP

LICENSE: Malware or Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

The following diagram shows how you can use the Defense Center to work with data from both a network-based advanced malware protection strategy and an endpoint-based FireAMP strategy.



Note that because FireAMP malware detection is performed at the endpoint at download or execution time, while managed devices detect malware in network traffic, the information in the two types of malware events is different. For example, endpoint-based malware events contain information on file path, invoking client application, and so on, while malware detections in network traffic contain port, application protocol, and originating IP address information about the connection used to transmit the file.

As another example, for network-based malware events, user information represents the user most recently logged into the host where the malware was destined, as determined by network discovery. On the other hand, FireAMP-reported users represent the user currently logged into the endpoint where the malware was detected, as determined by the local connector.

IMPORTANT! The IP addresses reported in endpoint-based malware events may not be in your network map—and may not even be in your monitored network. Depending on your deployment, network architecture, level of compliance, and other factors, the endpoints where connectors are installed may not be the same hosts as those monitored by your managed devices.

Note that because you cannot use a Malware license with a DC500, nor enable a Malware license on a Series 2 device, you cannot use those appliances to capture

or block individual files, submit files for dynamic analysis, or view trajectories of files for which you conduct a malware cloud lookup.

The following table summarizes the differences between the two strategies.

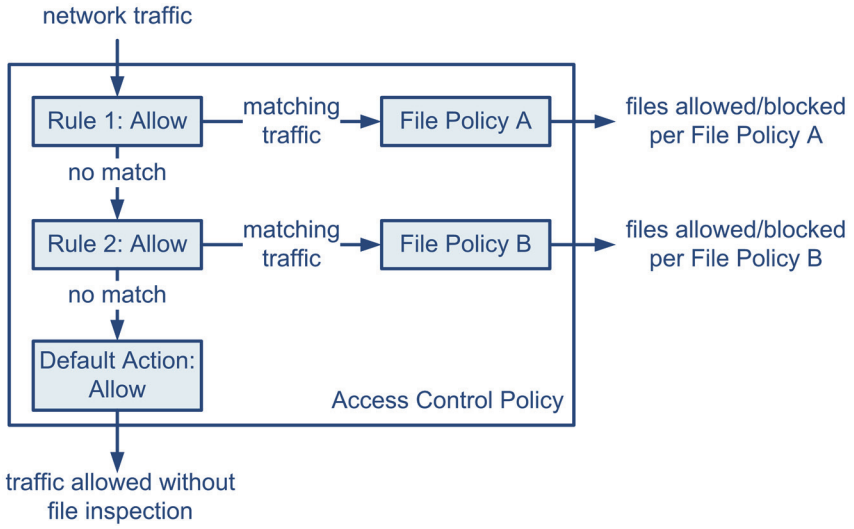
Network vs Endpoint-Based Malware Protection Strategies

FEATURE	NETWORK-BASED	ENDPOINT-BASED (FIREAMP)
file type detection and blocking method (file control)	in network traffic, using access control and file policies	not supported
malware detection and blocking method	in network traffic, using access control and file policies	on individual endpoints, using an installed connector that communicates with the Sourcefire cloud
network traffic inspected	traffic passing through a managed device	none; connectors installed on endpoints directly inspect files
malware detection robustness	limited file types	all file types
malware analysis choices	Defense Center-based, plus analysis in the cloud	Defense Center-based, plus additional options on the FireAMP portal
malware mitigation	malware blocking in network traffic, Defense Center-initiated remediations	FireAMP-based quarantine and outbreak control options, Defense Center-initiated remediations
events generated	file events, captured files, malware events, and retrospective malware events	malware events
information in malware events	basic malware event information, plus connection data (IP address, port, and application protocol)	in-depth malware event information; no connection data
network file trajectory	Defense Center-based	Defense Center-based, plus additional options on the FireAMP portal
required licenses or subscriptions	Protection license to perform file control; Malware license to perform malware protection	FireAMP subscription (not license-based)

Understanding and Creating File Policies

LICENSE: Protection or Malware
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

A file policy is a set of configurations that the system uses to perform advanced malware protection and file control, as part of your overall access control configuration. Consider the following diagram of a simple access control policy in an inline deployment.



The policy has two access control rules, both of which use the Allow action and are associated with file policies. The policy's default action is also to allow traffic, but without file policy inspection. In this scenario, traffic is handled as follows:

- Traffic that matches `Rule 1` is inspected by `File Policy A`.
- Traffic that does not match `Rule 1` is evaluated against `Rule 2`. Traffic that matches `Rule 2` is inspected by `File Policy B`.
- Traffic that does not match either rule is allowed; you cannot associate a file policy with the default action.

A file policy, like its parent access control policy, contains rules that determine how the system handles files that match the conditions of each rule. You can configure separate file rules to take different actions for different file types, application protocols, or directions of transfer.

Once a file matches a rule, the rule can:

- allow or block files based on simple file type matching
- block files based on Malware file disposition
- store captured files to the device
- submit captured files for dynamic analysis

In addition, the file policy can:

- automatically treat a file as if it is clean or malware based on entries in the clean list or custom detection list
- treat a file as if it is malware if the file's threat score exceeds a configurable threshold

You can associate a single file policy with an access control rule whose action is **Allow**, **Interactive Block**, or **Interactive Block with reset**. The system then uses that file policy to inspect network traffic that meets the conditions of the access control rule. By associating file policies with individual access control rules, you have granular control over how you identify and block files transmitted on your network. In other words, this association tells the system that before it passes traffic that matches an access control rule's conditions, you first want to inspect the traffic with a file policy.

Keep in mind that the system can perform file inspection on interactively blocked traffic only if the user bypasses the warning and clicks through to the originally requested site. Otherwise, the connection is denied without either file or intrusion inspection; see Understanding Rule Actions on page 519 and Adding an HTTP Response Page on page 474.

You can associate different file policies with individual access control rules in the same access control policy. This allows you to match various file and malware detection profiles against different types of traffic on your network. Note, however, that you **cannot** use a file policy to inspect traffic handled by the access control default action.

Also note that because you cannot use a Malware license with a DC500, you cannot use that appliance to apply file policies that perform network-based malware protection. Similarly, because you cannot enable a Malware license on a Series 2 device, you cannot apply a file policy that performs network-based malware protection to those appliances.

File and Intrusion Policy Interaction

You can associate both a file policy and an intrusion policy with an access control rule. When you do so, note that the two policies interact in ways that may change how traffic is inspected.

File inspection occurs before any intrusion policy inspection; that is, the system does not inspect files blocked by a file policy for intrusions. Within a file policy, simple blocking by type takes precedence over malware inspection and blocking.

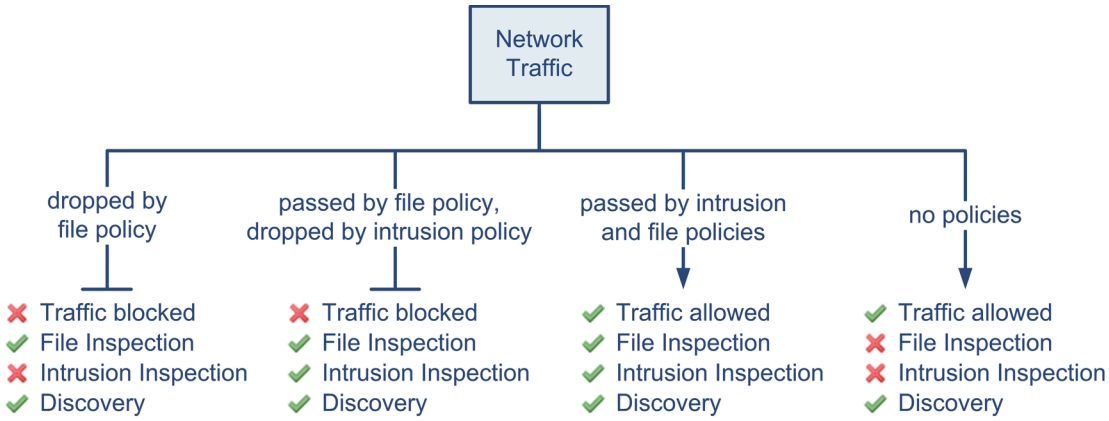
For example, consider a scenario where you normally want to allow certain network traffic as defined in an access control rule. However, as a precaution, you want to block the download of executable files, examine downloaded PDFs for malware and block any instances you find, and perform intrusion inspection on the traffic. You create an access control policy with a rule that matches any traffic and that is associated with both an intrusion policy and a file policy. The file policy has a rule that matches downloaded PDFs and has a Block Files action. It has

another rule that matches downloaded executable files and has a Block Malware action. After you apply the policy:

- First, the system blocks the download of all PDF files, based on simple type matching specified in the file policy. Because they are immediately blocked, these files are subject to neither malware lookup nor intrusion inspection.
- Next, the system performs malware cloud lookups for executables downloaded to a host on your network. Any executables with a malware file disposition are blocked, and are not subject to intrusion inspection.
- Finally, the system uses the intrusion policy associated with the access control rule to inspect any remaining traffic, including files not blocked by the file policy.

The diagram below illustrates the types of inspection performed on traffic that meets the conditions of either an Allow or user-bypassed Interactive Block access control rule. For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with a single access control rule. You can, however, configure one without the other. Without a file policy, traffic flow is determined by the intrusion policy; without an intrusion policy, traffic flow is determined by the file policy.

Regardless of whether the traffic is inspected or dropped by an intrusion or file policy, the system can inspect it using network discovery; see Introduction to Network Discovery on page 1303.



File Rules

You populate a file policy with file rules. The following table describes the components of a file rule.

File Rule Components

File Rule Component	Description
application protocol	The system can detect and inspect files transmitted via FTP, HTTP, SMTP, IMAP, POP3, and NetBIOS-ssn (SMB). To improve performance, you can restrict file detection to only one of those application protocols on a per-file rule basis.
direction of transfer	You can inspect incoming FTP, HTTP, IMAP, POP3, and NetBIOS-ssn (SMB) traffic for downloaded files; you can inspect outgoing FTP, HTTP, SMTP, and NetBIOS-ssn (SMB) traffic for uploaded files.
file categories and types	The system can detect various types of files. These file types are grouped into basic categories, including multimedia (swf, mp3), executables (exe, torrent), and PDFs. You can configure file rules that detect individual file types, or on entire categories of file types. For example, you could block all multimedia files, or just ShockWave Flash (swf) files. Or, you could configure the system to alert you when a user downloads a BitTorrent (torrent) file. **WARNING!** Frequently triggered file rules can affect system performance. For example, detecting multimedia files in HTTP traffic (YouTube, for example, transmits significant Flash content) could generate an overwhelming number of events.
file rule action	A file rule's action determines how the system handles traffic that matches the conditions of the rule. **IMPORTANT!** File rules are evaluated in rule-action, not numerical, order. For more information, see the next section, File Rule Actions and Evaluation Order.

File Rule Actions and Evaluation Order

Each file rule has an associated action that determines how the system handles traffic that matches the conditions of the rule. You can set separate rules within a

file policy to take different actions for different file types, application protocols, or directions of transfer. The rule actions are as follows, in rule-action order:

1. *Block Files* rules allow you to block specific file types.
2. *Block Malware* rules allow you to calculate the SHA-256 hash value of specific file types, then use a cloud lookup process to first determine if files traversing your network contain malware, then block files that represent threats.
3. *Malware Cloud Lookup* rules allow you to log the malware disposition of files traversing your network based on a cloud lookup, while still allowing their transmission.
4. *Detect Files* rules allow you to log the detection of specific file types to the database, while still allowing their transmission.

For each file rule action, you can configure options to reset the connection when a file transfer is blocked, store captured files to the managed device, and submit captured files to the cloud for dynamic and Spero analysis. The following table details the options available to each file action.

File Rule Actions

Action	Resets Connection?	Stores Files?	Dynamic Analysis?	Spero Analysis for MSEXE?
Block Files	yes (recommended)	yes, you can store all matching file types	no	no
Block Malware	yes (recommended)	yes, you can store file types matching the file dispositions you select	yes, you can submit executable files with unknown file dispositions	yes, you can submit executable files
Detect Files	no	yes, you can store all matching file types	no	no
Malware Cloud Lookup	no	yes, you can store file types matching the file dispositions you select	yes, you can submit executable files with unknown file dispositions	yes, you can submit executable files

File and Malware Detection, Capture, and Blocking Notes and Limitations

Note the following details and limitations on file and malware detection, capture, and blocking behavior:

- If an end-of-file marker is not detected for a file, regardless of transfer protocol, the file will not be blocked by a **Block Malware** rule or the custom detection list. The system waits to block the file until the entire file has been received, as indicated by the end-of-file marker, and blocks the file when the marker is detected.
- If the end-of-file marker for an FTP file transfer is transmitted separately from the final data segment, the marker will be blocked and the FTP client will indicate that the file transfer failed, but the file will actually completely transfer to disk.
- If the traffic from an FTP data session and its control session are not load-balanced to the same Snort, files in that FTP session may not be blocked by file rules with **Block Files** or **Block Malware** actions or by the custom detection list. File events should be generated for the session.
- For an access control policy using a file policy with **Block Malware** rules for FTP, if you set the default action to an intrusion policy with **Drop when Inline** disabled, the system generates events for detected files or malware matching the rules, but does not drop the files. To block FTP fire transfers and use an intrusion policy as the default action for the access control policy where you select the file policy, you must select an intrusion policy with **Drop when Inline** enabled.
- File rules with **Block Files** and **Block Malware** actions block automatic resumption of file download via HTTP by blocking new sessions with the same file, URL, server, and client application detected for 24 hours after the initial file transfer attempt occurs.
- In rare cases, if traffic from an HTTP upload session is out of order, the system cannot reassemble the traffic correctly and therefore will not block it or generate a file event.
- If you transfer a file over NetBios-ssn (such as an SMB file transfer) that is blocked with a **Block Files** rule, you may see a file on the destination host. However, the file is unusable because it is blocked after the download starts, resulting in an incomplete file transfer.

- If you create file rules to detect or block files transferred over NetBios-ssn (such as an SMB file transfer), the system does not inspect files transferred in an established TCP or SMB session started before you apply an access control policy invoking the file policy so those files will not be detected or blocked.
- If the total number of bytes for all file names for files in a POP3, POP, SMTP, or IMAP session exceeds 1024, file events from the session may not reflect the correct file names for files that were detected after the file name buffer filled.
- If Mac or Linux-based hosts upload text-based files using Mozilla Thunderbird over SMTP, or download text-based files over IMAP or POP, and a file rule captures the file, the captured file size may be different than the actual file size. Mac-based hosts use the CR newline character; Linux-based hosts use the LF newline character. Thunderbird replaces CR and LF in text-based files with the CRLF newline character.
- Sourcefire recommends that you enable **Reset Connection** for the **Block Files** and **Block Malware** actions to prevent blocked application sessions from remaining open until the TCP connection resets. If you do not reset connections, the client session will remain open until the TCP connection resets itself.
- If a file rule is configured with a **Malware Cloud Lookup** or **Block Malware** action and the Defense Center cannot establish connectivity with the cloud, the system cannot perform any configured rule action options unless cloud connectivity is restored.
- If you are monitoring high volumes of traffic, do **not** store all captured files, or submit all captured files for dynamic analysis. Doing so can negatively impact system performance.

File Rule Evaluation Example

Unlike in access control policies, where rules are evaluated in numerical order, file policies handle files in File Rule Actions and Evaluation Order on page 1239. That is, simple blocking takes precedence over malware inspection and blocking, which takes precedence over simple detection and logging. As an example, consider four rules that handle PDF files in a single file policy. Regardless of the

order in which they appear in the web interface, these rules are evaluated in the following order:

File Rule Evaluation Order Example

App. Protocol	Direction	Action	Action Options	Result
SMTP	Upload	Block Files	Reset Connection	Blocks users from emailing PDF files and resets the connection.
FTP	Download	Block Malware	Store Files with Unknown Disposition, Reset Connection	Blocks the download of malware PDF files via file transfer, stores files with an Unknown file disposition to the device, and resets the connection.
POP3, IMAP	Download	Malware Cloud Lookup	Store Files with Unknown Disposition, Dynamic Analysis	Inspects PDF files received via email for malware, and stores files with an Unknown file disposition to the device. Submits the files to the Sourcefire cloud for dynamic analysis.
Any	Any	Detect Files	none	Detects and logs, but allows the traffic, when users view PDF files on the web (that is, via HTTP).

The Defense Center uses warning icons ( ) to designate conflicting file rules. For details, hover your pointer over a warning icon.

Note that you cannot perform malware analysis on all file types detected by the system. After you select values from the **Application Protocol**, **Direction of Transfer**, and **Action** drop-down lists, the system constrains the list of file types.

Note that because you cannot use a Malware license with a DC500, you cannot create file rules that use the Block Malware or Malware Cloud Lookup action or use that appliance to apply file policies that contain rules with those actions. Similarly, because you cannot enable a Malware license on a Series 2 device, you cannot apply a file policy containing rules with those actions to those appliances.

Logging Captured Files, File Events, Malware Events and Alerts

When you associate a file policy with an access control rule, the system automatically enables file and malware event logging for matching traffic. If the file policy is configured to capture and store files, the system also automatically

enables captured file logging when a file is captured. When the system inspects a file, it can generate the following types of events:

- *file events*, which represent detected or blocked files, and detected malware files
- *malware events*, which represent detected malware files
- *retrospective malware events*, which are generated when the Malware file disposition for a previously detected file changes

When a file policy generates a file or malware event, or captures a file, the system automatically logs the end of the associated connection to the Defense Center database, regardless of the logging configuration of the invoking access control rule.

IMPORTANT! File events generated by inspecting NetBIOS-ssn (SMB) traffic do not immediately generate connection events because the client and server establish a persistent connection. The system generates connection events after the client or server ends the session.

For each of these connection events:

- The **Files** field contains an icon () that indicates the number of files (including malware files) detected in the connection; click the icon to see a list of those files and, for malware files, their file dispositions.
- The **Reason** field indicates the reason the connection event was logged, which depends on the file rule action:
  - `File Monitor` for Detect Files and Malware Cloud Lookup file rules and for files on the clean list
  - `File Block` for Block Files or Block Malware file rules
  - `File Custom Detection` if the system encountered a file on the custom detection list
  - `File Resume Allow` where file transmission was originally blocked by a Block Files or Block Malware file rule. After a new access control policy was applied that allowed the file, the HTTP session automatically resumed.
  - `File Resume Block` where file transmission was originally allowed by a Detect Files or Malware Cloud Lookup file rule. After a new access control policy was applied that blocked the file, the HTTP session automatically stopped.
- For connections where a file or malware was blocked, the **Action** is `Block`.

As with any kind of event generated by the Sourcefire 3D System, you can view, manipulate, and analyze file and malware events using the Defense Center's web

interface. You can also use malware events to trigger correlation policy violations, or alert you via email, SMTP, or syslog.

IMPORTANT! The Defense Center can also receive malware events using your organization's FireAMP subscription. Because these malware events are generated on endpoints at download or execution time, their information is different from that in network-based malware events.

For more information on connection, file, and malware events, as well as additional details on how they are logged, see:

- Logging Connection, File, and Malware Information on page 560
- Working with File Events on page 1265
- Working with Malware Events on page 1274
- Understanding Connection Data on page 585

Internet Access and High Availability

The system uses port 443 to perform malware cloud lookups for network-based AMP. You must open that port outbound on the Defense Center. Although they share file policies and related configurations, Defense Centers in a high availability pair share neither cloud connections nor captured files, file events, and malware events. To ensure continuity of operations, and to ensure that detected files' malware dispositions are the same on both Defense Centers, both primary and secondary Defense Centers must have access to the cloud.

To submit files to the cloud for dynamic analysis, you must also open port 443 outbound on the device.

Managing File Policies

You create, edit, delete, and compare file policies on the File Policies page (**Policies > Files**), which displays a list of existing file policies along with their last-modified dates.

Clicking the apply icon ( ) for a file policy displays a dialog box that tells you which access control policies use the file policy, then redirects you to the Access Control page. This is because you cannot apply a file policy independently, as a file policy is considered part of its parent access control policies. To use a new file policy, or to apply changes made to an existing file policy, you must apply or reapply the parent access control policies.

Note the following:

- The system checks the cloud for updates to the list of file types eligible for dynamic analysis (no more than once a day). If the list of eligible file types changes, this constitutes a change in the file policy; any access control policy using the file policy is marked out-of-date if applied to any devices. You must reapply the parent access control policy to apply the updated file policy to the device.
- You cannot delete a file policy used in a saved or applied access control policy.

For more information on managing file policies, see the following sections:

- Creating a File Policy on page 1246
- Working with File Rules on page 1247
- Comparing Two File Policies on page 1252

Creating a File Policy

LICENSE: Protection or Malware
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

After you create a file policy and populate it with rules, you can use it in an access control policy.

Note that because you cannot use a Malware license with a DC500, you cannot create file rules that use the Block Malware or Malware Cloud Lookup action or use that appliance to apply file policies that contain rules with those actions. Similarly, because you cannot enable a Malware license on a Series 2 device, you cannot apply a file policy containing rules with those actions to those appliances.

TIP! To make a copy of an existing file policy, click the copy icon (), then type a unique name for the new policy in the dialog box that appears. You can then modify the copy.

To create a file policy:

ACCESS: Admin/Access Admin

1. Select **Policies > Files**.

   The File Policies page appears.

2. Click **New File Policy**.

   The New File Policy dialog box appears.

   For a new policy, the web interface indicates that the policy is not in use. If you are editing an in-use file policy, the web interface tells you how many access control policies use the file policy. In either case, you can click the text to jump to the Access Control Policies page; see Managing Access Control Policies on page 496.

3. Enter a **Name** and optional **Description** for your new policy, then click **Save**.

   The File Policy Rules tab appears.

4. Add one or more rules to the file policy.

   File rules give you granular control over which file types you want to log, block, or scan for malware. For information on adding file rules, see Working with File Rules on page 1247.

   Because you cannot use a Malware license with a DC500, you cannot create file rules that use the Block Malware or Malware Cloud Lookup action or use that appliance to apply file policies that contain rules with those actions. Similarly, because you cannot enable a Malware license on a Series 2 device, you cannot apply a file policy containing rules with those actions to those appliances.

5. Configure the advanced options. See Configuring Advanced File Policy Options on page 1251 for more information.

6. Click **Save**.

   To use your new policy, you must add the file policy to an access control rule, then apply the access control policy. If you are editing an existing file policy, you must reapply any access control policies that use the file policy.

Working with File Rules

License: Protection or Malware
Supported Devices: feature dependent
Supported Defense Centers: feature dependent

To be effective, a file policy must contain one or more rules. You create, edit, and delete rules on the File Policy Rules page, which appears when you create a new

file policy or edit an existing policy. The page lists all the rules in the policy, along with each rule's basic characteristics.

The page also notifies you of how many access control policies use this file policy. You can click the notification to display a list of the parent policies and, optionally, continue to the Access Control Policies page.

To create a file rule:

Access: Admin/Access Admin

1. Select **Policies > Files**.

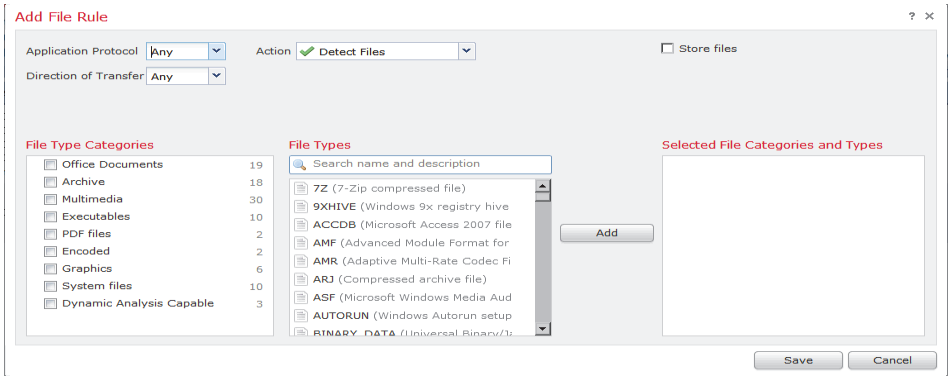
   The File Policies page appears.

2. You have the following options:

   - To add rules to a new policy, click **New File Policy** to create a new policy; see Creating a File Policy on page 1246.
   - To add rules to an existing policy, click the edit icon ( ) next to the policy.

3. On the File Policy Rules page that appears, click **Add File Rule**.

   The Add File Rule dialog box appears.



4. Select an **Application Protocol**.

   Any, the default, detects files in HTTP, SMTP, IMAP, POP3, FTP, and NetBIOS-ssn (SMB) traffic.

5. Select a **Direction of Transfer**.

   You can inspect the following types of incoming traffic for downloaded files:

   - HTTP
   - IMAP
   - POP3
   - FTP
   - NetBIOS-ssn (SMB)

   You can inspect the following types of outgoing traffic for uploaded files:

   - HTTP
   - FTP
   - SMTP
   - NetBIOS-ssn (SMB)

   Use **Any** to detect files over multiple application protocols, regardless of whether users are sending or receiving.

6. Select a file rule **Action**. See the File Rule Actions table on page 1240 for more information.

   When you select either Block Files or Block Malware, Reset Connection is enabled by default. To **not** reset the connection where a blocked file transfer occurs, clear the option.

   IMPORTANT! Sourcefire recommends that you leave **Reset Connection** enabled to prevent blocked application sessions from remaining open until the TCP connection resets.

   For detailed information on file rule actions, see File Rule Actions and Evaluation Order on page 1239.

   Note that because you cannot use a Malware license with a DC500, you cannot create file rules that use the Block Malware or Malware Cloud Lookup action or use that appliance to apply file policies that contain rules with those actions. Similarly, because you cannot enable a Malware license on a Series 2 device, you cannot apply a file policy containing rules with those actions to those appliances.

7. Select one or more **File Types**. Use the Shift and Ctrl keys to select multiple file types. You can filter the list of file types in the following ways:
   - Select one or more **File Type Categories**.
   - Search for a file type by its name or description. For example, type `windows` in the **Search name and description** field to display a list of Microsoft Windows-specific files.

   TIP! Hover your pointer over a file type to view its description.

   The file types that you can use in a file rule vary depending on your selections for **Application Protocol**, **Direction of Transfer**, and **Action**.

   For example, selecting **Download** as the **Direction of Transfer** removes `GIF`, `PNG`, `JPEG`, `TIFF`, and `ICO` from the **Graphics** category to prevent an excess of file events.

8. Add the selected file types to the **Selected Files Categories and Types** list:
   - Click **Add** to add selected file types to the rule.
   - Drag and drop one or more file types into the **Selected Files Categories and Types** list.
   - With a category selected, click **All types in selected Categories**, then either click **Add** or drag and drop that selection to the **Selected Files Categories and Types** list.

9. Click **Save**.

   The file rule is added to the policy. If you are editing an existing file policy, you must reapply any access control policies that use the file policy for your changes to take effect.

Configuring Advanced File Policy Options

LICENSE: Malware
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

In a file policy, you can set the following advanced options:

Advanced File Policy Options

FIELD	DESCRIPTION	DEFAULT VALUE
Enable Custom Detection List	Select this to block files on the custom detection list when detected.	enabled
Enable Clean List	Select this to allow files on the clean list when detected.	enabled
Mark files as malware based on dynamic analysis threat score	Select a threshold value to automatically treat files with that threat score or higher as if they are malware. Select **Disabled** to disable this. Note that as you select lower threshold values, you increase the number of files treated as malware. Depending on the action selected in your file policy, this can result in an increase of blocked files.	**Very High (76 and above)**

Note that because you cannot use a Malware license with a DC500, you cannot use or modify these settings. Similarly, because you cannot enable a Malware license on a Series 2 device, you cannot apply a file policy with these settings enabled.

To configure advanced file policy options:

ACCESS: Admin/Access Admin

1. Select **Policies > Files**.

   The File Policies page appears.

2. Click the edit icon ( ) next to the policy you want to edit.

   The File Policy Rule page appears.

3. Select the Advanced tab.

   The Advanced tab appears.

4. Modify the options as described in the Advanced File Policy Options table on page 1251.

5. Click **Save**.

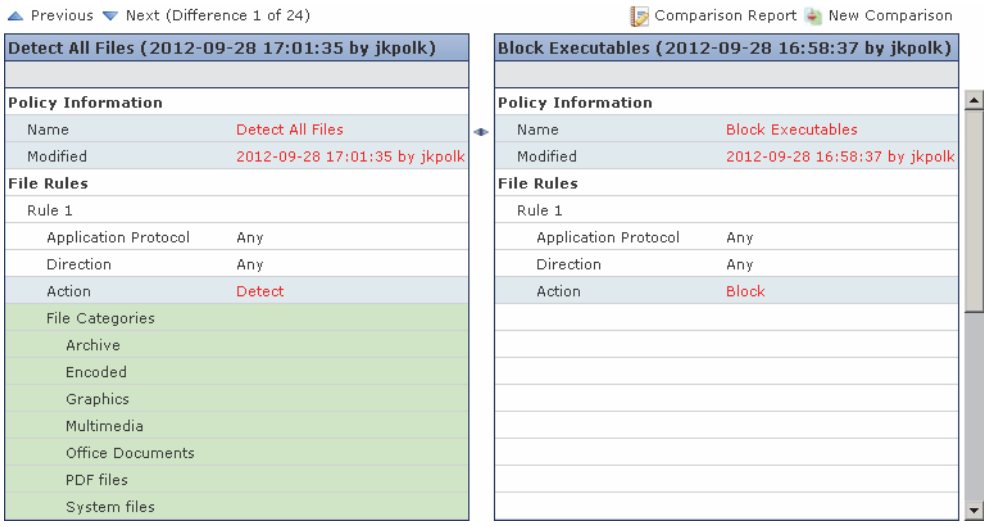
   You must reapply any access control policies that use the file policy.

Comparing Two File Policies

LICENSE: Protection

To review policy changes for compliance with your organization's standards or to optimize system performance, you can examine the differences between any two file policies, or two revisions of the same policy.

The file policy *comparison view* displays two file policies or revisions in a side-by-side format, with the time of last modification and the last user to modify displayed next to each policy name.



Differences between the two policies are highlighted:

- Blue indicates that the highlighted setting is different in the two policies, and the difference is noted in red text.
- Green indicates that the highlighted setting appears in one policy but not the other.

You can navigate through the differences by clicking **Previous** and **Next**. The double-arrow icon () centered between the left and right sides moves, and the **Difference** number adjusts to identify which difference you are viewing. Optionally, you can generate a file policy *comparison report*, which is a PDF version of the comparison view.

To compare two file policies:

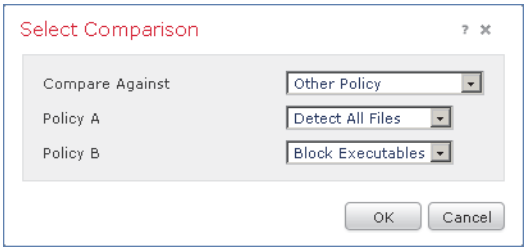
Access: Admin/Access Admin

1. Select **Policies > Files.**

   The File Policies page appears.

2. Click **Compare Policies**.

   The Select Comparison dialog box appears.



3. From the **Compare Against** drop-down list, select the type of comparison you want to make:
   - To compare two different policies, select either **Running Configuration** or **Other Policy**. The practical difference between the two options is that if you select **Running Configuration**, the system limits one of your comparison choices to the set of currently applied file policies.
   - To compare revisions of the same policy, select **Other Revision**.

   The dialog box refreshes, displaying your comparison options.

4. Depending on the comparison type you selected, you have the following choices:
   - If you are comparing two different policies, select the policies you want to compare: **Policy A** or **Target/Running Configuration A**, and **Policy B**.
   - If you are comparing revisions of the same policy, select the **Policy** you want to use, then select the two revisions: **Revision A** and **Revision B**. Revisions are listed by date and user name.

5. Click **OK**.

   The comparison view appears.

6. Optionally, click **Comparison Report** to generate the access control policy comparison report.

   The comparison report appears. Depending on your browser settings, the report may appear in a pop-up window, or you may be prompted to save the report to your computer.

Working with Sourcefire Cloud Connections for FireAMP

LICENSE: Any

FireAMP is Sourcefire's enterprise-class advanced malware analysis and protection solution. If your organization has a FireAMP subscription, individual users install FireAMP Connectors on their computers and mobile devices. These lightweight agents communicate with the Sourcefire cloud, which in turn communicate with the Defense Center. After you configure the Defense Center to connect to the cloud, you can receive records of scans, malware detections, and quarantines. The records are stored in the Defense Center database as malware events. For more information, see Understanding Malware Protection and File Control on page 1228.

Each Defense Center in your deployment can connect to the Sourcefire cloud. By default, the cloud sends malware events for all groups within your organization, but you can restrict by group when you configure the connection.

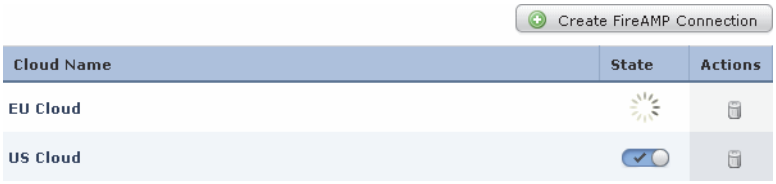
Internet Access and High Availability

The system uses port 443/HTTPS to connect to the Sourcefire cloud to receive endpoint-based malware events. You must open that port, both inbound and outbound, on the Defense Center. Additionally, the Defense Center must have direct access to the Internet. The default health policy includes the FireAMP Status Monitor, which warns you if the Defense Center cannot connect to the cloud after an initial successful connection, or if the connection is deregistered using the FireAMP portal.

Cloud connections to receive endpoint-based malware events are **not** shared between members of a high availability pair. To ensure continuity of operations, connect both the primary and secondary Defense Centers to the cloud.

Managing Sourcefire Cloud Connections

Use the Defense Center's FireAMP Management page (**FireAMP > FireAMP Management**) to view and create connections to the Sourcefire cloud, as well as disable and delete those connections.



A spinning state icon indicates that the connection is pending, for example, if you configured the connection on the Defense Center, but now must authorize the connection using the FireAMP portal. A failed or denied icon ( ) indicates that the cloud denied the connection or the connection failed for another reason.

TIP! Click any cloud name to open the FireAMP portal in a new browser window.

For more information, see:

- Creating a Sourcefire Cloud Connection on page 1255
- Deleting or Disabling a Sourcefire Cloud Connection on page 1256

Creating a Sourcefire Cloud Connection

LICENSE: Any

Creating a connection between the Defense Center and the Sourcefire cloud is a two-step process. First, configure the Defense Center to connect to the cloud. Then, log into the FireAMP portal to authorize the connection. If you do not have a FireAMP subscription, you cannot complete the registration process.

To re-register a Defense Center that was restored to factory defaults or reverted while registered to the cloud, you must connect to FireAMP and remove the Defense Center before re-registering it.

To create a Sourcefire cloud connection for FireAMP:

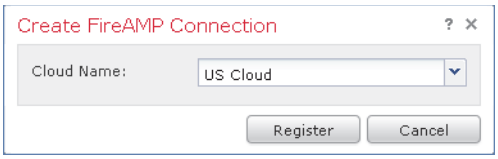
ACCESS: Admin

1. Select **FireAMP > FireAMP Management**.

   The FireAMP Management page appears.

2. Click **Create FireAMP Connection**.

   The Create FireAMP Connection dialog box appears.



3. Select the **Cloud Name** for the cloud you want to use, then click **Register**.
4. Confirm that you want to continue to the FireAMP portal, then log into the portal.

   The Applications page on the portal appears. Use this page to authorize the Sourcefire cloud to send malware events to the Defense Center.
5. Optionally, select specific groups within your organization for which you want to receive malware events.

   Select groups only if you want to restrict the events you receive. By default, the Defense Center receives malware events for all groups.

   TIP! To manage groups, select **Management > Groups** on the FireAMP portal. For detailed information, refer to the online help on the portal.

6. Click **Allow**.

   You are returned to the FireAMP Management page on the Defense Center. Your connection is enabled and the Defense Center begins receiving malware events from the cloud.

   Clicking **Deny** also returns you to the Defense Center, where the cloud connection is marked as denied. Similarly, if you navigate away from the Applications page on the FireAMP portal, and neither deny nor allow the connection, the connection is marked as pending on the Defense Center's web interface. The health monitor does **not** alert in either of these situations. If you want to connect to the cloud later, you must delete the failed or pending connection, then recreate it.

Deleting or Disabling a Sourcefire Cloud Connection

LICENSE: Any

Delete a Sourcefire cloud connection if you no longer want to receive malware events from the cloud. To temporarily stop malware events from being sent for a particular connection, you can disable the connection rather than deleting it. In

this situation, the cloud stores the events until you re-enable the connection; the cloud then sends the stored events.

WARNING! In rare cases — for example, with a very high event rate or a long-term disabled connection — the cloud may not be able to store all events generated while the connection is disabled.

Note that deregistering a connection using the FireAMP portal (instead of the Defense Center's web interface) stops events from being sent, but does not remove the connection from the Defense Center. Deregistered connections show a failed state on the FireAMP Management page and you must delete them.

To enable or disable a Sourcefire cloud connection using the Defense Center:

Access: Admin

- On the FireAMP Management page, next to the connection you want to delete, click the slider, then confirm that you want to either enable or disable the connection.

  When you enable a connection, the cloud begins sending events to the Defense Center, including any events that occurred while the connection was disabled. The cloud does not send events for disabled connections.

To delete a Sourcefire cloud connection using the Defense Center:

Access: Admin

- On the FireAMP Management page, next to the connection you want to delete, click the delete icon ( ), then confirm you want to remove the connection.

  The connection is removed and the cloud stops sending events to the Defense Center.

Working with File Storage

License: Malware
Supported Devices: Any except Series 2
Supported Defense Centers: Any except DC500

Based on your file policy configuration, you can use the file control feature to detect and block files. However, files originating from a suspicious host or network, or an excess of files sent to a monitored host on your network, may require further analysis. The file storage feature allows you to capture selected files detected in traffic, and automatically store them to a device's hard drive or, if installed, the malware storage pack.

When a device detects a file in traffic, it can capture that file. This creates a copy the system can either store or submit for dynamic analysis. After your device captures the files, you have several options:

- Store captured files on the device's hard drive for later analysis. See Understanding Captured File Storage on page 1259 for more information.
- Download the stored file to a local computer for further manual analysis or archival purposes. See Downloading Stored Files to Another Location on page 1260 for more information.
- Submit captured files to the Sourcefire cloud for dynamic analysis. See Working with Dynamic Analysis on page 1261 for more information.

Note that once a device stores a file, it will not re-capture it if detected in the future and the device still has the file stored.

IMPORTANT! Any file detected for the first time ever carries a file disposition of Unavailable, as the cloud has no prior information on the file. You cannot configure a file rule with a Malware Cloud Lookup or Block Malware action to store files with an Unavailable file disposition. As a result, the first time the system detects a file, if it matches such a file rule, it cannot initially store the file. However, the subsequent cloud lookup returns a disposition; you can review this information in the generated file or malware event even though the file is not stored. On subsequent detection, the file has a disposition other than Unavailable, and can be stored if it matches the file rule.

Whether the system captures or stores a file, you can:

- Review information about the captured file from the event viewer, including whether the file was stored or submitted for dynamic analysis, file disposition, and threat score, allowing you to quickly review possible malware threats detected on your network. See Working with Captured Files on page 1288 for more information.
- View the file's trajectory to determine how it traversed your network and which hosts have a copy. See Analyzing Network File Trajectory on page 1296 for more information.
- Add the file to the clean list or custom detection list to always treat the file as if it had a clean or malware disposition on future detection. See Working with File Lists on page 218 for more information.

You configure file rules in a file policy to capture and store files of a specific type, or with a particular file disposition, if available. Once you associate the file policy with an access control policy and apply it to your devices, matching files in traffic are captured and stored. You can also configure the access control policy to limit the minimum and maximum file sizes to store. See Configuring Advanced Access Control Policy Settings on page 485 and Working with File Rules on page 1247 for more information.

File storage requires a device running Version 5.3 or later, a Malware license, and sufficient disk space on the device. If the device's primary hard drive does not have enough space, and you do not have a malware storage pack installed, you cannot store files on the device.

WARNING! Do not attempt to install a hard drive that was not supplied by Sourcefire in your device. Installing an unsupported hard drive may damage the device. Malware storage pack kits are available for purchase **only** from Sourcefire, and are for use **only** with 8000 Series devices running Version 5.3 or later of the Sourcefire 3D System. Contact Sourcefire Support if you require assistance with the malware storage pack. See the *Sourcefire 3D System Malware Storage Pack Guide* for more information.

Note that because you cannot use a Malware license with a DC500, nor can you enable a Malware license on a Series 2 device, you cannot use those appliances to capture or store files.

For more information, see:

- Understanding Captured File Storage on page 1259
- Downloading Stored Files to Another Location on page 1260

Understanding Captured File Storage

LICENSE: Malware
SUPPORTED DEVICES: 8000 Series

Based on your file policy configuration, your device may store a substantial amount of file data to the hard drive. You can install a malware storage pack in the device; the system stores files to the malware storage pack, allowing more room on the primary hard drive to store events and configuration files. The system periodically deletes older files.

WARNING! Do not attempt to install a hard drive that was not supplied by Sourcefire in your device. Installing an unsupported hard drive may damage the device. Malware storage pack kits are available for purchase **only** from Sourcefire, and are for use **only** with 8000 Series devices running Version 5.3 or later of the Sourcefire 3D System. Contact Sourcefire Support if you require assistance with the malware storage pack. See the *Sourcefire 3D System Malware Storage Pack Guide* for more information.

Without a malware storage pack installed, when you configure a device to store files, it allocates a set portion of the primary hard drive's space solely to captured file storage. When you install a malware storage pack in a device and configure the device to store files, the device instead allocates the entire malware storage pack for storing captured files. The device cannot store any other information on the malware storage pack.

When the allocated space for captured file storage fills to capacity, the system deletes the oldest stored files until the allocated space reaches a system-defined threshold. Based on the number of files stored, you may see a substantial drop in disk usage after the system deletes files.

If a device has already stored files when you install a malware storage pack, the next time you restart the device, any captured files stored on the primary hard drive are moved to the malware storage pack. Any future files the device stores are stored to the malware storage pack. If the device's primary hard drive does not have enough available space nor an installed malware storage pack, you cannot store files.

Note that you cannot include stored files in system backup files. For more information, see Creating Backup Files on page 2287.

Downloading Stored Files to Another Location

LICENSE: Malware
SUPPORTED DEVICES: Any except Series 2
SUPPORTED DEFENSE CENTERS: Any except DC500

Once a device stores a file, as long as the Defense Center can communicate with that device and it has not deleted the file, you can download the file. You can manually analyze the file, or download it to a local host for long-term storage and analysis. You can download a file from any associated file event, malware event, captured file view, or the file's trajectory. For more information, see Using the Context Menu on page 70 and Summary Information on page 1296.

Because malware is harmful, by default, you must confirm every file download. However, you can disable the confirmation in the file download prompt. To re-enable the confirmation, see File Preferences on page 2301.

WARNING! Sourcefire strongly recommends you do **not** download malware, as it can cause adverse consequences. Exercise caution when downloading any file, as it may contain malware. Ensure you have taken any necessary precautions to secure the download destination before downloading files.

Because files with a disposition of Unknown may contain malware, when you download a file, the system first archives the file in a .zip package. The .zip file name contains the file disposition and file type, if available, and SHA-256 value. You can password-protect the .zip file to prevent accidental unpacking. To edit or remove the default .zip file password, see File Preferences on page 2301.

Working with Dynamic Analysis

LICENSE: Malware
SUPPORTED DEVICES: Any except Series 2
SUPPORTED DEFENSE CENTERS: Any except DC500

To increase the accuracy of the cloud, and to provide additional malware analysis and threat identification, you can submit eligible captured files to the Sourcefire cloud for dynamic analysis. The cloud runs the file in a test environment, and based on the results, returns a threat score and dynamic analysis summary report to the Defense Center. You can also submit eligible files to the cloud for Spero analysis, which examines the file's structure to supplement the malware identification.

Submitting a file to the cloud for dynamic analysis depends on the type of file captured, as well as the allowable minimum and maximum file sizes configured in the access control policy. You can submit:

- a file automatically for dynamic analysis if a file rule performs a malware cloud lookup on an executable file and the file disposition is Unknown
- up to twenty-five files at once manually for dynamic analysis if stored and a supported file type, such as PDFs, Microsoft Office documents, and others

Once submitted, the files are queued for analysis in the cloud. You can view captured files and a file's trajectory to determine whether a file has been submitted for dynamic analysis. Note that each time a file is submitted for dynamic analysis, the cloud analyzes the file, even if the first analysis generated results.

For more information, see Working with File Rules on page 1247 and Submitting Files for Dynamic Analysis on page 1262.

IMPORTANT! The system checks the cloud for updates to the list of file types eligible for dynamic analysis and the minimum and maximum file sizes you can submit (no more than once a day).

The cloud performs dynamic analysis by running the file in a sandbox environment. It returns:

- a threat score, which details the likelihood a file contains malware.
- a dynamic analysis summary report, which details why the cloud assigned the threat score.

Based on the file policy configuration, you can automatically block files whose threat score falls above a defined threshold. You can also review the dynamic analysis summary report to better identify malware and fine tune your detection capabilities.

To supplement dynamic analysis, if a file rule performs a malware cloud lookup on an executable file, you can automatically submit the file for Spero analysis. The cloud examines the executable file's structure, including metadata and header

information, and can identify files as malware. See Understanding Malware Protection and File Control on page 1228 for more information.

Dynamic and Spero analysis require a device running Version 5.3 or later and a Malware license. Note that because you cannot use a Malware license with a DC500, nor can you enable a Malware license on a Series 2 device, you cannot use those appliances to submit files for dynamic analysis or Spero analysis.

IMPORTANT! You can configure your managed devices to submit files to the Sourcefire cloud via HTTP proxy. To configure physical appliances, see Configuring Network Settings on page 2088 for more information. To configure virtual appliances, see http-proxy on page 2354. Sourcefire Software for X-Series does not support proxy settings.

For more information, see:

- Understanding Spero Analysis on page 1262
- Submitting Files for Dynamic Analysis on page 1262
- Reviewing the Threat Score and Dynamic Analysis Summary on page 1263

Understanding Spero Analysis

License: Malware
Supported Devices: Any except Series 2
Supported Defense Centers: Any except DC500

Spero analysis supplements analysis of SHA-256 hashes, allowing for more complete identification of malware in executable files. Spero analysis involves the device examining file structural characteristics such as metadata and header information. After generating a Spero signature based on this information, the device submits it to the Spero heuristic engine in the Sourcefire cloud. Based on the Spero signature, the Spero engine returns whether the file is malware. If so, and the file currently has an unknown file disposition, the system assigns a Malware file disposition. For more information on file dispositions, see Understanding Malware Protection and File Control on page 1228.

Note that you can only submit executable files for Spero analysis upon detection; you cannot manually submit them later. You can submit the file for Spero analysis without also submitting it for dynamic analysis. For more information, see Working with File Rules on page 1247.

Submitting Files for Dynamic Analysis

License: Malware
Supported Devices: Any except Series 2
Supported Defense Centers: Any except DC500

From the event viewer context menu or network file trajectory, you can manually submit a file for dynamic analysis. In addition to executable files, you can also

submit file types not eligible for automatic submission, such as PDFs, Microsoft Office documents, and others. See Using the Context Menu on page 70 and Summary Information on page 1296 for more information.

To analyze multiple files after an incident, regardless of file disposition, you can manually submit up to 25 files (of specific types) at a time from the captured file view. This allows you to more quickly analyze a broad range of files and pinpoint the exact causes of the incident. For more information, see Working with Captured Files on page 1288 and Selecting Rows on a Workflow Page on page 1910.

Reviewing the Threat Score and Dynamic Analysis Summary

License: Malware
Supported Devices: Any except Series 2
Supported Defense Centers: Any except DC500

After you submit a file for dynamic analysis, the Sourcefire cloud analyzes a file's signatures and returns both a threat score and a dynamic analysis summary. These can help you more closely analyze potential malware threats and fine tune your detection strategy.

Threat Scores

Files fall into one of four threat score ratings that correspond with the likelihood the file is malicious:

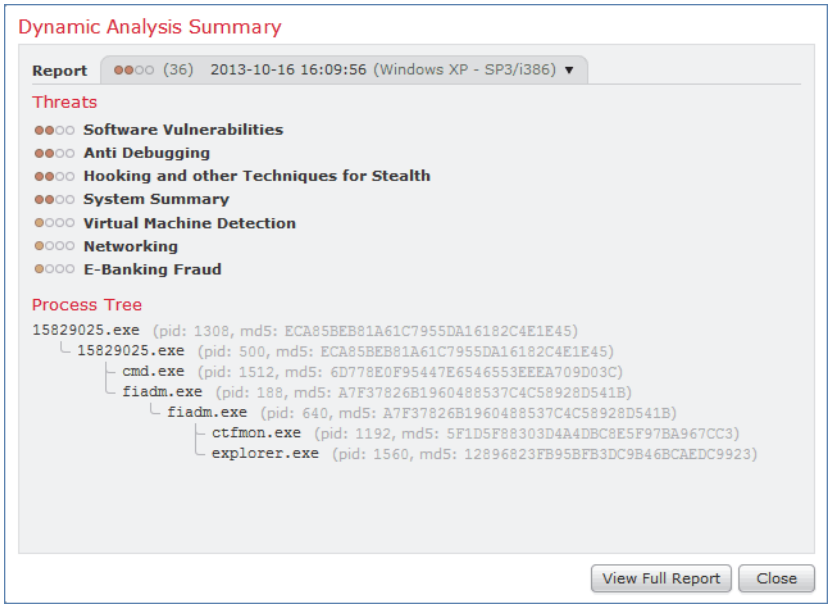
Threat Score Ratings

Threat Score	Icon	Rating
Low		1-25
Medium		26-50
High		51-75
Very High		76-100

The Defense Center caches a file's threat score locally for the same amount of time as the file's disposition. If the system later detects these files, it displays the cached threat scores to the user instead of again querying the Sourcefire cloud. Based on your file policy configuration, you can automatically assign a malware file disposition to any file with a threat score that exceeds the defined malware threshold threat score. For more information, see Creating a File Policy on page 1246.

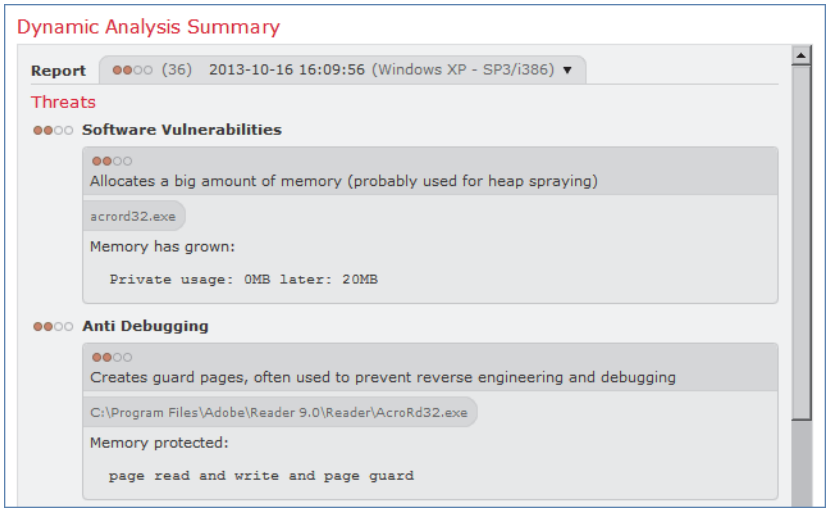
Dynamic Analysis Summary

If a dynamic analysis summary is available, you can click the threat score icon to view it. The dynamic analysis summary describes the various component ratings that comprise the overall threat score assigned by the Vulnerability Research Team (VRT) file analysis, as well as other processes started when the cloud attempted to run the file.



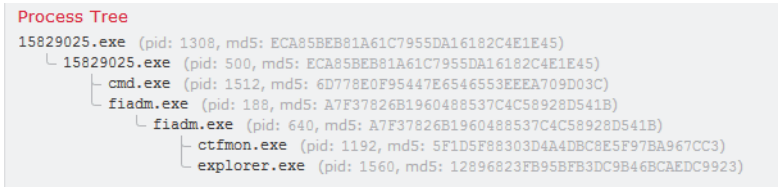
If multiple reports exist, this summary is based on the most recent report matching the exact threat score. If none match the exact threat score, then the report with the highest threat score is displayed. If more than one report exists, you can select a threat score to view each separate report.

The summary lists each component threat comprising the threat score. Each component threat is expandable to list the VRT's findings, as well as any processes related to this component threat.



The process tree shows the processes that started when the cloud attempted to run the file. This can help identify whether a file that contains malware is attempting to access processes and system resources beyond what is expected (for example, running a Word document opens Microsoft Word, then starts Explorer, then starts Java).

Each listed process contains a process identifier and md5 checksum you can use to verify the actual process. The process tree displays processes started as a result of parent processes as child nodes.



From the dynamic analysis summary, you can click **View Full Report** to view the VRT's Analysis report, detailing the VRT's full analysis, including general file information, a more in-depth review of all detected processes, a breakdown of the file analysis, and other relevant information.

Working with File Events

LICENSE: Protection

The system logs the file events generated when a managed device detects or blocks a file in network traffic, according to the rules in currently applied file policies. Note that when the system generates a file event, the system also logs

the end of the associated connection to the Defense Center database, regardless of the logging configuration of the invoking access control rule. For more information, see Understanding and Creating File Policies on page 1236.

IMPORTANT! Files detected in network traffic and identified as malware by the Sourcefire 3D System generate both a file event and a malware event. This is because to detect malware in a file, the system must first detect the file itself. Endpoint-based malware events do not have corresponding file events. For more information, see Working with Malware Events on page 1274 and Working with Captured Files on page 1288.

You can use the Defense Center's event viewer to view, search, and delete file events. Additionally, the Files Dashboard provides an at-a-glance view of detailed information about the files (including malware files) detected on your network, using charts and graphs. Network file trajectory offers a more in-depth view of individual files, providing summary information about the file and how it has moved through the network over time. Using file identification data, you can trigger correlation rules and create reports, the latter using either the predefined Files Report template or a custom report template.

For more information, see:

- Viewing File Events on page 1266
- Understanding the File Events Table on page 1268
- Using Geolocation on page 1892
- Searching for File Events on page 1271

Viewing File Events

LICENSE: Protection

The Sourcefire 3D System's event viewer allows you to view file events in a table, as well as manipulate the event view depending on the information relevant to your analysis.

The page you see when you access file events differs depending on the workflow, which is simply a series of pages you can use to evaluate events by moving from

a broad to a more focused view. The system is delivered with the following predefined workflows for file events:

- *File Summary*, the default, provides a quick breakdown of the different file event categories and types, along with any associated malware file dispositions.
- *Hosts Receiving Files* and *Hosts Sending Files* provide a list of hosts that have received or sent files, grouped by the associated malware dispositions for those files.

IMPORTANT! File dispositions appear only for files for which the system performed a malware cloud lookup; see File Rule Actions and Evaluation Order on page 1239.

You can also create a custom workflow that displays only the information that matches your specific needs. For information on specifying a different default workflow, including a custom workflow, see Configuring Event View Settings on page 2300.

Using the event viewer, you can:

- search for, sort, and constrain events, as well as change the time range for displayed events
- specify the columns that appear (table view only)
- view the host profile associated with an IP address, or the user details and host history associated with a user identity
- view the connections where specific files were detected
- view events using different workflow pages within the same workflow
- view events using a different workflow altogether
- drill down page-to-page within a workflow, constraining on specific values
- bookmark the current page and constraints so you can return to the same data (assuming the data still exists) at a later time
- view the sending and receiving countries and continents for routable IP addresses associated with a file
- view a file's trajectory
- add a file to a file list, download a file, submit a file for dynamic analysis, or view the full text of a file's SHA-256 value
- view a file's Dynamic Analysis Summary report, if available
- create a report template using the current constraints
- delete events from the database
- use the IP address context menu to whitelist, blacklist, or obtain additional available information about a host or IP address associated with a file event

For detailed information on using the event viewer, including creating custom workflows, see Understanding and Using Workflows on page 1865.

To view file events:

ACCESS: Admin/Any Security Analyst

▶ Select **Analysis > Files > File Events**.

The first page of your default file events workflow appears. For information on the columns that appear, see Understanding the File Events Table on page 1268.

TIP! To quickly view the connections where specific files were detected, select the files using the check boxes in the event viewer, then select **Connections Events** from the **Jump to** drop-down list. For more information, see Navigating Between Workflows on page 1911.

Understanding the File Events Table

LICENSE: Protection

The Defense Center logs a file event when a managed device detects or blocks a file being transmitted in monitored network traffic, according to the settings in an applied file policy.

The table view of file events, which is the final page in predefined file event workflows, and which you can add to custom workflows, includes a column for each field in the files table. Some fields in the table view of file events are disabled by default. To enable a field for the duration of your session, click the expand arrow ( ) to expand the search constraints, then click the column name under **Disabled Columns**. The File Event Fields table below describes the file event fields.

Keep in mind that although you can perform file control with only a Protection license, a Malware license allows you to perform advanced malware protection for certain file types and track files transferred on your network.

File Event Fields

FIELD	DESCRIPTION
Time	The date and time the event was generated.
Action	The action associated with the file policy rule that detected the file, and any associated file action options.
Sending IP	The IP address of the host sending the detected file.

File Event Fields (Continued)

Field	Description
Sending Country	The country of the host sending the detected file. Note that the DC500 Defense Center does not support this feature.
Receiving IP	The IP address of the host receiving the detected file.
Receiving Country	The country of the host receiving the detected file. Note that the DC500 Defense Center does not support this feature.
Sending Port	The source port used by the traffic where the file was detected.
Receiving Port	The destination port used by the traffic where the file was detected.
User	The user logged into the host (**Receiving IP**) where the file was destined. Note that because the user is associated with the destination host, users are not associated with file events where the user uploaded a file.
File Name	The name of the file.
Disposition	One of the following file dispositions: • `Malware` indicates that the cloud categorized the file as malware, or that the file's threat score exceeded the malware threshold defined in the file policy. • `Clean` indicates that the cloud categorized the file as clean, or that a user added the file to the clean list. • `Unknown` indicates that a malware cloud lookup occurred before the cloud assigned a disposition. The file is uncategorized. • `Custom Detection` indicates that a user added the file to the custom detection list. • `Unavailable` indicates that the Defense Center could not perform a malware cloud lookup. • `N/A` indicates a Detect Files or Block Files rule handled the file and the Defense Center did not perform a malware cloud lookup.
SHA256	The SHA-256 hash value of the file, as well as a network file trajectory icon representing the most recently detected file event and file disposition, if this file was detected as the result of: • a Detect Files file rule with **Store Files** enabled • a Block Files file rule with **Store Files** enabled • a Malware Cloud Lookup file rule • a Block Malware file rule To view the network file trajectory, click the trajectory icon. For more information, see Analyzing Network File Trajectory on page 1296.

File Event Fields (Continued)

Field	Description
Threat Score	The threat score most recently associated with this file: • `Low` (●○○○) • `Medium` (●●○○) • `High` (●●●○) • `Very High` (●●●●) To view the Dynamic Analysis Summary report, click the threat score icon.
Type	The type of file, for example, `HTML` or `MSEXE`.
Category	The general categories of file type, for example: `Office Documents`, `Archive`, `Multimedia`, `Executables`, `PDF files`, `Encoded`, `Graphics`, or `System Files`.
Size (KB)	The size of the file, in kilobytes. Note that if the system determines the file type of a file before the file is fully received, the file size may not be calculated and this field is blank.
URI	The originating URI of the file, for example, the URL where a user downloaded it.
Application Protocol	The application protocol used by the traffic in which a managed device detected the file.
Application Protocol, Client, or Web Application Category or Tag	Criteria that characterize the application to help you understand the application's function. For more information, see the Application Characteristics table on page 1317.
Client	The client application used in the connection to transmit a file.
Web Application	For files transmitted using HTTP, the web application (content or requested URL) detected in the connection and used to transmit the file.
Application Risk	The risk associated with the application traffic detected in the connection: `Very High`, `High`, `Medium`, `Low`, or `Very Low`. Each type of application detected in the connection has an associated risk; this field displays the highest of those. For more information, see the Application Characteristics table on page 1317.

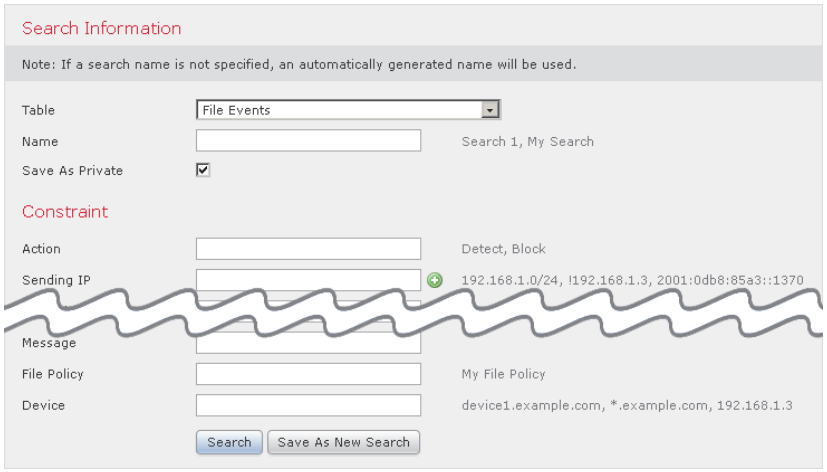
File Event Fields (Continued)

Field	Description
Business Relevance	The business relevance associated with the application traffic detected in the connection: `Very High`, `High`, `Medium`, `Low`, or `Very Low`. Each type of application detected in the connection has an associated business relevance; this field displays the lowest (least relevant) of those. For more information, see the Application Characteristics table on page 1317.
Message	For files where a malware disposition has changed, that is, for files associated with retrospective malware events, information about when and how the disposition changed.
File Policy	The file policy that detected the file.
Device	The name of the device that detected the file.
Count	The number of events that match the information in each row. This field appears after you apply a constraint that creates two or more identical rows.

Searching for File Events

License: Protection

Using the Defense Center's Search page, you can search for specific file events, display the results in the event viewer, and save your search criteria to reuse later. Custom Analysis dashboard widgets, report templates, and custom user roles can also use saved searches.



Keep in mind that your search results depend on the available data in the events you are searching. In other words, depending on the available data, your search constraints may not apply. For example, the **Disposition** and **SHA256** fields are

populated only for files for which the Defense Center performed a malware cloud lookup.

Note that because the DC500 does not support geolocation, searches using these fields from a DC500 return no results, regardless of whether geolocation information was detected.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- Specify `n/a` in any field to identify events where information is not available for that field; use `!n/a` to identify the events where that field is populated.
- Click the add object icon () that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

Special Search Syntax for File Events

To supplement the general search syntax listed above, the following table describes some special search syntax for file events.

File Event Special Search Syntax

Search Criterion	Special Syntax
Sending/Receiving Continent	The system returns all events where either the **Sending Continent** or the **Receiving Continent** matches the continent you specify.
Sending/Receiving Country	The system returns all events where either the **Sending Country** or the **Receiving Country** matches the country you specify.
Sending/Receiving IP	The system returns all events where either the **Sending IP** or the **Receiving IP** matches the IP address you specify.

File Event Special Search Syntax (Continued)

Search Criterion	Special Syntax
URI or Message	The system performs a partial match, that is, you can search for all or part of the field contents without using asterisks.
File Storage	Specify one or more of the following: • `Stored` - returns all events where the associated file is currently stored • `Stored in connection` - returns all events where the system captured and stored the associated file, regardless of whether the associated file is currently stored • `Failed` - returns all events where the system failed to store the associated file

To search for file events:

Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **File Events**.

   The page reloads with the appropriate constraints.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields.

   See the File Event Fields table on page 1268 for information on the fields in the file events table.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

   If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in your default malware events workflow, constrained by the current time range.

- Click **Save** if you are modifying an existing search and want to save your changes.
- Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**).

Working with Malware Events

LICENSE: Malware or Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

The system logs malware events to the Defense Center database when:

- a managed device detects a file in network traffic that is then identified as malware by a malware cloud lookup
- a managed device detects a file on the custom detection list in network traffic
- the system learns that a file's malware disposition has changed; these are called retrospective malware events
- a FireAMP Connector installed on an endpoint in your organization detects a threat and communicates that threat to the Sourcefire cloud

Because FireAMP malware detection is performed at the endpoint at download or execution time, while managed devices detect files in network traffic, the information in these malware events is different. Retrospective malware events also contain slightly different data than other network-based malware events, or endpoint-based malware events.

The following sections briefly describe the different kinds of malware events. For information on the overall malware detection process, see Understanding Malware Protection and File Control on page 1228.

Endpoint-Based (FireAMP) Malware Events

If your organization has a FireAMP subscription, individual users install FireAMP Connectors on their computers and mobile devices. These lightweight agents communicate with the Sourcefire cloud, which in turn communicates with your Defense Center; see Working with Sourcefire Cloud Connections for FireAMP on page 1254. The cloud can send notification of threats, as well other kinds of information including data on scans, quarantines, blocked executions, and cloud

recalls. The Defense Center logs this information to its database as malware events.

IMPORTANT! The IP addresses reported in endpoint-based malware events may not be in your network map — and may not even be in your monitored network at all. Depending on your deployment, level of compliance, and other factors, endpoints in your organization where FireAMP Connectors are installed may not be the same hosts as those monitored by your managed devices.

Malware Events Based on Network Traffic

SUPPORTED DEVICES: Series 3, virtual, X-Series
SUPPORTED DEFENSE CENTERS: Any except DC500

With a Malware license, your managed devices can detect malware in network traffic as part of your overall access control configuration; see Understanding and Creating File Policies on page 1236.

The following scenarios can lead to generating malware events:

- If a managed device detects one of a set of specific file types, the Defense Center performs a malware cloud lookup, which returns a file disposition to the Defense Center of `Malware`, `Clean`, or `Unknown`.
- If the Defense Center cannot establish a connection with the cloud, or the cloud is otherwise unavailable, the file disposition is `Unavailable`.
- If the threat score associated with a file exceeds the malware threshold threat score defined in the file policy that detected the file, the Defense Center assigns a file disposition of `Malware` to the file.
- If the managed device detects a file whose SHA-256 value is stored on the custom detection list, the Defense Center assigns a file disposition of `Custom Detection` to the file.
- If the managed device detects a file on the clean list, the Defense Center assigns a file disposition of `Clean` to the file.

The Defense Center logs records of files' detection and dispositions, along with other contextual data, as malware events.

IMPORTANT! Files detected in network traffic and identified as malware by the Sourcefire 3D System generate both a file event and a malware event. This occurs because to detect malware in a file, the system must first detect the file itself. For more information, see Working with File Events on page 1265 and Working with Captured Files on page 1288.

Retrospective Malware Events

SUPPORTED DEVICES: Series 3, virtual, X-Series
SUPPORTED DEFENSE CENTERS: Any except DC500

For malware files detected in network traffic, file dispositions can change. For example, the Sourcefire cloud can determine that a file that was previously thought to be clean is now identified as malware, or the reverse — that a malware-identified file is actually clean.

The cloud notifies the Defense Center if the file disposition changes for a file for which you performed a malware lookup in the last week. Then, two things happen:

- The Defense Center generates a new retrospective malware event.

  This new retrospective malware event represents a disposition change for all files detected in the last week that have the same SHA-256 hash value. For that reason, these events contain limited information: the date and time the Defense Center was notified of the disposition change, the new disposition, the SHA-256 hash value of the file, and the threat name. They do not contain IP addresses or other contextual information.

- The Defense Center changes the file disposition for previously detected files with the retrospective event's associated SHA-256 hash value.

  If a file's disposition changes to malware, the Defense Center logs a new malware event to its database. Except for the new disposition, the information in this new malware event is identical to that in the file event generated when the file was initially detected.

  If a file's disposition changes to clean, the Defense Center does not remove the malware event from the malware table. Instead, the event simply reflects the change in disposition. This means that files with clean dispositions can appear in the malware table, but only if they were originally thought to be malware. Files that were never identified as malware appear only in the files table.

  In either case, the malware event's **Message** indicates how and when the disposition changed, for example:

  ```
  Retrospective Event, Mon Oct 1 20:44:00 2012 (UTC), Old
  Disp: Unknown, New Disp: Malware
  ```

Using Malware Events

You can use the Defense Center's event viewer to view, search, and delete malware events. Additionally, the Files Dashboard and Context Explorer provide an at-a-glance view of detailed information about the files (including malware files) detected on your network, using charts and graphs. Network file trajectory offers a more in-depth view of individual malware files, providing summary information about the file and how it has moved through the network over time. Using malware detection data, you can trigger correlation rules and create reports, the latter using either the predefined Malware Report template or a custom report template.

For more information, see:

- Viewing Malware Events on page 1277
- Understanding the Malware Events Table on page 1278
- Searching for Malware Events on page 1285

Viewing Malware Events

LICENSE: Malware or Any

The Sourcefire 3D System's event viewer allows you to view malware events in a table, as well as manipulate the event view depending on the information relevant to your analysis.

The page you see when you access malware events differs depending on the workflow, which is simply a series of pages you can use to evaluate events by moving from a broad to a more focused view. The system is delivered with the following predefined workflows for malware events:

- *Malware Summary*, the default, provides a list of detected malware, grouped by individual threat.
- *Malware Event Summary* provides a quick breakdown of the different malware event types and subtypes.
- *Hosts Receiving Malware* and *Hosts Sending Malware* provide a list of hosts that have received or sent malware, grouped by the associated malware dispositions for those files. Note that dispositions appear only for files detected as the result of Malware Cloud Lookup or Block Malware file rules.
- *Applications Introducing Malware* provides a list of the client applications that accessed or executed the malware detected on endpoints in your organization. From this list, you can drill down into the individual malware files accessed by each parent client.

You can also create a custom workflow that displays only the information that matches your specific needs. For information on specifying a different default workflow, including a custom workflow, see Configuring Event View Settings on page 2300.

Using the event viewer, you can:

- search for, sort, and constrain events, as well as change the time range for displayed events
- specify the columns that appear (table view only)
- view the host profile associated with an IP address, or the user details and host history associated with a user identity
- view the connections where specific malware was detected (for network-based malware events only)
- view events using different workflow pages within the same workflow

- view events using a different workflow altogether
- drill down page-to-page within a workflow, constraining on specific values
- bookmark the current page and constraints so you can return to the same data (assuming the data still exists) at a later time
- view geolocation information for routable IP addresses associated with a file
- view a file's trajectory
- create a report template using the current constraints
- delete events from the database
- add a file to a file list, download a file, submit a file for dynamic analysis, or view the full text of a file's SHA-256 value
- view a file's Dynamic Analysis Summary report, if available
- use the IP address context menu to whitelist, blacklist, or obtain additional available information about a host or IP address associated with a malware event

Note that neither Series 2 devices nor the DC500 Defense Center support network-based malware protection, which can affect the data displayed. For example, a Series 3 Defense Center managing only Series 2 devices can display only endpoint-based malware events.

For detailed information on using the event viewer, including creating custom workflows, see Understanding and Using Workflows on page 1865.

To view malware events:

Access: Admin/Any Security Analyst

▶ Select **Analysis > Files > Malware Events**.

The first page of your default malware events workflow appears. For information on the columns that appear, see Understanding the Malware Events Table on page 1278.

Understanding the Malware Events Table

License: Malware or Any
Supported Devices: feature dependent
Supported Defense Centers: feature dependent

The system logs malware events to the Defense Center database when a FireAMP Connector installed on an endpoint in your organization detects a threat, or a managed device detects a file in network traffic that is then identified as malware by a malware cloud lookup. The system also logs retrospective malware events when it learns that a file's malware disposition has changed. Note that neither Series 2 devices nor the DC500 Defense Center support network-based malware protection, which can affect the data displayed. For example, a Series 3 Defense Center managing only Series 2 devices can display only endpoint-based malware events. For more information, see Understanding Malware Protection

and File Control on page 1228 and Working with Malware Events on page 1274.

The table view of malware events, which is the final page in predefined malware event workflows, and which you can add to custom workflows, includes a column for each field in the files table. Some fields in the table view of malware events are disabled by default. To enable a field for the duration of your session, click the expand arrow () to expand the search constraints, then click the column name under **Disabled Columns**.

Keep in mind that not every field is populated for every event; the different types of malware event can contain different information. For example, because FireAMP malware detection is performed at the endpoint at download or execution time, endpoint-based malware events contain information on file path, invoking client application, and so on. In contrast, because managed devices detect malware files in network traffic, their associated malware events contain port, application protocol, and originating IP address information about the connection used to transmit the file.

The following table lists each malware event field, and indicates whether the system displays information in that field, depending on the malware event type. Note that the DC500 Defense Center does not support sending or receiving continent or country geolocation information.

Malware Event Fields

Field	Description	Network	Endpoint	Retrospective from Cloud
Time	The date and time the event was generated.	yes	yes	yes
Action	The file rule action associated with the rule action for the rule the file matched, and any associated file rule action options.	yes	no	yes
Sending IP	The IP address of the host sending detected malware.	yes	no	no
Sending Continent	The continent of the host sending detected malware.	yes	no	yes
Sending Country	The country of the host sending detected malware.	yes	no	no
Receiving IP	For network-based malware events, the IP address of the host receiving detected malware. For endpoint-based malware events, the IP address of the endpoint where the FireAMP Connector is installed and where the malware event occurred.	yes	yes	no

Malware Event Fields (Continued)

Field	Description	Network	Endpoint	Retrospective from Cloud
Receiving Continent	The continent of the host receiving detected malware.	yes	no	yes
Receiving Country	The country of the host receiving detected malware.	yes	no	no
Sending Port	The source port used by the traffic in which a managed device detected malware.	yes	no	no
Receiving Port	The destination port used by the traffic in which a managed device detected malware.	yes	no	no
User	The user of the host (**Receiving IP**) where the malware event occurred. For network-based malware events, this user is determined by network discovery. Because the user is associated with the destination host, users are not associated with malware events where the user uploaded a malware file. For endpoint-based malware events, FireAMP Connectors determine user names. FireAMP users **cannot** be tied to user discovery or control. They do not appear in the Users table, nor can you view details for these users.	yes	yes	no
Event Type	The type of malware event. For a full list of event types, see Malware Event Types on page 1284.	yes	yes	yes
Event Subtype	The FireAMP action that led to malware detection, for example, `Create`, `Execute`, `Move`, or `Scan`.	no	yes	no
Threat Name	The name of the detected malware.	yes	yes	yes
File Name	The name of the malware file.	yes	yes	no

Malware Event Fields (Continued)

Field	Description	Network	Endpoint	Retrospective from Cloud
File Disposition	One of the following file dispositions: • `Malware` indicates that the cloud categorized the file as malware, or that the file's threat score exceeded the malware threshold defined in the file policy. • `Clean` indicates that the cloud categorized the file as clean, or that a user added the file to the clean list. • `Unknown` indicates that a malware cloud lookup occurred before the cloud assigned a disposition. The file is uncategorized. • `Custom Detection` indicates that a user added the file to the custom detection list. • `Unavailable` indicates that the Defense Center could not perform a malware cloud lookup. Note that clean files appear in the malware table only if they were changed to clean; see Retrospective Malware Events on page 1276.	yes	no	yes
File SHA256	The SHA-256 hash value of the file, as well as a network file trajectory icon representing the most recently detected file event and file disposition. To view the network file trajectory, click the trajectory icon. For more information, see Analyzing Network File Trajectory on page 1296.	yes	yes	yes
Threat Score	The threat score most recently associated with this file: • `Low` (●○○○) • `Medium` (●●○○) • `High` (●●●○) • `Very High` (●●●●) To view the Dynamic Analysis Summary report, click the threat score icon.	yes	no	no
File Path	The file path of the malware file, not including the file name.	no	yes	no
File Type	The file type of the malware file, for example, `HTML` or `MSEXE`.	yes	yes	no

Malware Event Fields (Continued)

Field	Description	Network	Endpoint	Retrospective from Cloud
File Type Category	The general categories of file type, for example: `Office Documents`, `Archive`, `Multimedia`, `Executables`, `PDF files`, `Encoded`, `Graphics`, or `System Files`.	yes	yes	no
File Timestamp	The time and date the malware file was created.	no	yes	no
File Size (KB)	The size of the malware file, in kilobytes.	yes	yes	no
File URI	The originating URI of the malware file, for example, the URL where a user downloaded it.	yes	no	no
Application File Name	The client application accessing the malware file when detection occurred. These applications are **not** tied to network discovery or application control.	no	yes	no
Application File SHA256	The SHA-256 hash value of the parent file accessing the FireAMP-detected or quarantined file when detection occurred.	no	yes	no
Application Protocol	The application protocol used by the traffic in which a managed device detected a malware file.	yes	no	no
Application Protocol, Client, or Web Application Category or Tag	Criteria that characterize the application to help you understand the application's function. For more information, see the Application Characteristics table on page 1317.	yes	no	yes
Client	The client application that runs on one host and relies on a server to send a file.	yes	no	yes
Web Application	The application that represents the content or requested URL for HTTP traffic detected in the connection.	yes	no	yes

Malware Event Fields (Continued)

Field	Description	Network	Endpoint	Retrospective from Cloud
IOC	Whether the malware event triggered an indication of compromise (IOC) against a host involved in the connection. When endpoint-based malware detection triggers an IOC rule, a full malware event is generated, with the type `FireAMP IOC`. For more information on IOC, see Understanding Indications of Compromise on page 1329.	yes	yes	yes
Application Risk	The risk associated with the application traffic detected in the connection: `Very High`, `High`, `Medium`, `Low`, or `Very Low`. Each type of application detected in the connection has an associated risk; this field displays the highest of those. For more information, see the Application Characteristics table on page 1317.	yes	no	yes
Business Relevance	The business relevance associated with the application traffic detected in the connection: `Very High`, `High`, `Medium`, `Low`, or `Very Low`. Each type of application detected in the connection has an associated business relevance; this field displays the lowest (least relevant) of those. For more information, see the Application Characteristics table on page 1317.	yes	no	yes
Detector	The FireAMP detector that identified the malware, such as ClamAV, Spero, or SHA.	no	yes	no
Message	Any additional information associated with the malware event. For network-based malware events, this field is populated only for files whose disposition has changed; see Retrospective Malware Events on page 1276.	yes	yes	no

Malware Event Fields (Continued)

Field	Description	Network	Endpoint	Retrospective from Cloud
FireAMP Cloud	The name of the Sourcefire cloud where the event originated.	no	yes	no
Device	For network-based malware events, the name of the device that detected the malware file. For endpoint-based malware events and retrospective malware events generated by the cloud, the name of the Defense Center.	yes	yes	yes
Count	The number of events that match the information in each row. This field appears after you apply a constraint that creates two or more identical rows.	n/a	n/a	n/a

Malware Event Types

License: Malware or Any
Supported Devices: feature dependent
Supported Defense Centers: feature dependent

For network-based malware events, the event type can be one of:

- Threat Detected in Network File Transfer
- Threat Detected in Network File Transfer (retrospective)

An endpoint-based malware event can have any of the following types:

- Blocked Execution
- Cloud Recall Quarantine
- Cloud Recall Quarantine Attempt Failed
- Cloud Recall Quarantine Started
- Cloud Recall Restore from Quarantine
- Cloud Recall Restore from Quarantine Failed
- Cloud Recall Restore from Quarantine Started
- FireAMP IOC
- Quarantine Failure
- Quarantined Item Restored
- Quarantine Restore Failed
- Quarantine Restore Started
- Scan Completed, No Detections
- Scan Completed With Detections

- Scan Failed
- Scan Started
- Threat Detected
- Threat Detected in Exclusion
- Threat Quarantined

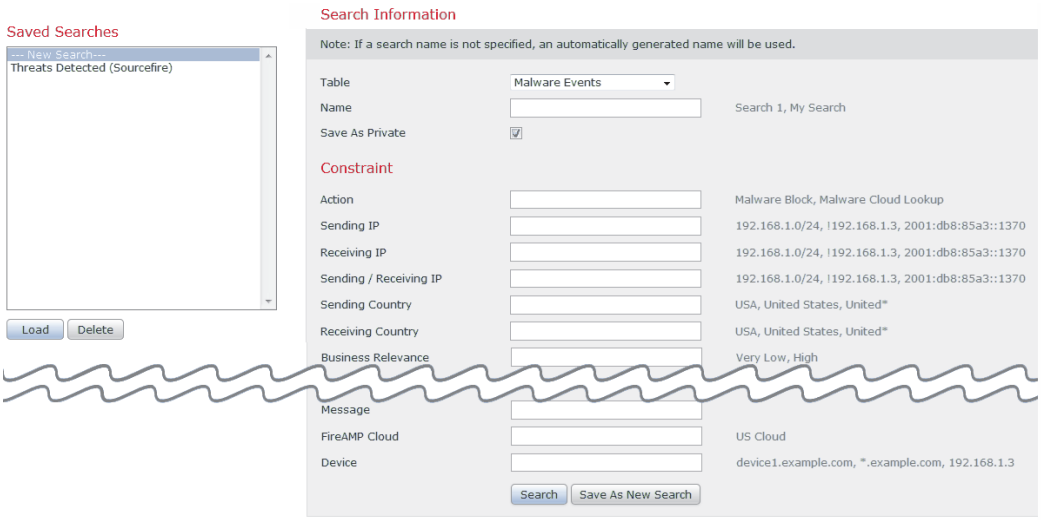
If a file's trajectory map contains malware events, the events are one of the following types: Threat Detected in Network File Transfer, Threat Detected in Network File Transfer (retrospective), Threat Detected, Threat Detected in Exclusion, and Threat Quarantined. See Working with Network File Trajectory on page 1293 for more information.

Note that neither Series 2 devices nor the DC500 Defense Center support network-based malware protection, which can affect the data displayed. For example, a Series 3 Defense Center managing only Series 2 devices can display only endpoint-based malware events.

Searching for Malware Events

LICENSE: Malware or Any

Using the Defense Center's Search page, you can search for specific malware events, display the results in the event viewer, and save your search criteria to reuse later. Custom Analysis dashboard widgets, report templates, and custom user roles can also use saved searches.



Searches delivered with the system, labeled with `(Sourcefire)` in the Saved Searches list, serve as examples.

Keep in mind that your search results depend on the available data in the events you are searching. In other words, depending on the available data, your search constraints may not apply. For example, because endpoint-based malware events

are not generated as a result of managed devices inspecting network traffic, they do not contain connection information (port, application protocol, and so on).

Note that because the DC500 does not support geolocation, searches using these fields from a DC500 return no results.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- Specify `n/a` in any field to identify events where information is not available for that field; use `!n/a` to identify the events where that field is populated.
- Click the add object icon () that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

Special Search Syntax for Malware Events

To supplement the general search syntax listed above, the following table describes some special search syntax for malware events.

Malware Event Special Search Syntax

Search Criterion	Special Syntax
Sending/Receiving IP	The system returns all events where either the **Sending IP** or the **Receiving IP** matches the IP address you specify.
Event Type	When searching for events with a specific malware event type (see Malware Event Types on page 1284), enclose the event type in quotation marks, for example, `"Scan Completed With Detection"`. Otherwise, the system performs a partial match. That is, if you search using the same string but do not use quotation marks, the system returns events with the following types: • Scan Completed, No Detections • Scan Completed With Detection
Initiator/Responder Continent	The system returns all events where either the **Initiator Continent** or the **Responder Continent** matches the continent you specify.

Malware Event Special Search Syntax (Continued)

Search Criterion	Special Syntax
Initiator/Responder Country	The system returns all events where either the **Initiator Country** or the **Responder Country** matches the country you specify.
URI or Message	The system performs a partial match, that is, you can search for all or part of the field contents without using asterisks.

To search for malware events:

Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Malware Events**.

   The page reloads with the appropriate constraints.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields.

   See the Malware Event Fields table on page 1279 for information on the fields in the malware events table.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

   If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in your default malware events workflow, constrained by the current time range.

   - Click **Save** if you are modifying an existing search and want to save your changes.

   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**).

Working with Captured Files

LICENSE: Malware
SUPPORTED DEVICES: Any except Series 2
SUPPORTED DEFENSE CENTERS: Any except DC500

The system logs when a managed device captures a file detected in network traffic according to the rules in currently applied file policies. From the event viewer, you can view information associated with the captured file, such as the most recent file name associated with the SHA-256 value, the file disposition and threat score, the file storage status, and whether the file was manually submitted for dynamic analysis.

IMPORTANT! Files captured by a device containing malware generate both a file event and a malware event, as malware must be detected before it is captured. For more information, see Working with File Events on page 1265 and Working with Malware Events on page 1274.

You can use the Defense Center's event viewer to view and search captured files, as well as submit captured files for dynamic analysis. Additionally, the Files Dashboard provides an at-a-glance view of detailed information about the files (including malware files) detected on your network, using charts and graphs.

For more information, see:

- Viewing Captured Files on page 1288
- Understanding the Captured Files Table on page 1289
- Searching for Captured Files on page 1291

Viewing Captured Files

LICENSE: Malware

The Sourcefire 3D System's event viewer allows you to view captured files in a table, as well as manipulate the event view depending on the information relevant to your analysis.

The page you see when you access captured files differs depending on the workflow, which is simply a series of pages you can use to evaluate events by moving from a broad to a more focused view. The system is delivered with the following predefined workflows for captured files:

- *Captured File Summary*, the default, provides a breakdown of captured files based on type, category, and threat score.
- *Dynamic Analysis Status* provides a count of captured files based on whether they have been submitted for dynamic analysis.

You can also create a custom workflow that displays only the information that matches your specific needs. For information on specifying a different default workflow, including a custom workflow, see Configuring Event View Settings on

page 2300.

Using the event viewer, you can:

- search for, sort, and constrain events, as well as change the time range for displayed events
- specify the columns that appear (table view only)
- view events using different workflow pages within the same workflow
- view events using a different workflow altogether
- drill down page-to-page within a workflow, constraining on specific values
- bookmark the current page and constraints so you can return to the same data (assuming the data still exists) at a later time
- view a file's trajectory
- add a file to a file list, download a file, submit a file for dynamic analysis, or view the full text of a file's SHA-256 value
- view a file's Dynamic Analysis Summary report, if available
- submit up to 25 files at a time for dynamic analysis
- create a report template using the current constraints

Note that neither Series 2 devices nor the DC500 Defense Center support network-based malware protection, which can affect the data displayed. For example, a Series 3 Defense Center managing only Series 2 devices cannot display captured files.

For detailed information on using the event viewer, including creating custom workflows, see Understanding and Using Workflows on page 1865.

To view file events:

Access: Admin/Any Security Analyst

▶ Select **Analysis > Files > Captured Files**.

The first page of your default file events workflow appears. For information on the columns that appear, see Understanding the Captured Files Table on page 1289.

Understanding the Captured Files Table

License: Malware

The Defense Center logs when a managed device captures a file being transmitted in monitored network traffic, according to the settings in an applied file policy.

The table view of captured files, which is the final page in predefined captured file workflows, and which you can add to custom workflows, includes a column for each field in the captured files table. Some fields in the table view of captured files are disabled by default. To enable a field for the duration of your session, click the expand arrow ( ) to expand the search constraints, then click the column

name under **Disabled Columns**. The Captured File Fields table below describes the captured file fields.

Captured File Fields

Field	Description
Last Changed	The last time the information associated with this file was updated.
File Name	The most recently detected file name associated with the file's SHA-256 hash value.
Disposition	One of the following file dispositions: • `Malware` indicates that the cloud categorized the file as malware, or that the file's threat score exceeded the malware threshold defined in the file policy. • `Clean` indicates that the cloud categorized the file as clean, or that a user added the file to the clean list. • `Unknown` indicates that a malware cloud lookup occurred before the cloud assigned a disposition. The file is uncategorized. • `Custom Detection` indicates that a user added the file to the custom detection list. • `Unavailable` indicates that the Defense Center could not perform a malware cloud lookup. • `N/A` indicates a Detect Files or Block Files rule handled the file and the Defense Center did not perform a malware cloud lookup.
SHA256	The SHA-256 hash value of the file, as well as a network file trajectory icon representing the most recently detected file event and file disposition. To view the network file trajectory, click the trajectory icon. For more information, see Analyzing Network File Trajectory on page 1296.
Threat Score	The threat score most recently associated with this file: • `Low` (●○○○) • `Medium` (●●○○) • `High` (●●●○) • `Very High` (●●●●) To view the Dynamic Analysis Summary report, click the threat score icon.
Type	The type of file, for example, `HTML` or `MSEXE`.

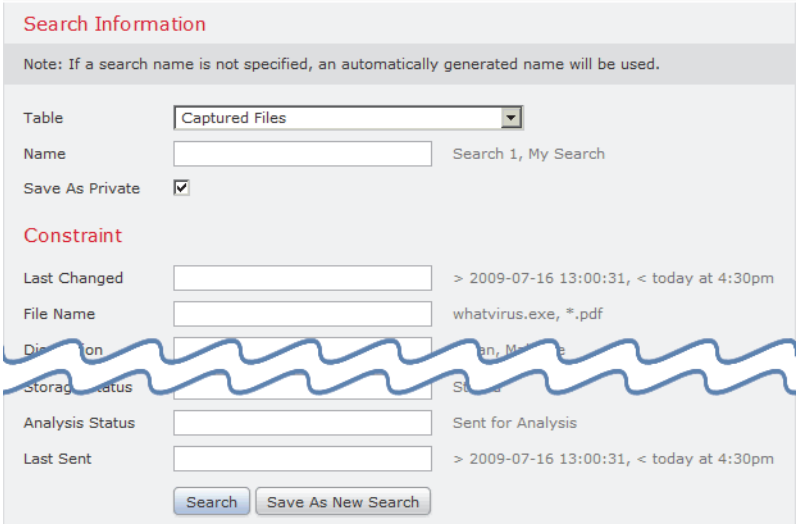
Captured File Fields (Continued)

Field	Description
Category	The general categories of file type, for example: `Office Documents`, `Archive`, `Multimedia`, `Executables`, `PDF files`, `Encoded`, `Graphics`, or `System Files`.
Storage Status	Whether the file is stored on a managed device.
Analysis Status	Whether the file was submitted for dynamic analysis.
Last Sent	The time the file was most recently submitted to the cloud for dynamic analysis.

Searching for Captured Files

License: Malware

Using the Defense Center's Search page, you can search for specific captured files, display the results in the event viewer, and save your search criteria to reuse later. Custom Analysis dashboard widgets, report templates, and custom user roles can also use saved searches.



Keep in mind that your search results depend on the available data in the events you are searching. In other words, depending on the available data, your search constraints may not apply. For example, if a file has never been submitted for dynamic analysis, it may not have an associated threat score.

Note that because the DC500 does not support geolocation, searches using these fields from a DC500 return no results.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- Specify `n/a` in any field to identify events where information is not available for that field; use `!n/a` to identify the events where that field is populated.
- Click the add object icon () that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

Special Search Syntax for Captured Files

To supplement the general search syntax listed above, the following table describes some special search syntax for captured files.

Captured Files Special Search Syntax

Search Criterion	Special Syntax
Storage Status	Specify one or more of the following: • `File Stored` - returns all captured files stored on the device • `Unable to Store File` - returns all captured files not stored on the device
Analysis Status	Specify one or more of the following: • `Sent for Analysis` - returns all captured files queued for dynamic analysis • `Not Sent for Analysis` - returns all captured files not submitted for dynamic analysis • `Analysis Complete` - returns all captured files submitted for dynamic analysis that received a threat score and dynamic analysis summary report • `Previously Analyzed` - returns all files with a cached threat score that a user tried to submit for dynamic analysis again • `Failure (Analysis Timeout)` - returns all captured files submitted for dynamic analysis for which the cloud has yet to return a result • `Failure (Network Issue)` - returns all files that did not get submitted for dynamic analysis due to a network connectivity failure • `Failure (Cannot Run File)` - returns all files submitted for dynamic analysis that the cloud could not run in the test environment

To search for captured files:

ACCESS: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Captured Files**.

   The page reloads with the appropriate constraints.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields.

   See the Captured File Fields table on page 1290 for information on the fields in the captured files table.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

   If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in your default captured file workflow, constrained by the current time range.

   - Click **Save** if you are modifying an existing search and want to save your changes.

   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**).

Working with Network File Trajectory

LICENSE: Malware or Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

The network file trajectory feature maps how hosts transferred files, including malware files, across your network. You can use the map to determine which hosts may have transferred malware, which hosts are at risk, and observe file transfer trends.

The trajectory map charts file transfer data, the disposition of the file, and if a file transfer was blocked or the file was quarantined. The data used to build the map can come from network-based malware events (any file event for which the system performed a malware cloud lookup and returned a malware disposition)

and certain endpoint-based malware events related to detecting and blocking malware (any Threat Detected or Threat Quarantined event type). Vertical lines between data points represent file transfers between hosts. Horizontal lines connecting the data points show a host's file activity over time.

You can track the transmission of any file type for which the system can perform a malware cloud lookup. To directly access a file's trajectory, you can use the Network File Trajectory List page (**Analysis > Files > Network File Trajectory**) and locate specific files. Additionally, if you are analyzing an intrusion and want to review the trajectory for a related file, you can access the file's trajectory from the Context Explorer, dashboard, or event views of connection, file, or malware events.

The data a single trajectory map displays depends on the licenses applied to your appliance. The following table lists the licenses necessary to track different types of file trajectory.

License Requirements for Network File Trajectory

TO VIEW...	YOU NEED THE FOLLOWING LICENSE...
network-based file and malware trajectories	Malware
endpoint-based threat and quarantine tracking	Any (you must have a FireAMP subscription)

See Understanding Malware Protection and File Control on page 1228 for more information.

Note that because you cannot use a Malware license with a DC500, nor enable a Malware license on a Series 2 device, you cannot use those appliances to capture, store or block individual files, submit files for dynamic analysis, or view file trajectories for files for which you conduct a malware cloud lookup. You can, however, still view file trajectories for endpoint-based threat and quarantine tracking.

For more information, see the following sections:

- Reviewing Network File Trajectory on page 1294
- Analyzing Network File Trajectory on page 1296

Reviewing Network File Trajectory

LICENSE: Malware or Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

As you review captured files, file events, and malware events, you can view a file's trajectory map from the Context Explorer, properly configured dashboard widgets, and various event views. You can also review the most recently viewed

network file trajectories and the most recently detected malware from the Network File Trajectory List page.

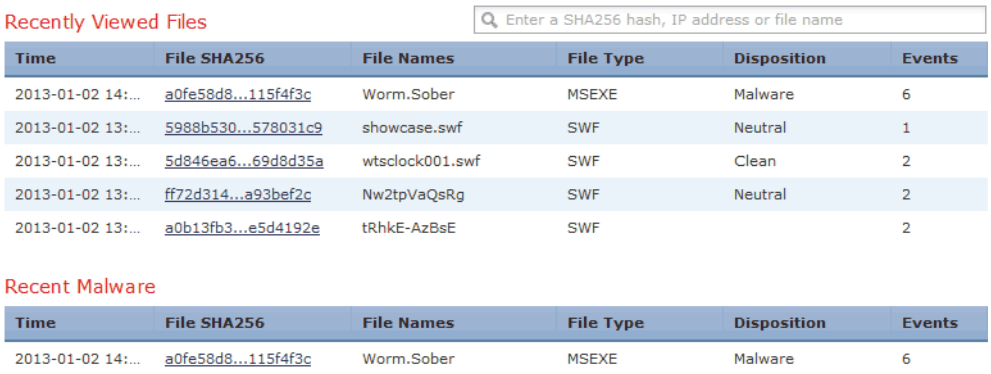
For more information, see the following sections:

- Viewing the Top File Names Graph on page 153
- Drilling Down on Context Explorer Data on page 164
- Understanding the Custom Analysis Widget on page 86
- Understanding the File Events Table on page 1268
- Understanding the Malware Events Table on page 1278
- Understanding the Captured Files Table on page 1289
- Information Available in Connection and Security Intelligence Events on page 597
- Accessing Network File Trajectory on page 1295

Accessing Network File Trajectory

LICENSE: Malware or Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

The Network File Trajectory List page allows you to locate files that have a SHA-256 hash value, whether to analyze the most recently detected malware, or to track a specific threat.



The page displays the malware most recently detected on your network, as well as the files whose trajectory maps you have most recently viewed. From these lists, you can view when the file was most recently seen on the network, the file's SHA-256 hash value, name, type, current file disposition, and the number of events associated with the file. For more information on the fields, see Understanding the File Events Table on page 1268.

The page also contains a search box that lets you locate files, either based on SHA-256 hash value or file name, or by the IP address of the host that transferred or received a file. After you locate a file, you can click the **File SHA256** value to view the detailed trajectory map. See Analyzing Network File Trajectory on page 1296

for more information.

Note that because you cannot use a Malware license with a DC500, nor can you enable a Malware license on a Series 2 device, you cannot use those appliances to view file trajectories for files for which you conduct a malware cloud lookup.

To locate a file from the Network File Trajectory List page:

Access: Any

1. Select **Analysis > Files > Network File Trajectory**.

   The Network File Trajectory List page appears, displaying the lists of recently viewed files and recent malware.

2. Optionally, you can type a complete SHA-256 hash value, host IP address, or file name of a file you want to track into the search field and press Enter.

   The Query Results page appears listing all files that match the search. If only one result matches, the Network File Trajectory page for that file appears.

Analyzing Network File Trajectory

License: Malware or Any
Supported Devices: feature dependent
Supported Defense Centers: feature dependent

You can trace a file through the network by viewing the detailed network file trajectory. The file's trajectory presents summary information about a file, displays the map charting data points over time, and also lists the event data tied to the data points in a table. Using the table and the map, you can pinpoint specific file events, hosts on the network that transferred or received this file, related events in the map, and other related events in a table constrained on selected values.

Note that because you cannot use a Malware license with a DC500, nor can you enable a Malware license on a Series 2 device, you cannot use those appliances to view file trajectories for files for which you conduct a malware cloud lookup.

For more information, see the following sections:

- Summary Information on page 1296
- Trajectory Map on page 1300
- Events Table on page 1302

Summary Information

License: Malware or Any
Supported Devices: feature dependent
Supported Defense Centers: feature dependent

A file's trajectory page displays basic information about the file, including file identification information, when the file was first seen and most recently seen on the network, the number of related events and hosts associated with the file, and the file's current disposition. From this section, if the managed device stored the

file, you can download it locally, submit the file for dynamic analysis, or add the file to a file list.

TIP! To view related file events, click a field value link. The first page in the File Events default workflow opens in a new window, displaying all file events that also contain the selected value.

The following table describes the summary information fields.

Network File Trajectory Summary Information Fields

NAME	DESCRIPTION
File SHA256	The SHA-256 hash value of the file. The hash is displayed by default in a condensed format. To view the full hash value, hover your pointer over it. If multiple SHA-256 hash values are associated with a file name, hover your pointer over the link to view all of the hash values. Click the download file icon ( ) to download the file to your local computer. If prompted, confirm you want to download the file. Follow your browser's prompts to save the file. If the file is unavailable for download, this icon is grayed out. **WARNING!** Sourcefire strongly recommends you do **not** download malware, as it can cause adverse consequences. Exercise caution when downloading any file, as it may contain malware. Ensure you have taken any necessary precautions to secure the download destination before downloading files.
File Names	The names of the file associated with the event, as seen on the network. If multiple file names are associated with a SHA-256 hash value, the most recent detected file name is listed. You can expand this to view the remaining file names by clicking `more`.
File Type	The file type of the file, for example, `HTML` or `MSEXE`.
File Category	The general categories of file type, for example, `Office Documents` or `System Files`.

Network File Trajectory Summary Information Fields (Continued)

NAME	DESCRIPTION
Parent Application	The client application accessing the malware file when detection occurred. These applications are **not** tied to network discovery or application control. This field only appears for endpoint-based malware events.
First Seen	The first time a managed device or FireAMP Connector detected the file, and the IP address of the host that first uploaded the file.
Last Seen	The most recent time a managed device or FireAMP Connector detected the file, and the IP address of the host that last downloaded the file.
Event Count	The number of events seen on the network associated with the file, and the number of events displayed in the map if there are more than 250 detected events.
Seen On	The number of hosts that either sent or received the file. Because one host can upload and download a file at different times, the total number of hosts may not match the total number of senders plus the total number of receivers in the `Seen On Breakdown` field.
Seen On Breakdown	The number of hosts that sent the file, followed by the number of hosts that received the file.

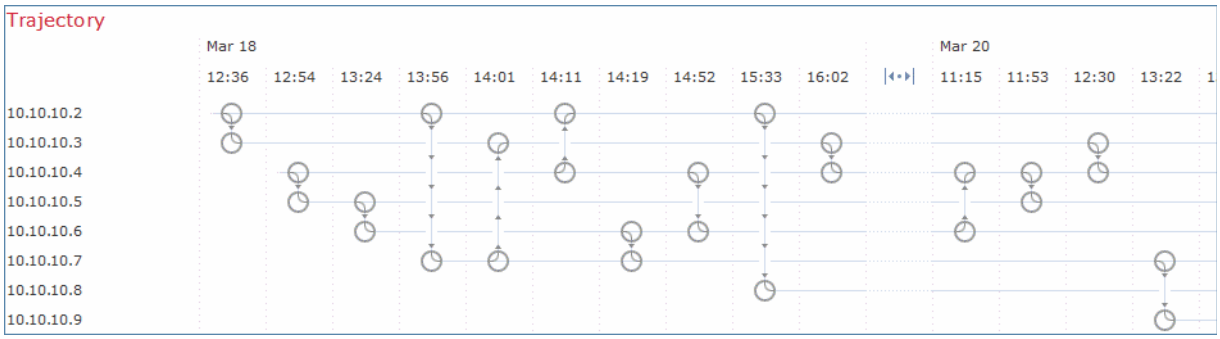
Network File Trajectory Summary Information Fields (Continued)

Name	Description
Current Disposition	One of the following file dispositions: • `Malware` indicates that the cloud categorized the file as malware, or that the file's threat score exceeded the malware threshold defined in the file policy. • `Clean` indicates that the cloud categorized the file as clean, or that a user added the file to the clean list. • `Unknown` indicates that a malware cloud lookup occurred before the cloud assigned a disposition. The file is uncategorized. • `Custom Detection` indicates that a user added the file to the custom detection list. • `Unavailable` indicates that the Defense Center could not perform a malware cloud lookup. • `N/A` indicates a Detect Files or Block Files rule handled the file and the Defense Center did not perform a malware cloud lookup. Click the edit icon () to add the file to or remove the file from the clean list or custom detection list. This field only appears for network-based malware events.
Threat Name	Name of the malware threat associated with the file. This field only appears for endpoint-based malware events.
Threat Score	The file's threat score: • `Low` () • `Medium` () • `High` () • `Very High` (). Click the threat score icon to view the Dynamic Analysis Summary report, click the threat score icon. Click the threat score link to view all captured files with that threat score. Click the cloud icon () to submit the file to the cloud for dynamic analysis. If the file is unavailable for submission or you cannot connect to the cloud, this icon is greyed out.

Trajectory Map

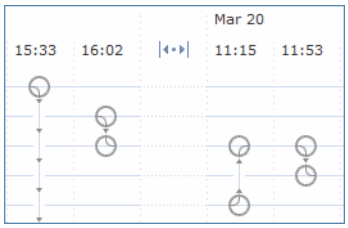
LICENSE: Malware or Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

A file's trajectory map visually tracks a file from the first detection on your network to the most recent. The map shows when hosts transferred or received the file, how often they transferred the file, and when the file was blocked or quarantined. The map also shows how often file events occurred for the file and when the system assigned the file a disposition or retrospective disposition. You can select a data point in the map and highlight a path that traces back to the first instance the host transferred that file; this path also intersects with every occurrence involving the host as either sender or receiver of the file. The following screenshot shows an example trajectory map:



The map's y-axis contains a list of all host IP addresses that have interacted with the file. The IP addresses are listed in descending order based on when the system first detected the file on that host. Each row contains all events associated with that IP address, whether a single file event, file transfer, or retrospective event. The x-axis contains the date and time the system detected each event. The timestamps are listed in chronological order. If multiple events occurred within a minute, all are listed within the same column. You can scroll the map horizontally and vertically to view additional events and IP addresses.

The map displays up to 250 events associated with the file SHA-256 hash. If there are more than 250 events, the map displays the first 10, then truncates extra events with an arrow icon (|◂•▸|). The map then displays the remaining 240 events. The following screenshot shows events truncated with the arrow icon:



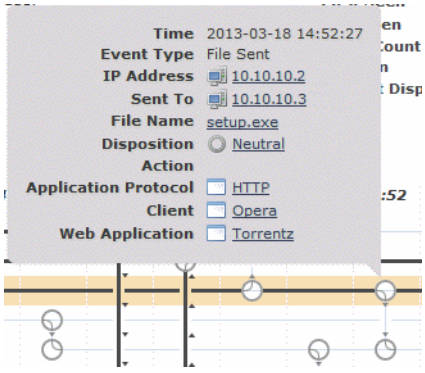
You can view all events not displayed in the File Summary event view by clicking the arrow icon (|◂•▸|). The first page of the File Events default workflow appears in

a new window with all the extra events constrained based on the file type. If endpoint-based malware events are not displayed, you must switch to the Malware Events table to view these.

Each data point represents an event plus the file disposition, as described in the legend below the map. For example, a Malware Block event icon combines the Malicious Disposition icon and the Block Event icon.

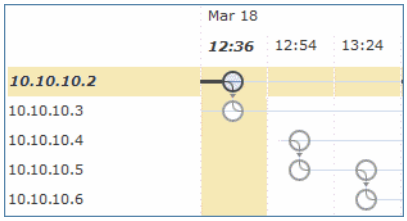
Endpoint-based malware events include one icon. A retrospective event displays an icon in the column for each host on which the file is detected. File transfer events always include two icons, one file send icon and one file receive icon, connected by a vertical line. Arrows indicate the file transfer direction from sender to receiver.

You can view summary information from the event icon by hovering your pointer over the event icon ( ). The displayed summary information matches the information displayed in the Events table. The following screenshot shows an event icon's summary information:



If you click any event summary information link, the first page of the File Events default workflow appears in a new window with all the extra events constrained based on the file type the File Summary event view opens in a new window, displaying all file events that match on the criteria value you clicked.

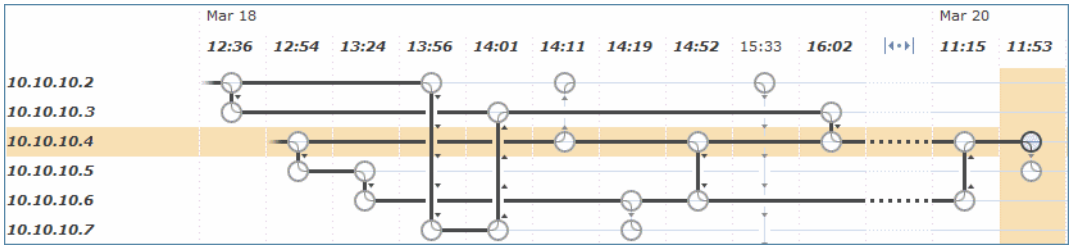
To locate the first time a file event occurred involving an IP address, click the address. This highlights a path to that data point, as well as any intervening file events and IP addresses related to the first file event. The corresponding event in the Events table is also highlighted. The map scrolls to that data point if not currently visible. The following screenshot shows the path highlighted after clicking an IP address:



To track a file's progress through the network, you can click any data point to highlight a path that includes all data points related to the selected data point. This includes data points associated with the following types of events:

- any file transfers in which the associated IP address was either sender or receiver
- any endpoint-based malware events involving the associated IP address
- if another IP address was involved, all file transfers in which that associated IP address was either sender or receiver
- if another IP address was involved, any endpoint-based malware events involving the other IP address

The following screenshot shows the path highlighted after clicking an event icon:



All IP addresses and timestamps associated with any highlighted data point are also highlighted. The corresponding event in the Events table is also highlighted. If a path includes truncated events, the path itself is highlighted with a dotted line. Truncated events might intersect the path, but are not displayed in the map.

Events Table

LICENSE: Malware or Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

The Events table lists event information for each data point in the map. You can sort events in ascending or descending order by clicking the column headers. You can highlight a data point in the map by selecting the table row. The map scrolls to display the selected file event if not currently visible. For more information on the fields, see Understanding the File Events Table on page 1268.

CHAPTER 32
INTRODUCTION TO NETWORK DISCOVERY

The Sourcefire 3D System uses a feature called *network discovery* to monitor traffic on your network and build a comprehensive map of your network assets.

As managed devices passively observe traffic on the network segments you specify, the system compares specific packet header values and other unique data from network traffic against established definitions (called *fingerprints*) to determine the number and types of hosts (including network devices) on your network, as well as the operating systems, active applications, and open ports on those hosts.

You can also configure Sourcefire managed devices to monitor user activity on your network, which allows you to identify the source of policy breaches, attacks, or network vulnerabilities.

To supplement the data gathered by the system, you can import records generated by NetFlow-enabled devices, Nmap active scans, the Sourcefire host input feature, and Sourcefire User Agents that reside on a Microsoft Active Directory server and report LDAP authentications. The Sourcefire 3D System integrates these records with the information it collects via direct network traffic observation by managed devices.

The system can correlate certain types of intrusion, malware, and other events occurring on hosts on your network to determine when hosts are potentially compromised, tagging those hosts with *indications of compromise* (IOC) tags. IOC data can give you a clear, direct picture of the threats to your monitored network as they relate to its hosts.

The system uses all of this information to help you with forensic analysis, behavioral profiling, access control, and mitigating and responding to the vulnerabilities and exploits to which your organization is susceptible.

For more information, see:

- Understanding Discovery Data Collection on page 1304
- Understanding NetFlow on page 1325
- Understanding Indications of Compromise on page 1329
- Creating a Network Discovery Policy on page 1332
- Obtaining User Data from LDAP Servers on page 1357

Understanding Discovery Data Collection

LICENSE: FireSIGHT

Discovery data includes information on your network's hosts and the operating systems, active applications, and user activity on those hosts.

To begin collecting discovery data, you must first apply an access control policy. The access control policy (see Using Access Control Policies on page 461) defines the traffic that you permit, and therefore the traffic you can monitor with network discovery. Note that this means if you block certain traffic using access control, the system cannot examine that traffic for host, user, or application activity. For example, if you block access to social networking applications, the system does not provide you with any discovery data on social network applications.

After you apply an access control policy, you must configure and apply a network discovery policy, which specifies the network segments and ports you want to monitor with your managed devices, and the kinds of data you want to collect. When you apply the network discovery policy, the system begins generating discovery data, which you can then view and analyze using the Defense Center web interface.

The system stores network discovery data in the Defense Center database; for information on storage limits, see Configuring Database Event Limits on page 2056. In addition to the database limits, the total number of detected hosts and users the Defense Center can store depends on your FireSIGHT license.

After you reach the licensed user limit, in most cases the system stops adding new users to the database. To add new users, you must either manually delete old or inactive users from the database, or purge all users from the database. On the other hand, after you reach the licensed host limit, you can configure the system either to stop adding new hosts to the database, or to replace the hosts that have remained inactive for the longest time.

To supplement the data gathered by the system, you can import records generated by NetFlow-enabled devices, Nmap active scans, the Sourcefire host input feature, and Sourcefire User Agents that reside on a Microsoft Active Directory server and report LDAP authentications. The Sourcefire 3D System integrates these records with the information it collects via direct network traffic observation by managed devices.

For more information, see:

- Understanding Host Data Collection on page 1305

- Uses for Discovery Data on page 1324

Understanding Host Data Collection

License: FireSIGHT

As the system passively monitors the traffic that travels through your network, it system compares specific packet header values and other unique data from network traffic against established definitions (called *fingerprints*) to determine the following information about the hosts on your network, including:

- the number and types of hosts (including network devices such as bridges, routers, load balancers, and NAT devices)
- basic network topology data, including the number of hops from the discovery point on the network to the hosts
- the operating systems running on the hosts

If the system cannot identify the operating system of a host, you can use the custom fingerprinting feature to create custom client or server fingerprints. The system uses these fingerprints to identify new hosts. You can map fingerprints to systems in the vulnerability database (VDB) to allow the appropriate vulnerability information to be displayed whenever a host is identified using the custom fingerprint. For more information, see Using Custom Fingerprinting on page 1720.

You can also add or update host and operating system data through the host input feature. In addition, if you create a NetFlow-enabled discovery rule with host detection enabled, hosts can be added to the network map from NetFlow data.

You can view the hosts detected by the system using the Defense Center web interface:

- For information on viewing and searching for hosts using the event viewer, see Working with Hosts on page 1465.
- For information on viewing the network map, which is a detailed representation of your network assets and topology, see Using the Network Map on page 1373.
- For information on viewing host profiles, which are complete views of all the information available for your detected hosts, see Using Host Profiles on page 1394.

Understanding User Data Collection

LICENSE: FireSIGHT

You can use the Sourcefire 3D System to monitor user activity on your network, which allows you to correlate threat, endpoint, and network intelligence with user identity information. By linking network behavior, traffic, and events directly to individual users, the system can help you to identify the source of policy breaches, attacks, or network vulnerabilities. In other words, the system can tell you the "who" behind the "what." For example, you could determine:

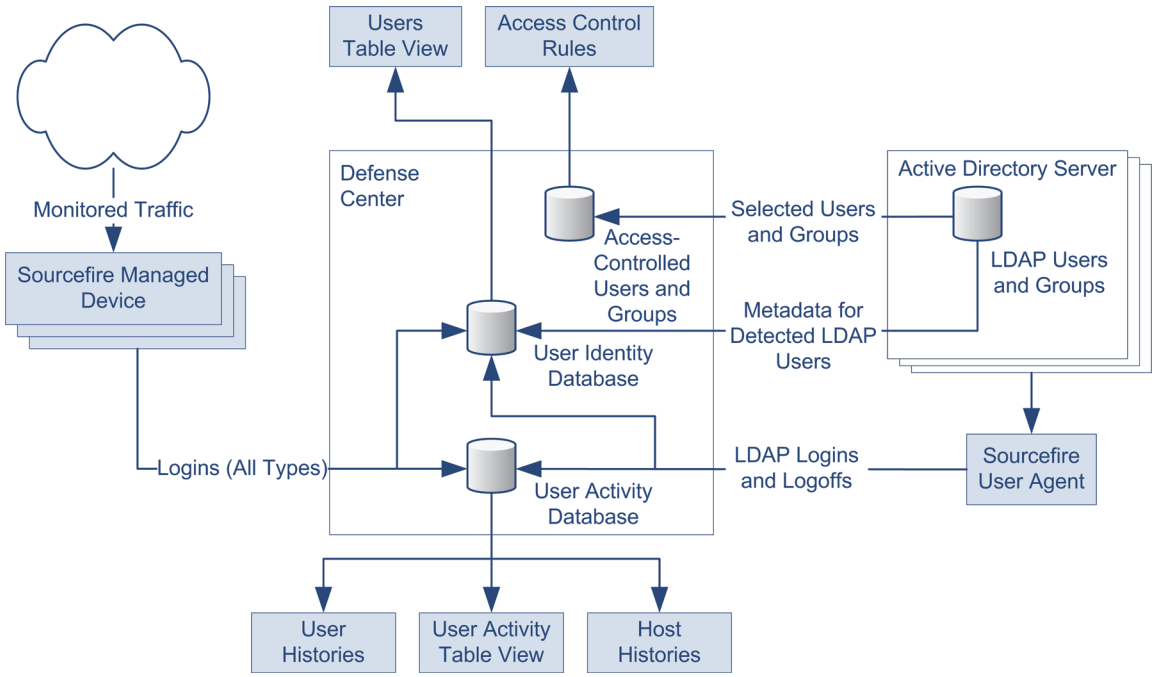
- who owns the host targeted by an intrusion event that has a Vulnerable (level 1: red) impact level
- who initiated an internal attack or portscan
- who is attempting unauthorized access of a server that has high host criticality
- who is consuming an unreasonable amount of bandwidth
- who has not applied critical operating system updates
- who is using instant messaging software or peer-to-peer file-sharing applications in violation of company IT policy

Armed with this information, you can take a targeted approach to mitigate risk, block users or user activity, and take action to protect others from disruption. These capabilities also significantly improve audit controls and enhance regulatory compliance.

The system downloads the users used in access control policies from the Microsoft Active Directory LDAP server, based on the user awareness settings in the LDAP connection. The Sourcefire User Agent then provides login data for these users and the users are added to the user database. These users are referred to as *access-controlled users*. When you author access control policies that include user conditions, you write those conditions against access-controlled users. For more information, see Adding User Conditions on page 541.

When the system detects user data from a user login, either from a Sourcefire User Agent, or from an email login over POP3, SMTP, or IMAP, the user from the login is checked against the list of users. If the login user matches an existing user reported by an agent, the data from the login is assigned to the user. Logins that do not match existing users cause a new user to be created, unless the login is in SMTP traffic. Non-matching logins in SMTP traffic are discarded.

The following diagram illustrates how the Sourcefire 3D System collects and stores user data.



As shown in the diagram, there are three sources for user data, and three places that data is stored. For more information on user data collection, see:

- Managed Devices on page 1307
- Sourcefire User Agents on page 1308
- Defense Center-LDAP Server Connections on page 1311
- Users Database on page 1311
- User Activity Database on page 1312
- Access-Controlled Users Database on page 1313
- User Data Collection Limitations on page 1314

Managed Devices

License: FireSIGHT

You use the network discovery policy to configure managed devices to passively detect LDAP, AIM, POP3, IMAP, Oracle, SIP (VoIP), and SMTP logins on the

networks you specify. Note that when you enable discovery of users in a network discovery rule, host discovery is automatically enabled.

IMPORTANT! Managed devices interpret only Kerberos logins for LDAP connections as LDAP authentications. Managed devices cannot detect encrypted LDAP authentications using protocols such as SSL or TLS.

When a device detects a login, it sends the following information to the Defense Center to be logged as user activity:

- the user name identified in the login
- the time of the login
- the IP address involved in the login, which can be the IP address of the user's host (for LDAP, POP3, IMAP, and AIM logins), the server (for SMTP and Oracle logins), or the session originator (for SIP logins)
- the user's email address (for POP3, IMAP, and SMTP logins)
- the name of the device that detected the login

If the user was previously detected, the Defense Center updates that user's login history. Note that the Defense Center can use the email addresses in POP3 and IMAP logins to correlate with LDAP users. This means that, for example, if the Defense Center detects a new IMAP login, and the email address in the IMAP login matches that for an existing LDAP user, the IMAP login does not create a new user, rather, it updates the LDAP user's history.

If the user has never been detected before, the Defense Center adds the user to the users database. Unique AIM, SIP, and Oracle logins always create new user records, because there is no data in those login events that the Defense Center can correlate with other login types.

The Defense Center does **not** log user activity or user identities in the following cases:

- if you configured the network discovery policy to ignore that login type, as described in Restricting User Logging on page 1343
- if a managed device detects an SMTP login, but the users database does not contain a previously detected LDAP, POP3, or IMAP user with a matching email address

Sourcefire User Agents

LICENSE: FireSIGHT

If your organization uses Microsoft Active Directory LDAP servers, Sourcefire recommends that you install Sourcefire User Agents to monitor user activity via your Active Directory servers. If you want to perform user control, you **must** install and use Sourcefire User Agents; the agents associate users with IP addresses, which in turn allows access control rules with user conditions to

trigger. You can use one agent to monitor user activity on up to five Active Directory servers.

To use an agent, you must configure a connection between each Defense Center connected to the agent and the monitored LDAP servers. This connection not only allows you to retrieve metadata for the users whose logins and logoffs were detected by User Agents, but also is used to specify the users and groups you want to use in access control rules. For more information on configuring LDAP servers for user discovery, see Creating LDAP Connections with the Defense Center on page 1357.

Each agent can monitor logins using encrypted traffic, either through regularly scheduled polling or real-time monitoring. Logins are generated by the Active Directory server when a user logs into a computer, whether at the workstation or through a Remote Desktop login.

Agents can also monitor and report user logoffs. Logoffs are generated by the agent itself when it detects a user logged out of a host IP address. Logoffs are also generated when the agent detects that the user logged into a host has changed, before the Active Directory server reports that the user has changed. Combining logoff data with login data develops a more complete view of the users logged into the network.

Polling an Active Directory server allows an agent to retrieve batches of user activity data at the defined polling interval. Real-time monitoring transmits user activity data to the agent as soon as the Active Directory server receives the data.

You can configure the agent to exclude reporting any logins or logoffs associated with a specific user name or IP address. This can be useful, for example, to exclude repeated logins to shared servers, such as file shares and print servers, as well as exclude users logging into machines for troubleshooting purposes.

The agents send records of all detected logins and logoffs that do not contain an excluded user name or IP address to Defense Centers, which log and report them as user activity. The agents detect the Defense Center version and send the login records in the appropriate data format. This supplements any user activity detected directly by managed devices. The logins reported by User Agents associate users with IP addresses, which in turn allows access control rules with user conditions to trigger.

User Agents monitor users as they log into the network or when accounts authenticate against Active Directory credentials for other reasons. Version 2.1 of the Sourcefire User Agent detects interactive user logins to a host, Remote Desktop logins, file-share authentication, and computer account logins, as well as user logoffs and Remote Desktop sessions where the user has logged off.

The type of login detected determines how the agent reports the login and how the login appears in the host profile. An *authoritative user login* for a host causes the current user mapped to the host IP address to change to the user from the new login. Other logins either do not change the current user or only change the current user for the host if the existing user on the host did not have an authoritative user login to the host. In these cases, if the expected user is no

longer logged in, the agent generates a logoff for that user. User logins detected by network discovery only change the current user for the host if the existing user on the host did not have an authoritative user login to the host. Agent-detected logins have the following effect on the network map:

- When the agent detects an interactive login to a host by a user or a Remote Desktop login, the agent reports an authoritative user login for the host and changes the current user for the host to the new user.
- If the agent detects a login for file-share authentication, the agent reports a user login for the host, but does not change the current user on the host.
- If the agent detects a computer account login to a host, the agent generates a NetBIOS Name Change discovery event and the host profile reflects any change to the NetBIOS name.
- If the agent detects a login from an excluded user name, the agent does not report a login to the Defense Center.

When a login or other authentication occurs, the agent sends the following information to the Defense Center:

- the user's LDAP user name
- the time of the login or other authentication
- the IP address of the user's host, and the link-local address if the agent reports an IPv6 address for a computer account login

The Defense Center records login and logoff information as user activity. When a Sourcefire User Agent reports user data from a user login or logoff, the reported user is checked against the list of users. If the reported user matches an existing user reported by an agent, the reported data is assigned to the user. Reported users that do not match existing users cause a new user to be created.

Even though the user activity associated with an excluded user name is not reported, related user activity may still be reported. If the agent detects a user login to a machine, then the agent detects a second user login, and you have excluded the user name associated with the second user login from reporting, the agent reports a logoff for the original user. However, no login for the second user is reported. As a result, no user is mapped to the IP address, even though the excluded user is logged into the host.

Note the following limitations on user names detected by the agent:

- User names ending with a dollar sign character (**$**) reported to a Version 5.0.2+ Defense Center update the network map, but do not appear as user logins. Agents do not report user names ending with a dollar sign character (**$**) to any other versions of Defense Centers.
- Defense Center display of user names containing Unicode characters may have limitations.

The total number of detected users the Defense Center can store depends on your RNA or FireSIGHT license. After you reach the licensed user limit, in most cases the system stops adding new users to the database. To add new users, you

must either manually delete old or inactive users from the database, or purge all users from the database.

IMPORTANT! Version 1.0 (legacy) Sourcefire Agents installed on Active Directory LDAP servers can continue to send user login data from the Active Directory server to a single Defense Center. Deployment requirements and detection capabilities of legacy agents are unchanged. You must install them on the Active Directory server to connect to exactly one Defense Center. Note, however, that the User Agent Status Monitor health module does not support legacy agents and should not be enabled on Defense Centers with legacy agents connected. You should plan to upgrade your deployment to use Version 2.1 of the Sourcefire User Agent as soon as possible, in preparation for future releases when support for legacy agents will be phased out.

Defense Center-LDAP Server Connections

LICENSE: FireSIGHT

The Defense Center-LDAP server connection allows you to retrieve metadata for certain detected users. You can retrieve metadata for LDAP users, whether their logins were detected by managed devices or by a User Agent; you can also retrieve metadata for POP3 and IMAP users if those users have the same email address as an LDAP user.

If your organization uses Microsoft Active Directory servers, the connection also allows you to specify the LDAP users and groups you want to use in access control rules. If you want to perform user control, you **must** configure a connection between the Defense Center and an Active Directory server. If your organization does not use Active Directory, you can still detect user logins using managed devices, and you can still obtain metadata for some of those users from an Oracle or OpenLDAP server. However, you cannot perform user control based on those users or their activity.

From the LDAP server, the Defense Center obtains the following information and metadata about each user:

- LDAP user name
- first and last names
- email address
- department
- telephone number

Users Database

LICENSE: FireSIGHT

The users database contains a record for each user detected by either managed devices or User Agents. The total number of detected users the Defense Center can store depends on your RNA or FireSIGHT license. After you reach the

licensed limit, in most cases the system stops adding new users to the database. To add new users, you must either manually delete old or inactive users from the database, or purge all users from the database.

However, the system favors authoritative user logins. If you have reached the limit and the system detects an authoritative user login for a previously undetected user, the system deletes the non-authoritative user who has remained inactive for the longest time, and replaces it with the new user.

You can view the contents of the users database with the Defense Center web interface. For information on viewing, search for, and deleting detected users, see Working with Users on page 1514.

User Activity Database

LICENSE: FireSIGHT

The user activity database contains records of user activity on your network, either from a connection to an Active Directory LDAP server that is also monitored by a Sourcefire User Agent, or though network discovery. The system logs events in the following circumstances:

- when it detects individual logins or logoffs
- when it detects a new user
- when you manually delete a user
- when the system detects a user that is not in the database, but cannot add the user because you have reached your FireSIGHT licensed limit

You can view the user activity detected by the system using the Defense Center web interface. For information on viewing, searching for, and deleting user activity, see Working with User Activity on page 1522. If you plan to use Version 2.1 of the Sourcefire 3D System User Agent to send LDAP login data to your Defense Centers, you must configure a connection for each agent on each Defense Center where you want the agent to connect. That connection allows the agent to establish a secure connection with the Defense Center, over which it can send login data. If the agent is configured to exclude specific user names, login data for those user names are not reported to the Defense Center.

In addition, if you are planning to implement user access control, you must set up a connection to each Microsoft Active Directory server where you plan to collect data, with user awareness parameters configured.

Whenever possible the Sourcefire 3D System correlates user activity with other types of events. For example, intrusion events can tell you the users who were logged into the source and destination hosts at the time of the event.

The system also uses user activity to generate *host histories*, which track the hosts that each user has logged into, and *user histories*, which track the users that have logged into each individual host. The system provides a graphical representation of the last twenty-four hours of each user's activity and the last twenty-four hours of the logins to each host. For more information, see Understanding User Details and Host History on page 1518 and Working with

User History in the Host Profile on page 1421.

Access-Controlled Users Database

LICENSE: Control

The access-controlled users database contains the users and groups that you can use in access control rules, so that you can perform user control with the Sourcefire 3D System. These users can be one of two types:

- An *access-controlled user* is a user that you can add to access control rules to perform user control. You specify the groups that access-controlled users must belong to when you configure the Defense Center-LDAP server connection.
- A *non-access-controlled user* is any other detected user.

You specify the groups that access-controlled users must belong to when you configure the Defense Center-LDAP server connection, as described in Creating LDAP Connections with the Defense Center on page 1357.

If you plan to use Version 2.1 of the Sourcefire 3D System User Agent to send LDAP login and logoff data to your Version 5.x Defense Centers, you must configure a connection for each agent on each Defense Center where you want the agent to connect. That connection allows the agent to establish a secure connection with the Defense Center, over which it can send the user activity data.

If the agent is configured to exclude specific user names, user activity data for those user names are not reported to the Defense Center. These excluded user names remain in the database, but are not associated with IP addresses.

In addition, if you are planning to implement user access control, you must set up a connection to each Microsoft Active Directory server where you plan to collect data, with user awareness parameters configured.

The maximum number of users you can use in access control depends on your FireSIGHT license. When configuring the Defense Center-LDAP server connection, make sure the total number of users you include is less than your FireSIGHT user license. See Understanding FireSIGHT Host and User License Limits on page 2127 for more information.

User Data Collection Limitations

LICENSE: FireSIGHT

The following table describes the limitations of user data collection.

User Awareness Limitations

LIMITATION	DESCRIPTION
user control	To perform user control, your organization **must** use Microsoft Active Directory LDAP servers. The system obtains the users and groups you can use in access control rules from Active Directory, and also ties users to IP addresses with the logins and logoffs reported by Sourcefire User Agents installed on Active Directory servers.
non-Kerberos logins for LDAP connections	Managed devices interpret only Kerberos logins for LDAP connections as LDAP authentications. Managed devices cannot detect encrypted LDAP authentications if they use other protocols, such as SSL or TLS. On the other hand, Sourcefire User Agents use the security logs on Active Directory servers to collect user login data and have no such limitations.
login detection	Version 2.1 of the Sourcefire User Agent reports user logins to hosts with IPv6 addresses to Defense Centers running Version 5.2+. The agent reports non-authoritative user logins and NetBIOS logins to Defense Centers running Version 5.0.1+. The agent reports authoritative logins from actual user names to Defense Centers running Version 4.10.x+. If you want to detect logins to an Active Directory server, you must configure the Active Directory server connection with the server IP address. See the *Sourcefire 3D System User Agent Configuration Guide* for more information. If multiple users are logged into a host using remote sessions, the agent may not detect logins from that host properly. See the *Sourcefire 3D System User Agent Configuration Guide* for more information on how to prevent this.

User Awareness Limitations (Continued)

LIMITATION	DESCRIPTION
logoff detection	The agent reports detected logoffs to Version 5.2+ Defense Centers. Logoffs may not be immediately detected. The timestamp associated with a logoff reflects when the agent detected the user was no longer mapped to the host IP address, which may not correspond to the actual time the user logged off of the host. Logoffs are generated by the agent itself when it detects a user logged out of a host IP address. Logoffs are also generated when the agent detects that the user logged into a host has changed, before the Active Directory server reports that the user has changed.
real-time data retrieval	The Active Directory server must be running Windows Server 2008 or Windows Server 2012.
multiple logins to the same host by different users	The system assumes that only one user is logged into any given host at a time, and that the current user of a host is the last authoritative user login. If only non-authoritative logins have been logged into the host, the last non-authoritative login is considered the current user. If multiple users are logged in through remote sessions, the last user reported by the Active Directory server is the user reported to the Defense Center.
multiple logins to the same host by the same user	The system records the first time that a user logs into a specific host and disregards subsequent logins. If an individual user is the only person who logs into a specific host, the only login that the system records is the original login. If another user logs into that host, however, the system records the new login. Then, if the original user logs in again, his or her new login is recorded.
Unicode characters	The user interface may not correctly display user names with Unicode characters. The agent does not report user names with Unicode characters to Version 4.10.x Defense Centers.

User Awareness Limitations (Continued)

LIMITATION	DESCRIPTION
LDAP user accounts in the users database	If you remove or disable an LDAP user on your user awareness or RUA LDAP servers, or exclude the user name from being reported to the Defense Center, the Defense Center does not remove that user from the users database, and that user continues to count against your licensed limit for user listed in the database. You must manually purge the user from the database. For Version 5.x, note that the user license limit is applied in parallel for access-controlled users; the user count for access-controlled users depends on the number of users retrieved by your LDAP configuration.
AOL Instant Messenger (AIM) login detection	Managed devices can detect AIM logins using the OSCAR protocol only. While most AIM clients use OSCAR, some use TOC2.

Understanding Application Detection

LICENSE: FireSIGHT

When the Sourcefire 3D System analyzes IP traffic, it attempts to identify the commonly used applications on your network. Application awareness is crucial to performing application-based access control.

There are three types of applications that the system detects:

- *application protocols* such as HTTP and SSH, which represent communications between hosts
- *clients* such as web browsers and email clients, which represent software running on the host
- *web applications* such as MPEG video and Facebook, which represent the content or requested URL for HTTP traffic

The system identifies applications in your network traffic either using ASCII or hexadecimal patterns in the packet headers, or the port that the traffic uses. Some application detectors use both port and pattern detection to increase the likelihood of correctly identifying traffic for a particular application. In addition, Secure Socket Layers (SSL) protocol detectors use information from the secured

session to identify the application from the session. There are two sources of application detectors in the Sourcefire 3D System:

- *Sourcefire-provided detectors*, which detect web applications, clients, and application protocols

  The availability of Sourcefire-provided detectors for applications (and operating systems, see Understanding Host Data Collection on page 1305) depend on the version of the Sourcefire 3D System and the version of the VDB you have installed. Release notes and advisories contain information on new and updated detectors. You can also import individual detectors authored by Sourcefire Professional Services. For a complete list of detected applications, see the Sourcefire Support Site.
- *user-defined application protocol detectors*, which you can create to enhance the system's application protocol detection capabilities

You can also detect application protocols through *implied application protocol detection*, which implies the existence of an application protocol based on the detection of a client.

The system characterizes each application that it detects using the criteria described in the following table. The system uses these characteristics to create application filters, or groups of applications. You can use these filters and filters that you create to perform access control, as well as to constrain searches, reports, and dashboard widgets. For more information, see Working with Application Filters on page 192.

Application Characteristics

CRITERION	DESCRIPTION	EXAMPLE
Risk	How likely the application is to be used for purposes that might be against your organization's security policy. An application's risk can range from **Very Low** to **Very High**.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is used within the context of your organization's business operations, as opposed to recreationally. An application's business relevance can range from **Very Low** to **Very High**.	Gaming applications tend to have a very low business relevance.

Application Characteristics (Continued)

Criterion	Description	Example
Type	The type of application: • **Application Protocols** represent communications between hosts. • **Clients** represent software running on a host. • **Web Applications** represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email clients are clients. MPEG video and Facebook are web applications.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the **social networking** category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged **high bandwidth** and **displays ads**.

To supplement the application data gathered by the system, you can use records generated by NetFlow-enabled devices, Nmap active scans, and the Sourcefire host input feature.

For more information, see:

- Understanding NetFlow on page 1325

Understanding the Application Protocol Detection Process

License: FireSIGHT

When the system detects application traffic, it first determines whether the application protocol is running on a port identified by a detector that uses that specific port as its only detection criterion. If the application protocol is running on

one of those ports, the system positively identifies the application protocol using the well-known port detector.

IMPORTANT! Because you can create and activate user-defined port-based application protocol detectors on ports used by Sourcefire-provided detectors, it is possible to override Sourcefire's detection capabilities. For example, if your user-defined detector identifies all application protocol traffic on port 22 as the `myapplication` application protocol, SSH traffic on port 22 will be misidentified as `myapplication` traffic.

If the application protocol is not running on one of those ports, the system employs a more robust method to identify it based on port and pattern matches. If two detectors both positively identify the traffic, the detector that employs the longer pattern match has precedence. Similarly, detectors with multiple pattern matches have precedence over single pattern matches.

Note that the system identifies only those application protocols running on hosts in your monitored networks, as defined in the network discovery policy. For example, if an internal host accesses an FTP server on a remote site that you are not monitoring, the system does not identify the application protocol as FTP. On the other hand, if a remote or internal host accesses an FTP server on a host you are monitoring, the system can positively identify the application protocol.

An exception occurs if the system can identify the client used in connections between a monitored host accessing a non-monitored server. In that case, the system positively identifies the appropriate application protocol that corresponds with the client in the connection, but does not add the application protocol to the network map. For more information, see Implied Application Protocol Detection from Client Detection on page 1320.

Note that client sessions must include a response from the server for application detection to occur.

The following table outlines how the Sourcefire 3D System identifies detected application protocols in the Defense Center web interface: the network map, host profiles, event views, and so on.

Sourcefire 3D System Identification of Application Protocols

APPLICATION	DESCRIPTION
the application protocol name	The Defense Center identifies an application protocol with its name if the application protocol was: • positively identified by the system • identified using NetFlow data and there is a port-application protocol correlation in `/etc/sf/services` • manually identified using the host input feature • identified by Nmap or another active source
`pending`	The Defense Center identifies an application protocol as `pending` if the system can neither positively nor negatively identify the application. Most often, the system needs to collect and analyze more connection data (from which applications are identified) before it can identify a pending application. In the Application Details and Servers tables and in the host profile, the `pending` status appears only for application protocols where specific application protocol traffic was detected (rather than implied by detected client or web application traffic).
`unknown`	The Defense Center identifies an application protocol as `unknown` if the application: • does not match any of the system's detectors • the application protocol was identified using NetFlow data, but there is no port-application protocol correlation in `/etc/sf/services`
blank	All available detected data has been examined and no application protocol was identified. In the Application Details and Servers tables and in the host profile, the application protocol is left blank for non-HTTP generic client traffic with no detected application protocol.

Implied Application Protocol Detection from Client Detection

LICENSE: FireSIGHT

If the system can identify the client used in a connection between a monitored host accessing a non-monitored server, the Defense Center infers that the connection is using the application protocol that corresponds with the client. (Because the system tracks applications only on monitored networks, connection logs usually do not include application protocol information for connections where a monitored host is accessing a non-monitored server.)

There are several consequences of the implied detection of an application protocol from the detection of a client:

- Because the system does not generate a New TCP Port or New UDP Port event for these servers, the server does not appear in the Servers table. In addition, you cannot trigger either discovery event alerts or correlation rules using the detection of these application protocol as a criterion.
- Because the application protocol is not associated with a host, you cannot view its details in host profiles, set its server identity, or use its information in host profile qualifications for traffic profiles or correlation rules. In addition, the system does not associate vulnerabilities with hosts based on this type of detection.

You can, however, trigger correlation events on the application protocol information in a connection. You can also use the application protocol information in connection logs to create connection trackers and traffic profiles.

Host Limits and Discovery Event Logging

LICENSE: FireSIGHT

When the system detects a client, server, or web application it generates a discovery event unless the associated host has already reached its maximum number of clients, servers, or web applications.

Host profiles display up to 16 clients, 100 servers, and 100 web applications per host. See Working with Servers in the Host Profile on page 1411 and Viewing Applications in the Host Profile on page 1419 for more information.

Note that actions dependent on the detection of clients, servers, or web applications are unaffected by this limit. For example, access control rules configured to trigger on a server will still log connection events.

Special Considerations for Application Protocol Detection: Squid

LICENSE: FireSIGHT

The system positively identifies Squid server traffic when either:

- the system detects a connection from a host on your monitored network to a Squid server where proxy authentication is enabled, or
- the system detects a connection from a Squid proxy server on your monitored network to a target system (that is, the destination server where the client is requesting information or another resource)

However, the system cannot identify Squid service traffic if:

- a host on your monitored network connects to a Squid server where proxy authentication is disabled, or
- the Squid proxy server is configured to strip Via: header fields from its HTTP responses

Special Considerations: SSL Application Detection

License: FireSIGHT

The Sourcefire 3D System provides detectors that can use session information from a Secure Socket Layers (SSL) session to identify the application protocol, client application, or web application in the session.

When the system detects an encrypted connection, it marks that connection as either a generic HTTPS connection or as a more specific secure protocol, such as SMTPS, when applicable. When the system detects an SSL session, it adds `SSL client` to the **Client** field in connection events for the session. If it identifies a web application for the session, the system generates discovery events for the traffic.

For SSL application traffic, managed devices running Version 5.2 or later can also detect the common name from the server certificate and match that against a client or web application from an SSL host pattern. When the system identifies a specific client, it replaces `SSL client` with the name of the client. Note that managed devices running versions earlier than Version 5.2 cannot detect applications in SSL traffic, even if managed by a Version 5.2 Defense Center.

Because the SSL application traffic is encrypted, the system can use only information in the certificate for identification, not application data within the encrypted stream. For this reason, SSL host patterns can sometimes only identify the company that authored the application, so SSL applications produced by the same company may have the same identification.

In some instances, such as when an HTTPS session is launched from within an HTTP session, managed devices running Version 5.2 or later detect the server name from the client certificate in a client-side packet.

To enable SSL application identification, you must create access control rules that monitor responder traffic. Those rules must have either an application condition for the SSL application or URL conditions using the URL from the SSL certificate. For network discovery, the responder IP address does not have to be in the networks to monitor in the network discovery policy; the access control policy configuration determines whether the traffic is identified. You can filter by the `SSL protocol` tag, in the application detectors list or when adding application conditions in access control rules, to identify detectors for SSL applications.

Special Considerations: Referred Web Applications

Web servers sometimes refer traffic to other websites, which are often advertisement servers. To help you better understand the context for referred traffic occurring on your network, the system lists the web application that referred the traffic in the Web Application field in events for the referred session. The VDB contains a list of known referred sites. When the system detects traffic from one of those sites, the referring site is stored with the event for that traffic. For example, if an advertisement accessed via Facebook is actually hosted on Advertising.com, the detected Advertising.com traffic is associated with the Facebook web application.

In events, if a referring application exists, it is listed as the web application for the traffic, while the URL is that for the referred site. In the example above, the web application for the connection event for that traffic would be Facebook, but the URL would be Advertising.com. If no referring web application is detected, if the host refers to itself, or if there is a chain of referrals, a referred application may appear as the web application in the event. In the dashboard, connection and byte counts for web applications include sessions where the web application is associated with traffic referred by that application.

Note that if you create a rule to act specifically on referred traffic, you should add a condition for the referred application, rather than the referring application. To block Advertising.com traffic referred from Facebook, for example, add an application condition to your access control rule for the Advertising.com application.

Importing Third-Party Discovery Data

License: FireSIGHT

You can use Nmap active scans to add information about operating systems, applications, and vulnerabilities, supplementing the data gathered by the system. For more information on Nmap scanning and scan results, see Understanding Nmap Scans on page 1765.

You can also use the host input feature to supplement the information that the system gathers from monitoring network traffic, either by configuring a third-party application to interact with the Sourcefire 3D System via an API, or by manually adding data. You can create product, vulnerability, and fix mappings to map third-party data to Sourcefire definitions, enabling impact correlation for operating systems and servers. For more information on the host input feature and mapping third-party data, see the *Sourcefire 3D System Host Input API Guide* and Importing Host Input Data on page 1752.

The system reconciles the collected data about operating system and server identities and determines each identity based on fingerprint source priority values, identity conflict resolution settings, and time of collection.

You can also configure your network map to use data from NetFlow-enabled devices to enhance your network map and event tables. For more information, see Understanding NetFlow on page 1325.

Uses for Discovery Data

LICENSE: FireSIGHT

Logging discovery data allows you to take advantage of many features in the Sourcefire 3D System, including:

- viewing the network map, which is a detailed representation of your network assets and topology that you can view by grouping hosts and network devices, host attributes, application protocols, or vulnerabilities; see Using the Network Map on page 1373
- viewing host profiles, which are complete views of all the information available for your detected hosts; see Using Host Profiles on page 1394
- viewing dashboards, which (among other capabilities) can provide you with an at-a-glance view of your network assets and user activity; see Using Dashboards on page 73
- viewing detailed information on the discovery events and user activity logged by the system; see Working with Discovery Events on page 1441
- creating reports based on discovery data; see Working with Reports on page 1796
- performing application and user control, that is, writing access control rules using application and user conditions; see Understanding and Writing Access Control Rules on page 512
- associating hosts and any servers or clients they are running with the exploits to which they are susceptible, which allows you to identify and mitigate vulnerabilities, evaluate the impact that intrusion events have on your network, and tune intrusion rule states so that they provide maximum protection for your network assets; see Working with Vulnerabilities in the Host Profile on page 1427, Using Impact Levels to Evaluate Events on page 688, Understanding Indications of Compromise on page 1329, and Managing FireSIGHT Rule State Recommendations on page 791
- alerting you via email, SNMP trap, or syslog when the system generates either an intrusion event with a specific impact flag, or a specific type of discovery event; see Configuring External Alerting on page 569
- monitor your organization's compliance with a white list of allowed operating systems, clients, application protocols, and protocols; see Using the Sourcefire 3D System as a Compliance Tool on page 1601
- creating correlation policies with rules that trigger and generate correlation events when the system generates discovery events or detects user activity; see Configuring Correlation Policies and Rules on page 1528
- if you log NetFlow connections, using that connection data; see Uses for Connection Data in the Sourcefire 3D System on page 601

Understanding NetFlow

LICENSE: FireSIGHT

NetFlow is an embedded instrumentation within Cisco IOS Software that characterizes network operation. Standardized through the RFC process, NetFlow is available not only on Cisco networking devices, but can also be embedded in Juniper, FreeBSD, and OpenBSD devices.

NetFlow-enabled devices are widely used to capture and export data about the traffic that passes through those devices. NetFlow-enabled devices have a database called the NetFlow cache that stores records of the flows that pass through the devices. A flow, called a *connection* in the Sourcefire 3D System, is a sequence of packets that represents a session between a source and destination host, using specific ports, protocol, and application protocol.

For the networks you specify, Sourcefire managed devices detect the records exported by NetFlow-enabled devices, generate connection events based on the data in those records, and finally send those events to the Defense Center to be logged in the database. You can also configure the system to add host and application protocol information to the database, based on the information in NetFlow connections.

You can use this discovery and connection data to supplement the data gathered directly by your managed devices. This is especially useful if you have NetFlow-enabled devices deployed on networks that your managed devices cannot monitor.

You configure NetFlow data collection, including connection logging, using rules in the network discovery policy. Contrast this with connection logging for connections detected by Sourcefire managed devices, which you configure per access control rule, as described in Logging Connection, File, and Malware Information on page 560. Because NetFlow data collection is linked to networks rather than access control rules, you do not have as much granular control over which connections you want to log, Also, the system automatically saves all NetFlow-based connection events to the Defense Center connection event database; you cannot send them to the system log or an SNMP trap server.

For more information, see:

- Differences Between NetFlow and FireSIGHT Data on page 1325
- Preparing to Analyze NetFlow Data on page 1328
- Uses for Discovery Data on page 1324
- Uses for Connection Data in the Sourcefire 3D System on page 601

Differences Between NetFlow and FireSIGHT Data

LICENSE: FireSIGHT

With one exception (TCP flags), the information available in NetFlow records is more limited than the information generated by monitoring network traffic using managed devices. Because the system cannot directly analyze the traffic

represented by NetFlow data, when the system processes NetFlow records it uses various methods to convert that data into connection logs as well as into host and application protocol records.

There are several differences between converted NetFlow data and the discovery and connection data gathered directly by your managed devices. You should keep the differences in mind when performing analysis that requires:

- statistics on the number of detected connections
- operating system and other host-related information (including vulnerabilities)
- application data, including client information, web application information, and vendor and version server information
- knowing which host in a connection is the initiator and which is the responder

TIP! For each field in a connection event, the Connection and Security Intelligence Data Based on Logging and Detection Methods table on page 599 indicates the available data depending on whether the connection was detected directly by Sourcefire managed devices, or if the connection event is based on NetFlow data.

Number of Connection Events Generated Per Monitored Session

For connections detected directly by managed devices, depending on the access control rule action, you can log a bidirectional connection event at the beginning or end of a connection, or both.

However, because NetFlow-enabled devices export unidirectional connection data, the system always generates at least two connection events for each connection detected by NetFlow-enabled devices, depending on how you configured the devices. This also means that a summary's connection count is incremented by two for every connection based on NetFlow data, providing an inflated count of the number of connections that are actually occurring on your network.

Note that if you configure your NetFlow-enabled devices to output records only when the connection ends, the system generates two connection events for that session. On the other hand, if you configure your NetFlow-enabled devices to output records at a fixed interval even if a connection is still ongoing, the system generates a connection event for each record exported by the device. For example, if you configure your NetFlow-enabled devices to output records for long-running connections every five minutes, and a particular connection lasts twelve minutes, the system generates six connection events for that session:

- one pair of events for the first five minutes
- one pair for the second five minutes
- a final pair when the connection is terminated

For this reason. Sourcefire **strongly** recommends that you configure your NetFlow-enabled devices to output records only when monitored sessions close.

Host and Operating System Data

Although you can configure the network discovery policy to add hosts to the network map based on NetFlow records, the host profile does not include any operating system or NetBIOS data for the hosts involved in the connection, nor can the system identify if the hosts are network devices (bridges, routers, NAT devices, or load balancers). You can, however, manually set a host's operating system identity using the host input feature.

Application Data

For connections detected directly by managed devices, the system can identify application protocols, clients, and web applications by examining the packets in the connection.

When the system processes NetFlow records, the system uses a port correlation in `/etc/sf/services` to extrapolate application protocol identity. However, there is no vendor or version information for those application protocols, nor do connection logs contain information on client or web applications used in the session. You can, however, manually provide this information using the host input feature.

Note that a simple port correlation means that application protocols running on non-standard ports may be unidentified or misidentified. Additionally, if no correlation exists, the system marks the application protocol as **unknown** in connection logs.

Vulnerability Mappings

The Sourcefire 3D System cannot determine which vulnerabilities might affect hosts added to the network map based on NetFlow records, unless you use the host input feature to manually set either a host's operating system identity or an application protocol identity. Note that because there is no client information in NetFlow connections, you cannot associate client vulnerabilities with NetFlow hosts.

Initiator and Responder Information in Connections

For connections detected directly by managed devices, the system can identify which host is the initiator, or source, and which is the responder, or destination. However, NetFlow data does not contain initiator or responder information.

When the system processes NetFlow records, it uses an algorithm to determine this information based on the ports each host is using, and whether those ports are well-known:

- If both or neither port being used is a well-known port, the system considers the host using the lower-number port to be the responder.
- If only one of the hosts is using a well-known port, the system considers that host to be the responder.

For this purpose, a well-known port is any port that is either numbered from 1 to 1023, or that contains application protocol information in `/etc/sf/services` on the managed device.

Preparing to Analyze NetFlow Data

LICENSE: FireSIGHT

Before you configure the Sourcefire 3D System to analyze NetFlow data, you must enable the NetFlow feature on the routers or other NetFlow-enabled devices you plan to use, and configure the devices to export NetFlow version 5 data to a destination network where the sensing interface of a managed device is connected.

Note that the system can parse both NetFlow version 5 and NetFlow version 9 records. Your NetFlow-enabled devices **must** use one of those versions if you want to use them with your Sourcefire 3D System deployment. In addition, the system requires that specific fields be in the templates and records that your NetFlow-enabled devices broadcast. If your NetFlow-enabled devices are using version 9, which you can customize, you **must** make sure that the templates and records that the devices broadcast contain the following fields, in any order:

- IN_BYTES (1)
- IN_PKTS (2)
- PROTOCOL (4)
- TCP_FLAGS (6)
- L4_SRC_PORT (7)
- IPV4_SRC_ADDR (8)
- L4_DST_PORT (11)
- IPV4_DST_ADDR (12)
- LAST_SWITCHED (21)
- FIRST_SWITCHED (22)
- IPV6_SRC_ADDR (27)
- IPV6_DST_ADDR (28)

Because the Sourcefire 3D System uses managed devices to analyze NetFlow data, your deployment must include at least one managed device that can monitor your NetFlow-enabled devices. At least one sensing interface on that

managed device must be connected to a network where it can collect the data that your NetFlow-enabled devices export. Because the sensing interfaces on managed devices do not usually have IP addresses, the system does not support the direct collection of NetFlow records.

In addition, Sourcefire **strongly** recommends that you configure your NetFlow-enabled devices to output records only when monitored sessions close. If you configure your NetFlow-enabled devices to output records at fixed intervals, analyzing the connection data derived from the NetFlow records may be more complicated; see Number of Connection Events Generated Per Monitored Session on page 1326.

Finally, note that the Sampled NetFlow feature available on some NetFlow-enabled devices collects NetFlow statistics on only a subset of packets that pass through the devices. Although enabling this feature can improve CPU utilization on the NetFlow-enabled device, it may affect the data you are collecting for analysis by the system.

Understanding Indications of Compromise

LICENSE: FireSIGHT

As a part of network discovery, the Sourcefire 3D System's Data Correlator can correlate various types of data (intrusion events, Security Intelligence, connection events, and malware events) associated with hosts to determine whether a host on your monitored network is likely to be compromised by malicious means. These correlations are known as *indications of compromise* (IOC). You activate this feature by enabling it and any of many Sourcefire-predefined *IOC rules* in the discovery policy editor. When the feature is enabled, you can also edit rule states for individual hosts from that host's host profile. Each IOC rule corresponds to one specific *IOC tag*, which is associated with a host.

In addition to the Data Correlator, endpoint-based FireAMP cloud data can also generate IOC tags from IOC rules. Because this data examines activity on a host itself — such as actions taken by or on individual programs — it can provide insights into possible threats that network-only data cannot. FireAMP IOC data from endpoints is transmitted via the FireAMP cloud connection.

Hosts with active IOC tags appear in the IP Address columns of event views with a compromised host icon ( ) instead of the normal host icon ( ). Event views for events that can trigger IOC tags indicate whether an event triggered an IOC.

Understanding Indications of Compromise Types

LICENSE: FireSIGHT

There are several tens of Indications of Compromise (IOC) rule and tag types. All are Sourcefire-predefined, and one IOC rule corresponds to one IOC tag. Because IOC rules trigger based on data provided by other features of the Sourcefire 3D System (and, for some events, the FireAMP cloud), those features must be

available and active for IOC rules to set IOC tags. The lists below detail IOC rule types, the features with which they are associated, and any additional licensing requirements (beyond the FireSIGHT license required for network discovery):

- Endpoint-Based Malware Event IOC Types on page 1330
- Intrusion Event IOC Types on page 1331
- Security Intelligence Event IOC Types on page 1331

Endpoint-Based Malware Event IOC Types

LICENSE: FireSIGHT

The following IOC types are associated with endpoint-based malware events, which require a FireAMP cloud subscription. For more information on configuring endpoint-based malware protection, see Working with Sourcefire Cloud Connections for FireAMP on page 1254 and Network-Based AMP vs Endpoint-Based FireAMP on page 1234:

- Impact 2 Attack — Impact 2 Intrusion Event - web-application-attack

Security Intelligence Event IOC Types

LICENSE: FireSIGHT+Protection
SUPPORTED DEVICES: All except Series 2
SUPPORTED DEFENSE CENTERS: All except DC500

The following IOC type is associated with Security Intelligence events, a type of connection event. The Security Intelligence feature requires a Protection license. For more information on configuring Security Intelligence and viewing Security Intelligence events, see Filtering Traffic Based on Security Intelligence Data on page 475 and Viewing Connection and Security Intelligence Data on page 602.

- CnC Connected — Security Intelligence Event - CnC

Viewing and Editing Indications of Compromise Data

LICENSE: FireSIGHT

Outside of the network discovery policy itself, you can view and edit indications of compromise (IOC) data in several other parts of the Sourcefire 3D System web interface:

- In the dashboard, the Threats tab of the Summary Dashboard displays, by default, IOC tags by host and new IOC rules triggered over time. The Custom Analysis widget offers presets based on IOC data. For information, see Using Dashboards on page 73 and Configuring the Custom Analysis Widget on page 90.
- The Indications of Compromise section of the Context Explorer displays graphs of hosts by IOC category and IOC categories by host. For information, see Understanding the Indications of Compromise Section on page 132.
- Event views for discovery (IOC), connection, Security Intelligence, intrusion, and malware events display (in the IOC column) whether an event triggered an IOC rule. Endpoint-based malware events that trigger IOC rules have the event type FireAMP IOC and appear with an event subtype that specifies the compromise. You can write compliance rules against all IOC data that appears in the event viewer. For more information, see the following sections:
  - Viewing Connection and Security Intelligence Data on page 602
  - Viewing Intrusion Events on page 649
  - Working with Malware Events on page 1274
  - Working with Indications of Compromise on page 1482
  - Configuring Correlation Policies and Rules on page 1528
- The Indications of Compromise tab of the network map lists hosts on your monitored network, grouped by IOC tag. For information, see Working with the Indications of Compromise Network Map on page 1379.
- In the host profile view for a potentially compromised host, you can view all IOC tags associated with that host, resolve any or all of its IOC tags, and configure IOC rule states. For information, see Working with Indications of Compromise in the Host Profile on page 1402.

Creating a Network Discovery Policy

License: FireSIGHT

The network discovery policy on the Defense Center controls how the system collects data on your organization's network assets and which network segments and ports are monitored.

Discovery rules within the policy specify what networks and ports the Sourcefire 3D System monitors to generate discovery data based on network data in traffic, and what zones the policy is applied to. Within a rule, you can configure whether hosts, applications, and users are discovered. You can create rules to exclude networks and zones from discovery. When you create a rule for discovery from a NetFlow device, you can choose to just log connections.

The network discovery policy has a a single default rule in place, configured to discover applications in any IPv4 traffic on the 0.0.0.0/0 network. Note that you

must have applied an access control policy to the targeted device before you can apply a network discovery policy. The rule does not exclude any networks, zones, or ports, host and user discovery is not configured, and a NetFlow device is not configured. Note that the policy is applied to any managed devices by default when they are registered to the Defense Center. To begin collecting host or data, you must add or modify discovery rules and reapply the policy to a device.

Remember that the access control policy (see Using Access Control Policies on page 461) defines the traffic that you permit, and therefore the traffic you can monitor with network discovery. Note that this means if you block certain traffic using access control, the system cannot examine that traffic for host, user, or application activity. For example, if you block access to social networking applications in the access control policy, the system will not provide you with any discovery data on those applications.

If you want to adjust the scope of network discovery, you can create additional discovery rules and modify or remove the default rule. You can configure discovery of data from NetFlow devices and can restrict the protocols for traffic where user data is discovered on your network.

If you want to use the Sourcefire 3D System to perform intrusion detection and prevention but do not need to take advantage of discovery data, you can optimize performance by disabling new discovery. First, make sure that your applied access control policies do not contain rules with user, application, or URL conditions. Then, remove all rules from your network discovery policy and apply it to your managed devices. For more information on configuring access control rules, see Understanding and Writing Access Control Rules on page 512.

If you enable user discovery in your discovery rules, you can detect users through user login activity in traffic over a set of application protocols. You can disable discovery in particular protocols across all rules if needed. Disabling some protocols can help avoid reaching the user limit associated with your FireSIGHT license, reserving available user count for users from the other protocols.

Advanced network discovery settings allow you to manage what data is logged, how discovery data is stored, what indications of compromise (IOC) rules are active, what vulnerability mappings are used for impact assessment, and what happens when sources offer conflicting discovery data. You can also add NetFlow devices and sources for host input.

For more information, see:

- Working with Discovery Rules on page 1334
- Restricting User Logging on page 1343
- Configuring Advanced Network Discovery Options on page 1345
- Applying the Network Discovery Policy on page 1356

Working with Discovery Rules

LICENSE: FireSIGHT

Discovery rules allow you to tailor the information discovered for your network map to include only the specific data you want. Rules in your network discovery policy are evaluated sequentially. Note that while you can create rules with overlapping monitoring criteria, doing so may affect your system performance.

When you exclude a host or a network from monitoring, the host or network does not appear in the network map and no events are reported for it. Sourcefire recommends that you exclude load balancers (or specific ports on load balancers) and NAT devices from monitoring. These devices may create excessive and misleading events, filling the database and overloading the Defense Center. For example, a monitored NAT device might exhibit multiple updates of its operating system in a short period of time. If you know the IP addresses of your load balancers and NAT devices, you can exclude them from monitoring.

TIP! The system can identify many load balancers and NAT devices by examining your network traffic. To determine which hosts on your network are load balancers and NAT devices, apply your network discovery policy, wait for the system to populate the network map, then perform a search of hosts constraining on host type. For more information, see Searching for Hosts on page 1472.

In addition, if you need to create a custom server fingerprint, you should temporarily exclude from monitoring the IP address that you are using to communicate with the host you are fingerprinting. Otherwise, the network map and discovery event views will be cluttered with inaccurate information about the host represented by that IP address. After you create the fingerprint, you can configure your policy to monitor that IP address again. For more information, see Fingerprinting Servers on page 1727.

Sourcefire also recommends that you **not** monitor the same network segment with NetFlow-enabled devices and Sourcefire managed devices. Although ideally you should configure your network discovery policy with non-overlapping rules, the system does drop duplicate connection logs generated by managed devices. Note that you **cannot** drop duplicate connection logs for connections detected by both a managed device and a NetFlow-enabled device.

For more information, see the following sections:

- Creating Network Objects on page 1342
- Creating Port Objects on page 1343

Understanding Device Selection

LICENSE: FireSIGHT

If you select a NetFlow device in a discovery rule, the rule is limited to discovery of NetFlow data for the specified networks. Select the NetFlow device before you configure other aspects of rule behavior, as the available rule actions change when you select a NetFlow device. In addition, you cannot configure port exclusions for NetFlow traffic.

Before you can select a NetFlow device in a network discovery rule, you must configure a connection to the NetFlow device in the network discovery advanced settings. For more information, see Adding NetFlow-Enabled Devices on page 1351.

Understanding Actions and Discovered Assets

LICENSE: FireSIGHT

When you configure a discovery rule, you must select an action for the rule. The action determines what assets are discovered or excluded when the system processes the rule. However, note that the affect of a rule action depends on whether you are using the rule to discover data from a managed device or from a NetFlow-enabled device.

Note that if you create a network discovery policy without any rules that discover hosts or users, applying the policy disables new discovery for the appliance. To optimize performance when using managed devices only for intrusion prevention, remove all discovery rules from your policy and apply it to the active devices.

The following table describes what assets are discovered by rules with the specified action settings in those two scenarios.

Discovery Rule Actions

ACTION	MANAGED DEVICE	NETFLOW
Exclude	Excludes the specified network from monitoring. If the source or destination host for a connection is excluded from discovery, the connection is recorded but discovery events are not created for excluded hosts.	
Discover: Hosts	Adds hosts to the network map based on discovery events. (Optional, unless user discovery is enabled, then required.)	Adds hosts to the network map based on NetFlow records. (Required)

Discovery Rule Actions (Continued)

Action	Managed Device	NetFlow
Discover: Applications	Adds applications to the network map based on application detectors. Note that you cannot discover hosts or users in a rule without also discovering applications. (Required)	Adds application protocols to the network map based on NetFlow records and the port-application protocol correlation in `/etc/sf/services`. (Optional)
Discover: Users	Adds users to the users table and logs user activity based on activity detected in traffic matching the user protocols configured in the network discovery policy. (Optional)	n/a
Log NetFlow Connections	n/a	Logs NetFlow connections only. Does not discover hosts or applications.

Understanding Monitored Networks

License: FireSIGHT

A discovery rule causes discovery of monitored assets only in traffic to and from hosts in the specified networks. For a discovery rule, discovery occurs for connections that have at least one IP address within the networks specified, with events generated only for IP addresses within the networks to monitor. The default discovery rule discovers applications only on the `0.0.0.0/0` and `::/0` networks.

For rules with a specified NetFlow device and the **Log Network Connections** option enabled, connections to and from IP addresses in the specified networks are also logged. Note that network discovery rules provide the only way to log NetFlow network connections.

You can also use network object or object groups to specify the networks to monitor. If you modify a network object used in the network discovery policy, you must reapply the policy for those changes to take effect for discovery.

Understanding Zones in Network Discovery Policies

License: FireSIGHT

For performance reasons, you should configure each discovery rule so that the zones in the rule include the sensing interfaces on your managed devices that are physically connected to the networks-to-monitor in the rule.

Unfortunately, you may not always be kept informed of network configuration changes. A network administrator may modify a network configuration through

routing or host changes without informing you, which may make it challenging to stay on top of proper network discovery policy configurations. If you do not know how the sensing interfaces on your managed devices are physically connected to your network, leave the zone configuration as the default, which is to apply the discovery rule to all zones in your deployment. (If no zones are excluded, the discovery policy is applied to all zones.)

Understanding Port Exclusions

LICENSE: FireSIGHT

Just as you can exclude hosts from monitoring (see Understanding Actions and Discovered Assets on page 1335), you can exclude specific ports from monitoring.

For example, load balancers can report multiple applications on the same port in a short period of time. You can configure your network discovery policy so that it excludes that port from monitoring, such as excluding port 80 on a load balancer that handles a web farm.

As another scenario, your organization may use a custom client that uses a specific range of ports. If the traffic from this client generates excessive and misleading events, you can exclude those ports from monitoring. Similarly, you may decide that you do not want to monitor DNS traffic. In that case, you could configure your policy so that it does not monitor port 53.

When adding ports to exclude, you can decide whether to use a reusable port object from the Available Ports list, add ports directly to the source or destination exclusion lists, or create a new reusable port and then move it into the exclusion lists.

Note that you cannot configure NetFlow-enabled devices to exclude ports from monitoring.

Adding a Discovery Rule

LICENSE: FireSIGHT

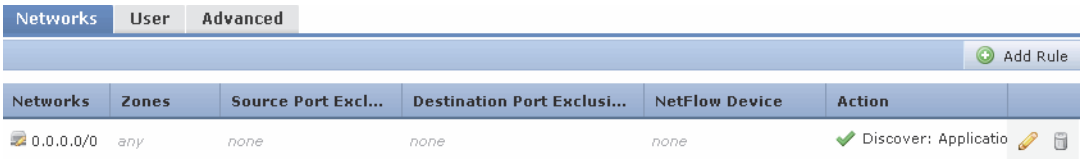
You can configure discovery rules to tailor the discovery of host and application data to your needs. Note that when you modify an object referenced in a rule, you must reapply the network discovery policy for those changes to take effect.

To add a discovery rule:

Access: Admin/Discovery Admin

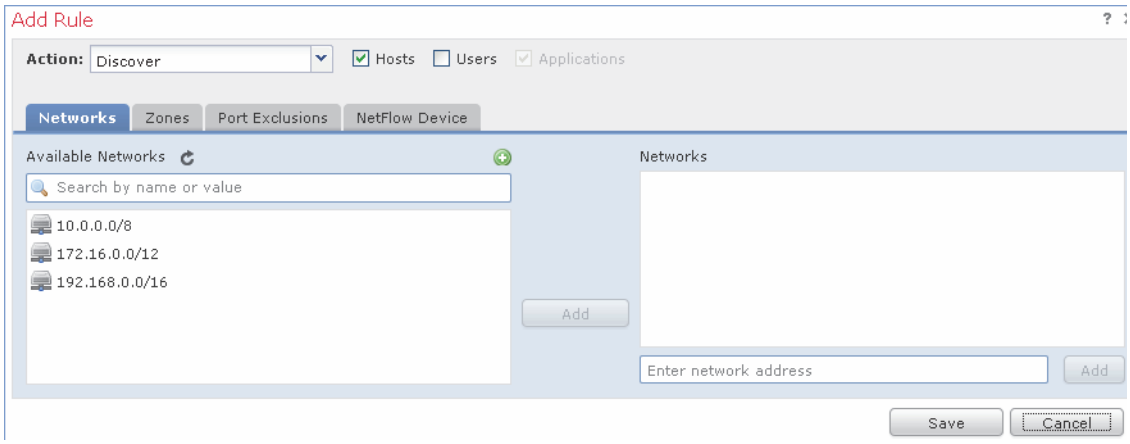
1. Check your access control policies to ensure that you are logging connections as needed for the traffic where you want to discover network data. For more information, see Logging Connection, File, and Malware Information on page 560 and Logging Connections for the Default Action on page 468. To discover the most data, log at the end of the connection for traffic you want to discover.
2. Select **Policies > Network Discovery**.

   The Network Discovery Policy page appears.



3. Click **Add Rule**.

   The Add Rule pop-up window appears.



4. You have two options:
   - If you plan to use the rule to monitor NetFlow traffic, within the Add Rule pop-up window, click **NetFlow Device**.

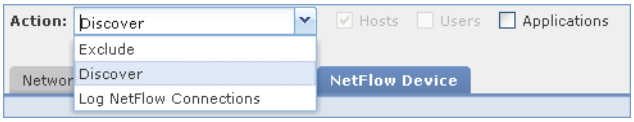
     The NetFlow Device page appears.

     Note that the NetFlow page is available only if you have added a NetFlow device to the discovery policy. For more information, see Adding NetFlow-Enabled Devices on page 1351.
   - If you plan to use the rule to monitor managed devices, skip to step 6.

   For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325 and Understanding Device Selection on page 1335
5. Select the IP address for the NetFlow device you want to use from the drop-down list.

6. Set the action for the rule:
   - To exclude all traffic that matches the rule from network discovery, select **Exclude**. Note that the Port Exclusions tab is disabled when you select this rule action.
   - To discover the selected types of data in traffic that matches the rule, select **Discovery** and select or clear the appropriate data type check boxes.

     If monitoring managed device traffic, application logging is required. If monitoring users, host logging is required. If monitoring NetFlow traffic, note that you cannot log users and that logging applications is optional.
   - If monitoring NetFlow traffic, to use the rule to log connections in NetFlow traffic, select **Log NetFlow Connections**. Note that this option only appears after you have selected a NetFlow device in the rule.



IMPORTANT! The system detects connections in NetFlow traffic based on network discovery policy settings. Connection logging in managed device traffic is configured in the access control policy. For more information, see Logging Connections for the Default Action on page 468.

For more information on rule actions and discovery of assets, see Understanding Actions and Discovered Assets on page 1335

7. Every discovery rule must include at least one network. Optionally, to restrict the rule action to specific networks, click the **Networks** tab, select a network from the **Available Networks** list, and click **Add**, or type the network below the Networks list and click **Add**.

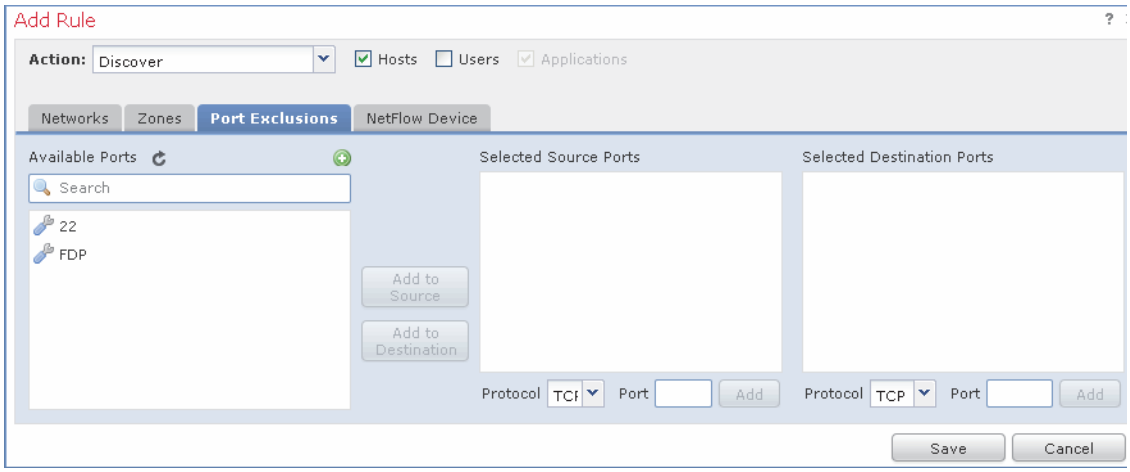
   For information on network monitoring, see Understanding Monitored Networks on page 1336. For information on adding network objects to the Available Networks list, see Creating Network Objects on page 1342. Note that If you modify a network object used in the network discovery policy, you must reapply the policy for those changes to take effect for discovery.

8. Optionally, to restrict the rule actions to traffic in specific zones, click **Zones**, select a zone or zones from the **Available Zones** list, and click **Add**.

   For information on selecting zones for monitoring, see Understanding Zones in Network Discovery Policies on page 1336.

9. To exclude ports from monitoring, click **Port Exclusions**.

   The Port Exclusions page appears.



10. To exclude specific source ports from monitoring, you have two options:

    - Select a port or ports from the **Available Ports** list and click **Add to Source**.
    - To exclude traffic from a specific source port without adding a port object, under the **Selected Source Ports** list, select the appropriate protocol from the **Protocol** drop-down list, type a port number from 1 to 65535 into the **Port** field, and click **Add**.

      For information on excluding ports from monitoring, see Understanding Port Exclusions on page 1337. For information on adding port objects to the Available Ports list, see Creating Port Objects on page 1343. Note that if you modify a port object used in the network discovery policy, you must reapply the policy for those changes to take effect for discovery.

11. To exclude specific destination ports from monitoring, you have two options:

    - Select a port or ports from the **Available Ports** list and click **Add to Destination**.
    - To exclude traffic from a specific destination port without adding a port object, under the **Selected Destination Ports** list, select the appropriate protocol from the **Protocol** drop-down list, type a port number from 1 to 65535 into the **Port** field, and click **Add**.

12. If you are finished editing the rule, click **Save** to return to the discovery policy rule list.

IMPORTANT! You must apply the network discovery policy for your changes to take effect. For more information, see Applying the Network Discovery Policy on page 1356.

Creating Network Objects

LICENSE: FireSIGHT

The list of available networks that appears in a discovery rule contains reusable network object and groups that can be used anywhere in the Sourcefire 3D System. You can add new network objects to the list. Note that when you modify an object referenced in a rule, you must reapply the network discovery policy for those changes to take effect.

To create a new network object:

ACCESS: Admin/Discovery Admin

1. Select **Policies > Network Discovery**.

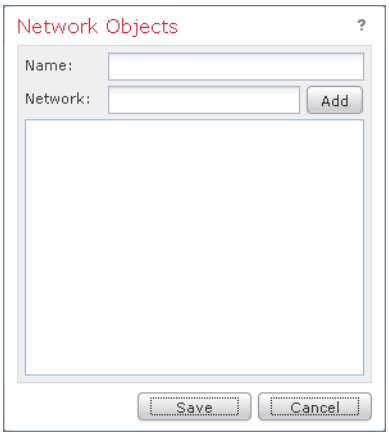
   The Network Discovery Policy page appears.

2. Click **Add Rule**.

   The Add Rule pop-up window appears.

3. On the Networks page, click the add icon ( ).

   The Network Objects pop-up window appears.



4. Type a **Name** for the network object.
5. For each IP address, CIDR block, and prefix length you want to add to the network object, type its value and click **Add**.
6. Click **Save** to add the network object to the Available Networks list.

TIP! If the network does not immediately appear on the list, click the refresh icon ( ).

Creating Port Objects

LICENSE: FireSIGHT

The list of available ports that appears in a discovery rule contains reusable port objects and groups that can be used anywhere in the Sourcefire 3D System. You can add new port objects to the list. Note that when you modify an object referenced in a rule, you must reapply the network discovery policy for those changes to take effect.

To create a new port object:

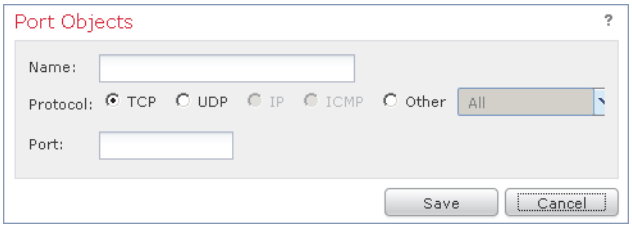
ACCESS: Admin/Discovery Admin

1. Click **Port Exclusions**.

   The Port Exclusions page appears.

2. To add a port to the Available Ports list, click the add object icon ( ).

   The Port Objects pop-up window appears.



3. Supply a **Name** for the port object.
4. In the **Protocol** field, specify the protocol of the traffic you want to exclude.

   Select **TCP**, **UDP**, or **Other** and choose an option from the drop-down list to select a protocol or **All**.
5. In the **Port(s)** field, enter the ports you want to exclude from monitoring.

   You can specify a single port, a range of ports using the dash (-), or a comma-separated list of ports and port ranges. Allowed port values are from 1 to 65535.
6. Click **Save** to add the port to the Available Ports list.

TIP! If the port does not immediately appear on the list, click the refresh icon ( ).

Restricting User Logging

LICENSE: FireSIGHT

When you apply a network discovery policy with rules that discover users, users are discovered in traffic that uses the AIM, IMAP, LDAP, Oracle, POP3, and SIP protocols. These users are added to the users table, accessible through the

Analysis menu. You can restrict the protocols where user activity is discovered to reduce the total number of detected users so you can focus on users likely to provide the most complete user information.

The total number of detected users the Defense Center can store depends on your FireSIGHT license. After you reach the licensed limit, in most cases the system stops adding new users to the database. To add new users, you must either manually delete old or inactive users from the database, or purge all users from the database. Restricting protocol detection helps minimize user name clutter and preserve FireSIGHT user licenses.

For example, obtaining user names through protocols such as AIM, POP3, and IMAP may introduce user names not relevant to your organization due to network access from contractors, visitors, and other guests.

As another example, AIM, Oracle, and SIP logins may create extraneous user records. This occurs because these login types are not associated with any of the user metadata that the system obtains from an LDAP server, nor are they associated with any of the information contained in the other types of login that your managed devices detect. Therefore, the Defense Center cannot correlate these users with other types of users.

Keep in mind that only managed devices can detect non-LDAP user logins. If you are using only Sourcefire User Agents installed on Microsoft Active Directory servers to detect user activity, restricting non-LDAP logins has no effect. Also, you cannot restrict SMTP logging. This is because users are not added to the database based on SMTP logins; although the system detects SMTP logins, the logins are not recorded unless there is already a user with a matching email address in the database.

You can choose whether or not to record failed login attempts for failed user logins detected in LDAP, POP3, or IMAP traffic. A failed login attempt does not add a new user to the list of users in the database. Note that the Sourcefire User Agent does not report failed login activity. The user activity type for detected failed login activity is Failed User Login.

To restrict the protocols where user logins are detected:

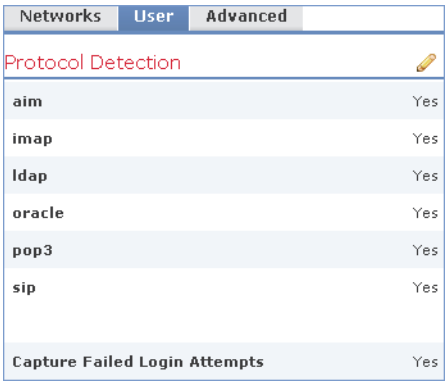
Access: Admin/Discovery Admin

1. Select **Policies > Network Discovery**.

   The Network Discovery Policy page appears.

2. Click **User**.

   The User page appears.



3. Click the edit icon ( ) to edit the User Detection settings.
4. Select check boxes for protocols where you want to detect logins or clear check boxes for protocols where you do not want to detect logins.
5. Click **Save** to save the network policy.

IMPORTANT! You must apply the network discovery policy for your changes to take effect. For more information, see Applying the Network Discovery Policy on page 1356.

Configuring Advanced Network Discovery Options

LICENSE: FireSIGHT

The Advanced tab of the network discovery policy allows you to configure policy-wide settings for what events are detected, how long discovery data is retained and how often it is updated, what vulnerability mappings are used for impact correlation, and how operating system and server identity conflicts are resolved. In addition, you can add host input sources and NetFlow devices to allow import of data from other sources.

Note that the database event limits for discovery and user activity events are set in the system policy. For more information, see Configuring Database Event Limits on page 2056.

To configure advanced settings:

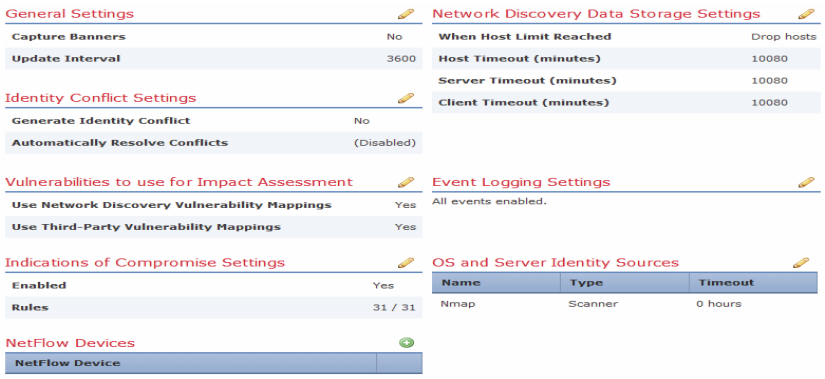
ACCESS: Admin/Discovery Admin

1. Select **Policies > Network Discovery**.

   The Network Discovery Policy page appears.

2. Click **Advanced**.

   The Advanced page appears.



3. Edit advanced settings as needed:
   - Configuring General Settings on page 1346
   - Configuring Identity Conflict Resolution on page 1347
   - Enabling Vulnerability Impact Assessment Mappings on page 1349
   - Setting Indications of Compromise Rules on page 1350
   - Adding NetFlow-Enabled Devices on page 1351
   - Configuring Data Storage on page 1352
   - Configuring Discovery Event Logging on page 1354
   - Adding Identity Sources on page 1354
4. When you finish configuring settings, click **Save** to save the policy.
5. When the policy is complete and saved, apply the policy to put the updated settings into effect. For more information, see Applying the Network Discovery Policy on page 1356.

Configuring General Settings

LICENSE: FireSIGHT

The general settings control how often the system updates information in the network map and whether server banners are captured during discovery.

Capture Banners

Select this check box if you want the system to store header information from network traffic that advertises server vendors and versions ("banners"). This information can provide additional context to the information gathered. You can access server banners collected for hosts by accessing server details.

Update Interval

The interval at which the system updates information (such as when any of a host's IP addresses was last seen, when an application was used, or the number of hits for an application). The default setting is 3600 seconds (1 hour).

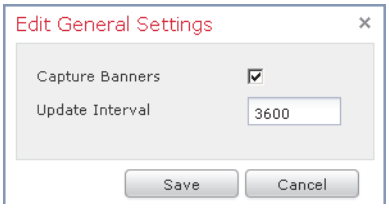
Note that setting a lower interval for update timeouts provides more accurate information in the host display, but generates more network events.

To update general settings:

Access: Admin/Discovery Admin

1. Click the edit icon ( ) next to **General Settings**.

   The Edit General Settings pop-up window appears.



2. Update the settings as needed.
3. Click **Save** to save the general settings and return to the Advanced tab of the network discovery policy.

IMPORTANT! You must apply the network discovery policy for your changes to take effect. For more information, see Applying the Network Discovery Policy on page 1356.

Configuring Identity Conflict Resolution

License: FireSIGHT

The system matches fingerprints for operating systems and servers against patterns in traffic to determine what operating system and which applications are running on a particular host. To provide the most reliable operating system and server identity information, the system collates fingerprint information from several sources.

The system uses all passive data to derive operating system identities and assign a confidence value. For more information on current identities and how the system selects the current identity, see Enhancing Your Network Map on page 1716.

By default, unless there is an identity conflict, identity data added by a scanner or third-party application overrides identity data detected by the Sourcefire 3D System. You can use the Identity Sources settings to rank scanner and third-party application fingerprint sources by priority. The system retains one identity for each

source, but only data from the highest priority third-party application or scanner source is used as the current identity. Note, however, that user input data overrides scanner and third-party application data regardless of priority.

An identity conflict occurs when the system detects an identity that conflicts with an existing identity that came from either the active scanner or third-party application sources listed in the Identity Sources settings or from a Sourcefire 3D System user. By default, identity conflicts are not automatically resolved and you must resolve them through the host profile or by rescanning the host or re-adding new identity data to override the passive identity. However, you can set your system to always automatically resolve the conflict by keeping the passive identity or to always resolve it by keeping the active identity.

Generate Identity Conflict Event

Enable this option to generate an event when an identity conflict occurs on a host in the network map.

Automatically Resolve Conflicts

You have the following options:

- To force manual conflict resolution of identity conflicts, select **Disabled** from the **Automatically Resolve Conflicts** drop-down list.
- To use the passive fingerprint when an identity conflict occurs, select **Identity** from the **Automatically Resolve Conflicts** drop-down list.
- To use the current identity from the highest priority active source when an identity conflict occurs, select **Keep Active** from the **Automatically Resolve Conflicts** drop-down list.

To update identity conflict resolution settings:

Access: Admin/Discovery Admin

1. Click the edit icon ( ) next to **Identity Conflict Settings**.

   The Edit Identity Conflict Settings pop-up window appears.

2. Update the settings as needed.

3. Click **Save** to save the identity conflict settings and return to the **Advanced** tab of the network discovery policy.

IMPORTANT! You must apply the network discovery policy for your changes to take effect. For more information, see Applying the Network Discovery Policy on page 1356.

Enabling Vulnerability Impact Assessment Mappings

LICENSE: FireSIGHT

You can configure how the Sourcefire 3D System performs impact correlation with intrusion events.

Your options are as follows:

- Select **Use Network Discovery Vulnerability Mappings** if you want to use Sourcefire vulnerability information to perform impact correlation.
- Select **Use Third-Party Vulnerability Mappings** if you want to use third-party vulnerability references to perform impact correlation. For more information, see Mapping Third-Party Vulnerabilities on page 1759 or the *Sourcefire 3D System Host Input API Guide*.

You can select either or both of the check boxes. If the system generates an intrusion event and the host involved in the event has servers or an operating system with vulnerabilities in the selected vulnerability mapping sets, the intrusion event is marked with the Vulnerable (level 1: red) impact icon. For any servers which do not have vendor or version information, note that you need to configure vulnerability mapping in the system policy. For more information, see Mapping Vulnerabilities for Servers on page 2075.

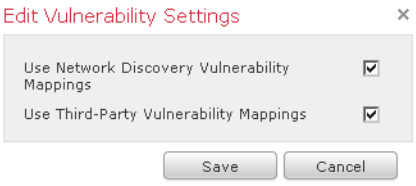
If you clear both check boxes, intrusion events will **never** be marked with the Vulnerable (level 1: red) impact icon. For more information, see Using Impact Levels to Evaluate Events on page 688.

To update vulnerability settings:

ACCESS: Admin/Discovery Admin

1. Click the edit icon ( ) next to **Vulnerabilities to use for Impact Assessment**.

   The Edit Vulnerability Settings pop-up window appears.



2. Update the settings as needed.

3. Click **Save** to save the vulnerability settings and return to the Advanced tab of the network discovery policy.

IMPORTANT! You must apply the network discovery policy for your changes to take effect. For more information, see Applying the Network Discovery Policy on page 1356.

Setting Indications of Compromise Rules

LICENSE: FireSIGHT

For your system to detect and tag indications of compromise (IOC), you must first activate at least one IOC rule in your discovery policy. Each IOC rule corresponds to one type of IOC tag, and all IOC rules are predefined by Sourcefire; you cannot create original rules. You can enable any or all rules, depending on the needs of your network and organization. For example, if hosts using software such as Microsoft Excel never appear on your monitored network, you may decide not to enable the IOC tags that pertain to Excel-based threats. For more information on the IOC feature, see Understanding Indications of Compromise on page 1329.

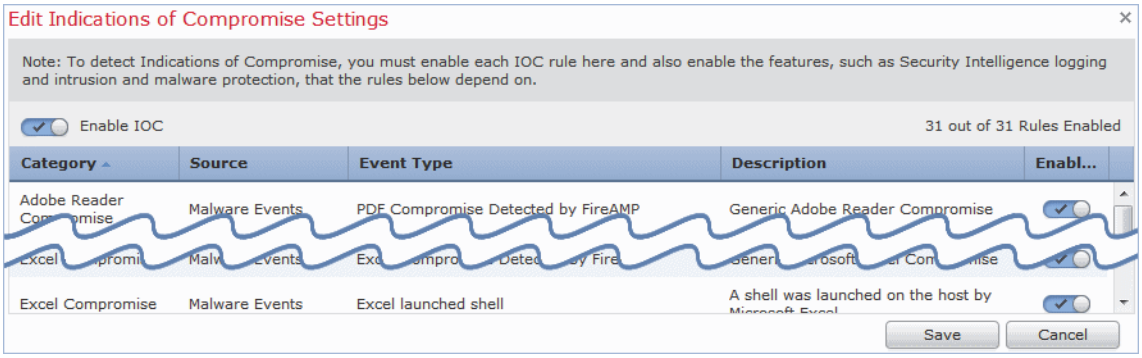
You must also enable the Sourcefire 3D System features associated with the IOC rules you enable, such as intrusion and malware protection; if a rule's associated feature is not enabled, no relevant data is collected and the rule cannot trigger. For more information on the types of IOC rules and their associated features, see Understanding Indications of Compromise Types on page 1329.

To set indications of compromise rules in the discovery policy:

ACCESS: Admin/Discovery Admin

1. Click the edit icon ( ) next to **Indications of Compromise Settings**.

   The Edit Indications of Compromise Settings pop-up window appears.



2. To toggle the entire IOC feature off or on, click the slider next to **Enable IOC**.
3. To enable or disable individual IOC rules, click the slider in the rule's **Enabled** column.

4. Click **Save** to save your IOC rule settings and return to the Advanced tab of the discovery policy.

   Your changes are saved.

IMPORTANT! You must apply the network discovery policy for your changes to take effect. For more information, see Applying the Network Discovery Policy on page 1356.

Adding NetFlow-Enabled Devices

LICENSE: FireSIGHT

If you have enabled the NetFlow feature on your NetFlow-enabled devices, you can use the connection data exported by these devices to supplement the connection data collected by Sourcefire devices.

Before you can use them in discovery rules, you must configure the NetFlow-enabled devices you plan to use (see Preparing to Analyze NetFlow Data on page 1328), then add them to the network discovery policy.

For more information on using NetFlow data with the Sourcefire 3D System, including information on additional prerequisites, see Understanding NetFlow on page 1325.

To add NetFlow-enabled devices for connection data collection:

ACCESS: Admin/Discovery Admin

1. Select **Policies > Network Discovery**.

   The Network Discovery Policy page appears.

2. Click **Advanced**.

   The Advanced page appears.

3. Click the add icon ( ) next to NetFlow Devices.

   The Add NetFlow Device pop-up window appears.

4. In the **IP Address** field, enter the IP address of the NetFlow-enabled device you want to use to collect connection data.

5. To add additional NetFlow-enabled devices, repeat steps 3 and 4.

TIP! To remove a NetFlow-enabled device, click the delete icon ( ) next to the device you want to remove. Keep in mind that if you use a NetFlow-enabled device in a discovery rule, you must delete the rule before you can delete the device from the Advanced page. For more information, see Working with Discovery Rules on page 1334.

6. Click **Save**.

   The device appears on the list of NetFlow-enabled devices.

IMPORTANT! You must apply the network discovery policy for your changes to take effect. For more information, see Applying the Network Discovery Policy on page 1356.

Configuring Data Storage

LICENSE: FireSIGHT

Data storage settings control the kinds of data stored in the database, and therefore determine the data that the Sourcefire 3D System can use. These settings also control how long data is retained in the network map.

The following options comprise the network discovery data storage settings.

When Host Limit Reached

You can control how hosts are handled when the Defense Center reaches its host limit (as determined by the FireSIGHT license) and the network map is full. This option is especially valuable if you want to prevent spoofed hosts from taking the place of valid hosts in the network map. To drop old hosts, select **Drop hosts** from the **When Host Limit Reached** drop-down list.To drop new hosts, select **Don't insert new hosts** from the **When Host Limit Reached** drop-down list. For more information, see Understanding FireSIGHT Host and User License Limits on page 2127.

Host Timeout

The amount of time that passes, in minutes, before the system drops a host from the network map due to inactivity. The default setting is 10080 minutes (7 days). Individual host IP and MAC addresses can time out individually, but a host does not disappear from the network map unless all of its associated addresses have timed out.

To avoid premature timeout of hosts, make sure that the host timeout value is longer than the update interval in the network discovery policy. For more information on the update interval, see Configuring General Settings on page 1346.

Server Timeout

The amount of time that passes, in minutes, before the system drops a server from the network map due to inactivity. The default setting is 10080 minutes (7 days).

To avoid premature timeout of servers, make sure that the service timeout value is longer than the update interval in the network discovery policy. For more information, see Configuring General Settings on page 1346.

Client Application Timeout

The amount of time that passes, in minutes, before the system drops a client from the network map due to inactivity. The default setting is 10080 minutes (7 days).

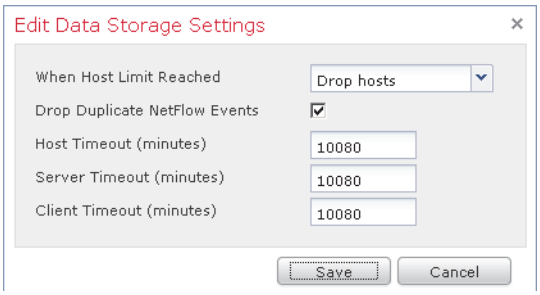
You should make sure that the client timeout value is longer than the update interval in the network discovery policy. For more information, see Configuring General Settings on page 1346.

To update data storage settings:

Access: Admin/Discovery Admin

1. Click the edit icon ( ) next to **Data Storage Settings**.

   The Edit Data Storage Settings pop-up window appears.



2. Update the settings as needed.
3. Click **Save** to save the data storage settings and return to the Advanced tab of the network discovery policy.

IMPORTANT! You must apply the network discovery policy for your changes to take effect. For more information, see Applying the Network Discovery Policy on page 1356.

Configuring Discovery Event Logging

License: FireSIGHT

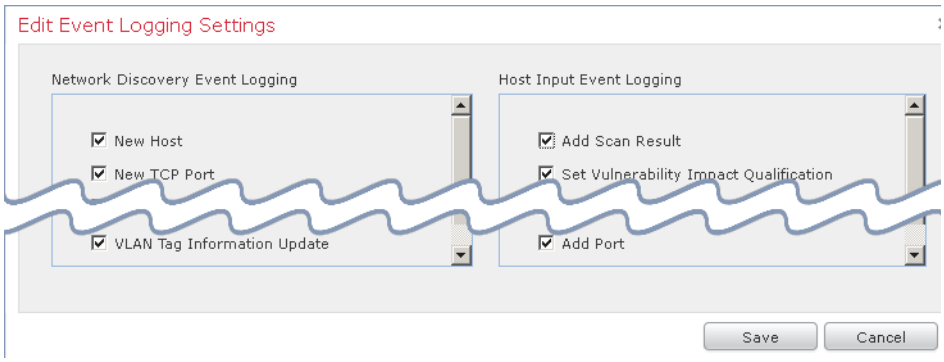
The Event Logging Settings control whether discovery and host input events are logged. If you do not log an event, you cannot retrieve it in event views or use it to trigger correlation rules.

To set event logging settings:

Access: Admin/Discovery Admin

1. Click the edit icon ( ) next to **Event Logging Settings**.

   The Edit Event Logging Settings pop-up window appears.



2. Select or clear the check boxes next to the discovery and host input event types you want to log in the database. See Understanding Discovery Event Types on page 1453 and Understanding Host Input Event Types on page 1458 for information about each event type.
3. Click **Save** to save the event logging settings and return to the Advanced tab of the network discovery policy.

IMPORTANT! You must apply the network discovery policy for your changes to take effect. For more information, see Applying the Network Discovery Policy on page 1356.

Adding Identity Sources

License: FireSIGHT

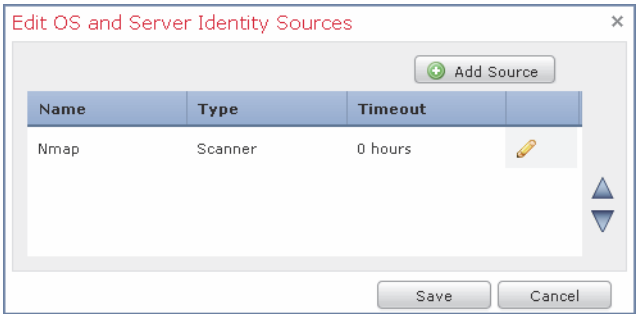
You can add new active sources through this page, or change the priority or timeout settings for existing sources. Note that adding a scanner to this page does not add the full integration capabilities that exist for the Nmap scanners, but does allow integration of imported third-party application or scan results. If you import data from a third-party application or scanner, remember to make sure that you map vulnerabilities from the source to the vulnerabilities in the network map. For more information, see Mapping Third-Party Vulnerabilities on page 1759.

To add identity sources:

Access: Admin/Discovery Admin

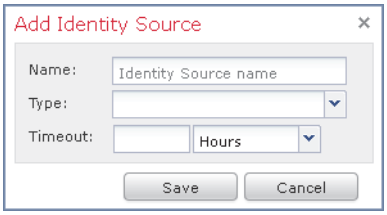
1. Click the edit icon ( ) next to **OS and Server Identity Sources**.

   The Edit OS and Server Identity Sources pop-up window appears.



2. To add a new source, click **Add Source**.

   The Add Identity Source pop-up window appears.



3. Type a **Name** for the source.
4. Select the input source type from the **Type** drop-down list:
   - Select **Scanner** if you plan to import scan results using the AddScanResult function.
   - Select **Application** if you do not plan to import scan results.
5. To indicate the duration of time that should elapse between the addition of an identity to the network map by this source and the deletion of that identity, select **Hours**, **Days**, or **Weeks** from the **Timeout** drop-down list and type the appropriate duration.

TIP! To delete a source that you added, click the delete icon ( ) next to the source.

6. Optionally, to promote a source and cause the operating system and application identities to be used in favor of sources below it in the list, select the source and click the up arrow.
7. Optionally, to demote a source and cause the operating system and application identities to be used only if there are no identities provided by sources above it in the list, select the source and click the down arrow.

8. Click **Save** to save the identity source settings and return to the Advanced tab of the network discovery policy.

IMPORTANT! You must apply the network discovery policy for your changes to take effect. For more information, see Applying the Network Discovery Policy on page 1356.

Applying the Network Discovery Policy

LICENSE: FireSIGHT

By default, the network discovery policy is applied to any targeted zones on managed devices when they are registered with the Defense Center. Applying the network discovery policy allows the system to begin monitoring your network according to your specifications. If you change the network discovery policy, you must reapply it before your changes take effect.

When you reapply the network discovery policy:

- the system deletes and then rediscovers MAC address, TTL, and hops information from the network map for the hosts in your monitored networks
- the affected managed devices discard any discovery data that has not yet been sent to the Defense Center

When you apply a network discovery policy, make sure that you have already applied an access control policy to the targeted zones on managed devices. If an access control policy has not been applied, the network discovery policy apply fails. Note that you cannot apply a network discovery policy on a Defense Center where no FireSIGHT license is installed.

If you modify a network or port object used in the network discovery policy, you must reapply the policy for those changes to take effect for discovery.

Note that you cannot apply a network discovery policy to stacked devices running different versions of the Sourcefire 3D System (for example, if an upgrade on one of the devices fails).

To apply the network discovery policy:

ACCESS: Admin/Security Approver

1. Select **Policies > Network Discovery**.

   The Network Discovery Policy page appears.

2. Click **Apply**.

   A message appears, confirming that you want to apply the policy to all zones targeted by access control policies on the Defense Center.

3. Click **Yes** to apply the policy.

Obtaining User Data from LDAP Servers

LICENSE: FireSIGHT

The Sourcefire 3D System can obtain both user identity and user activity information from your organization's LDAP servers.

Sourcefire User Agents allow you to monitor users when they authenticate against Active Directory credentials on Microsoft Active Directory servers. You can install an agent on any Microsoft Windows 7 or Microsoft Windows Server 2008 device with TCP/IP access to the Microsoft Active Directory servers you want to monitor. Each agent can monitor logins on up to five servers.

The agents send records of those logins to the Defense Center, which logs and reports them as user activity. This supplements any user activity detected directly by managed devices. More important, the logins reported by User Agents associate users with IP addresses, which in turn allows access control rules with user conditions to trigger.

You can configure a connection between the Defense Center and LDAP servers. This connection not only allows you to retrieve metadata for the users whose logins were detected by User Agents, but also is used to specify the users and groups you want to use in access control rules.

IMPORTANT! Legacy agents, which you install on your Microsoft Active Directory servers, also monitor users when they authenticate against Active Directory credentials. However, you should plan to transition to Version 2.0 of the Sourcefire User Agent as soon as possible in preparation for end of support for legacy agents in future releases.

For more information, see:

- Understanding User Data Collection on page 1306
- Adding User Conditions on page 541
- Creating LDAP Connections with the Defense Center on page 1357
- Enabling and Disabling User Awareness LDAP Connections on page 1365
- Performing an On-Demand User Data Retrieval for Access Control on page 1366
- Configuring Defense Center-User Agent Connections on page 1366

Creating LDAP Connections with the Defense Center

LICENSE: FireSIGHT

If you want to perform user control (that is, write access control rules with user conditions), you must configure a connection between the Defense Center and at least one of your organization's Microsoft Active Directory servers. This configuration, called an *LDAP connection* or a *user awareness authentication object*, contains connection settings and authentication filter settings for the

server. The connection's user and group access control parameters specify the users and groups you can use in access control rules.

IMPORTANT! If you want to perform user control, you **must** use Microsoft Active Directory. The system uses Sourcefire User Agents running on Active Directory servers to associate users with IP addresses, which is what allows access control rules to trigger.

Note that you can also create authentication objects to manage external authentication to the Sourcefire 3D System's web interface; see Managing Authentication Objects on page 1928. Those objects are similar to the authentication objects you create for user control, and you configure them in a similar way.

After you create an LDAP connection for user control, the Defense Center queries the LDAP server on a schedule that you specify. If you add new users or remove users from the LDAP server, you must wait until the Defense Center performs its scheduled update for those changes to take effect for access control. Alternately, you can perform an on-demand query.

The Defense Center-LDAP server connection also allows you to retrieve metadata for users, both access-controlled and non-access-controlled, whose logins were detected by User Agents, as well as for certain users whose activity was detected directly by managed devices. The Defense Center regularly queries the LDAP server to obtain metadata for new LDAP, POP3, and IMAP users whose activity was detected since the last query. If a user already exists in the Defense Center's Users database, the Defense Center updates the metadata if it has not been updated in the last 12 hours.

The Defense Center uses the email addresses in POP3 and IMAP logins to correlate with users on the LDAP server. For example, if a managed device detects a POP3 login for a user with the same email address as an LDAP user, the Defense Center associates the LDAP user's metadata with that user. Note that it may take several minutes for the Defense Center to update with user metadata after the system detects a new user login.

The Defense Center obtains the following information and metadata about each user:

- LDAP user name
- first and last name
- email address

- department
- telephone number

IMPORTANT! If you remove a user that has been detected by the system from your LDAP servers, the Defense Center does **not** remove that user from its users database; you must manually delete it. However, your LDAP changes **are** reflected in access control rules when the Defense Center next updates its list of access-controlled users.

For more information, see:

- Preparing to Connect to an LDAP Server on page 1359
- Creating an LDAP Connection for User Control on page 1360

Preparing to Connect to an LDAP Server

LICENSE: FireSIGHT

The Sourcefire 3D System supports connections to LDAP servers running the following:

- Microsoft Active Directory on Windows Server 2003 and Windows Server 2008
- Oracle Directory Server Enterprise Edition 7.0 on Windows Server 2003 and Windows Server 2008
- OpenLDAP on Linux

You must have TCP/IP access from the Defense Center to the LDAP servers. In addition, your LDAP servers must use the LDAP field names shown in the following table. For example, the system maps the givenname metadata for a particular user on an LDAP server to the first name of that user in the Defense Center database. If you rename the field on the LDAP server, the Defense Center cannot populate its database with the information in that field.

Mapping LDAP Fields to Sourcefire Fields

Defense Center Field	Microsoft Active Directory	Oracle Directory Server	OpenLDAP
Username	samaccountname	cn uid	cn uid
First Name	givenname	givenname	givenname
Last Name	sn	sn	sn

Mapping LDAP Fields to Sourcefire Fields (Continued)

Defense Center Field	Microsoft Active Directory	Oracle Directory Server	OpenLDAP
Email	mail userprincipalname (if mail has no value)	mail	mail
Department	department distinguishedname (if department has no value)	department	ou
Phone	telephonenumber	n/a	telephonenumber

Creating an LDAP Connection for User Control

License: FireSIGHT

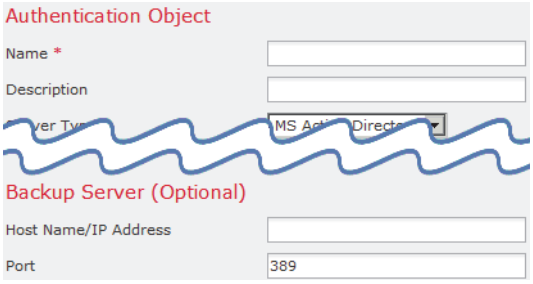
You configure a connection between the Defense Center and an LDAP server by creating a *user awareness* authentication object. This object contains connection settings and authentication filter settings for the LDAP server from which you want to retrieve user information. It also specifies the users and groups you can use in access control rules. The method you use to create a user awareness authentication object is similar to creating an external authentication object, as described in Managing Authentication Objects on page 1928.

TIP! To delete an LDAP connection, click the delete icon ( ) and confirm that you want to delete it. To modify a connection, click the edit icon ( ) and see the procedure in this section for settings you can configure. If the connection is enabled, your changes take effect when the Defense Center next queries the LDAP server.

The following list contains the information you must provide when creating an LDAP connection. You should work closely with your LDAP administrators to obtain the information.

Server Type, IP Address, and Port

You must specify the server type, IP address or hostname, and port for a primary, and optionally a backup, LDAP server. If you want to perform user control, you **must** use a Microsoft Active Directory server.



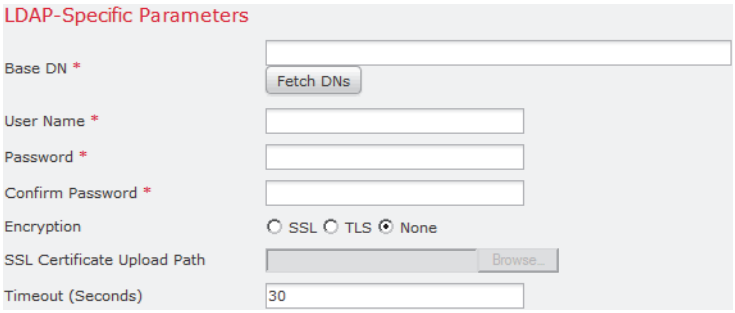
LDAP-Specific Parameters

When the Defense Center searches the LDAP directory server to retrieve user information on the authentication server, it needs a starting point for that search. You can specify the *namespace,* or directory tree, that the local appliance should search by providing a base distinguished name, or *base DN*. Typically, the base DN has a basic structure indicating the company domain and operational unit. For example, the Security organization of the Example company might have a base DN of `ou=security,dc=example,dc=com`. Note that after you identify a primary server, you can automatically retrieve a list of available base DNs from the server and select the appropriate base DN.

You must supply user credentials for a user with appropriate rights to the user information you want to retrieve. Remember that the distinguished name for the user you specify must be unique to the directory information tree for the directory server.

You can also specify an encryption method for the LDAP connection. Note that if you are using a certificate to authenticate, the name of the LDAP server in the certificate **must** match the host name that you specified in the Defense Center web interface. For example, if you use `10.10.10.250` when configuring the LDAP connection but `computer1.example.com` in the certificate, the connection fails.

Finally, you must specify the timeout period after which attempts to contact an unresponsive LDAP server roll over to the backup connection.



User and Group Access Control Parameters

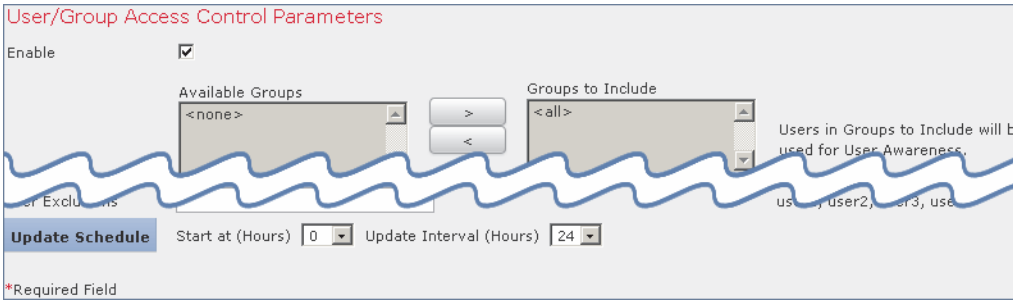
If you enable an authentication object for user awareness, you must specify the groups you want to use in access control.

Including a group automatically includes all of that group's members, including members of any sub-groups. However, if you want to use the sub-group in access control rules, you must explicitly include the sub-group. You can also exclude groups and individual users. Excluding a group excludes all the members of that group, even if the users are members of an included group.

The maximum number of users you can use in access control depends on your FireSIGHT license. When choosing which users and groups to include, make sure the total number of users is less than your FireSIGHT user license.

IMPORTANT! If you do not specify any groups to include, the system retrieves user data for all the groups that match the LDAP parameters you provided. For performance reasons, Sourcefire recommends that you explicitly include only the groups that represent the users you want to use in access control. Note that you **cannot** include the Users or Domain Users groups.

You must also specify how often the Defense Center queries the LDAP server to obtain new users to use in access control.

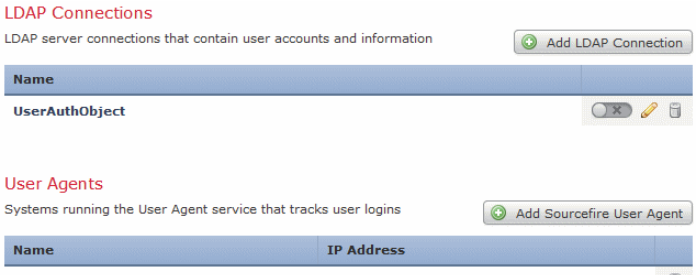


To create an LDAP connection for user control:

Access: Admin/Discovery Admin

1. Select **Policies > Users**.

   The Users Policy page appears.



2. Click **Add LDAP Connection**.

   The Create User Awareness Authentication Object page appears.

3. Type a **Name** and **Description** for the object.

4. Select the LDAP **Server Type**.

   If you want to perform user control, you **must** use a Microsoft Active Directory server. If you use any other type of LDAP server, you are limited to retrieving metadata for some users whose activity was detected directly by managed devices (as opposed to by Sourcefire User Agents).

   IMPORTANT! Sourcefire User Agents cannot transmit Active Directory user names ending with the $ character to the Defense Center. If your Active Directory server contains such user names, you must edit those names to remove the final $ character if you want to monitor them.

5. Specify an **IP Address** or **Host Name** for a primary and, optionally, a backup LDAP server.

6. Specify the **Port** that your LDAP servers use for authentication traffic.

7. Specify the **Base DN** for the LDAP directory you want to access.

   For example, to authenticate names in the Security organization at the Example company, type `ou=security,dc=example,dc=com`.

   TIP! To fetch a list of all available domains, click **Fetch DNs** and select the appropriate base distinguished name from the drop-down list.

8. Specify the distinguished **User Name** and **Password** that you want to use to validate access to the LDAP directory. Confirm the password.

   For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute and the object for the administrator in the Security division at our example company has a `uid` value of `NetworkAdmin`, you would type `uid=NetworkAdmin,ou=security,dc=example,dc=com.`

9. Choose an **Encryption** method. If you are using encryption, you can add an **SSL Certificate**.

   The host name in the certificate **must** match the host name of the LDAP server you specified in step 5.

10. Specify the **Timeout** period (in seconds) timeout period after which attempts to contact an unresponsive primary LDAP server roll over to the backup connection.

11. Optionally, before you specify user awareness settings for the object, test the connection by clicking **Test**.

12. You have two options, depending on the type of LDAP server you selected in step 4:

    - If you are connecting to an Active Directory server, you can enable **User/Group Access Control Parameters** to specify users to use in access control. Continue with the next step.
    - If you are connecting to any other kind of server, or do not want to perform user control, skip to step 17.

13. Click **Fetch Groups** to populate the available groups list using the LDAP parameters you provided.

14. Specify the users you want to use in access control by using the right and left arrow buttons to include and exclude groups.

    Including a group automatically includes all of that group's members, including members of any sub-groups. However, if you want to use the sub-group in access control rules, you must explicitly include the sub-group. Excluding a group excludes all the members of that group, even if the users are members of an included group.

15. Specify any particular **User Exclusions**.

    Excluding a user prevents you from writing an access control rule using that user as a condition. Separate multiple users with commas. You can also use an asterisk (*) as a wildcard character in this field.

16. Specify how often you want the Defense Center to query the LDAP server to obtain new user and group information.

    By default, the Defense Center queries the server once a day at midnight:

    - Use the **Start At** drop-down list to specify when you want the query to occur. **0** represents midnight, **1** represents 1:00 AM, and so on.
    - Use the **Update Interval** drop-down list to specify how often, in hours, you want to query the server.

17. Click **Save**.

    If you added or made changes to user and group access control parameters, confirm that you want to implement your changes. The object is saved. Note that you must enable the connection before the Defense Center can query the LDAP server; see the next section, Enabling and Disabling User Awareness LDAP Connections.

Enabling and Disabling User Awareness LDAP Connections

License: FireSIGHT

Only enabled LDAP connections allow the Defense Center to query the LDAP servers. To stop queries, you can temporarily disable LDAP connections rather than deleting them.

When you enable an LDAP connection where you have specified user and group access control parameters, you can force the Defense Center to query the server immediately, or you can wait until the first scheduled query occurs, as defined by the access control parameters in the LDAP connection. Note that you can also perform an on-demand query; see the next section, Performing an On-Demand User Data Retrieval for Access Control.

The maximum number of users the Defense Center can retrieve from the server depends on your FireSIGHT license. If your access control parameters are too broad, the Defense Center obtains information on as many users as it can and reports the number of users it failed to retrieve in the task queue.

To enable or disable an LDAP connection:

Access: Admin/Discovery Admin

1. Select **Policies > Users**.

   The Users Policy page appears.

2. Next to the LDAP connection you want to enable or disable, click the slider.

   If the connection was enabled, it is disabled. If it was disabled, it is enabled.

3. If you are enabling the connection and your connection has user and group access control parameters, choose whether you want to immediately query the LDAP server to obtain user and group information.

   If you do not immediately query the LDAP server, the query occurs at the scheduled time.

   The query begins. You can monitor its progress in the task queue (**System > Monitoring > Task Status**).

Performing an On-Demand User Data Retrieval for Access Control

License: FireSIGHT

If you change the user and group access control parameters in an LDAP connection, or if you change the users or groups on your LDAP server and want your changes to be immediately available for access control, you can force the Defense Center to perform an on-demand user data retrieval from an LDAP server.

The maximum number of users the Defense Center can retrieve from the server depends on your FireSIGHT license. If the access control parameters in your LDAP connection are too broad, the Defense Center obtains information on as many users as it can and reports the number of users it failed to retrieve in the task queue.

To perform an on-demand user data retrieval:

Access: Admin/Discovery Admin

1. Select **Policies > Users**.

   The Users Policy page appears.

2. Next to the LDAP connection you want to use to query the LDAP server, click the download icon ( ).

   The query begins. You can monitor its progress in the task queue (**System > Monitoring > Task Status**).

Configuring Defense Center-User Agent Connections

License: FireSIGHT

If you use Microsoft Active Directory LDAP servers, Sourcefire recommends that you connect Sourcefire User Agents to your Active Directory servers. User Agents monitor users as they log into the network or when accounts authenticate against Active Directory credentials for other reasons (for example, your organization may use services or applications that rely on Active Directory for centralized authentication).

The agents send records of those logins and logoffs to the Defense Center, which logs and reports them as user activity. The Defense Center uses this data in two main ways:

- to supplement user activity detected directly by managed devices, as defined in your network discovery policy
- to associate users with IP addresses, which in turn allows access control rules with user conditions to trigger

IMPORTANT! If you want to perform user control, you **must** install and use Sourcefire User Agents. However, User Agents only detect LDAP logins. If you want to detect other types of logins, you must use managed devices; see Understanding Actions and Discovered Assets.

You can use Version 2.1 of the Sourcefire User Agent to report user logins and logoffs to any Version 5.x Sourcefire 3D System Defense Center. If you have agents prior to Version 2.1, you can continue to use those agents to report Active Directory server login data to your Defense Centers. Note, however, that support for legacy agents will be phased out in future releases. Sourcefire recommends that you transition to Version 2.1 of the Sourcefire User Agent as soon as possible.

You can use the Sourcefire User Agent Status Monitor health module to monitor the heartbeat of agents connected to a Defense Center. For more information, see Configuring User Agent Status Monitoring on page 2226.

To use a Sourcefire User Agent, first configure the Defense Center to connect to the Windows host where you plan to install the agent. Then, install and configure the agent.

User Agents can connect to up to five Defense Centers at a time. In a high availability deployment, connect agents to both the primary Defense Center and the secondary Defense Center. To do so you must make sure agents can communicate with both the primary Defense Center and the secondary Defense Center.

For more information, see:

- Configuring the Defense Center to Connect to a Sourcefire User Agent on page 1368
- Installing a Sourcefire User Agent on page 1369
- Configuring User and Security Permissions on page 1371
- Configuring a Sourcefire User Agent on page 1371

Configuring the Defense Center to Connect to a Sourcefire User Agent

LICENSE: FireSIGHT

The first step in collecting LDAP user login information using Sourcefire User Agents is to configure each Defense Center to allow connections from the agents you plan to connect to your Active Directory servers.

TIP! To delete the Defense Center-User Agent connection, click the delete icon ( ) and confirm that you want to delete it.

To configure the Defense Center to connect to a Sourcefire User Agent:

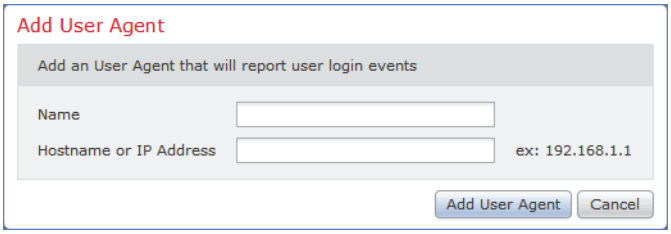
ACCESS: Admin/Discovery Admin

1. Select **Policies > Users**.

   The Users Policy page appears.

2. Click **Add Sourcefire User Agent**.

   The Add User Agent pop-up window appears.



3. Type a descriptive name for the agent in the **Name** field.
4. Type the IP address or host name of the computer where the agent will reside in the **Hostname or IP Address** field.
5. Click **Add User Agent**.

   The Defense Center can now connect to a User Agent on the configured host.

   If you want to perform user control (that is, write access control rules with user conditions), you must configure and enable a connection between the Defense Center and at least one of your organization's Microsoft Active Directory servers. This configuration, called an *LDAP connection* or a *user awareness authentication object*, contains connection settings and authentication filter settings for the server. The connection's user and group access control parameters specify the users and groups you can use in access control rules. See Creating an LDAP Connection for User Control on page 1360 for more information.

   Continue with the next section, Installing a Sourcefire User Agent on page 1369.

Installing a Sourcefire User Agent

LICENSE: FireSIGHT

After you configure the Defense Center to connect to the Windows computer where you plan to install each agent, install and configure the agents. Set up the Windows computer with the following prerequisites:

- The computer is running Windows Vista, Windows 7, Windows 8, Windows Server 2003, Windows Server 2008, or Windows Server 2012. The computer does not have to be an Active Directory server.
- The computer has Microsoft .NET Framework Version 4.0 Client Profile and Microsoft SQL Server Compact (SQL CE) Version 3.5 installed. The framework is available from Microsoft as the .NET Framework Version 4.0 Client Profile redistributable package (`dotNetFx40_Client_x86_x64.exe`). The SQL CE is available from Microsoft as an executable file (`SSCERuntime-ENU.exe`).

IMPORTANT! If you do not have both the .NET Framework and SQL CE installed, when you open the agent executable file (`Sourcefire_User_Agent_2.1.0-build_number_Setup.exe`), it prompts you to download the appropriate files.

- The computer has TCP/IP access to the Active Directory servers you want to monitor, and uses the same version of the Internet Protocol as the Active Directory servers. If the agent is monitoring the Active Directory servers real-time, the computer's TCP/IP access must be on at all times to retrieve login data.
- The computer has TCP/IP access to the Defense Centers where you want to report data and an IPv4 address.
- The computer has an IPv6 address, if you want to detect logoffs from hosts with IPv6 addresses, or an IPv4 address, if you want to detect logoffs from hosts with IPv4 addresses.
- The computer does not have a legacy agent or Version 2.0.x agent already installed. As these agents do not automatically uninstall, to uninstall an existing agent, open **Add/Remove Programs** in the control panel.

Once you set up the computer with the prerequisites, install the agent.

The agent runs as a service using the **Local system** account. If the Windows computer where the agent is running is connected to the network, the service continues to poll and send user data, even if a user is not actively logged into the system.

IMPORTANT! Do not make changes to the service configuration; the agent does not function correctly using a different account.

In a high availability configuration, add both Defense Centers to the agent to enable update of user login data to both the primary and the secondary so the data remains current on both.

To install a Sourcefire User Agent:

Access: Any

1. Download the Sourcefire User Agent setup file (`Sourcefire_User_Agent_2.1.0-`*`build_number`*`_Setup.zip`, where *`build_number`* represents the number of the agent build) from the Sourcefire Support Site.

   IMPORTANT! Download the setup file directly from the Support Site and do not transfer it by email. If you transfer the setup file by email, it may become corrupted.

2. Copy the setup file to the Windows computer where you want to install the agent and unpack the file.

   The agent requires 3 MB free on the hard drive for installation. Sourcefire recommends you allocate 4 GB on the hard drive for the agent local database.

3. Open the setup executable file (`Sourcefire_User_Agent_2.1.0-`*`build_number`*`_Setup.exe`).

   TIP! If you are using an account that is not a member of the Administrators group and do not have permissions to install new applications on the Windows computer, you must elevate to a user that does belong to the group to have the appropriate permissions to start the installation. To access the escalation option, right click the `Sourcefire_User_Agent_2.1.0-`*`build_number`*`_Setup.exe` file and select **Run As**. Select an appropriate user and supply the password for that user.

4. If you do not have both Microsoft .NET Framework Version 4.0 Client Profile and SQL CE Version 3.5 installed on the Windows computer where you install the agent, you are prompted to download the appropriate files. Download and install the files.

   The setup wizard appears.

5. Follow the prompts in the wizard to install the agent.

   The agent is installed. The Sourcefire User Agent starts as a service on the Windows system. Continue with Configuring User and Security Permissions on page 1371.

Configuring User and Security Permissions

After you prepare the computer with all agent prerequisites, configure user permissions and Windows security permissions to allow the agent to communicate with the Active Directory server, access the security logs to retrieve login data, and optionally, retrieve logoff data. Optionally, enable idle session timeouts in the group policy to help prevent the agent from detecting and reporting extraneous logins due to multiple sessions on a host. For more information, see the *Sourcefire 3D System User Agent Configuration Guide*.

Continue with Configuring a Sourcefire User Agent on page 1371.

Configuring a Sourcefire User Agent

License: FireSIGHT

Once the agent is installed, you can configure it to receive data from Active Directory servers, report the information to Defense Centers, exclude specific user names and IP addresses from the reporting, and log status messages to a local event log or the Windows application log.

To configure the agent:

Access: Any

- On the computer where you installed the agent, select **Start > Programs > Sourcefire > Configure Sourcefire User Agent**.

  The Sourcefire Active Directory User Agent dialog box appears, with the General tab active.

The User Agent Configuration Actions table describes the actions you can take when configuring the agent and where to configure them. For more information, see the *Sourcefire 3D System User Agent Configuration Guide*.

User Agent Configuration Actions

To...	You can...
change the agent name, change the logoff check frequency, and start and stop the service	select the **General** tab.
add, modify, or remove Active Directory servers, enable real-time Active Directory server data retrieval, and modify the Active Directory server polling interval and maximum poll length	select the **Active Directory Servers** tab.
add or remove Defense Centers	select the **Sourcefire DCs** tab.
add, modify, or remove user names excluded from reporting	select the **Excluded Usernames** tab.
add, modify, or remove IP addresses excluded from reporting	select the **Excluded Addresses** tab.
view, export, and clear the event log, log to Windows application logs, and modify how long messages should be kept	select the **Logs** tab.
perform troubleshooting and maintenance tasks, as directed by Sourcefire Support	select the **Logs** tab, enable **Show Debug Messages in Log**, then select the **Maintenance** tab.
save changes to the agent settings	click **Save**. A message displays below **Save** stating when you have unsaved changes.
close the agent without saving changes to the agent settings	click **Cancel**.

CHAPTER 33
USING THE NETWORK MAP

The Sourcefire 3D System passively collects traffic traveling over the network, decodes the data, and then compares it to established operating system and fingerprints. From this information, the system builds a *network map*, which is a detailed representation of your network.

The network map allows you to use the Defense Center to view your network topology in terms of hosts and network devices (bridges, routers, NAT devices, and load balancers). It is a useful tool for a quick, overall view of your network. The network map also allows you to drill down on associated host attributes, applications, clients, indications of compromised hosts, and vulnerabilities. In other words, you can select different views of the network map to suit the analysis you perform.

You can augment the information your system collects by adding operating system, application, client, protocol, or host attribute information from a third-party application using the host input feature. You can also actively scan hosts in the network map using Nmap and add the scan results to your network map.

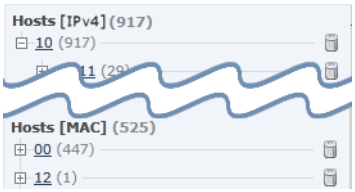
You can use the custom topology feature to help you organize and identify subnets in the views of the network map. For example, if each department in your organization uses a different subnet, you can assign familiar labels to those subnets using the custom topology feature.

For more information, see the following sections:

Understanding the Network Map

LICENSE: FireSIGHT

Each view of the network map has the same format: a hierarchical tree with expandable categories and sub-categories. When you click a category, it expands to show you the sub-categories beneath it. You can select different views of the network map depending on the kind of analysis you are performing.



The Defense Center gathers data from all security zones where discovery policies are applied (including zones that process data from NetFlow-enabled devices). If multiple devices detect the same network asset, the Defense Center combines the information into a composite representation of the asset.

Although you can configure your network discovery policy to add data exported by NetFlow-enabled devices, the available information about these hosts is limited. For example, there is no operating system data available for these hosts, unless you provide it using the host input feature. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

From any network map, you can view any host's *host profile*, which provides a complete view of all the information collected by the system for that host. The host profile contains general information, such as the host name, operating system, and all associated IP addresses, as well as more specific information including detected protocols, applications, indications of compromise, and clients that are running on the host. The host profile also includes information about the vulnerabilities associated with the host and its detected assets. For more information on host profiles, see Using Host Profiles on page 1394.

You can delete an item from the network map if you are no longer interested in investigating it. You can delete hosts and applications from the network map; you can also delete or deactivate vulnerabilities. If the system detects activity associated with a deleted host, it re-adds the host to the network map. Similarly, deleted applications are re-added to the applications network map if the system detects a change in the application (for example, if an Apache web server is

upgraded to a new version). Vulnerabilities are reactivated on specific hosts if the system detects a change that makes the host vulnerable.

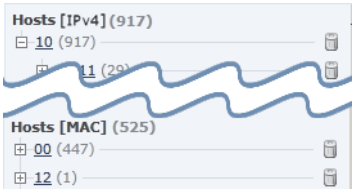
You can also use the network map to deactivate vulnerabilities network-wide, which means that you deem these hosts, which the system has judged to be vulnerable, to be safe from that particular attack or exploit.

TIP! If you want to permanently exclude a host or subnet from the network map, modify the network discovery policy. You may wish to exclude load balancers and NAT devices from monitoring. They may create excessive and misleading events, filling the database and overloading the Defense Center. See Understanding Host Data Collection on page 1305 for more information.

Working with the Hosts Network Map

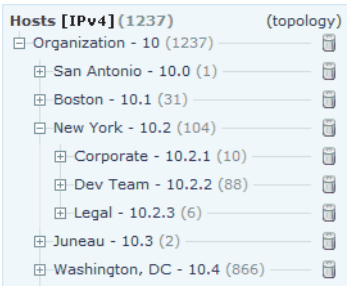
LICENSE: FireSIGHT

Use the hosts network map to view the hosts on your network, organized by subnet in a hierarchical tree, as well as to drill down to the host profiles for specific hosts. This network map view provides a count of all unique hosts detected by the system, regardless of whether the hosts have one IP address or multiple IP addresses.



Although you can configure your network discovery policy to add hosts to the network map based on data exported by NetFlow-enabled devices, the available information about these hosts is limited. For example, there is no operating system data available for hosts added to the network map using NetFlow data, unless you provide it using the host input feature.

By creating a custom topology for your network, you can assign meaningful labels to your subnets, such as department names, that appear in the hosts network map.



You can also view the hosts network map according to the organization you specified in the custom topology; see Working with Custom Network Topologies on page 1387.

You can delete entire networks, subnets, or individual hosts from the hosts network map. For example, if you know that a host is no longer attached to your network, you can delete it from the network map to simplify your analysis. If the system afterwards detects activity associated with the deleted host, it re-adds the host to the network map. If you want to permanently exclude a host or subnet from the network map, modify the network discovery policy. See Creating a Network Discovery Policy on page 1332 for more information.

IMPORTANT! Sourcefire **strongly** recommends that you do **not** delete network devices from the network map, because the system uses their locations to determine network topology (including generating network hops and TTL values for monitored hosts). Although you cannot delete network devices from the network devices network map, make sure you do not delete them from the hosts network map.

To view the hosts network map:

Access: Admin/Any Security Analyst

1. Select **Analysis > Hosts > Network Map**, then select the **Hosts** tab.

   The hosts network map appears, displaying a host count and a list of host IP addresses and MAC addresses. Each address or partial address is a link to the next level.

2. Drill down to the specific IP address or MAC address of the host you want to investigate.

   For example, to view a host with the IP address 192.168.40.11, click **192**, then **192.168**, then **192.168.40**, then **192.168.40.11**. When you click **192.168.40.11**, the host profile appears. For more information on host profiles, see Using Host Profiles on page 1394.

   To filter by IP or MAC addresses, type an address in the search field. To clear the search, click the clear icon (✖).

3. Optionally, to delete a subnet, IP address, or MAC address, click the delete icon ( ) next to the element you want to delete, then confirm that you want to delete the host or subnet.

   The host is deleted. If the system rediscovers the host, it re-adds the host to the network map.

4. Optionally, switch between the hosts view and the topology view of the hosts network map:

   - To switch to a view of the hosts network map organized by your custom topology, on the hosts view (the default), click **(topology)** at the top of the network map.
   - To switch to a view of the hosts network map organized by subnet, on the topology view, click **(hosts)** at the top of the network map.

   For information on configuring custom topologies, see Working with Custom Network Topologies on page 1387.

Working with the Network Devices Network Map

LICENSE: FireSIGHT

Use the network devices network map to view the network devices (bridges, routers, NAT devices, and load balancers) that connect one segment of your network to another, as well as to drill down to the host profiles of those network devices. The network devices network map is separated into two sections: IP and MAC. The IP section lists network devices identified by an IP address; the MAC section lists network devices identified by a MAC address. This network map view also provides a count of all unique network devices detected by the system, regardless of whether the devices have one IP address or multiple IP addresses.

If you create a custom topology for your network, the labels you assign to your subnets appear in the network devices network map.

The methods the system uses to distinguish network devices include:

- the analysis of Cisco Discovery Protocol (CDP) messages, which can identify network devices and their types (Cisco devices only)
- the detection of the Spanning Tree Protocol (STP), which identifies a device as a switch or bridge
- the detection of multiple hosts using the same MAC address, which identifies the MAC address as belonging to a router
- the detection of TTL value changes from the client side, or TTL values that change more frequently than a typical boot time, which identify NAT devices and load balancers

If a network device communicates using CDP, it may have one or more IP addresses. If it communicates using STP, it may only have a MAC address.

You cannot delete network devices from the network map, because the system uses their locations to determine network topology (including generating network hops and TTL values for monitored hosts).

The host profile for a network device has a Systems section rather than an Operating Systems section, which includes a Hardware column that reflects the hardware platform for any mobile devices detected behind the network device. If a value for a hardware platform is listed under Systems, that system represents a mobile device or devices detected behind the network device. Note that mobile devices may or may not have hardware platform information, but hardware platform information is never detected for systems that are not mobile devices.

To view the network devices network map:

Access: Admin/Any Security Analyst

1. Select **Analysis > Hosts > Network Map > Network Devices**.

   The network devices network map appears, displaying a count of unique network devices and a list of network device IP addresses and MAC addresses. Each address or partial address is a link to the next level of addresses or to the host profile for an individual host.

2. Drill down to the specific IP address or MAC address of the network device you want to investigate.

   The host profile for the network device appears. For more information on host profiles, see Using Host Profiles on page 1394.

3. Optionally, to filter by IP or MAC addresses, type an address in the search field. To clear the search, click the clear icon (✖).

Working with the Indications of Compromise Network Map

LICENSE: FireSIGHT

Use the indications of compromise (IOC) network map to view the compromised hosts on your network, organized by IOC category. Affected hosts are listed beneath each category.

The system uses data from multiple sources to determine a host's compromised status, including intrusion events, Security Intelligence, and FireAMP.

From the indications of compromise network map, you can view the host profile of each host determined to have been compromised in a specific way. You can also delete (mark as resolved) any IOC category or any specific host, which removes the IOC tag from the relevant hosts. For example, you can delete an IOC category from the network map if you have determined that the issue is addressed and unlikely to recur.

Marking a host or IOC category resolved from the network map does not remove it from your network. A resolved host or IOC category reappears in the network map if your system newly detects information that triggers that IOC.

To view the indications of compromise network map:

ACCESS: Admin/Any Security Analyst

1. Select **Analysis > Hosts > Network Map > Indications of Compromise**.

   The indications of compromise network map appears.

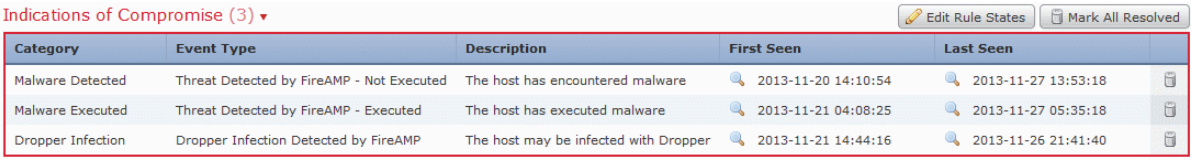
2. Click the specific IOC category you want to investigate.

   For example, if you want to view hosts on which malware was detected, click **Malware Detected**.

   To filter by IP or MAC addresses, type an address in the search field. To clear the search, click the clear icon (✖).

3. Drill down to a specific IP address under the IOC category you selected. Each address or partial address is a link to the next level.

   The host profile of the compromised host appears with the indications of compromise section expanded. For more information about the IOC section of the host profile, see Working with Indications of Compromise in the Host Profile on page 1402.



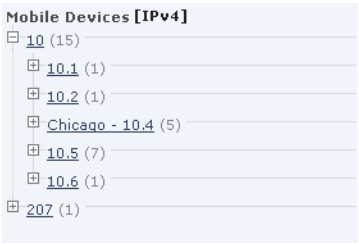
4. Optionally, to mark any IOC category, compromised host, or group of compromised hosts resolved, click the delete icon ( ) next to the element you want to resolve, then confirm that you want to resolve it.

   The category or host is resolved (IOC tags removed). If the IOC is triggered again, it is re-added to the network map.

Working with the Mobile Devices Network Map

LICENSE: FireSIGHT

Use the mobile devices network map to view mobile devices attached to your network, and to drill down to the host profiles for those devices. This network map view also provides a count of all unique mobile devices detected by the system, regardless of whether the devices have one IP address or multiple IP addresses.



The methods the system uses to distinguish mobile devices include:

- analysis of user agent strings in HTTP traffic from the mobile device's mobile browser
- monitoring of HTTP traffic of specific mobile applications

If you create a custom topology for your network, the labels you assign to your subnets appear in the mobile devices network map.

To view the mobile devices network map:

ACCESS: Admin/Any Security Analyst

1. Select **Analysis > Hosts > Network Map**, then select the **Mobile Devices** tab.

   The mobile devices network map appears, displaying a count of unique mobile devices and a list of mobile device IP addresses. Each address or partial address is a link to the next level.

2. Drill down to the specific IP address of the mobile device you want to investigate.

   For example, to view a device with the IP address 10.11.40.11, click **10**, then **10.11**, then **10.11.40**, then **10.11.40.11**. When you click **10.11.40.11**, the host profile appears. For more information on host profiles, see Using Host Profiles on page 1394.

   To filter by IP or MAC addresses, type an address in the search field. To clear the search, click the clear icon (✖).

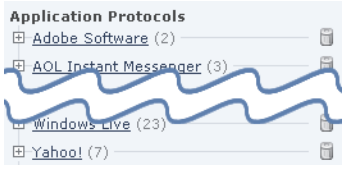
3. Optionally, to delete a subnet or IP address, click the delete icon ( ) next to the element you want to delete, then confirm that you want to delete the device or subnet.

   The device is deleted. If the system rediscovers the device, it re-adds the device to the network map.

Working with the Applications Network Map

LICENSE: FireSIGHT

Use the applications network map to view the applications on your network, organized in a hierarchical tree by application name, vendor, version, and finally by the hosts running each application.



The applications that the system detects may change with system software and VDB updates, and also if you import any add-on detectors. The release notes or advisory text for each system or VDB update contains information on any new and updated detectors. For a comprehensive up-to-date list of detectors, see the Support Site.

From the applications network map, you can view the host profile of each host that runs a specific application as well as delete any application category, any application running on all hosts, or any application running on a specific host. For example, you can delete an application from the network map if you know it is

disabled on the host and you want to make sure the system does not use it for impact level qualification.

Deleting an application from the network map does not remove it from your network. A deleted application reappears in the network map if your system detects a change in the application (for example, if an Apache web server is upgraded to a new version) or if you restart your system's discovery function.

Depending on what you delete, the behavior differs:

- If you delete an application category, the application category is removed from the network map. All applications that reside beneath the category are removed from any host profile that contains the applications.

  For example, if you delete **http**, all applications identified as **http** are removed from all host profiles and **http** no longer appears in the applications view of the network map.
- If you delete a specific application, vendor, or version, the affected application is removed from the network map and from any host profiles that contain it.

  For example, if you expand the **http** category and delete **Apache**, all applications listed as Apache with any version listed beneath Apache are removed from any host profiles that contain them. Similarly, if instead of deleting **Apache**, you delete a specific version (**1.3.17**, for example), only the version you selected will be deleted from affected host profiles.
- If you delete a specific IP address, the IP address is removed from the application list and the application itself is removed from the host profile of the IP address you selected.

  For example, if you expand **http**, **Apache**, **1.3.17 (Win32)**, and then delete **172.16.1.50:80/tcp**, the Apache 1.3.17 (Win32) application is deleted from the host profile of IP address 172.16.1.50.

To view the applications network map:

Access: Admin/Any Security Analyst

1. Select **Analysis > Hosts > Network Map > Applications**.

   The applications network map appears.

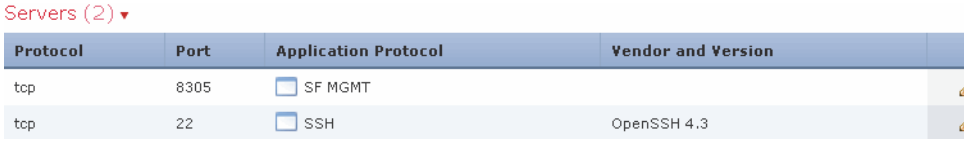
2. Drill down to the specific application you want to investigate.

   For example, if you want to view a specific type of web server like Apache, click **http**, then click **Apache**, and then click the version of the Apache web server you want to view.

   To filter by IP or MAC addresses, type an address in the search field. To clear the search, click the clear icon (✖).

3. Click a specific IP address under the application you selected.

   The host profile of the host running the application appears with the applications section expanded. For more information about the applications section of the host profile, see Working with Servers in the Host Profile on page 1411.



4. Optionally, to delete any application category, any application running on all hosts, or any application running on a specific host, click the delete icon ( ) next to the element you want to delete, then confirm that you want to delete it.

   The application is deleted. If the system rediscovers the application, it is re-added to the network map.

Working with the Vulnerabilities Network Map

LICENSE: FireSIGHT

Use the vulnerabilities network map to view the vulnerabilities that the system has detected on your network, organized by Sourcefire vulnerability ID (SVID), Bugtraq ID, CVE ID, or Snort ID. The vulnerabilities are arranged by identification number, with affected hosts listed beneath each vulnerability.

From the vulnerabilities network map, you can view the details of specific vulnerabilities; you can also view the host profile of any host subject to a specific vulnerability. This can help you evaluate the threat posed by that vulnerability to specific affected hosts.

If you deem that a specific vulnerability is not applicable to the hosts on your network (for example, you have applied a patch), you can deactivate the vulnerability. Deactivated vulnerabilities still appear on the network map, but the IP addresses of their previously affected hosts appear in gray italics. The host profiles for those hosts show deactivated vulnerabilities as invalid, though you can manually mark them as valid for individual hosts; see Setting Vulnerabilities for Individual Hosts on page 1432 for more information.

If there is an identity conflict for an application or operating system on a host, the system lists the vulnerabilities for both potential identities. When the identity conflict is resolved, the vulnerabilities remain associated with the current identity.

For more information, see Understanding Current Identities on page 1718 and Understanding Identity Conflicts on page 1719.

By default, the vulnerability network map displays the vulnerabilities of a detected application only if the packet contains the application's vendor and version. However, you can configure the system to list the vulnerabilities for applications lacking vendor and version data by enabling the vulnerability mapping setting for the application in the system policy. For information on setting the vulnerability mapping for an application, see Mapping Vulnerabilities for Servers on page 2075.

The numbers next to a vulnerability ID (or range of vulnerability IDs) represent two counts:

- The first number is a count of non-unique hosts that are affected by a vulnerability or vulnerabilities. If a host is affected by more than one vulnerability, it is counted multiple times. Therefore, it is possible for the count to be higher than the number of hosts on your network. Deactivating a vulnerability decrements this count by the number of hosts that are potentially affected by the vulnerability. If you have not deactivated any vulnerabilities for any of the potentially affected hosts for a vulnerability or range of vulnerabilities, this count is not displayed.
- The second number is a similar count of the total number of non-unique hosts that the system has determined are *potentially* affected by a vulnerability or vulnerabilities.

Deactivating a vulnerability renders it inactive only for the hosts you designate. You can deactivate a vulnerability for all hosts that have been judged vulnerable or for a specified individual vulnerable host. If the system subsequently detects the vulnerability on a host where it has not been deactivated (for example, on a new host in the network map), the system activates the vulnerability for that host. You have to explicitly deactivate the newly discovered vulnerability. Also, if the system detects an operating system or application change for a host, it may reactivate associated deactivated vulnerabilities.

To view the vulnerabilities network map:

Access: Admin/Any Security Analyst

1. Select **Analysis > Hosts > Network Map > Vulnerabilities**.

   The vulnerabilities network map appears.

2. From the **Type** drop-down list, select the class of vulnerability you want to view. By default, vulnerabilities are displayed by Sourcefire vulnerability ID (SVID).

3. Drill down to the specific vulnerability you want to investigate.

   To filter by IP or MAC addresses, type an address in the search field. To clear the search, click the clear icon (✖).

   The vulnerability details appear. For details on the information provided, see Viewing Vulnerability Details on page 1429.

   In addition, on the network map, the Defense Center displays the IP addresses of affected hosts. You can click any IP address to display the host profile for that host.

4. Optionally, deactivate the vulnerability:

   - To deactivate the vulnerability for all hosts affected by the vulnerability, click the delete icon ( ) next to the vulnerability number.
   - To deactivate the vulnerability for an individual host, click the delete icon ( ) next to the host's IP address.

   The vulnerability is deactivated. The applicable hosts' IP addresses appear in gray italics in the network map. In addition, host profiles for those hosts show deactivated vulnerabilities as invalid.

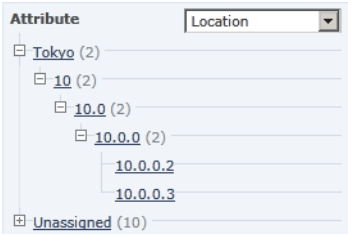
TIP! See Setting Vulnerabilities for Individual Hosts on page 1432 for more information on reactivating vulnerabilities.

Working with the Host Attributes Network Map

LICENSE: FireSIGHT

Use the host attributes network map to view the hosts on your network organized by their host attributes. When you select the host attribute you want to use to organize your hosts, the Defense Center lists the possible values for that attribute in the network map and groups hosts based on their assigned values. You can also view the host profile of any host assigned a specific host attribute value.

The host attributes network map can organize hosts based on user-defined host attributes. For any of these attributes, the network map displays hosts that do not have a value assigned as Unassigned.



For more information, see Working with User-Defined Host Attributes on page 1434.

In addition, the host attributes network map can organize hosts based on the host attributes that correspond to any compliance white lists you have created. Each compliance white list that you create automatically creates a host attribute with the same name as the white list.

Possible white list host attribute values are:

- `Compliant`, for hosts that are compliant with the white list
- `Non-Compliant`, for hosts that violate the white list
- `Not Evaluated`, for hosts that are not valid targets of the white list or have not been evaluated for any reason

For more information on compliance white lists, see Using the Sourcefire 3D System as a Compliance Tool on page 1601.

IMPORTANT! You cannot organize hosts using predefined host attributes, such as host criticality, on the host attributes network map.

To view the host attributes network map:

Access: Admin/Any Security Analyst

1. Select **Analysis > Hosts > Network Map > Host Attributes**.

   The host attributes network map appears.

2. From the **Attribute** drop-down list, select a host attribute.

   The Defense Center lists the values for the host attribute and indicates, in parentheses, the number of hosts assigned that value.

   To filter by IP or MAC addresses, type an address in the search field. To clear the search, click the clear icon (✖).

3. Click any host attribute value to view hosts assigned the value.
4. Click a host IP address to view the host profile for that host.

Working with Custom Network Topologies

LICENSE: FireSIGHT

Use the custom topology feature to help you organize and identify subnets in your hosts and network devices network maps.

For example, if each department within your organization uses a different subnet, you can label those subnets using the custom topology feature. Then, when you view the hosts or network devices network map, the labels you assign to your subnets appear, as shown in the following graphic.

You can also view the hosts network map according to the organization you specified in the custom topology.

For more information about the hosts and network devices network maps, see Working with the Hosts Network Map on page 1375 and Working with the Network Devices Network Map on page 1377.

For more information, see the following sections:

- Creating Custom Topologies on page 1388
- Managing Custom Topologies on page 1392

Creating Custom Topologies

LICENSE: FireSIGHT

To create a custom topology, you must specify its networks. You can do this using any or all of three strategies:

- by importing the Sourcefire-discovered topology, which adds networks using a "best guess" at how your network is deployed based on the hosts and network devices the system has detected
- by importing networks from a network discovery policy, which adds the networks that you configured the Sourcefire 3D System to monitor in a network discovery policy
- by adding networks to your topology manually, if the other two methods create an inaccurate or incomplete representation of your deployment

You must save and activate the topology before using it with the network map.

To create a custom topology:

ACCESS: Admin/Discovery Admin

1. Select **Policies > Network Discovery**, then click **Custom Topology**.

   The Custom Topology page appears.

2. Click **Create Topology**.

   The Create Topology page appears.

3. Provide basic topology information, such as the topology name and description.

   See Providing Basic Topology Information on page 1389.

4. Add networks to your topology. You can use any or all of the following strategies:
   - To add networks to your topology by importing the Sourcefire-discovered topology, follow the procedure in Importing a Discovered Topology on page 1389.
   - To add networks to your topology by importing them from a network discovery policy, follow the procedure in see Importing Networks from a Network Discovery Policy on page 1390.
   - To add networks to your topology manually, follow the procedure in Manually Adding Networks to Your Custom Topology on page 1391.

5. Refine your topology:
   - To remove a network from your custom topology, click **Delete** next to the network you want to remove.
   - To rename a network, click **Rename** next to the network. In the pop-up window that appears, type the new name in the **Name** field and click **Rename**. This name labels the network in the network map.

6. Click **Save**.

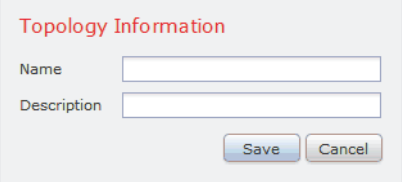
   The topology is saved.

> **IMPORTANT!** You must activate the topology before you can use it in the network map. For more information, see Managing Custom Topologies on page 1392.

Providing Basic Topology Information

LICENSE: FireSIGHT

You must give each custom topology a name, and, optionally, a short description.



To provide basic topology information:

ACCESS: Admin

1. On the Edit Topology page, in the **Name** field, type a name for the topology.
2. Optionally, in the **Description** field, type a description for the topology.
3. Optionally, continue with the procedures in the following sections, depending on how you want to build your custom topology:
   - Importing a Discovered Topology on page 1389
   - Importing Networks from a Network Discovery Policy on page 1390
   - Manually Adding Networks to Your Custom Topology on page 1391

Importing a Discovered Topology

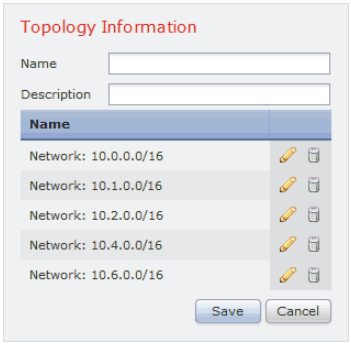
LICENSE: FireSIGHT

One way you can add networks to your custom topology is to import the topology discovered by your Sourcefire 3D System. This discovered topology is the system's "best guess" at how your network is deployed based on the hosts and network devices it has detected.

To import a discovered topology:

ACCESS: Admin

1. On the Edit Topology page, click **Import Discovered Topology**.
2. The discovered networks populate the page.



3. Optionally, continue with the procedures in the following sections, depending on how you want to build your custom topology:
   - Importing a Discovered Topology on page 1389
   - Importing Networks from a Network Discovery Policy on page 1390
   - Manually Adding Networks to Your Custom Topology on page 1391

Importing Networks from a Network Discovery Policy

LICENSE: FireSIGHT

One way you can add networks to your custom topology is to import the networks that you configured the Sourcefire 3D System to monitor in a network discovery policy. For information on discovery policies, see Creating a Network Discovery Policy on page 1332.

To import networks from a network discovery policy:

ACCESS: Admin

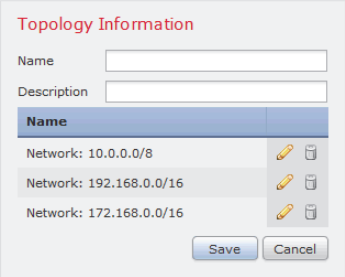
1. On the Edit Topology page, click **Import Policy Networks**.

   A pop-up window appears.

2. From the drop-down list, choose the network discovery policy you want to use and click **Load**.

3. The monitored networks in your network discovery policy populate the page.

   For example, if you configured your network discovery policy to monitor the 10.0.0.0/8, 192.168.0.0/16, and 172.12.0.0/16 networks, those networks appear on the page.



4. To add networks from a different network discovery policy, repeat steps 1 and 2.

5. Optionally, follow the procedures in the following sections, depending on how you want to build your custom topology:

   - Importing a Discovered Topology on page 1389
   - Manually Adding Networks to Your Custom Topology on page 1391

Manually Adding Networks to Your Custom Topology

License: FireSIGHT

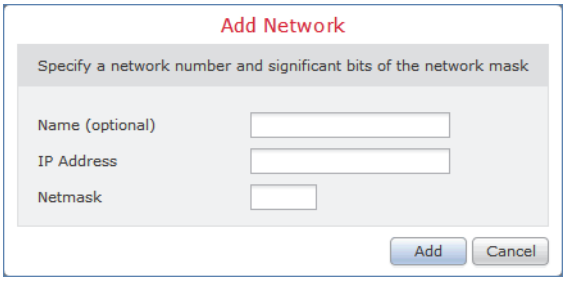
If importing the Sourcefire-discovered topology and importing networks from your network discovery policy creates an inaccurate or incomplete representation of your network deployment, you can add networks to your custom topology manually.

To add a network to a custom topology manually:

Access: Admin

1. On the Edit Topology page, click **Add Network**.

   A pop-up window appears.



2. Optionally, name the network by typing a name in the **Name** field.

   This name labels the networks in the hosts and network devices network maps after you activate the topology.

   For more information, see Working with the Hosts Network Map on page 1375 and Working with the Network Devices Network Map on page 1377.

3. In the **IP Address** and **Netmask** fields, enter the IP address and network mask (in CIDR notation) that represent the network you want to add to your topology.

   For information on using CIDR notation in the Sourcefire 3D System, see IP Address Conventions on page 63.

4. Click **Add**.

   The network is added to your topology.

5. To add additional networks to your topology, repeat steps 1 through 4.

TIP! To delete a network from your topology, click **Delete** next to the network you want to delete, and confirm that you want to delete the network, as well as all links to the network.

6. Optionally, follow the procedures in the following sections, depending on how you want to build your custom topology:

   - Importing a Discovered Topology on page 1389
   - Importing Networks from a Network Discovery Policy on page 1390

Managing Custom Topologies

LICENSE: FireSIGHT

Use the Custom Topology page to manage custom topologies. You can create, modify, and delete topologies.

A topology's status appears with its name. If the light bulb icon next to the policy name is lit, the topology is active and affects your network map. If it is dark, the topology is inactive. Only one custom topology can be active at any time. If you have created multiple topologies, activating one automatically deactivates the currently active topology.

Use the following procedures to either activate or deactivate a custom topology, modify a topology, or delete a topology.

If you delete the active topology, your changes take effect immediately; that is, your network map no longer displays your custom topology.

To activate or deactivate a custom topology:

Access: Admin

1. Select **Policies > Network Discovery > Custom Topology**.

   The Custom Topology page appears.

2. You have two options:
   - To **activate** a topology, click **Activate** next to the policy.
   - To **deactivate** a topology, click **Deactivate** next to the policy.

To modify a custom topology:

Access: Admin

1. Select **Policies > Network Discovery > Custom Topology**.

   The Custom Topology page appears.

2. Click the edit icon ( ) next to the topology you want to edit.

   The Edit Topology page appears. See Creating Custom Topologies on page 1388 for information on the various configurations you can change.

3. Make changes as needed and click **Save**.

   The topology is changed. If the topology is active, the changes you made take effect in the network map immediately.

To delete a custom topology:

Access: Admin

1. Select **Policies > Network Discovery > Custom Topology**.

   The Custom Topology page appears.

2. Click **Delete** next to the topology you want to delete. If the topology is active, confirm that you want to delete it.

   The topology is deleted.

CHAPTER 34
USING HOST PROFILES

A host profile provides a complete view of all the information the system has gathered about a single host. You can access general host information, such as the host name and operating system, through the profile. If you need to quickly find the MAC address for a host, for example, you can look in the host profile.

Host attributes for that host are also listed in the profile. Host attributes are user-defined descriptions that you can apply to a host. For example, you might assign a host attribute that indicates the building where the host is located. From a host profile, you can view the existing host attributes applied to that host and can modify the host attribute values. As another example, you can use the *host criticality* attribute to designate the business criticality of a given host and to tailor correlation policies and alerts based on host criticality.

Host profiles also provide you with information about the servers, clients, and host protocols running on a particular host, including whether they are in compliance with a compliance white list. You can remove servers from the servers list, and view details for those servers. You can also view *connection events* for servers, log information about the session where server traffic was detected. You can also view details and connection events for clients and delete servers, clients or host protocols from the host profile.

If your Sourcefire 3D System deployment includes a FireSIGHT license, you can view *indications of compromise* (IOC) in the host profile. These indications correlate various types of data (intrusion events, Security Intelligence, connection events, and file or malware events) associated with hosts to determine whether a host on your monitored network is likely to be compromised by malicious means. From the host profile, you can see an overview of a host's IOC tags, view the events associated with IOC, mark IOC tags resolved, and edit IOC rule states in the discovery policy.

If your deployment includes a Protection license, you can tailor the way the system processes traffic so it best fits the type of operating system on the host and the servers and clients the host is running. For more information, see Using Adaptive Profiles on page 1030.

You can also see user history information for a host if you have configured the system to track it. A graphic representation of the last twenty-four hours of user activity is then available.

You can modify the list of vulnerabilities for the host from the host profile. You can use this capability to track which vulnerabilities have been addressed for the host. You can also apply fixes for vulnerabilities, causing all vulnerabilities addressed by the fix to be automatically marked invalid.

You can work with the vulnerability information generated by the Sourcefire system, and also use information on vulnerabilities detected by third-party scanners, which you import onto the Defense Center using the host input feature.

Optionally, you can perform an Nmap scan from the host profile, to augment the server and operating system information in your host profile. The Nmap scanner actively probes the host to obtain information about the operating system and servers running on the host. The results of the scan are added to the list of operating system and server identities for the host.

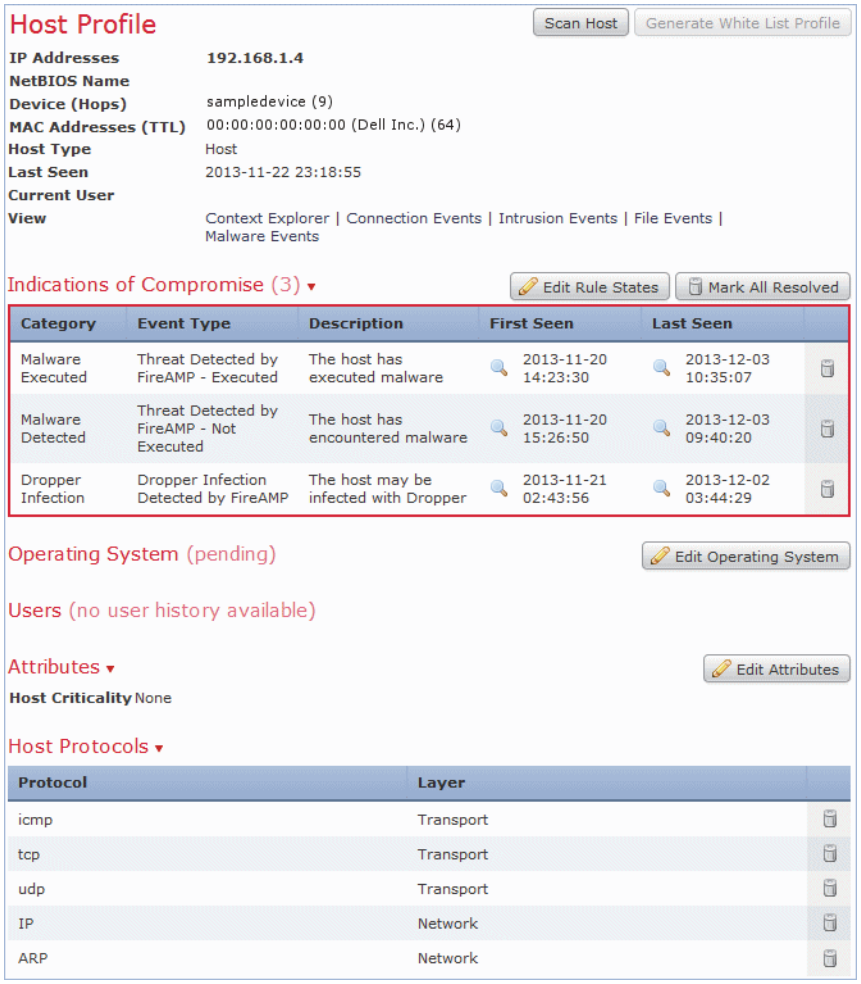
Note that a host profile may not be available for every host on your network. Possible reasons include:

- the host was deleted from the network map because it timed out
- you have reached your FireSIGHT host license limit
- the host resides in a network segment that is not monitored by your network discovery policy

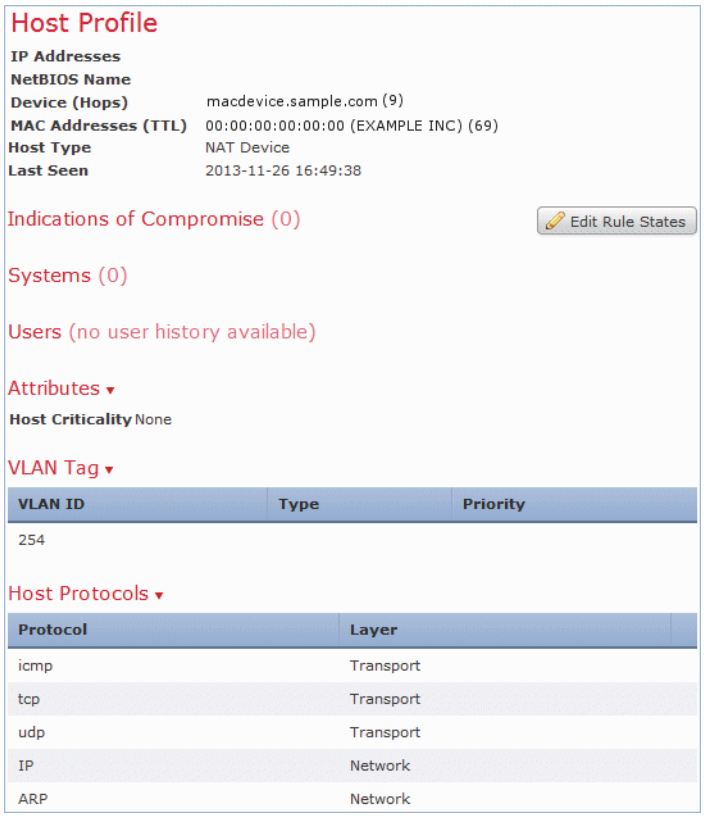
Note that the information displayed in a host profile may vary according to the type of host and the information available about the host. For example, if your system detects a host using a non-IP-based protocol like STP, SNAP, or IPX, the host is added to the network map as a MAC host and much less information is available than for an IP host.

As another example, although you can configure your network discovery policy to add hosts and server and clients to the network map based on data exported by NetFlow-enabled devices, the available information about these hosts and servers and clients is limited. For example, no operating system data is available for these hosts, unless you provide it using a scanner or the host input feature. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

The following graphic shows an example of a host profile.



The following graphic shows an example of a host profile for a MAC host.



For more information about each section of the host profile, see the following:

- Viewing Host Profiles on page 1398 explains how to access a host profile.
- Working with Basic Host Information in the Host Profile on page 1399 describes the information provided in the Host section of a host profile.
- Working with IP Addresses in the Host Profile on page 1402 describes the information provided in the IP Addresses section of a host profile.
- Working with Indications of Compromise in the Host Profile on page 1402 describes the information provided in the Indications of Compromise section of a host profile.
- Working with Operating Systems in the Host Profile on page 1405 describes the information provided in the Operating System or Operating System Conflicts section of a host profile and explains how to edit the operating system or resolve an operating system conflict.
- Working with Servers in the Host Profile on page 1411 describes the information provided in the Servers, Server Detail, and Server Banner sections of a host profile.
- Working with Applications in the Host Profile on page 1418 describes the information provided in the Clients section of a host profile.

- Working with VLAN Tags in the Host Profile on page 1421 describes the information provided in the VLAN Tag section of a host profile.
- Working with User History in the Host Profile on page 1421 describes the information provided in the User History section of a host profile.
- Working with Host Attributes in the Host Profile on page 1422 describes the information provided in the Attributes section of a host profile.
- Working with the Predefined Host Attributes on page 1433 explains how to set the host criticality attribute and how to add notes to a host profile.
- Working with User-Defined Host Attributes on page 1434, which provides information about creating and using user-defined host attributes.
- Working with Host Protocols in the Host Profile on page 1423 describes the information provided in the Host Protocols section of a host profile.
- Working with White List Violations in the Host Profile on page 1424 describes the information provided in the White List Violations section of a host profile.
- Working with Malware Detections in the Host Profile on page 1426 describes the information provided in the Most Recent Malware Detections section of a host profile.
- Working with Vulnerabilities in the Host Profile on page 1427, which describes the information provided in the Vulnerabilities and Vulnerability Detail sections of a host profile.

Viewing Host Profiles

LICENSE: FireSIGHT

You can access a host profile from any network map or from any event view that includes the IP addresses of hosts on monitored networks. For example, the table view of discovery events includes a link to the host profile next to every entry in the IP Address column. If you have any indication of compromise (IOC) rules enabled, potentially compromised hosts appear with a different host profile icon.

To view a host profile from an event view:

ACCESS: Admin/Any Security Analyst

▶ On any event view, click the host profile icon () or the compromised host icon () next to the IP address of the host whose profile you want to view.

The host profile appears in a pop-up window.

To view a host profile from a network map:

ACCESS: Admin/Any Security Analyst

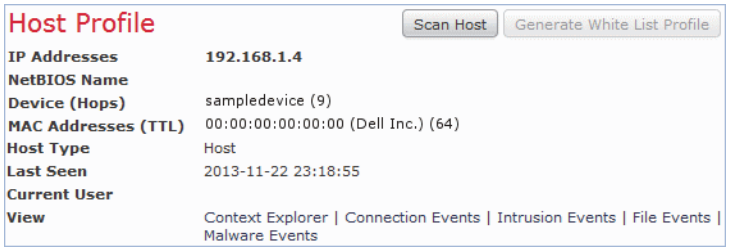
- On any network map, drill down to the IP address of the host whose profile you want to view.

  The host profile appears. See Working with the Hosts Network Map on page 1375 for an example of how to access a host profile from a network map.

Working with Basic Host Information in the Host Profile

LICENSE: FireSIGHT

Each host profile provides basic information about a detected host or other device.



Descriptions of each of the basic host profile fields follow.

IP Addresses

All IP addresses (both IPv4 and IPv6) associated with the host. IPv6 hosts often have at least two IPv6 addresses (local-only and globally routable), and may also have IPv4 addresses. IPv4-only hosts may have multiple IPv4 addresses. Where available, routable host IP addresses also include a flag icon and country code indicating the geolocation data associated with that address. For more information on this and other geolocation features, see Using Geolocation on page 1892.

Hostname

The fully qualified domain name of the host, if known.

NetBIOS Name

The NetBIOS name of the host, if available. Microsoft Windows hosts, as well as Macintosh, Linux, or other platforms configured to use NetBIOS, can have a NetBIOS name. For example, Linux hosts configured as Samba servers have NetBIOS names.

Device (Hops)

Either:

- the reporting device for the network where the host resides, as defined in the network discovery policy, or
- the device that processed the NetFlow data that added the host to the network map

The device and the number of network hops between the device that detected the host and the host itself follows the device name, in parentheses. If multiple devices can see the host, the reporting device is displayed in bold.

If this field is blank, either:

- the host was added to the network map by a device that is not explicitly monitoring the network where the host resides, as defined in the network discovery policy, or
- the host was added using the host input feature and has not also been detected by the Sourcefire 3D System

MAC Addresses (TTL)

The host's detected MAC address or addresses and associated NIC vendors, with the NIC's hardware vendor and current time-to-live (TTL) value in parentheses. If the MAC address is displayed in a bold font, the MAC address is the actual MAC address of the host, detected by the system through ARP and DHCP traffic. If multiple devices detected the host, the Defense Center displays all MAC addresses and TTL values associated with the host, regardless of which device reported them.

You can click the MAC address to view a list of hosts with the same MAC address. Router host profiles typically show the hosts (IP addresses) in the network segments they route in this list, and the IP addresses of monitored routers frequently appear in this list for monitored workstations and servers. The true IP address for the MAC address is displayed in bold.

Host Type

The type of device that the system detected: host, mobile device, jailbroken mobile device, router, bridge, NAT device, or load balancer.

The methods the system uses to distinguish network devices include:

- the analysis of Cisco Discovery Protocol (CDP) messages, which can identify network devices and their type (Cisco devices only)
- the detection of the Spanning Tree Protocol (STP), which identifies a device as a switch or bridge

- the detection of multiple hosts using the same MAC address, which identifies the MAC address as belonging to a router
- the detection of TTL value changes from the client side, or TTL values that change more frequently than a typical boot time, which identify NAT devices and load balancers

The methods the system uses to distinguish mobile devices include:

- analysis of user agent strings in HTTP traffic from the mobile device's mobile browser
- monitoring of HTTP traffic of specific mobile applications

If a device is not identified as a network device or a mobile device, it is categorized as a host.

Last Seen

The date and time that any of a host's IP addresses was last detected.

Current User

The user most recently logged into this host.

Note that a non-authoritative user logging into a host only registers as the current user on the host if the existing current user is not an authoritative user. For more information, see Users Database on page 1311.

View

Links to views of event data, using the default workflow for that event type and constrained to show events related to the host; where possible, these events include all IP addresses associated with the host. For more information, see the following sections:

- Content Explorer — for more information, see Using the Context Explorer on page 128.
- Connection Events — for more information, see Understanding Connection Data on page 585.
- Discovery Events — for more information, see Working with Discovery Events on page 1441.
- Malware Events — for more information, see Working with Malware Events on page 1274.
- Intrusion Events by Source — for more information, see Working with Intrusion Events on page 640.
- Intrusion Events by Destination — for more information, see Working with Intrusion Events on page 640.

Working with IP Addresses in the Host Profile

LICENSE: FireSIGHT

The system detects IP addresses associated with hosts and, where supported, groups multiple IP addresses used by the same host. IPv6 hosts usually have at least two IPv6 addresses: local-only and globally routable. They may also have one or more assigned IPv4 addresses. IPv4-only hosts may have multiple IPv4 addresses.

The host profile lists all detected IP addresses associated with that host. Where available, IP addresses also feature a small flag icon and ISO country code that indicate the associated country. You can click the flag icon or country code for further geolocation details. For more information, see Using Geolocation on page 1892.

Note that only the first three addresses are shown by default. Click **show all** to show all addresses for a host.

Working with Indications of Compromise in the Host Profile

LICENSE: FireSIGHT

The Sourcefire 3D System can correlate various types of data (intrusion events, Security Intelligence, connection events, and file or malware events) associated with hosts to determine whether a host on your monitored network is likely to be compromised by malicious means. Certain combinations and frequencies of event data trigger indications of compromise (IOC) tags on affected hosts. The Indications of Compromise section of the host profile displays all IOC tags for a host. In this section, you can view details of the threats facing the host, jump to the events that triggered an IOC tag, edit IOC rule states, as well as resolve IOC tags that are no longer relevant.

To use the IOC feature, you must activate the feature and at least one IOC rule in your discovery policy. You can also edit IOC rule states for individual hosts from that host's host profile page. Each IOC rule corresponds to one type of IOC tag; you can activate any or all rules depending on your organization's needs. For more information on IOC in the discovery policy and overall, see Understanding Indications of Compromise on page 1329.

In addition to its presence in the host profile, you can also analyze IOC data in the event viewer. For more information, see Working with Indications of Compromise on page 1482.

Descriptions of the IOC information fields displayed in the host profile follow.

IP Address

The IP address associated with the host that triggered the IOC.

Category

Brief description of the type of compromise indicated, such as `Malware Executed` or `Impact 1 Attack`.

Event Type

Identifier associated with a specific Indication of Compromise (IOC), referring to the event that triggered it.

Description

Description of what threatens the potentially compromised host, such as `This host may be under remote control` or `Malware has been executed on this host`.

First/Last Seen

The first (or most recent) date and time that events triggering a host's IOC occurred.

For additional information on working with IOC data in the host profile, see the following sections:

- Editing Indication of Compromise Rule States for a Single Host on page 1403
- Viewing Source Events for Indications of Compromise on page 1404
- Resolving Indications of Compromise on page 1405

Editing Indication of Compromise Rule States for a Single Host

LICENSE: FireSIGHT

For your system to detect and tag indications of compromise (IOC), you must first activate the IOC feature in the discovery policy and activate at least one IOC rule (either policy-wide or for individual hosts). From the host profile, you can set the IOC rule states that apply to that individual host. For more information on configuring IOC in the discovery policy and setting policy-wide IOC rule states, see Setting Indications of Compromise Rules on page 1350.

From the host profile, you can access and edit the list of IOC rules with the **Edit Rule States** link in the Indications of Compromise section. You can enable any or all rules, depending on the needs of your network and organization. For example, if hosts using software such as Microsoft Excel never appear on your monitored network, you may decide not to enable the IOC tags that pertain to Excel-based threats.

All IOC rules are predefined by Sourcefire; you cannot create original rules, although you can write compliance rules against triggered IOC tags. For more information, see Configuring Correlation Policies and Rules on page 1528. Each IOC rule is triggered by only one type of event (such as malware or intrusion) and corresponds to one specific IOC tag. Both rule and tag have identical Category,

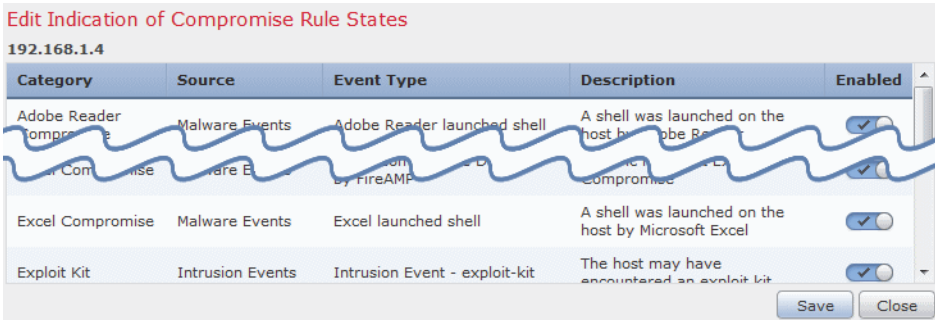
Event Type, and Description data for easy correspondence; the Edit page for IOC rule states also lists an event data Source for each rule, to give you a clear picture of what system features you need for a rule to trigger.

To edit Indication of Compromise rule states for a host:

ACCESS: Admin/Any Security Analyst

1. In a host profile, click **Edit Rule States** in the **Indications of Compromise** section.

   The Edit Indication of Compromise Rule States page appears in a new window.



2. In the **Enabled** column for a rule, click the slider to enable or disable it.
3. Click **Save**.

   Your changes are saved.

Viewing Source Events for Indications of Compromise

LICENSE: FireSIGHT

You can use the Indications of Compromise section to navigate quickly to the events that triggered IOC tags on a host. Analyzing these events can give you the information you need to determine what, and whether, action is required to address threats to a potentially compromised host.

Clicking the view icon ( ) next to the timestamp of an IOC tag navigates to the table view of events for the relevant event type, constrained to show only the event that triggered the IOC tag.

For more information on the types of events and features that trigger IOC tags, see the following:

- Working With Connection and Security Intelligence Data on page 584
- Working with Intrusion Events on page 640
- Working with Malware Protection and File Control on page 1226

To view source events for an Indications of Compromise tag:

Access: Admin/Any Security Analyst

- In the host profile's **Indications of Compromise** section, click the view icon ( ) in the **First Seen** or **Last Seen** column for the IOC tag you want to investigate.

  The table view of events for the appropriate event that triggered the IOC appears, constrained to show only the triggering event. If you are viewing the host profile page in a separate window, the event view appears in the main window.

Resolving Indications of Compromise

License: FireSIGHT

After you have analyzed and addressed the threats indicated by an IOC tag, or if you determine that an IOC tag represents a false positive, you can mark tags resolved. Marking an IOC tag resolved removes it from the host profile; when all active IOC tags on a host are resolved, the host no longer appears marked with the compromised host icon ( ). Note that you can still view the IOC-triggering events for the resolved IOC.

If the events that triggered a host's IOC tag recur, the tag is set again. You can resolve individual IOC tags on a host or mark all of a host's tags as resolved.

To resolve an Indications of Compromise tag:

Access: Admin/Any Security Analyst

- In the host profile's **Indications of Compromise** section, you have two options:
  - To mark an individual IOC tag resolved, click the resolve icon ( ) to the right of the tag you want to resolve.
  - To mark all IOC tags on a host resolved, click **Mark All Resolved**.

  Your changes are saved and the IOC tags you selected are removed.

Working with Operating Systems in the Host Profile

License: FireSIGHT

The system passively detects the identity of the operating system running on a host by analyzing the network and application stack in traffic generated by the host or by analyzing host data reported by the Sourcefire User Agent. The system also collates operating system information from other sources, such as the Nmap scanner or application data imported through the host input feature. The system considers the priority assigned to each identity source when determining which identity to use. By default, user input has the highest priority, followed by application or scanner sources, followed by the Sourcefire-discovered identity.

Sometimes the system supplies a general operating system definition rather than a specific one because the traffic and other identity sources do not provide

sufficient information for a more focused identity. The system collates information from the sources to use the most detailed definition possible.

Descriptions of the operating system information fields displayed in the host profile follow.

Hardware

The hardware platform for a mobile device.

OS Vendor/Vendor

The operating system vendor.

OS Product/Product

The operating system determined most likely to be running on the host, based on the identity data collected from all sources.

If the operating system is `Pending`, the system has not yet identified an operating system and no other identity data is available. If the operating system is `unknown`, the system cannot identify the operating system and no other identity data is available for the operating system.

If the host's operating system is not one the system is capable of detecting, you may want to use one of the following strategies:

- create a custom fingerprint for the host, as described in Using Custom Fingerprinting on page 1720
- run an Nmap scan against the host, as described in Scanning a Host from the Host Profile on page 1440
- import data into the network map, using the host input feature described in the *Sourcefire 3D System Host Input API Guide*
- manually enter operating system information, as described in Working with Operating Systems in the Host Profile on page 1405

OS Version/Version

The operating system version. If a host is a jailbroken mobile device, `Jailbroken` is indicated in parentheses after the version.

Source

One of the following values:

- User: *`user_name`*
- Application: *`app_name`*
- Scanner: *`scanner_type`* (Nmap or scanner added through system policy)
- `FireSIGHT`

The system may reconcile data from multiple sources to determine the identity of an operating system; see Understanding Current Identities on page 1718.

Because the vulnerabilities list for the host and the event impact correlation for events targeting the host depend on the operating system, you may want to manually supply more specific operating system information. In addition, you can indicate that fixes have been applied to the operating system, such as service packs and updates, and invalidate any vulnerabilities addressed by the fixes.

For example, if the system identifies a host's operating system as Microsoft Windows 2003, but you know that the host is actually running Microsoft Windows XP Professional with Service Pack 2, you can set the operating system identity accordingly. Setting a more specific operating system identity refines the list of vulnerabilities for the host, so your impact correlation for that host is more focused and accurate.

If the system detects operating system information for a host and that information conflicts with a current operating system identity that was supplied by an active source, an identity conflict occurs. When an identity conflict is in effect, the system uses both identities for vulnerabilities and impact correlation.

Although you can configure the network discovery policy to add hosts to the network map based on data exported by NetFlow-enabled devices, there is no operating system data available for these hosts, unless you set the operating system identity. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

Note that if a host is running an operating system that violates a compliance white list in an activated network discovery policy, the Defense Center marks the operating system information with the white list violation icon ( ). In addition, if a jailbroken mobile device violates an active white list, the icon appears next to the operating system for the device.

You can set a custom display string for the host's operating system identity. That display string is then used in the host profile.

IMPORTANT! Note that changing the operating system information for a host may change its compliance with a compliance white list.

In the host profile for a network device, the label for the Operating Systems section changes to Systems and an additional Hardware column appears. If a value for a hardware platform is listed under Systems, that system represents a mobile device or devices detected behind the network device. Note that mobile

devices may or may not have hardware platform information, but hardware platform information is never detected for systems that are not mobile devices.

Systems (5)

Hardware	OS Vendor	OS Product	OS Version
	Linux	Linux	2.6
iPhone	Apple	iOS	1.x, 1.0.1, 1.0.2, 1.1.0, 1.1.1, 1.1.2, 1.1.3, 1.1.4, 2.0.0, 2.0.1, 2.0.2, 2.1.0, 2.2.0, 2.2.1, 3.0.0, 3.0.1, 3.1, 4.2.1, 5.x
	Microsoft	Windows	2000, XP, Server 2003
	Apple	Mac OSX	10.5, 10.6, Server 10.5, Server 10.6
	Google	Android	2.2.1, 2.3.4, 4.0.3

Viewing Operating System Identities

LICENSE: FireSIGHT

You can view the specific operating system identities discovered or added for a host. The system uses source prioritization to determine the current identity for the host. In the list of identities, the current identity is highlighted by boldface text.

For each operating system identity, the host profile may include the information described in Working with Operating Systems in the Host Profile on page 1405.

Note that the View button is only available if multiple operating system identities exist for the host.

To view the list of operating system identities for a host:

ACCESS: Admin/Any Security Analyst

▶ Click **View** in the **Operating System** or **Operating System Conflicts** section of the host profile.

The Operating System Identity Information pop-up window appears.

TIP! Click the delete icon ( ) next to any operating system identity to remove the identity from the Operating System Identity Information pop-up window and, if applicable, to update the current identity for the operating system in the host profile. Note that you cannot delete Sourcefire-detected operating system identities.

Operating System Identity Information

Vendor	Product	Version	Source	Confidence	Created On
Microsoft, Corp.	**Windows 7**	**Professional**	**User: admin**	**100**	**2011-10-14 11:46:18**
Apple	Mac OS X	10.5, 10.6, Server 10.5, Server 10.6	RNA	98	2011-10-14 11:44:53

Editing an Operating System

LICENSE: FireSIGHT

You can set the current operating system identity for a host using the Sourcefire 3D System web interface. Setting the identity through the web interface overrides all other identity sources so that identity is used for vulnerability assessment and impact correlation. However, note that if the system detects a conflicting operating system identity for the host after you edit the operating system, an operating system conflict occurs.

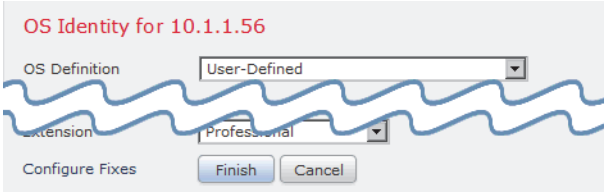
Both operating systems are then considered current until you resolve the conflict. For more information, see Resolving Operating System Identity Conflicts on page 1410.

To change the operating system identity:

ACCESS: Admin/Any Security Analyst

1. In a host profile, click **Edit** in the **Operating System** section.

   A pop-up window appears where you can set the operating system identity.



2. You have several options:
   - Select **Current Definition** from the **OS Definition** drop-down list to confirm the current operating system identity through host input, then skip to step 6.
   - Select a variation on the current operating system identity from the **OS Definition** drop-down list, then skip to step 6.
   - Select **User-Defined** from the **OS Definition** drop-down list, then continue with step 3.
3. Optionally, select **Use Custom Display String** and modify the custom strings you want to display in the **Vendor String**, **Product String**, and **Version String** fields.
4. Optionally, to change to an operating system from a different vendor, select the vendor and other operating system details from the **Vendor** and **Product** drop-down lists.
5. Optionally, to configure the operating system product release level, select the applicable items in the **Major**, **Minor**, **Revision**, **Build, Patch,** and **Extension** drop-down lists.
6. Optionally, if you want to indicate that fixes for the operating system have been applied, click **Configure Fixes**.

   The list of available package fixes displays.

7. Choose the applicable fixes in the drop-down list and click **Add**.
8. Optionally, add the relevant patches and extensions using the **Patch** and **Extension** drop-down lists.
9. Click **Finish** to complete the operating system identity configuration.

Resolving Operating System Identity Conflicts

License: FireSIGHT

An operating system identity conflict occurs when a new identity detected by the system conflicts with the current identity, if that identity was provided by an active source, such as a scanner, application, or user.

The list of operating system identities in conflict displays in bold in the host profile.

You can resolve an identity conflict and set the current operating system identity for a host through the system web interface. Setting the identity through the web interface overrides all other identity sources so that identity is used for vulnerability assessment and impact correlation.

To make one of the conflicting identities current:

Access: Admin/Any Security Analyst

▶ You have two options:

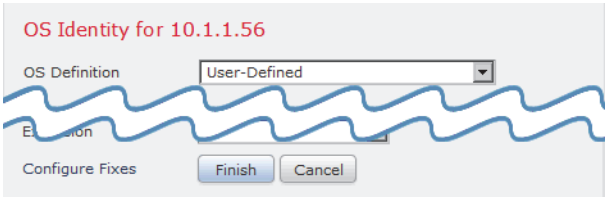
- Click **Make Current** next to the operating system identity you want to set as the operating system for the host.
- If the identity that you *do not* want as the current identity came from an active source, delete the unwanted identity.

To resolve an operating system identity conflict:

Access: Admin/Any Security Analyst

1. In a host profile, click **Resolve** in the **Operating System Conflicts** section.

   A pop-up window appears where you can set the current operating system identity.

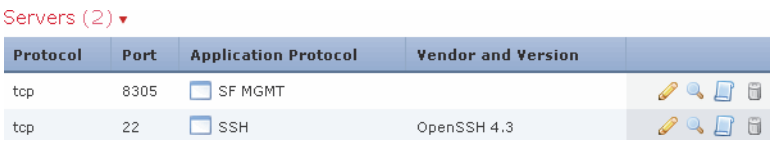


2. You have several options:
   - Select **Current Definition** from the **OS Definition** drop-down list to confirm the current operating system identity through host input, then skip to step 6.
   - Select a variation on one of the conflicting operating system identities from the **OS Definition** drop-down list, then skip to step 6.
   - Select **User-Defined** from the **OS Definition** drop-down list, then continue with step 3.
3. Optionally, select **Use Custom Display String** and type the custom strings you want to display in the **Vendor String**, **Product String**, and **Version String** fields.
4. Optionally, to change to an operating system from a different vendor, select the vendor and other operating system details.
5. Optionally, to configure the operating system product release level, select the applicable items in the **Major**, **Minor**, **Revision**, **Build, Patch,** and **Extension** drop-down lists.
6. Optionally, if you want to indicate that fixes for the operating system have been applied, click **Configure Fixes**.
7. Add the fixes you have applied to the fixes list.
8. Click **Finish** to complete the operating system identity configuration and return to the host profile.

Working with Servers in the Host Profile

License: FireSIGHT

If the system detects servers running on a host on your monitored network or if servers are added through the host input feature or through a scanner or other active source, the Defense Center lists them in the Servers section of the host profile.



The Defense Center lists up to 100 servers per host. After that limit is reached, new server information from any source, whether active or passive, is discarded until you delete a server from the host or a server times out. For more information, see Host Limits and Discovery Event Logging on page 1321.

If you scan a host using Nmap, Nmap adds the results of previously undetected servers running on open TCP ports to the Servers list. If you perform an Nmap scan on a host or import Nmap results, an expandable Scan Results section also appears in the host profile, listing the server information detected on the host by the Nmap scan. See Working with Scan Results in a Host Profile on page 1439

and Setting up Nmap Scans on page 1774 for more information. In addition, note that if the host is deleted from the network map, the Nmap scan results for that server for the host are discarded.

IMPORTANT! Although you can configure your network discovery policy to add server and clients to the network map based on data exported by NetFlow-enabled devices, the available information about these applications is limited. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

The process for working with servers in the host profile differs depending on how you accessed the profile:

- If you accessed the host profile by drilling down through the Servers network map, the details for that server appear with the server name highlighted in bold. If you want to view the details for any other server on the host, click the view icon ( ) next to that server name.
- If you accessed the host profile in any other way, expand the Servers section and click the view icon ( ) next to the server whose details you want to see.

You can also perform the following actions:

- To analyze the connection events associated with a particular server on the host, click the events icon next to the server.

  The first page of your preferred workflow for connection events appears, showing connection events constrained by the port and protocol of the server, as well as the IP address of the host. If you do not have a preferred workflow for connection events, you must select one. For more information about connection data, see Working With Connection and Security Intelligence Data on page 584.
- To delete a server from the host profile, click the delete icon ( ) next to the server.

  The server is deleted from the host profile, but will appear again if the system detects traffic from the server again. Note that deleting a server from a host may bring the host into compliance with a white list.
- To resolve a server identity conflict, click the resolve icon next to the server.

  You can choose one of the conflicting identities, choose a variation on one of those identities, or set a new user-defined identity.
- To edit a server identity, click the edit icon ( ) next to the server.

  You can choose the current identity, choose a variation on that identity, or set a new user-defined identity.

Descriptions of the columns in the Servers list follow.

Protocol

The name of the protocol the server uses.

Port

The port where the server runs.

Application Protocol

One of:

- the name of the application protocol
- **pending**, if the system cannot positively or negatively identify the application protocol for one of several reasons
- **unknown**, if the system cannot identify the application protocol based on known application protocol fingerprints or if the server was added through host input by adding a vulnerability with port information without adding a corresponding server

When you hover the mouse on an application protocol name, the tags display. For information on tags, see Understanding Application Detection on page 1316.

Vendor and Version

The vendor and version identified by the Sourcefire 3D System, by Nmap, or by another active source, or acquired via the host input feature. The field is blank if none of the available sources provides an identification.

Note that if the host is running a server that violates a compliance white list in an activated correlation policy, the Defense Center marks the non-compliant server with the white list violation icon ( ).

See the following sections for more information:

- Server Detail on page 1413
- Editing Server Identities on page 1416
- Resolving Server Identity Conflicts on page 1417

Server Detail

License: FireSIGHT

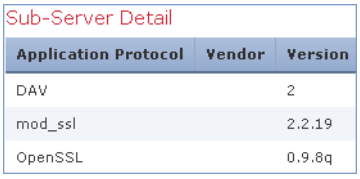
The Defense Center lists up to 16 passively detected (Sourcefire- or NetFlow-detected) identities per server. A server can have multiple passive identities if the system detects multiple vendors or versions of that server. For example, a load balancer between your managed device and your web server

farm may cause your system to identify multiple passive identities for HTTP if your web servers are not running the same version of the server software. Note that the Defense Center does not limit the number of server identities from active sources such as user input, scanners, or other applications.

The Defense Center displays the current identity in bold. The system uses the current identity of a server for multiple purposes, including assigning vulnerabilities to a host, impact assessment, evaluating correlation rules written against host profile qualifications and compliance white lists, and so on.

TIP! For information on changing the server identity and resolving identity conflicts from the server detail, see Editing Server Identities on page 1416 and Resolving Server Identity Conflicts on page 1417.

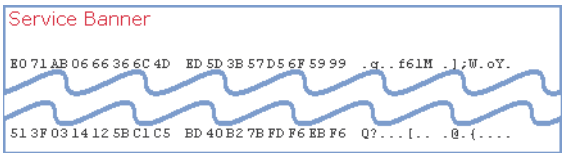
The server detail may also display updated sub-server information known about the selected server. The following graphic displays sub-server information for a detected application.



Sub-Server Detail

Application Protocol	Vendor	Version
DAV		2
mod_ssl		2.2.19
OpenSSL		0.9.8q

Finally, the server detail may display the server banner, which appears below the server details when you view a server from the host profile.



Server banners provide additional information about a server that may help you identify the server. The system cannot identify or detect a misidentified server when an attacker purposely alters the server banner string. The server banner displays the first 256 bytes of the first packet detected for the server. It is collected only once, the first time the server is detected by the system. Banner content is listed in two columns, with a hexadecimal representation on the left and a corresponding ASCII representation on the right.

IMPORTANT! To view server banners, you must enable the **Capture Banners** check box in the network discovery policy. This option is disabled by default.

Descriptions of the information provided in the server detail follow.

Protocol

The name of the protocol the server uses.

Port

The port where the server runs.

Hits

The number of times the server was detected by a Sourcefire managed device or Nmap. Note that the number of hits is 0 for servers imported through host input, unless the system detects traffic for that server.

Last Used

The time and date the server was last detected. Note that the last used time for host input data reflects the initial data import time, unless the system detects new traffic for that server. Note also that scanner and application data imported through the host input feature times out according to settings in the system policy, but user input through the Defense Center web interface does not time out.

Application Protocol

The name of the application protocol used by the server, if known.

Vendor

The server vendor. This field does not appear if the vendor is unknown.

Version

The server version. This field does not appear if the version is unknown.

Source

One of the following values:

- User: *user_name*
- Application: *app_name*
- Scanner: *scanner_type* (Nmap or scanner added through system policy)
- `FireSIGHT`, `FireSIGHT Port Match`, or `FireSIGHT Pattern Match`, for Sourcefire-detected applications
- `NetFlow`, for servers added to the network map based on NetFlow data

The system may reconcile data from multiple sources to determine the identity of a server; see Understanding Current Identities on page 1718.

To view the server detail for a server:

Access: Admin/Any Security Analyst

▶ Click the view icon ( ) next to a server in the **Servers** section of a host profile.

The Server Detail pop-up window appears.

Editing Server Identities

License: FireSIGHT

You can manually update the identity settings for a server on a host and configure any fixes that you have applied to the host to remove the vulnerabilities addressed by the fixes. You can also delete server identities.

Note that deleting an identity does not delete the server, even if that is the only identity. Deleting an identity does remove the identity from the Server Detail pop-up window and, if applicable, updates the current identity for the server in the host profile.

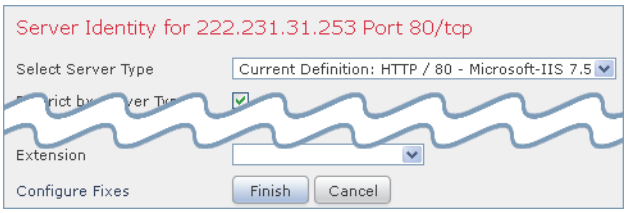
You cannot edit or delete server identities added by a Sourcefire-managed device.

To edit the server identity:

Access: Admin/Any Security Analyst

1. In the **Servers** section in a host profile, click **View** to open the Server Detail pop-up window.
2. You have two options:
   - To delete a server identity, click the delete icon ( ) next to the server identity you want to remove.
   - To modify a server identity, click the edit icon ( ) next to the server in the servers list.

     The Server Identity pop-up window appears.

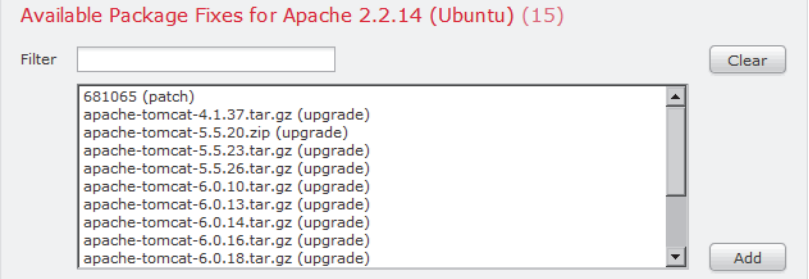


3. You have two options:
   - Select the current definition from the **Select Server Type** drop-down list.
   - Select the type of server from the **Select Server Type** drop-down list.
4. Optionally, to only list vendors and products for that server type, select the **Restrict by Server Type** check box.

5. Optionally, to customize the name and version of the server, select the **Use Custom Display String** and type a **Vendor String** and **Version String**.
6. In the **Product Mappings** section, select the operating system, product, and versions you want to use.

   For example, if you want the server to map to Red Hat Linux 9, select **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.
7. If you want to indicate that fixes for the server have been applied, click **Configure Fixes**. Otherwise, skip to step 9.

   The Available Package Fixes page appears.



8. Add the patches you want to apply for that server to the fixes list.
9. Click **Finish** to complete the server identity configuration.

Resolving Server Identity Conflicts

License: FireSIGHT

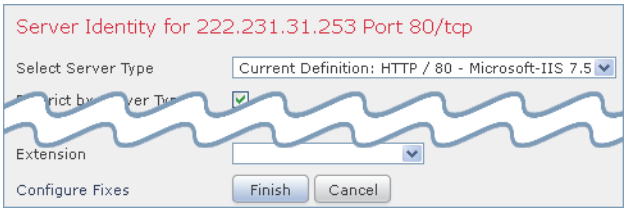
A server identity conflict occurs when an active source, such as an application or scanner, adds identity data for a server to a host, then the system detects traffic for that port that indicates a conflicting server identity.

To resolve a server identity conflict:

Access: Admin/Any Security Analyst

1. Click the resolve icon next to the server in the **Servers** list.

   The Server Identity pop-up window appears.

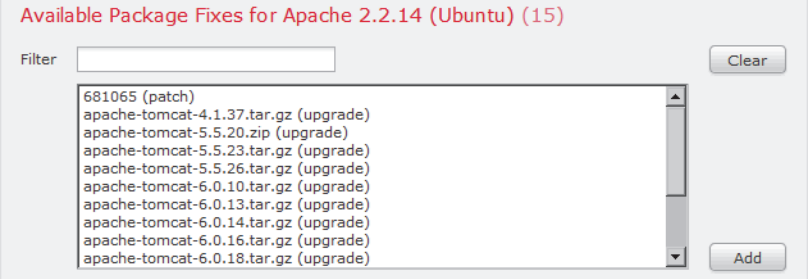


2. Select the type of server from the **Select Server Type** drop-down list.
3. Optionally, to only list vendors and products for that server type, select the **Restrict by Server Type** check box.

4. Optionally, to customize the name and version of the server, select the **Use Custom Display String** and type a **Vendor String** and **Version String**.
5. In the **Product Mappings** section, select the operating system, product, and versions you want to use.

   For example, if you want the server to map to Red Hat Linux 9, select **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.
6. If you want to indicate that fixes for the server have been applied, click **Configure Fixes**. Otherwise, skip to step 9.

   The Available Package Fixes page appears.



7. Add the patches you want to apply for that server to the fixes list.
8. Click **Finish** to complete the server identity configuration and return to the host profile.

Working with Applications in the Host Profile

LICENSE: FireSIGHT

You can see the applications running on a host in the host profile. If you want to remove an application from a host profile, you can delete that application.

For more information on managing applications in the host profile, see:

- Viewing Applications in the Host Profile on page 1419
- Deleting Applications from the Host Profile on page 1420

Viewing Applications in the Host Profile

LICENSE: FireSIGHT

The system can detect a variety of clients and web applications running on the hosts on your network.

IMPORTANT! Note that you must select the **Applications** check box in discovery rules for NetFlow devices in your network discovery policy for the system to detect applications on the hosts in your monitored network. This option is enabled by default in NetFlow rules and cannot be disabled for rules used for discovery via managed devices.

The host profile displays the product and version of the detected applications on a host, any available client or web application information, and the time that the application was last detected in use.

Applications (11)

Application Protocol	Client	Version	Web Application
Gnutella	Shareaza	2.5.0.0	
HTTP	Internet Explorer	6.0	Dropbox
HTTP	Internet Explorer	6.0	Facebook
HTTP	Internet Explorer	6.0	Google Analytics
HTTP	Internet Explorer	6.0	Microsoft Update
HTTP	Internet Explorer	6.0	Shockwave
HTTP	Firefox	3.5	Web Browsing
HTTP	Internet Explorer	5.0	Web Browsing
HTTP	Internet Explorer	7.0	Web Browsing
HTTP	Internet Explorer	8.0	Web Browsing
HTTP	Internet Explorer	6.0	Yahoo!

The Defense Center lists up to 16 clients running on the host. After that limit is reached, new client information from any source, whether active or passive, is discarded until you delete a client application from the host or the system deletes the client from the host profile due to inactivity (the client times out).

Additionally, for each detected web browser, the host profile displays the first 100 web applications accessed. After that limit is reached, new web applications associated with that browser from any source, whether active or passive, are discarded until either:

- the web browser client application times out, or
- you delete application information associated with a web application from the host profile

Descriptions of the application information that appears in a host profile follow.

Application Protocol

Displays the application protocol used by the application (HTTP browser, DNS client, and so on).

Client

Client information derived from payload if identified by the Sourcefire 3D System, or captured by Nmap, or by another active source, or acquired via the host input feature. The field is blank if none of the available sources provides an identification.

Version

Displays the version of the client.

Web Application

For web browsers, the content detected by the system in the http traffic. Web application information indicates the specific type of content (for example, WMV or QuickTime) identified by the Sourcefire 3D System, captured by Nmap, captured by another active source, or acquired via the host input feature. The field is blank if none of the available sources provides an identification.

Note that if the host is running an application that violates a compliance white list in an activated correlation policy, the Defense Center marks the non-compliant application with the white list violation icon ( ).

To analyze the connection events associated with a particular application on the host, click the events icon ( ) next to the application. The first page of your preferred workflow for connection events appears, showing connection events constrained by the type, product, and version of the application, as well as the IP address(es) of the host. If you do not have a preferred workflow for connection events, you must select one. For more information about connection data, see Working With Connection and Security Intelligence Data on page 584.

Deleting Applications from the Host Profile

LICENSE: FireSIGHT

You can delete an application from a host profile to remove applications that you know are not running on the host. Note that deleting an application from a host may bring the host into compliance with a white list.

IMPORTANT! If the system detects the application again, it re-adds it to the network map and the host profile.

To delete an application from a host profile:

Access: Admin/Any Security Analyst

▶ In the **Applications** section of the host profile, click the delete icon ( ) next to the application you want to delete.

The application is deleted for that host.

Working with VLAN Tags in the Host Profile

License: FireSIGHT

The VLAN Tag section of the host profile appears if the host is a member of a Virtual LAN (VLAN).

Physical network equipment often uses VLANs to create logical network segments from different network blocks. The system detects 802.1q VLAN tags and displays the following information for each:

- **VLAN ID** identifies the VLAN where the host is a member. This can be any integer between zero and 4095 for 802.1q VLANs.
- **Type** identifies the encapsulated packet containing the VLAN tag, which can be either Ethernet or Token Ring.
- **Priority** identifies the priority in the VLAN tag, which can be any integer from zero to 7, where 7 is the highest priority.

If VLAN tags are nested within the packet, the system processes and the Defense Center displays the innermost VLAN tag. The system collects and the Defense Center displays VLAN tag information only for MAC addresses that it identifies through ARP and DHCP traffic.

VLAN tag information can be useful, for example, if you have a VLAN composed entirely of printers and the system detects a Microsoft Windows 2000 operating system in that VLAN. VLAN information also helps the system generate more accurate network maps.

Working with User History in the Host Profile

License: FireSIGHT

The user history portion of the host profile provides a graphic representation of the last twenty-four hours of user activity. A typical user logs off in the evening and may share the host resource with another user. Periodic login requests, such as those made to check email, are indicated by short regular bars. A list of user identities is provided with bar graphs to indicate when the user login was detected. Note that for non-authoritative logins, the bar graph is gray.

Note that the system does associate a non-authoritative user login to a host with an IP address of that host, so the user does appear in the host's user history. However, if an authoritative user login is detected for the same host, the user associated with the authoritative user login takes over the association with the host IP address, and new non-authoritative user logins do not disrupt that user association with the host IP address. For more information on the types of users, see Users Database on page 1311. If you configure capture of failed logins in the network discovery policy, the list includes users that failed to log into the host.

Working with Host Attributes in the Host Profile

LICENSE: FireSIGHT

You can use *host attributes* to classify hosts in ways that are important to your network environment. Host attribute values can be positive integers, strings, or URLs. You can also create a list of string values and assign them automatically based on host IP addresses. For information about creating and managing user-defined host attributes, see Working with User-Defined Host Attributes on page 1434.

The Sourcefire 3D System includes two predefined host attributes: Host Criticality and Notes. See Working with the Predefined Host Attributes on page 1433 for information about working with these predefined host attributes.

In addition, each compliance white list that you create automatically creates a host attribute with the same name as the white list. Its possible values are Compliant (for hosts that are compliant with the white list), Non-Compliant (for hosts that violate the white list), or Not Evaluated (for hosts that are not valid targets of the white list or have not been evaluated for any reason). You **cannot** manually change the value of a white list host attribute. For more information on white lists, see Using the Sourcefire 3D System as a Compliance Tool on page 1601.

Assigning Host Attribute Values

LICENSE: FireSIGHT

You can specify positive integers, strings, or URLs as values for existing host attributes.

TIP! You can quickly assign host attributes for a host by clicking the **Edit** link in the **Attributes** section of the host profile page. This launches a pop-up window containing fields for all the host attributes.

To assign a host attribute value:

ACCESS: Admin/Any Security Analyst

1. Open a host profile.
2. Under **Attributes**, click the name of the host attribute to which you want to assign a value.

   A pop-up window appears.
3. Enter a value for the attribute or select a value from the drop-down list.
4. Click **Save**.

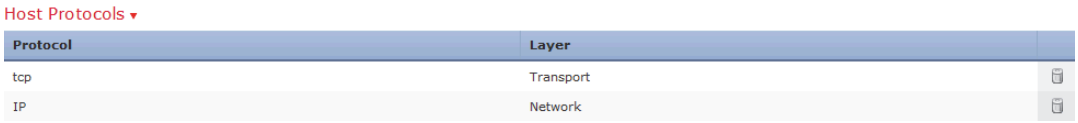
   The host attribute value is saved.

Working with Host Protocols in the Host Profile

LICENSE: FireSIGHT

You can view the protocols running on a host through the host profile. If needed, you can also delete host protocols for a particular host from the profile.

Each host profile contains information about the protocols detected in the network traffic associated with the host.



Descriptions of the protocol and network layer information follow.

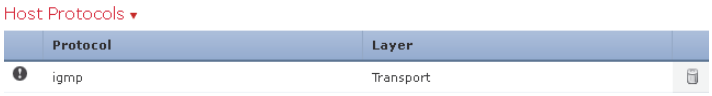
Protocol

The name of a protocol used by the host.

Layer

The network layer where the protocol runs (`Network` or `Transport`).

Note that if the host is running a protocol that violates a compliance white list in an activated correlation policy, the Defense Center marks the non-compliant protocol with the white list violation icon ( ).



You can delete a protocol from a host profile to remove protocols you know are not running on the host. Note that deleting a protocol from a host may bring the host into compliance with a compliance white list.

IMPORTANT! If the system detects the protocol again, it re-adds it to the network map and the host profile.

To delete a protocol from a host profile:

ACCESS: Admin/Any Security Analyst

- In the **Protocols** section of the host profile, click the delete icon ( ) next to the protocol you want to delete.

  The protocol is deleted for that host.

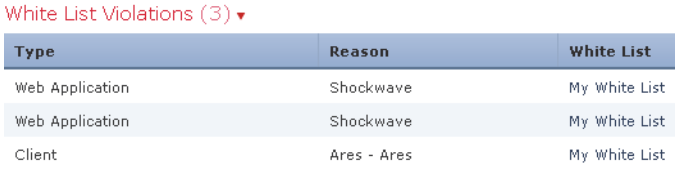
Working with White List Violations in the Host Profile

LICENSE: FireSIGHT

A *compliance white list* (or *white list*) is a set of criteria that allows you to specify the operating systems, application protocols, clients, web applications, and protocols that are allowed to run on a specific subnet.

If you add a white list to an active correlation policy, when the system detects that a host is violating the white list, the Defense Center logs a white list event—which is a special kind of correlation event— to the database. Each of these white list events is associated with a *white list violation*, which indicates how and why a particular host is violating a white list. If a host violates one or more white lists, you can view these violations in its host profile in two ways.

First, the host profile lists all of the individual white list violations associated with the host.



Descriptions of the white list violation information in the host profile follow.

Type

The type of the violation, that is, whether the violation occurred as a result of a non-compliant operating system, application, server, or protocol.

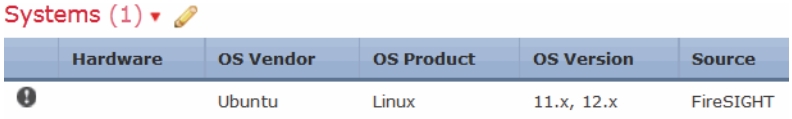
Reason

The specific reason for the violation. For example, if you have a white list that allows only Microsoft Windows hosts, the host profile displays the current operating system running on the host (such as `Linux Linux 2.4, 2.6`)

White List

The name of the white list associated with the violation.

Second, in the sections associated with operating systems, applications, protocols, and servers, the Defense Center marks non-compliant elements with the white list violation icon ( ). For example, for a white list that allows only Microsoft Windows hosts, the host profile displays the white list violation icon next to the operating system information for that host.



Note that you can use a host's profile to create a shared host profile for compliance white lists. For more information, see the next section, Creating a White List Host Profile from a Host Profile.

Creating a White List Host Profile from a Host Profile

License: FireSIGHT

Shared host profiles for compliance white lists specify which operating systems, application protocols, clients, web applications, and protocols are allowed to run on target hosts across multiple white lists. That is, if you create multiple white lists but want to use the same host profile to evaluate hosts running a particular operating system across the white lists, use a shared host profile.

You can use a host profile of any host with a known IP address to create a shared host profile that your compliance white lists can use. However, note that you cannot create a shared host profile based on an individual host's host profile if the system has not yet identified the operating system of the host.

To create a shared host profile for compliance white lists based on a host profile:

Access: Admin

1. Access a host profile from any network map or any event view.

   For more information, see Viewing Host Profiles on page 1398.

2. Click **Generate White List Profile**.

   The Edit Shared Profiles page appears. The fields on the page are pre-populated based on the information in the host profile you accessed.

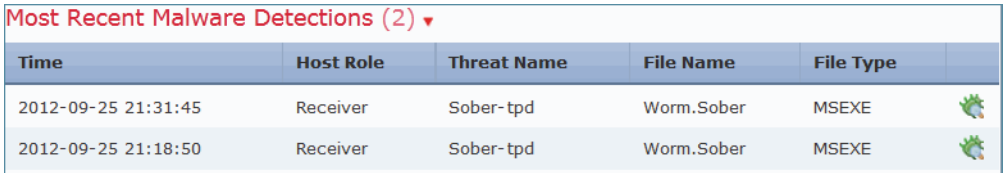
3. Modify and save the shared host profile according to your specific needs.

   For more information on creating shared host profiles for compliance white lists, see Working with Shared Host Profiles on page 1635.

Working with Malware Detections in the Host Profile

LICENSE: FireSIGHT and Malware

The Most Recent Malware Detections section lists the most recent malware events where the host sent or received a malware file, up to 100 events. The host profile lists both network-based and endpoint-based malware events.



Most Recent Malware Detections (2)

Time	Host Role	Threat Name	File Name	File Type
2012-09-25 21:31:45	Receiver	Sober-tpd	Worm.Sober	MSEXE
2012-09-25 21:18:50	Receiver	Sober-tpd	Worm.Sober	MSEXE

If the host is involved in a file event where the file is then retrospectively identified as malware, the original events where the file was transmitted appear in the malware detections list after the malware identification occurs. When a file identified as malware is retrospectively determined not to be malware, the malware events related to that file no longer appear in the list. For example, if a file has a disposition of `Malware` and that disposition changes to `Clean`, the event for that file is removed from the malware detections list on the host profile. For more information on malware events, see Working with Malware Events on page 1274.

Description of the columns in the Most Recent Malware Detections sections of the host profile follow.

Time

The date and time the event was generated.

For an event where the file was retrospectively identified as malware, note that this is the time of the original event, not the time when the malware was identified.

Host Role

The host's role in the transmission of detected malware, either sender or receiver. Note that for endpoint-based malware events, the host is always the receiver.

Threat Name

The name of the detected malware.

File Name

The name of the malware file.

File Type

The type of file; for example, PDF or MSEXE.

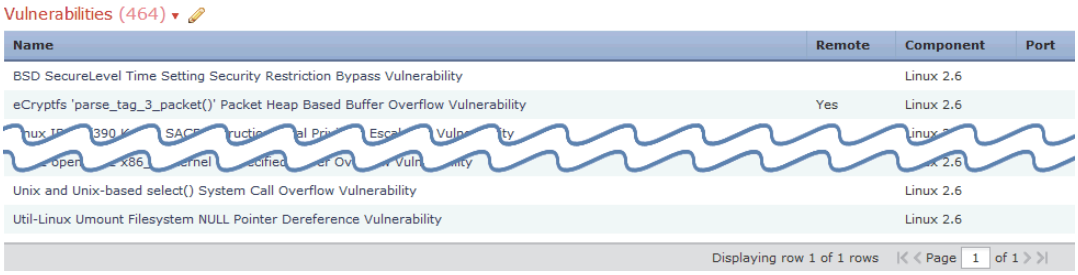
When viewing malware detections in the host profile, you can view malware events for that host in the event viewer. To view events, click the malware icon ().

Working with Vulnerabilities in the Host Profile

LICENSE: FireSIGHT

The Vulnerabilities sections of the host profile list the vulnerabilities that affect that host.

The Sourcefire Vulnerabilities section lists vulnerabilities based on the operating system, servers, and applications that the system detected on the host.



If there is an identity conflict for either the identity of the host's operating system or one of the application protocols on the host, the system lists vulnerabilities for both identities until the conflict is resolved.

Because there is no operating system information available for hosts added to the network map based on NetFlow data, the Defense Center cannot determine which vulnerabilities may affect those hosts, unless you use the host input feature to manually set the hosts' operating system identity.

Server vendor and version information is often not included in traffic. By default, the system does not map the associated vulnerabilities for the sending and receiving hosts of such traffic. However, using the system policy, you can configure the system to map vulnerabilities for specific application protocols that do not have vendor or version information. For more information, see Mapping Vulnerabilities for Servers on page 2075.

If you use the host input feature to add third-party vulnerability information for the hosts on your network, additional Vulnerabilities sections appear. For example, if you import vulnerabilities from a QualysGuard Scanner, host profiles on your include a QualysGuard Vulnerabilities section.

You can associate third-party vulnerabilities with operating systems and application protocols, but not clients. For information on importing third-party vulnerabilities, see the *Sourcefire 3D System Host Input API Guide.*

Description of the columns in the Vulnerabilities sections of the host profile follow.

Name

The name of the vulnerability.

Remote

Indicates whether the vulnerability can be remotely exploited. If this column is blank, the vulnerability definition does not include this information.

Component

The name of the operating system, application protocol, or client associated with the vulnerability.

Port

A port number, if the vulnerability is associated with an application protocol running on a specific port.

Keep in mind that for third-party vulnerabilities, the information in the corresponding Vulnerabilities section in the host profile is limited to the information that you provided when you imported the vulnerability data using the host input feature.

When viewing vulnerabilities in the host profile, you can:

- sort the columns in the **Vulnerabilities** sections by clicking a column heading. To reverse the sort, click again.
- view technical details about a vulnerability, including known solutions, by clicking the name of the vulnerability. See Viewing Vulnerability Details on page 1429 for more information. Note that you can also access vulnerability details from the vulnerability event views or the Vulnerabilities network map.
- prevent a vulnerability from being used to evaluate impact correlations. See Setting the Vulnerability Impact Qualification on page 1431 for more information.

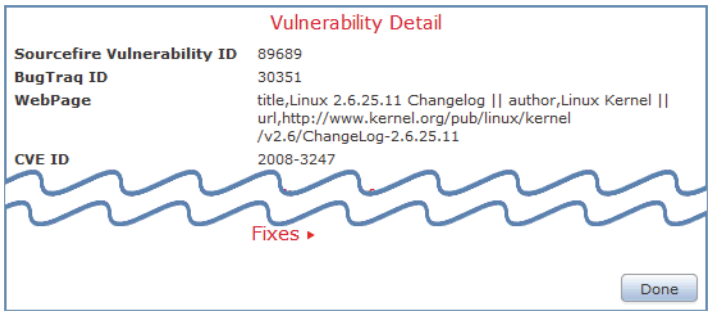
- download patches to mitigate the vulnerabilities discovered on the hosts on your network. See Downloading Patches for Vulnerabilities on page 1432 for more information.
- mark hosts as not vulnerable to individual vulnerabilities if you know that the hosts have been patched. See Setting Vulnerabilities for Individual Hosts on page 1432 for more information.

Viewing Vulnerability Details

LICENSE: FireSIGHT

Vulnerability details include a technical description of the vulnerability and known solutions.

To access the vulnerability details for a specific vulnerability, select **Analysis > Vulnerabilities** or **Analysis > Third-Party Vulnerabilities** and click the view icon ( ) next to the SVID. You can also access vulnerability details from the network map and the host profile.



Descriptions of the fields on the Vulnerability Detail page follow.

Sourcefire Vulnerability ID

The identification number (SVID) that the system uses to track vulnerabilities.

Snort ID

The identification number associated with the vulnerability in the Snort ID (SID) database. That is, if an intrusion rule can detect network traffic that exploits a particular vulnerability, that vulnerability is associated with the intrusion rule's SID.

Note that a vulnerability can be associated with more than one SID (or no SIDs at all). If the vulnerability does not have an associated SID, this field does not appear.

BugTraq ID

The identification number associated with the vulnerability in the Bugtraq database (http://www.securityfocus.com/bid).

CVE ID

The identification number associated with the vulnerability in MITRE's Common Vulnerabilities and Exposures (CVE) database (http://www.cve.mitre.org/).

Title

The title of the vulnerability.

Impact Qualification

Use the drop-down list to enable or disable a vulnerability. The Defense Center ignores disabled vulnerabilities in its impact correlations.

The setting you specify here determines how the vulnerability is treated on a system-wide basis and is not limited to the host profile where you select the value. See Setting the Vulnerability Impact Qualification on page 1431 for information about using this feature to enable and disable a vulnerability.

Date Published

The date that the vulnerability was published.

Vulnerability Impact

The severity assigned to the vulnerability in the Bugtraq database on a scale of 1 to 10, with 10 being the most severe. The vulnerability impact is determined by the writer of the Bugtraq entry, who determines the vulnerability impact level based on his or her best judgment, guided by SANS Critical Vulnerability Analysis (CVA) criteria.

Remote

Indicates whether the vulnerability is remotely exploitable.

Available Exploits

Indicates whether there are known exploits for the vulnerability.

Description

Summary description of the vulnerability.

Technical Description

Detailed technical description of the vulnerability.

Solution

Information about repairing the vulnerability.

Additional Information

Click the arrow to view additional information (if available) about the vulnerability, such as known exploits and their availability, exploit scenarios, and mitigation strategies.

Fixes

Provides links to downloadable patches for the selected vulnerability.

TIP! If direct links to fix or patch downloads appear, right-click the link and save it to your local computer.

Setting the Vulnerability Impact Qualification

LICENSE: FireSIGHT

If the system reports a vulnerability that is not applicable to your network, you can prevent it from being used to evaluate impact flag correlations. Note that if you deactivate a vulnerability in a host profile, it deactivates it for all hosts on your network. You can, however, reactivate it at any time.

When a conflict exists for the identity of the host's operating system or one of the applications on the host, the system lists vulnerabilities for both conflicting identities until the conflict is resolved. For more information, see Understanding Identity Conflicts on page 1719 and Resolving Operating System Identity Conflicts on page 1410.

Note also that the system does not recommend a rule state for an intrusion rule based on a vulnerability that you disable using the Impact Qualification feature. For more information, see Managing FireSIGHT Rule State Recommendations on page 791.

TIP! You can also deactivate vulnerabilities from the network map and from vulnerability event views. For more information, see Working with the Vulnerabilities Network Map on page 1383 and Deactivating Sourcefire Vulnerabilities on page 1507.

To change the use of a vulnerability across the system:

ACCESS: Admin/Any Security Analyst

1. Access the host profile of a host affected by the vulnerability you want to deactivate.
2. Expand the **Vulnerabilities** section.
3. Click the name of the vulnerability you want to enable or disable.

   A pop-up window appears with the vulnerability details. For more information, see Viewing Vulnerability Details on page 1429.

4. Select **Disabled** or **Enabled** from the **Impact Qualification** drop-down list to specify how the vulnerability is used.
5. Confirm that you want to change the Impact Qualification for all hosts on the network map.

   The vulnerability is enabled or disabled.
6. Click **Done** to close the vulnerability details pop-up window.

Downloading Patches for Vulnerabilities

License: FireSIGHT

If they are available, you can download patches to mitigate the vulnerabilities discovered on the hosts on your network.

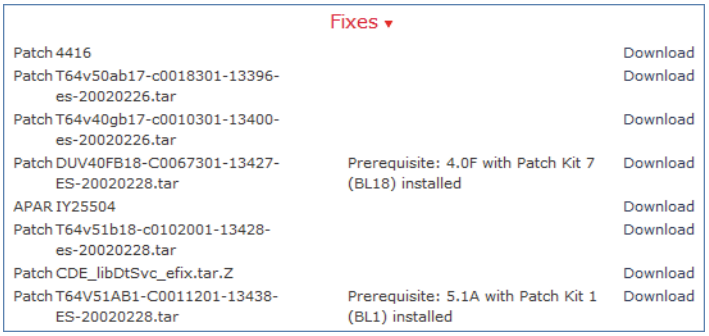
To download a patch for a vulnerability:

Access: Admin/Any Security Analyst

1. Access the host profile of a host for which you want to download a patch.
2. Expand the **Vulnerabilities** section.
3. Click the name of the vulnerability you want to patch.

   The Vulnerability Detail page appears.
4. Expand the **Fixes** section.

   The list of downloadable patches for the vulnerability appears.



5. Click **Download** next to the patch you want to download.

   A download page from the patch vendor appears.
6. Download the patch and apply it to your affected systems.

Setting Vulnerabilities for Individual Hosts

License: FireSIGHT

You can use the host vulnerability editor to activate or deactivate vulnerabilities on a host-by-host basis. When you deactivate a vulnerability for a host, it is still used

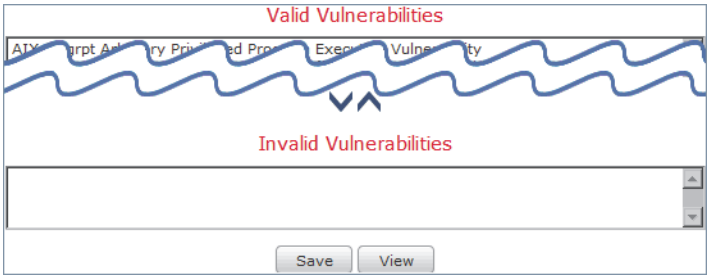
for impact correlations for that host, but the impact level is automatically reduced one level.

To activate or deactivate a vulnerability for a single host:

ACCESS: Admin/Security Analyst

1. Open a host profile.
2. Next to **Vulnerabilities**, click **Edit**.

   The Host Vulnerabilities editor page appears.



TIP! To view details about a vulnerability, select it and click **View**. For more information, see Viewing Vulnerability Details on page 1429.

3. You have two options:
   - To deactivate a vulnerability, select it from the **Valid Vulnerabilities** list, then click the down arrow.
   - To activate a vulnerability, select it from the **Invalid Vulnerabilities** list, then click the up arrow.

TIP! Use Ctrl or Shift while clicking to select multiple vulnerabilities. You can click and drag to select multiple adjacent vulnerabilities; you can also double-click any vulnerability to move it from list to list.

4. Click **Save**.

   Your changes are saved.

Working with the Predefined Host Attributes

LICENSE: FireSIGHT

There are two predefined host attributes that you can assign to each host: host criticality and host-specific notes. Use the host criticality attribute to designate the business criticality of a given host and to tailor correlation policies and alerts based on host criticality. For example, if you consider your organization's mail servers more critical to your business than a typical user workstation, you can

assign a value of High to your mail servers and other business-critical devices and Medium or Low to other hosts. You can then create a correlation policy that launches different alerts based on the criticality of an affected host.

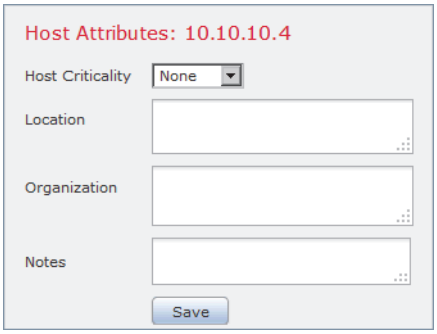
Use the Notes feature to record information about the host that you want other analysts to view. For example, if you have a computer on the network that has an older, unpatched version of an operating system that you use for testing, you can use the Notes feature to indicate that the system is intentionally unpatched.

To set pre-defined host attributes in the host profile:

Access: Admin/Security Analyst

1. Open the host profile for the host for which you want to set a business criticality.
2. Next to **Attributes**, click the pencil icon ( ).

   The Host Attributes pop-up window appears.



3. Form the **Host Criticality** drop-down list, select the value you want to apply: **None**, **Low**, **Medium**, or **High**.
4. Click **Save**.

   Your selection is saved.

Working with User-Defined Host Attributes

License: FireSIGHT

The Sourcefire 3D System includes two predefined host attributes, host criticality and host notes, that you can use to indicate the business criticality of the hosts on your network. If you have other criteria that you would like to use to identify your hosts, you can create user-defined host attributes.

User-defined host attributes appear in the host profile page, where you can assign values on a per-host basis. You can then use those attributes in correlation

policies and searches. You can also view the attributes on the host attribute table view of events and generate reports based on them.

IMPORTANT! Host attributes are defined globally rather than per policy. After you create a host attribute, it is available regardless of the policy applied.

Some examples of user-defined host attributes include:

- assigning physical location identifiers to hosts, such as a facility code, city, or room number.
- assigning a Responsible Party Identifier that indicates which system administrator is responsible for a given host. You can then craft correlation rules and policies to send alerts to the correct system administrator when problems related to a host are detected.

Host attributes can be text strings or values selected from predefined lists of text or ranges of numbers. You can also automatically assign values to hosts from a predefined list based on the hosts' IP addresses. You can use this feature to automatically assign values to new hosts when they appear on your network for the first time.

Host attributes can be one of the following types:

Text

Allows you to manually assign a text string up to 255 characters to a host.

Integer

Allows you to specify the first and last number of a range of positive integers, then manually assign one of these numbers to a host.

List

Allows you to create a list of string values, then manually assign one of the values to a host. You can also automatically assign values to hosts based on the host's IP addresses.

IMPORTANT! If you auto-assign values based on one IP address of a host with multiple IP addresses, those values will apply across all addresses associated with that host. Keep this in mind when you view the Host Attributes table.

URL

Allows you to manually assign a URL value to a host.

Note that each compliance white list that you create automatically creates a host attribute with the same name as the white list. Its possible values are `Compliant`

(for hosts that are compliant with the white list), `Non-Compliant` (for hosts that violate the white list), and `Not Evaluated` (for hosts that are not valid targets of the white list or have not been evaluated for any reason). You **cannot** manually change the value of a white list host attribute. For more information on white lists, see Using the Sourcefire 3D System as a Compliance Tool on page 1601.

See the following sections for more information:

- Creating User-Defined Host Attributes on page 1436
- Editing a User-Defined Host Attribute on page 1438
- Deleting a User-Defined Host Attribute on page 1439

Creating User-Defined Host Attributes

LICENSE: FireSIGHT

The following procedure explains how to create a user-defined host attribute.

IMPORTANT! Host attributes are defined globally rather than per policy. After you create a host attribute, it is available regardless of the policy applied.

To create a new host attribute:

ACCESS: Admin/Discovery Admin

1. Select **Analysis > Hosts > Host Attributes**.

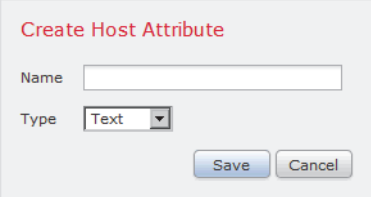
   The Host Attributes page appears.

2. Click **Host Attribute Management**.

   The Host Attribute Management page appears.

3. Click **Create Attribute**.

   The Create Attribute page appears.



4. In the **Name** field, type a name for the host attribute using alphanumeric characters and spaces.

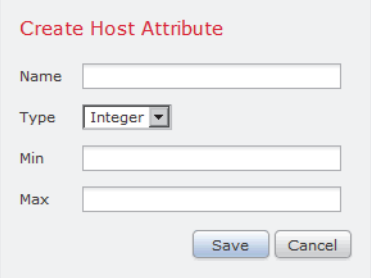
5. Select the type of attribute that you want to create from the **Type** drop-down list, as described in Working with Host Attributes in the Host Profile on page 1422:
   - If you are creating a **Text** or **URL** host attribute, continue with step 6.
   - If you are creating an **Integer** host attribute, see Creating Integer Host Attributes on page 1437.
   - If you are creating a **List** host attribute, see Creating List Host Attributes on page 1437.
6. Click **Save**.

   The new user-defined host attribute is saved.

Creating Integer Host Attributes

License: FireSIGHT

When you define an integer-based host attribute, you must specify the range of numbers that the attribute accepts.



To create an integer-based host attribute:

Access: Admin/Discovery Admin

1. In the **Min** field, enter the minimum integer value that can be assigned to a host.
2. In the **Max** field, enter the maximum integer value that can be assigned to a host.
3. Click **Save**.

   The new integer-based host attribute is saved.

Creating List Host Attributes

License: FireSIGHT

When you define a list-based host attribute, you must supply each of the values for the list. These values can contain alphanumeric characters, spaces, and symbols.

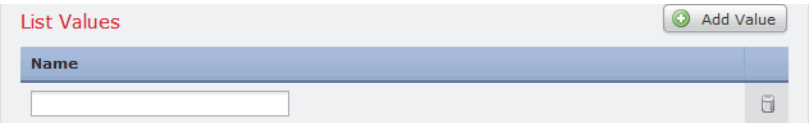
When you create a value for the host attribute, you can also auto-assign it to a block of IP addresses so that when a new host is discovered, it is automatically assigned a value for the host attribute.

To create a list-based host attribute:

ACCESS: Admin/Discovery Admin

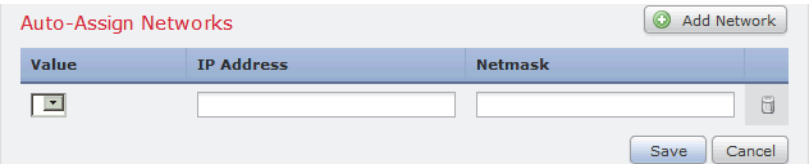
1. To add a value to the list, click **Add Value**.

   The List Values section expands.



2. In the **Name** field, enter the first value you want to add, using alphanumeric characters, symbols, and spaces.
3. Optionally, to auto-assign the attribute value you just added to your hosts, click **Add Networks**.

   The Auto-Assign Networks section expands.



4. Select the value you added from the **Value** drop-down list.
5. In the **IP Address** and **Netmask** fields, enter the IP address and network mask (in CIDR notation) that represent the IP address block where you want to auto-assign this value.

   For information on using CIDR notation in the Sourcefire 3D System, see IP Address Conventions on page 63.
6. Repeat steps 1 through 5 to add additional values to the list and assign them automatically to new hosts that fall within an IP address block.

TIP! If you do not want to auto-assign list values to the hosts in specific IP blocks, you can manually assign them as described in Working with the Predefined Host Attributes on page 1433.

Editing a User-Defined Host Attribute

LICENSE: FireSIGHT

When you modify an existing user-defined host attribute, you can change the definition of a value, but you cannot change the attribute type (text, list, integer, URL). In addition, you **cannot** modify compliance white list host attributes.

To edit an existing user-defined host attribute:

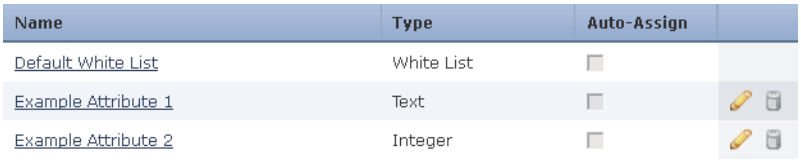
Access: Admin/Discovery Admin

1. Select **Analysis > Hosts > Host Attributes**.

   The Host Attributes page appears.

2. Click **Host Attribute Management**.

   The Host Attribute Management page appears.



3. Click the edit icon ( ) next to the host attribute you want to edit.

   The host attribute page appears with the selected attribute's settings.

4. Modify any of the settings that you want and click **Save**.

   See Creating User-Defined Host Attributes on page 1436 for more information about the attribute types that you can edit and the values those attributes can contain.

Deleting a User-Defined Host Attribute

License: FireSIGHT

Delete a user-defined host attribute to remove it from every host profile where it is used. Note that you **cannot** delete compliance white list host attributes.

To delete a host attribute:

Access: Admin/Discovery Admin

1. Select **Analysis > Hosts > Host Attributes**.

   The Host Attributes page appears.

2. Click **Host Attribute Management**.

   The Host Attribute Management page appears.

3. Click the delete icon ( ) next to the host attribute you want to delete.

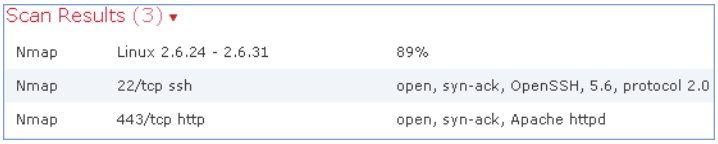
   The selected host attribute is removed from the system.

Working with Scan Results in a Host Profile

License: FireSIGHT

When you scan a host using Nmap, or when you import results from an Nmap scan, those results appear in the host profile for any hosts included in the scan.

The information that Nmap collects about the host operating system and any servers running on open unfiltered ports is added directly into the Operating System and Servers sections of the host profile, respectively. In addition, Nmap adds a list of the scan results for that host in the Scan Results section.



Each result indicates the source of the information, the number and type of the scanned port, the name of the server running on the port, and any additional information detected by Nmap, such as the state of the port or the vendor name for the server. If you scan for UDP ports, servers detected on those ports only appear in the Scan Results section.

Note that you can run an Nmap scan from the host profile. For more information, see the next section, Scanning a Host from the Host Profile.

Scanning a Host from the Host Profile

License: FireSIGHT

You can perform a Nmap scan against a host from the host profile. After the scan completes, server and operating system information for that host are updated in the host profile. Any additional scan results are added to the Scan Results section of the host profile.

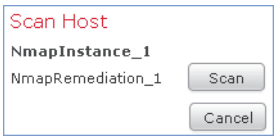
WARNING! Nmap-supplied server and operating system data remains static until you run another Nmap scan or override it with higher priority host input. If you plan to scan a host using Nmap, you may want to set up regularly scheduled scans to keep Nmap-supplied operating system and server data up to date. For more information, see Automating Nmap Scans on page 2013.

To scan a host from the host profile:

Access: Admin

1. In the host profile, click **Scan Host**.

   The Scan Host pop-up window appears.



2. Click **Scan** next to the scan remediation you want to use to scan the host.

   The host is scanned and the results are added to the host profile.

CHAPTER 35
WORKING WITH DISCOVERY EVENTS

Discovery events alert you to the activity on your network and provide you with the information you need to respond appropriately. They are triggered by the changes that your managed devices detect in the network segments they monitor. Your *network discovery policy* specifies the kinds of data the system collects, the monitored network segments, and the specific hardware interfaces that your system uses to monitor traffic. For more information on network discovery, see Understanding Discovery Data Collection on page 1304.

As a simple example of a discovery event, you may have conference rooms or spare work spaces where visiting employees attach to your network. You would expect to see New Host events generated on these segments on a regular basis, and you would not suspect malicious intent. However, if you see a New Host event on a network segment that is locked down, then you can escalate your response accordingly.

User discovery events provide information about users logged into the hosts on your network. You can view events that catalog user activity on the network and drill down to view information on a particular user. For example, if you want to see what user is associated with a new host, you can check the host profile to find out what users have been detected in traffic going to or from that host.

Discovery events provide you with much greater depth of insight into the activity on your network and with much more granularity than this simple example shows. For each monitored host, you can configure the system to detect related application protocols, network protocols, clients, users, and potential vulnerabilities. The system can also provide information on vulnerabilities detected by third-party scanners that you import onto the Defense Center using the host input feature. Indications of compromise (IOC) use intrusion, malware, and other data to identify hosts whose security may be compromised. In addition,

you can track any changes in host criticality, host attribute, or vulnerability settings that users enter via the user interface.

The system provides a set of predefined workflows that you can use to analyze the discovery events that your system generates. You can also create custom workflows that display only the information that matches your specific needs.

To collect and store network discovery data for analysis, make sure that your network discovery policy is configured to discover the appropriate data on the networks and zones where your Sourcefire-managed devices and NetFlow-enabled devices monitor traffic. To exclude monitored areas from discovery, configure that in the network discovery policy. Note that an access control policy must be applied to the managed device before you can apply a network discovery policy. For more information, see Creating a Network Discovery Policy on page 1332.

For more information, see:

Viewing Discovery Event Statistics

License: FireSIGHT

The Discovery Statistics Summary page displays a summary of the hosts, events, protocols, application protocols, and operating systems detected by the system:

- The statistics summary provides general statistics about the total events, application protocols, hosts, network devices, and information about your host limit usage; see Statistics Summary on page 1443.
- The event breakdown provides statistics about the types of events occurring on the system; see Event Breakdown on page 1445.

- The protocol breakdown provides statistics about the protocols that detected hosts are using. See Protocol Breakdown on page 1446.
- The application protocol breakdown provides statistics about the application protocols running on the network; see Application Protocol Breakdown on page 1446.
- The operating system breakdown lists the operating systems that are running on the network and how many hosts are using each operating system; see OS Breakdown on page 1447.

The page lists statistics for the last hour and the total accumulated statistics. You can select statistics for a particular device, or all devices. You can also view events that match the entries on the page by clicking the event, server, operating system, or operating system vendor listed within the summary.

To view the Event Statistics Summary:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Summary > Discovery Statistics**.

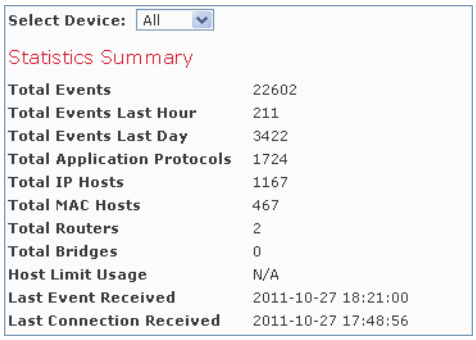
   The statistics summary page appears.

2. From the **Select Device** list, select the device whose statistics you want to view. Select **All** to view statistics for all devices managed by the Defense Center.

Statistics Summary

LICENSE: FireSIGHT

The statistics summary provides general statistics about the total events, application protocols, hosts, network devices, and information about your host limit usage.



Descriptions of the rows of the Statistics Summary section follow.

Total Events

Total number of discovery events stored on the Defense Center.

Total Events Last Hour

Total number of discovery events generated in the last hour.

Total Events Last Day

Total number of discovery events generated in the last day.

Total Application Protocols

Total number of application protocols from servers running on detected hosts.

Total IP Hosts

Total number of detected hosts identified by unique IP address.

Total MAC Hosts

Total number of detected hosts not identified by IP address.

Note that the Total MAC Hosts statistic remains the same whether you are viewing discovery statistics for all devices or for a specific device. This is so because managed devices discover hosts based on their IP addresses. This statistic gives the total of all hosts that are identified by other means and is independent of a given managed device.

Total Routers

Total number of detected nodes identified as routers.

Total Bridges

Total number of detected nodes identified as bridges.

Host Limit Usage

Total percentage of the host limit currently in use. The host limit is defined by your FireSIGHT license. Note that the host limit usage only appears if you are viewing statistics for all managed devices. For more information on monitoring host usage, see Configuring FireSIGHT Host Usage Monitoring on page 2212.

IMPORTANT! If the host limit is reached and a host is deleted, the host will not reappear on the network map until you restart network discovery on all managed devices configured to perform discovery.

Last Event Received

The date and time that the most recent discovery event occurred.

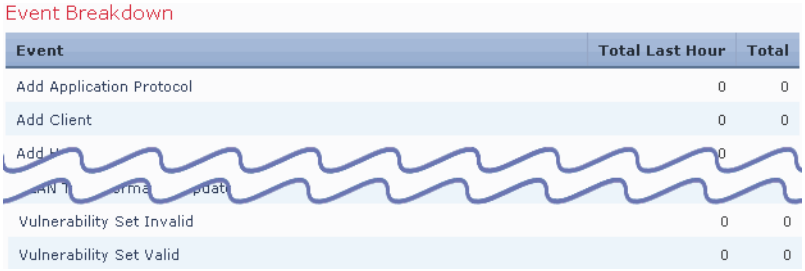
Last Connection Received

The date and time that the most recent connection was completed.

Event Breakdown

LICENSE: FireSIGHT

The Event Breakdown section lists a count of each type of network discovery and host input event that occurred within the last hour, as well as a count of the total number of each event type stored in the database. For full descriptions of each event type, see Understanding Discovery Event Types on page 1453 and Understanding Host Input Event Types on page 1458.



Event Breakdown

Event	Total Last Hour	Total
Add Application Protocol	0	0
Add Client	0	0
Add H	0	
[illegible]		
Vulnerability Set Invalid	0	0
Vulnerability Set Valid	0	0

You can also use the Event Breakdown section to view details on discovery and host input events.

To view network discovery and host input events by type:

ACCESS: Admin/Any Security Analyst

- Click the type of event you want to view.

  The first page of the default discovery events workflow appears, constrained by the event type you picked. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. If no events appear, you may need to adjust the time range; see Setting Event Time Constraints on page 1896.

  For information on working with discovery events, see Working with Discovery and Host Input Events on page 1452.

Protocol Breakdown

LICENSE: FireSIGHT

The Protocol Breakdown section lists the protocols currently in use by detected hosts. It displays each detected protocol name, its "layer" in the protocol stack, and the total number of hosts that communicate using the protocol.

Protocol Breakdown

Protocol	Layer	Total
IP	Network	1167
tcp	Transport	1002
udp	Transport	854
ARP	Network	542
icmp	Transport	431
igmp	Transport	308
sctp	Transport	1

Application Protocol Breakdown

LICENSE: FireSIGHT

The Application Protocol Breakdown section lists the application protocols that are currently in use by detected hosts. It lists the protocol name, the total number of hosts running the application protocol in the past hour, and the total number of hosts that have been detected running the protocol at any point.

Application Protocol Breakdown

Application	Total Last Hour	Total
Unknown	0	1044
SSH	26	324
SSL	4	177
[illegible]	[illegible]	[illegible]
Active Directory	[illegible]	1
Tivoli	0	1
1000008	0	1

You can also use the Application Protocol Breakdown section to view details on servers using the detected protocols.

To view servers that use a listed application protocol:

ACCESS: Admin/Any Security Analyst

- Click the name of the application protocol you want to view.

  The first page of the default servers workflow appears, constrained by the application protocol you picked. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

  For information on working with servers, see Working with Servers on page 1486.

OS Breakdown

LICENSE: FireSIGHT

The OS Breakdown section lists the operating systems currently running on the monitored network, along with their vendors and the total number of hosts running each operating system.

A value of **unknown** for the operating system name or version means that the operating system or its version does not match any of the system's fingerprints. A value of **pending** means that the system has not yet gathered enough information to identify the operating system or its version.

OS Breakdown

OS Name	OS Vendor	Total
Linux	Linux	539
pending	pending	261
AIX	IBM	131
Mac OS X	Apple	130
Windows	Microsoft	120
unknown	unknown	105
FreeBSD	FreeBSD	11
OpenBSD	OpenBSD	2
Linux	Debian	1

You can use the OS Breakdown section to view details on the detected operating systems.

To view hosts by operating system or vendor:

ACCESS: Admin/Any Security Analyst

▶ You have two options:

- To view all hosts running a specific operating system, under **OS Name**, click the operating system name.
- To view all hosts running any operating system from a specific vendor, under **OS Vendor**, click the vendor name.

The first page of the default hosts workflow appears, constrained by the operating system or vendor you picked. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

For information on working with hosts, see Working with Hosts on page 1465.

Viewing Discovery Performance Graphs

LICENSE: FireSIGHT

You can generate graphs that display performance statistics for managed devices with discovery events.

IMPORTANT! New data is accumulated for statistics graphs every five minutes. Therefore, if you reload a graph quickly, the data may not change until the next five-minute increment occurs.

Descriptions of the available graph types follow.

Processed Events/Sec

Displays a graph that represents the number of events that the Data Correlator processes per second

Processed Connections/Sec

Displays a graph that represents the number of connections that the Data Correlator processes per second

Generated Events/Sec

Displays a graph that represents the number of events that the system generates per second

Mbits/Sec

Displays a graph that represents the number of megabits of traffic that are analyzed by the discovery process per second

Avg Bytes/Packet

Displays a graph that represents the average number of bytes included in each packet analyzed by the discovery process

K Packets/Sec

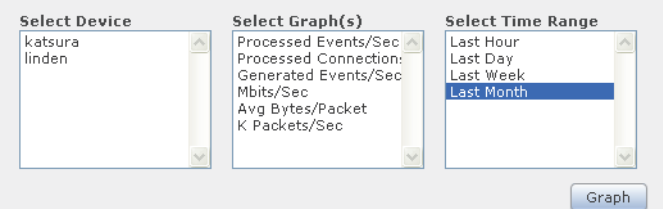
Displays a graph that represents the number of packets analyzed by the discovery process per second, in thousands

To generate discovery performance graphs:

Access: Admin/Maint

1. Select **Overview > Summary > Discovery Performance.**

   The Discovery Performance page appears.



2. From the **Select Device** list, select the Defense Center or managed devices you want to include.

   Depending on which appliance you select, the **Select Graph(s)** list adjusts to display the available graphs.

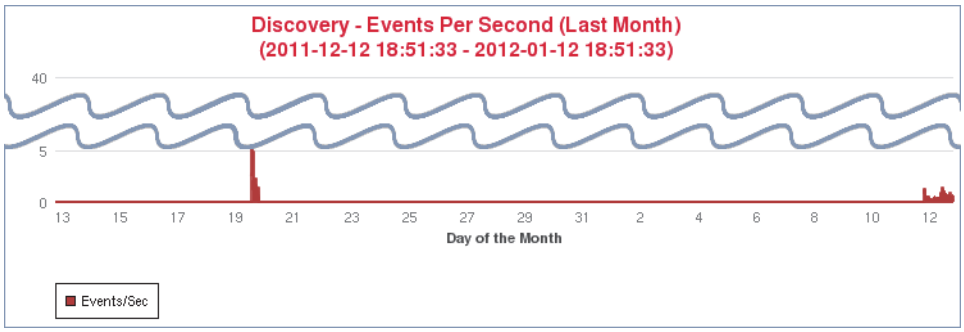
3. From the **Select Graph(s)** list, select the type of graph you want to create.

   TIP! You can select multiple graphs by holding down the Ctrl or Shift keys while clicking on the graph type.

4. From the **Select Time Range** list, select the time range you would like to use for the graph. You can choose from last hour, last day, last week, or last month.

5. Click **Graph** to graph the selected statistics.

   The selected graph appears.



Understanding Discovery Event Workflows

LICENSE: FireSIGHT

The Defense Center provides a set of workflows that you can use to analyze the discovery events that are generated for your network. The workflows are, along with the network map, a key source of information about your network assets. These workflows contain tables that are populated with discovery data generated by the system.

Access network discovery workflows from the **Analysis > Hosts** menu. The Defense Center provides predefined workflows for discovery events, as well as for detected hosts and their host attributes, servers, applications, application details, vulnerabilities, user activities, and users. You can also create custom workflows. For more information on workflows, see Understanding and Using Workflows on page 1865.

TIP! Select **Analysis > Custom > Custom Tables** to access workflows based on custom tables.

When you are using a network discovery workflow, you can perform many common actions, whatever the type of event. These common functions are described in the Common Discovery Event Actions table.

Common Discovery Event Actions

To...	You can...
view the host profile for an IP address	click the host profile icon ( ) or, for hosts with active indications of compromise (IOC) tags, the compromised host icon ( ) that appears next to the IP address. For information on IOC, see Working with Indications of Compromise on page 1482.
view user profile information	click the user icon ( ) that appears next to the user identity. For more information, see Understanding User Details and Host History on page 1518.
sort data	click the column title. Click the column title again to reverse the sort order.
drill down to the next page in the workflow	use one of the following methods: • To drill down to the next workflow page constraining on a specific value, click a value within a row. Note that this only works on drill-down pages. Clicking a value within a row in a table view only constrains the table view and does not drill down to the next page. • To drill down to the next workflow page constraining on some events, select the check boxes next to the events you want to view on the next workflow page, then click **View**. • To drill down to the next workflow page keeping the current constraints, click **View All**. **TIP!** Table views always include "Table View" in the page name. For more information, see Constraining Events on page 1905.
constrain the columns that appear	click the close icon (✖) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**. **TIP!** To hide or show other columns, Select or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, click the expand arrow to expand the search constraints, then click the column name under Disabled Columns.
navigate within the current workflow page	find more information in Navigating to Other Pages in the Workflow on page 1911.

Common Discovery Event Actions (Continued)

To...	You can...
navigate between pages in the current workflow, keeping the current constraints	click the appropriate page link at the top left of the workflow page. For more information, see Using Workflow Pages on page 1889.
delete items from the system, including: • discovery and host input events from discovery event workflows • hosts and network devices from host workflows • host attributes from host attribute workflows • servers from server workflows • applications from application workflows • third-party vulnerabilities from third-party vulnerability workflows • users from user workflows	use one of the following methods: • To delete some items, select the check boxes next to items you want to delete, then click **Delete**. • To delete all items in the current constrained view, click **Delete All**, then confirm you want to delete all the items. These items remain deleted until the system's discovery function is restarted, when they may be detected again. **TIP!** See Purging Discovery Data from the Database on page 2319 for information on deleting all discovery events from the database and also for information on how to restart discovery. Note that you **cannot** delete Sourcefire (as opposed to third-party) vulnerabilities; you can, however, mark them reviewed. For more information, see Working with Sourcefire Vulnerabilities on page 1503.
navigate to other event views to view associated events	find more information in Navigating Between Workflows on page 1911.

Working with Discovery and Host Input Events

License: FireSIGHT

The system generates discovery events that communicate the details of changes in your monitored network segments. *New* events are generated for newly discovered network features, and change events are generated for any change in previously identified network assets.

During its initial network discovery phase, the system generates new events for each host and any TCP or UDP servers discovered running on each host. Optionally, you can configure the system to use data exported by NetFlow-enabled devices to generate these new host and server events.

In addition, the system generates new events for each network, transport, and application protocol running on each discovered host. When you create a discovery rule configured to include NetFlow-enabled devices, you can disable detection of application protocols. However, you cannot disable application detection in discovery rules that do not use a configured NetFlow-enabled device. If you enable host or user discovery in non-NetFlow discovery rules, applications are automatically discovered.

After the initial network mapping is complete, the system continuously records network changes by generating change events. Change events are generated whenever the configuration of a previously discovered asset changes.

When a discovery event is generated, it is logged to the database. You can use the Defense Center web interface to view, search, and delete discovery events.You can also use discovery events in correlation rules. Based on the type of discovery event generated as well as other criteria that you specify, you can build correlation rules that, when used in a correlation policy, launch remediations and syslog, SNMP, and email alert responses when network traffic meets your criteria.

You can add data to the network map using the host input feature. You can add, modify, or delete operating system information, which causes the system to stop updating that information for that host. You can also manually add, modify, or delete application protocols, clients, servers, and host attributes or modify vulnerability information. When you do this, the system generates host input events.

See the following sections for more information:

- Understanding Discovery Event Types on page 1453
- Understanding Host Input Event Types on page 1458
- Viewing Discovery and Host Input Events on page 1460
- Understanding the Discovery Events Table on page 1461
- Searching for Discovery Events on page 1463

Understanding Discovery Event Types

License: FireSIGHT

There are many types of discovery events. For example, the system generates and logs a New Host event when it detects a new host on your monitored network segment. When you view a table of discovery events, the event type is listed in the **Event** column. For more information, see Viewing Discovery and Host Input Events on page 1460.

Contrast discovery events, which are generated when the system detects a change in your monitored network (such as detecting traffic from a previously undetected host), with host input events, which are generated when a user takes a specific action (such as manually adding a host). For more information on host input events, see Understanding Host Input Event Types on page 1458.

You can configure the types of discovery events the system logs by modifying your network discovery policy. By default, the system logs all types of discovery events. For more information, see Configuring Database Event Limits on page 2056.

If you understand the information the different types of discovery events provide, you can more effectively determine which events you want to log and alert on, and how to use these alerts in correlation policies. In addition, knowing the

names of the event types can help you craft more effective event searches. Descriptions of the different types of discovery events follow.

Additional MAC Detected for Host

This event is generated when the system detects a new MAC address for a previously discovered host.

This event is often generated when the system detects hosts passing traffic through a router. While each host has a different IP address, they all appear to have the MAC address associated with the router. When the system detects the actual MAC address associated with the IP address, it displays the MAC address in bold text within the host profile and displays an "ARP/DHCP detected" message within the event description in the event view.

Client Timeout

This event is generated when the system drops a client from the database due to inactivity.

Client Update

This event is generated when the system detects a payload (that is, a specific type of content, such as audio, video, or webmail) in HTTP traffic.

DHCP: IP Address Changed

This event is generated when the system detects that a host IP address has changed due to DHCP address assignment.

DHCP: IP Address Reassigned

This event is generated when a host is reusing an IP address; that is, when a host obtains an IP address formerly used by another physical host due to DHCP IP address assignment.

Hops Change

This event is generated when the system detects a change in the number of network hops between a host and the device that detects the host.

This may happen if the device sees host traffic through different routers and is able to make a better determination of the host's location. This may also happen if the device detects an ARP transmission from the host, indicating that the host is on a local segment.

Host Deleted: Host Limit Reached

This event is generated when the host limit on the Defense Center is exceeded and a monitored host is deleted from the Defense Center's network map.

Host Dropped: Host Limit Reached

This event is generated when the host limit on the Defense Center is reached and a new host is dropped. Compare this with the previous event where old hosts are deleted from the network map when the host limit is reached.

To drop new hosts when the host limit is reached, go to **Policies > Network Discovery > Advanced** and set **When Host Limit Reached** to **Drop hosts**. See Configuring Data Storage on page 1352 for more information.

Host Indications of Compromise Set

This event is generated when an Indication of Compromise (IOC) occurs on a host.

Host Timeout

This event is generated when a host is dropped from the network map because the host has not produced traffic within the interval defined in the network discovery policy. Note that individual host IP addresses and MAC addresses time out individually; a host does not disappear from the network map unless all of its associated addresses have timed out. See Configuring Data Storage on page 1352 for information about configuring the host timeout value.

If you change the networks you want to monitor in your network discovery policy, you may want to manually delete old hosts from the network map so that they do not count against your FireSIGHT license. For more information, see Working with the Hosts Network Map on page 1375.

Host Type Changed to Network Device

This event is generated when the system detects that a detected host is actually a network device.

Identity Conflict

This event is generated when the system detects a new server or operating system identity that conflicts with a current active identity for that server or operating system.

If you want to resolve identity conflicts by rescanning the host to obtain newer active identity data, you can use Identity Conflict events to trigger an Nmap remediation. For more information, see Configuring Nmap Remediations on page 1694.

For more information, see Understanding Identity Conflicts on page 1719 and Configuring Identity Conflict Resolution on page 1347. For information on manually resolving conflicts, see Resolving Operating System Identity Conflicts on page 1410 and Resolving Server Identity Conflicts on page 1417.

Identity Timeout

This event is generated when identity data that was added to the network map through an active source times out.

If you want to refresh identity data by rescanning the host to obtain newer active identity data, you can use Identity Conflict events to trigger an Nmap remediation. For more information, see Configuring Nmap Remediations on page 1694.

For more information, see Resolving Server Identity Conflicts on page 1417.

MAC Information Change

This event is generated when the system detects a change in the information associated with a specific MAC address or TTL value.

This event often occurs when the system detects hosts passing traffic through a router. While each host has a different IP address, they will all appear to have the MAC address associated with the router. When the system detects the actual MAC address associated with the IP address, it displays the MAC address in bold text within the host profile and displays an "ARP/DHCP detected" message within the event description in the event view. The TTL may change because the traffic may pass through different routers or if the system detects the actual MAC address of the host.

NETBIOS Name Change

This event is generated when the system detects a change to a host's NetBIOS name. This event will only be generated for hosts using the NetBIOS protocol.

New Client

This event is generated when the system detects a new client.

IMPORTANT! To collect and store client data for analysis, make sure that you enable application detection in your discovery rules in the network discovery policy. For more information, see Understanding Application Detection on page 1316.

New Host

This event is generated when the system detects a new host running on the network.

If you select the **Discover** option and select **Hosts** in a network discovery rule where a NetFlow device is selected, this event is also generated when a device processes NetFlow data that involves a new host.

New Network Protocol

This event is generated when the system detects that a host is communicating with a new network protocol (IP, ARP, and so on).

New OS

This event is generated when the system either detects a new operating system for a host, or a change in a host's operating system.

New TCP Port

This event is generated when the system detects a new TCP server port (for example, a port used by SMTP or web services) active on a host. Note that this event is not used to identify the application protocol or the server associated with it; that information is transmitted in the TCP Server Information Update event.

If you select the **Discover** option and select **Applications** in a network discovery rule for NetFlow data, this event is also generated when a device processes NetFlow data involving a server on your monitored networks that does not already exist in the network map.

New Transport Protocol

This event is generated when the system detects that a host is communicating with a new transport protocol, such as TCP or UDP.

New UDP Port

This event is generated when the system detects a new UDP server port running on a host.

If you select the **Discover** option and select **Applications** in a network discovery rule for NetFlow data, this event is also generated when a device processes NetFlow data involving a server on your monitored networks that does not already exist in the network map.

TCP Port Closed

This event is generated when the system detects that a TCP port has closed on a host.

TCP Port Timeout

This event is generated when the system has not detected activity from a TCP port within the interval defined in the system's network discovery policy. See Configuring Data Storage on page 1352 for information about configuring the server timeout value.

TCP Server Information Update

This event is generated when the system detects a change in a discovered TCP server running on a host.

This event may be generated if a TCP server is upgraded.

UDP Port Closed

This event is generated when the system detects that a UDP port has closed on a host.

UDP Port Timeout

This event is generated when the system has not detected activity from a UDP port within the interval defined in the network discovery policy. See Configuring Data Storage on page 1352 for information about configuring the server timeout value.

UDP Server Information Update

This event is generated when the system detects a change in a discovered UDP server running on a host.

This event may be generated if a UDP server is upgraded.

VLAN Tag Information Update

This event is generated when the system detects a change in the VLAN tag attributed to a host. For more information about VLAN tags, see Working with VLAN Tags in the Host Profile on page 1421.

Understanding Host Input Event Types

LICENSE: FireSIGHT

There are many types of host input events. For example, the system generates and logs an Add Host event when a user adds a host using the host import feature. When you view a table of discovery events, the event type is listed in the **Event** column. For more information, see Viewing Discovery and Host Input Events on page 1460.

Contrast host input events, which are generated when a user takes a specific action (such as manually adding a host), with discovery events, which are generated when the system itself detects a change in your monitored network (such as detecting traffic from a previously undetected host). For more information on host input events, see Understanding Discovery Event Types on page 1453.

You can configure the types of host input events that the system logs by modifying your network discovery policy. By default, the system logs all types of host input events. For more information, see Configuring Database Event Limits on page 2056.

If you understand the information the different types of host input events provide, you can more effectively determine which events you want to log and alert on, and how to use these alerts in correlation policies. In addition, knowing the names of the event types can help you craft more effective event searches. Descriptions of the different types of host input events follow.

Add Client

This event is generated when a user adds a client.

Add Host

This event is generated when a user adds a host.

Add Protocol

This event is generated when a user adds a protocol.

Add Scan Result

This event is generated when the system adds the results of an Nmap scan to a host.

Add Port

This event is generated when a user adds a server port.

Delete Client

This event is generated when a user deletes a client from the system.

Delete Host/Network

This event is generated when a user deletes an IP address or subnet from the system.

Delete Protocol

This event is generated when a user deletes a protocol from the system.

Delete Port

This event is generated when a user deletes a server port or group of server ports from the system.

Host Attribute Add

This event is generated when a user creates a new host attribute.

Host Attribute Delete

This event is generated when a user deletes a user-defined host attribute.

Host Attribute Delete Value

This event is generated when a user deletes a value assigned to a host attribute.

Host Attribute Set Value

This event is generated when a user sets a host attribute value for a host.

Host Attribute Update

This event is generated when a user changes the definition of a user-defined host attribute.

Set Host Criticality

This event is generated when a user sets or modifies the host criticality value for a host.

Set Operating System Definition

This event is generated when a user sets the operating system for a host.

Set Server Definition

This event is generated when a user sets the vendor and version definitions for a server.

Set Vulnerability Impact Qualification

This event is generated when a vulnerability impact qualification is set.

When a vulnerability is disabled at a global level from being used for impact qualifications, or when a vulnerability is enabled at a global level, this event is generated.

Vulnerability Set Invalid

This event is generated when a user invalidates (or reviews) a vulnerability or vulnerabilities.

Vulnerability Set Valid

This event is generated when a user validates a vulnerability that was previously marked as invalid.

Viewing Discovery and Host Input Events

LICENSE: FireSIGHT

Both discovery events and host input events can be viewed using Discovery Events workflows. Discovery events record the detection of network discovery data based on the configured network discovery policy for an appliance. Host input events record the input of host data into the network map through the host input feature. For more information, see Understanding Discovery Event Types on page 1453 and Understanding Host Input Event Types on page 1458.

You can use the Defense Center to view a table of discovery or host input events. Then, you can manipulate the event view depending on the information you are looking for.

The page you see when you access events differs depending on the workflow you use. You can use the predefined workflow, which includes the table view of discovery events and a terminating host view page. You can also create a custom workflow that displays only the information that matches your specific needs. For information on creating a custom workflow, see Creating Custom Workflows on page 1916.

The Discovery Event Actions table below describes some of the specific actions you can perform on a discovery events workflow page. You can also perform the tasks described in the Common Discovery Event Actions table on page 1451.

Discovery Event Actions

To...	You can...
modify the time and date range for displayed events	find more information in Setting Event Time Constraints on page 1896. Note that events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.
learn more about the contents of the columns in the table	find more information in Understanding the Discovery Events Table on page 1461.

To view discovery events:

Access: Admin/Any Security Analyst

- Select **Analysis > Hosts > Discovery Events**.

  The first page of the default discovery events workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. If no events appear, you may need to adjust the time range; see Setting Event Time Constraints on page 1896.

Understanding the Discovery Events Table

License: FireSIGHT

The system generates discovery events that communicate the details of changes in your monitored network segments. *New* events are generated for newly discovered network features, and change events are generated for any change in previously identified network assets.

During its initial network discovery phase, the system generates new events for each host and any TCP or UDP servers it discovers on each host. In addition, the system generates new events for each network, transport, or application protocol running on each discovered host. For NetFlow-related traffic, you can control whether the system generates new events when it detects application protocols running on a host. After the initial network mapping is complete, the system continuously records network changes by generating change events. Change events are generated whenever the configuration of a previously discovered host, server, or client changes.

Descriptions of the fields in the discovery events table follow.

Time

The time that the system generated the event.

Event

The event type. See Understanding Discovery Event Types on page 1453 and Understanding Host Input Event Types on page 1458 for a description of each available event.

IP Address

The IP address associated with the host involved in the event.

User

The last user to log into the host involved in the event before the event was generated. If only non-authoritative users log in after an authoritative user, the authoritative user remains the current user for the host unless another authoritative user logs in.

MAC Address

The MAC address of the NIC used by the network traffic that triggered the discovery event. This MAC address can be either the actual MAC address of the host involved in the event, or the MAC address of a network device that the traffic passed through.

MAC Vendor

The MAC hardware vendor of the NIC used by the network traffic that triggered the discovery event.

Port

The port used by the traffic that triggered the event, if applicable.

Description

The text description of the event.

Device

The name of the device that generated the event. For new host and new server events based on NetFlow data, this is the device that processed the NetFlow data.

Searching for Discovery Events

LICENSE: FireSIGHT

You can search for specific discovery events. You may want to create searches customized for your network environment, then save them to reuse later.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.
- IP addresses may be specified using CIDR notation.
- Click the add object icon ( ) that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

Special Search Syntax for Discovery Events

The following table notes search information specific to particular discovery event fields. For more information on discovery event fields, see Understanding the Hosts Table on page 1467.

Discovery Event Search Criteria Notes

Field	Search Criteria Notes
Event	The range of event names is listed in Understanding Discovery Event Types on page 1453 and Understanding Host Input Event Types on page 1458
MAC Vendor	To search for virtual MAC vendors, that is, for events that involve virtual machines, type `virtual_mac_vendor`. To search for a vendor whose name includes a comma, enclose the entire search term in quotes. Otherwise, the Defense Center treats the term as two searches and returns events that match each search term.
Port	Note that you cannot: • enter a port/protocol combination as you can when searching for other kinds of events • use spaces when specifying port numbers or ranges.

To search for discovery events:

Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Discovery Events**.

   The page reloads with the appropriate constraints.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields, as described in General Search Syntax on page 1463 and Special Search Syntax for Discovery Events on page 1464.

   If you enter multiple criteria, the search returns only the records that match all the criteria. Click the add icon ( ) that appears next to a search field to use an object as a search criterion.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

   If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in the default discovery events workflow, constrained by the current time range. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**) so that you can run it at a later time.

Working with Hosts

License: FireSIGHT

The system generates an event when it detects a host and collects information about it to build the host profile. You can use the Defense Center web interface to view, search, and delete hosts.

While viewing hosts, you can create traffic profiles and compliance white lists based on selected hosts. You can also assign host attributes, including host criticality values (which designate business criticality) to groups of hosts. You can then use these criticality values, white lists, and traffic profiles within correlation rules and policies.

Although you can configure the network discovery policy to add hosts to the network map based on data exported by NetFlow-enabled devices, the available information about these hosts is limited. For example, there is no operating system data available for these hosts, unless you provide it using the host input feature. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

For more information, see the following sections:

- Viewing Hosts on page 1466
- Understanding the Hosts Table on page 1467
- Creating a Traffic Profile for Selected Hosts on page 1471
- Creating a Compliance White List Based on Selected Hosts on page 1472
- Searching for Hosts on page 1472
- Setting Host Attributes for Selected Hosts on page 1479

Viewing Hosts

LICENSE: FireSIGHT

You can use the Defense Center to view a table of hosts that the system has detected. Then, you can manipulate the view depending on the information you are looking for.

The page you see when you access hosts differs depending on the workflow you use. Both predefined workflows terminate in a host view, which contains a host profile for every host that meets your constraints. You can also create a custom workflow that displays only the information that matches your specific needs. For more information, see Creating Custom Workflows on page 1916.

The Host Actions table below describes some of the specific actions you can perform on an hosts workflow page. You can also perform the tasks described in the Common Discovery Event Actions table on page 1451.

Host Actions

TO...	YOU CAN...
learn more about the contents of the columns in the table	find more information in Understanding the Hosts Table on page 1467.
assign a host attribute to selected hosts	find more information in Setting Host Attributes for Selected Hosts on page 1479.
create traffic profiles for selected hosts	find more information in Creating a Traffic Profile for Selected Hosts on page 1471.
create a compliance white list based on selected hosts	find more information in Creating a Compliance White List Based on Selected Hosts on page 1472.

To view hosts:

ACCESS: Admin/Any Security Analyst

- Select **Analysis > Hosts > Hosts**.

  The first page of the default hosts workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

TIP! If you are using a custom workflow that does not include the table view of hosts, click **(switch workflow)**, then select **Hosts**.

Understanding the Hosts Table

LICENSE: FireSIGHT

When the system discovers a host, it collects data about that host. That data can include the host's IP addresses, the operating system it is running, and more. You can view some of that information in the table view of hosts. For more information on the data that the system collects about detected hosts, see Using Host Profiles on page 1394.

Descriptions of the fields in the hosts table follow below.

Although you can configure the network discovery policy to add hosts to the network map based on data exported by NetFlow-enabled devices, the available information about these hosts is limited. For example, there is no operating system data available for these hosts, unless you provide it using the host input feature. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

Last Seen

The date and time any of the host's IP addresses was last detected by the system. The Last Seen value is updated at least as often as the update interval you configured in the network discovery policy, as well as when the system generates a new host event for any of the host's IP addresses.

For hosts with operating system data updated using the host input feature, the Last Seen value indicates the date and time when the data was originally added.

IP Address

The IP addresses associated with the host.

MAC Address

The host's detected MAC address of the NIC.

The MAC Address field appears in the Table View of Hosts, which you can find in the Hosts workflow. You can also add the MAC Address field to:

- custom tables that include fields from the Hosts table
- drill-down pages in custom workflows based on the Hosts table

MAC Vendor

The host's detected MAC hardware vendor of the NIC.

The MAC Vendor field appears in the Table View of Hosts, which you can find in the Hosts workflow. You can also add the MAC Vendor field to:

- custom tables that include fields from the Hosts table
- drill-down pages in custom workflows based on the Hosts table

Current User

The user identity (username) of the currently logged in user on the host.

Note that when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Host Criticality

The user-specified criticality value assigned to the host. See the description of the Host Criticality column in Understanding the Host Attributes Table on page 1477 for more information about this field.

NetBIOS Name

The NetBIOS name of the host. Only hosts running the NetBIOS protocol will have a NetBIOS name.

VLAN ID

VLAN ID used by the host. For more detailed information about VLAN IDs, see Working with VLAN Tags in the Host Profile on page 1421.

Hops

The number of network hops from the device that detected the host to the host.

Host Type

The type of host (host, mobile device, jailbroken mobile device, router, bridge, NAT device, or load balancer). The methods the system uses to distinguish network devices include:

- the analysis of Cisco Discovery Protocol (CDP) messages, which can identify network devices and their type (Cisco devices only)
- the detection of the Spanning Tree Protocol (STP), which identifies a device as a switch or bridge
- the detection of multiple hosts using the same MAC address, which identifies the MAC address as belonging to a router
- the detection of TTL value changes from the client side, or TTL values that change more frequently than a typical boot time, which identify NAT devices and load balancers

If a device is not identified as a network device, it is categorized as a host.

Hardware

The hardware platform for a mobile device.

OS

The detected operating system (name, vendor, and version) running on the host, or updated using Nmap or the host input feature. This field appears when you invoke the hosts event view from the Custom Analysis widget on the dashboard. It is also a field option in custom tables based on the Hosts table.

Note if the system detects multiple identities, it displays those identities in a comma-separated list.

In this field, a value of **unknown** means that the operating system does not match any of the known fingerprints. A value of **pending** means that the system has not yet gathered enough information to identify the operating system.

OS Vendor

The vendor of the operating system detected on the host or updated using Nmap or the host input feature.

Note if the system detects multiple vendors, it displays those vendors in a comma-separated list.

In this field, a value of **unknown** means that the operating system does not match any of the known fingerprints. A value of **pending** means that the system has not yet gathered enough information to identify the operating system.

OS Name

The detected operating system running on the host or updated using Nmap or the host input feature.

Note if the system detects multiple names, it displays those names in a comma-separated list.

In this field, a value of **unknown** means that the operating system does not match any of the known fingerprints. A value of **pending** means that the system has not yet gathered enough information to identify the operating system.

OS Version

The version of the operating system detected on the host or updated using Nmap or the host input feature.

Note if the system detects multiple versions, it displays those versions in a comma-separated list.

In this field, a value of **unknown** means that the operating system does not match any of the known fingerprints. A value of **pending** means that the system has not yet gathered enough information to identify the operating system.

Source Type

One of the following values for the source of the host's operating system identity:

- User: *user_name*
- Application: *app_name*
- Scanner: *scanner_type* (Nmap or scanner added through network discovery configuration)
- FireSIGHT, for operating systems detected by the system

The system may reconcile data from multiple sources to determine the identity of an operating system; see Understanding Current Identities on page 1718.

Confidence

One of:

- the percentage of confidence that the system has in the identity of the operating system running on the host, for hosts detected by the system
- 100%, for operating systems identified by an active source, such as the host input feature or Nmap scanner
- **unknown**, for hosts for which the system cannot determine an operating system identity, and for hosts added to the network map based on NetFlow data

Notes

The user-defined content of the Notes host attribute.

Device

Either:

- the managed device that detected the traffic or
- the device that processed the NetFlow or host input data that added the host to the network map

If this field is blank, either:

- the host was added to the network map by a device that is not explicitly monitoring the network where the host resides, as defined in the network discovery policy, or
- the host was added using the host input feature and has not also been detected by the system

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Creating a Traffic Profile for Selected Hosts

License: FireSIGHT

A traffic profile is a profile of the traffic on your network, based on connection data collected over a timespan that you specify. After you create a traffic profile, you can detect abnormal network traffic by evaluating new traffic against your profile, which presumably represents normal network traffic.

You can use the Hosts page to create a traffic profile for a group of hosts that you specify. The traffic profile will be based on connections detected where one of the hosts you specify is the initiating host. Use the sort and search features to isolate the hosts for which you want to create a profile.

To create a traffic profile for selected hosts:

Access: Admin

1. On a table view in the hosts workflow, select the check boxes next to the hosts for which you want to create a traffic profile.
2. At the bottom of the page, click **Create Traffic Profile**.

   The Create Profile page appears, populated with the IP addresses of the hosts you specified as the hosts to be monitored.

3. Modify and save the traffic profile according to your specific needs.

   For more information on creating traffic profiles, see Creating Traffic Profiles on page 1656.

Creating a Compliance White List Based on Selected Hosts

License: FireSIGHT

Compliance white lists allow you to specify which operating systems, clients, and network, transport, or application protocols are allowed on your network.

You can use the Hosts page to create a compliance white list based on the host profiles of a group of hosts that you specify. Use the sort and search features to isolate the hosts that you want to use to create a white list.

To create a compliance white list based on selected hosts:

Access: Admin

1. On a table view in the hosts workflow, select the check boxes next to the hosts for which you want to create a white list.
2. At the bottom of the page, click **Create White List**.

   The Create White List page appears, populated with the information in the host profiles of the hosts you specified.
3. Modify and save the white list according to your specific needs.

   For more information on creating compliance white lists, see Creating Compliance White Lists on page 1612.

Searching for Hosts

License: FireSIGHT

You can search for specific hosts by using one of the predefined searches or by using your own search criteria.

When searching for hosts, you should keep in mind that although you can configure the network discovery policy to add hosts to the network map based on data exported by NetFlow-enabled devices, the available information about these hosts is limited. For example, there is no operating system data available for these hosts, unless you provide it using the host input feature. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

You can search for specific discovery events. You may want to create searches customized for your network environment, then save them to reuse later.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.
- IP addresses may be specified using CIDR notation. For information on entering IP addresses in the Sourcefire 3D System, see IP Address Conventions on page 63.

> **IMPORTANT!** When you search for hosts by IP address, the results include all hosts for which at least one IP address matches your search conditions, that is, a search for an IPv6 address may return hosts whose primary address is IPv4.

- When you search hosts by IP address,
- Click the add object icon () that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

Special Search Syntax for Hosts

The following table notes search information specific to particular host fields. For more information on host fields, see Understanding the Hosts Table on page 1467.

Host Search Criteria

Field	Search Criteria Notes
Host Type	To search for all network devices, type `!host`.
MAC Vendor	To search for virtual MAC vendors, that is, for events that involve virtual machines, type `virtual_mac_vendor`. To search for a vendor whose name includes a comma, enclose the entire search term in quotes. Otherwise, the Defense Center treats the term as two searches and returns events that match each search term.
OS Vendor/Name/ Version	Type `unknown` to search for hosts where the operating system is unknown. Type `n/a` to search for hosts where the operating system has not yet been identified.
Confidence	You can precede the confidence with greater than (>), greater than or equal to (>=), less than (<), less than or equal to (<=), or equal to (=) operators. Matches to an `n/a` search include hosts added to the network map based on NetFlow data.
OS Conflict	Note that the OS Conflict column does not appear in search results. To determine whether you are viewing hosts with or without operating system conflicts, expand the search constraints on the workflow page. For more information on resolving operating system conflicts, see Resolving Operating System Identity Conflicts on page 1410.

For more information on searching, including how to load and delete saved searches, see Searching for Events on page 1842.

To search for hosts:

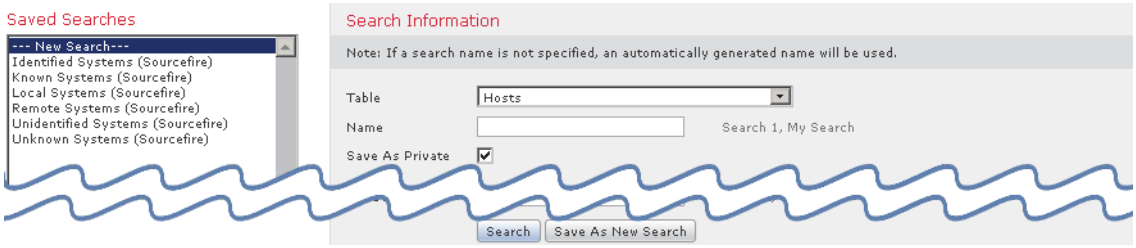
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Hosts**.

   The page reloads with the appropriate constraints.



TIP! To search the database for a different kind of event, select it from the **Table** drop-down list.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, the Defense Center automatically creates one when you save the search.

4. Enter your search criteria in the appropriate fields, as described in the Host Search Criteria table. If you enter multiple criteria, the Defense Center returns only the records that match all the criteria. Click the add icon ( ) that appears next to a search field to use an object as a search criterion.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search so that only you can use it.

TIP! If you want to save a search as a restriction for custom user roles with restricted privileges, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in the default hosts workflow. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

Working with Host Attributes

LICENSE: FireSIGHT

The Sourcefire 3D System collects information about the hosts it detects and uses that information to build host profiles. However, there may be additional information about the hosts on your network that you want to provide to your analysts. You can add notes to a host profile, set the business criticality of a host, or provide any other information that you choose. Each piece of information is called a host attribute.

You can use host attributes in host profile qualifications, which constrain the data you collect while building a traffic profile, and also can limit the conditions under which you want to trigger a correlation rule. You can also set attribute values in response to a correlation rule.

For more information, see:

- Viewing Host Attributes on page 1476
- Understanding the Host Attributes Table on page 1477
- Setting Host Attributes for Selected Hosts on page 1479
- Searching for Host Attributes on page 1480
- Configuring Set Attribute Remediations on page 1700

Viewing Host Attributes

LICENSE: FireSIGHT

You can use the Defense Center to view a table of hosts detected by the system, along with their host attributes. Then, you can manipulate the view depending on the information you are looking for.

The page you see when you access host attributes differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of host attributes that lists all detected hosts and their attributes, and terminates in a host view page, which contains a host profile for every host that meets your constraints.

You can also create a custom workflow that displays only the information that matches your specific needs. For information on creating a custom workflow, see Creating Custom Workflows on page 1916.

The Host Attribute Actions table below describes some of the specific actions you can perform on a host attributes workflow page. You can also perform the tasks described in the Common Discovery Event Actions table on page 1451.

Host Attribute Actions

To...	You can...
learn more about the contents of the columns in the table	find more information in Understanding the Host Attributes Table on page 1477.
assign a host attribute to selected hosts	find more information in Setting Host Attributes for Selected Hosts on page 1479

To view host attributes:

Access: Admin/Any Security Analyst

- Select **Analysis > Hosts > Host Attributes**.

  The first page of the default host attributes workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

TIP! If you are using a custom workflow that does not include the table view of host attributes, click **(switch workflow)**, then select **Attributes**.

Understanding the Host Attributes Table

License: FireSIGHT

The Sourcefire 3D System collects information about the hosts it detects and uses that information to build host profiles. However, there may be additional information about the hosts on your network that you want to provide to your analysts. You can add notes to a host profile, set the business criticality, or provide any other information that you choose. Each piece of information is called a host attribute.

You can use host attributes in host profile qualifications, which constrain the data you collect while building a traffic profile, and also can limit the conditions under which you want to trigger a correlation rule.

Note that the host attributes table does not display hosts identified only by MAC addresses.

For more information on host attributes, see Working with the Predefined Host Attributes on page 1433 and Working with User-Defined Host Attributes on page 1434.

Descriptions of the fields in the host attributes table follow.

IP Address

The IP addresses associated with a host.

Current User

The user identity (username) of the currently logged in user on the host.

Note that when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Host Criticality

The user-assigned importance of a host to your enterprise. You can use the host criticality in correlation rules and policies to tailor policy violations and their responses to the importance of a host involved in an event. You can assign a host criticality of low, medium, high, or none.

For information on setting a host's criticality, see Working with the Predefined Host Attributes on page 1433 and Setting Host Attributes for Selected Hosts on page 1479.

Notes

Information about the host that you want other analysts to view. For information on how to add a note, see Working with the Predefined Host Attributes on page 1433.

Any user-defined host attribute, including those for compliance white lists

The value of the user-defined host attribute.

The host attributes table contains a field for each user-defined host attribute. For more information, see Working with User-Defined Host Attributes on page 1434.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Setting Host Attributes for Selected Hosts

LICENSE: FireSIGHT

There are two predefined host attributes that you can assign to each host: host criticality and host-specific notes.

Use the host criticality to designate the business criticality of a given host. You can tailor correlation policies and alerts based on host criticality. For example, your organization's mail servers are more critical to your business than a typical user workstation. You can assign a high host criticality value to your mail servers and other business-critical servers and medium or low values to other hosts. You could then create a correlation policy that launches different alerts based on the criticality of an affected host.

Use notes to record information about a host that you want other analysts to view. For example, if you have a computer on the network that has an older, unpatched version of an operating system that you use for testing, you can use the notes feature to indicate that the system is intentionally unpatched.

You can also create user-defined host attributes. For example, you could create a host attribute that assigns physical location identifiers to hosts, such as a facility code, city, or room number. For more information on created user-defined host attributes, see Creating User-Defined Host Attributes on page 1436.

You can also set the host criticality of selected hosts in a host workflow, and from within a host profile, or set it through a remediation. For more information, see Working with the Predefined Host Attributes on page 1433 or Configuring Set Attribute Remediations on page 1700.

To set host attributes for selected hosts:

ACCESS: Admin/Any Security Analyst

1. Select the check boxes next to the hosts to which you want to add a host attribute.

   TIP! Use the sort and search features to isolate the hosts to which you want to assign particular attributes.

2. At the bottom of the page, click **Set Attributes**.

   The Host Attributes pop-up window appears.

3. Optionally, set the host criticality for the hosts you selected.

   You can select **None**, **Low**, **Medium**, or **High**.

4. Optionally, add notes to the host profiles of the hosts you selected by entering up to 255 alphanumeric characters, special characters, and spaces in the text box.

5. Optionally, set any user-defined host attributes you have configured.

6. Click **Save**.

   The host attributes you specified are assigned to the selected hosts.

Searching for Host Attributes

LICENSE: FireSIGHT

You can search for hosts that have specific host attributes. For example, if your company has several regional offices, you could configure a host attribute that tells you which city any one host resides in. You could then search for hosts in specific regions. For more information on host attributes, see Working with User-Defined Host Attributes on page 1434.

You may want to create searches customized for your network environment, then save them to reuse later. For more information on the host attribute fields, see Understanding the Host Attributes Table on page 1477.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.
- IP addresses may be specified using CIDR notation. For information on entering IPv4 and IPv6 addresses in the Sourcefire 3D System, see IP Address Conventions on page 63.
- Click the add object icon () that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

To search for host attributes:

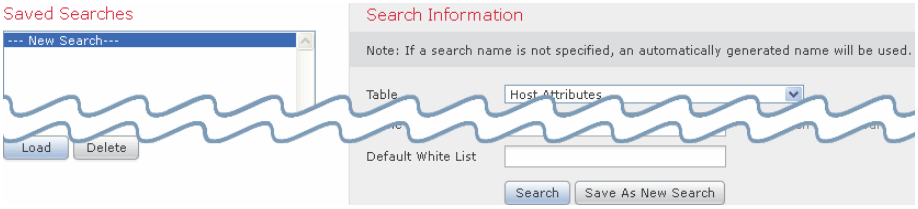
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Host Attributes**.

   The page reloads with the appropriate constraints.



TIP! To search the database for a different kind of event, select it from the **Table** drop-down list.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, the Defense Center automatically creates one when you save the search.

4. Enter your search criteria in the appropriate fields, as described in Understanding the Host Attributes Table on page 1477. If you enter multiple criteria, the Defense Center returns only the records that match all the criteria. Click the add icon ( ) that appears next to a search field to use an object as a search criterion.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search so that only you can use it.

TIP! If you want to save a search as a restriction for custom user roles with restricted privileges, you **must** save it as a private search.

6. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in the default host attributes workflow. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

Working with Indications of Compromise

License: FireSIGHT

The Sourcefire 3D System correlates various types of data (intrusion events, Security Intelligence, connection events, and file or malware events) associated with hosts to determine whether a host on your monitored network is likely to be compromised by malicious means. Certain combinations and frequencies of event data trigger indications of compromise (IOC) tags on affected hosts. IOC-tagged host IP addresses appear in event views with a special compromised host icon (); you also can write compliance rules that account for IOC-tagged hosts.

To use this feature, you must have IOC rules enabled in your network discovery policy. You can enable any or all of the predefined rules to trigger IOC tags on compromised hosts. For more information, see Setting Indications of Compromise Rules on page 1350.

See the following sections for detailed information about indications of compromise:

Viewing Indications of Compromise

License: FireSIGHT

You can use the Defense Center to view a table of triggered Indications of Compromise (IOC). Then, you can manipulate the event view depending on the information you are looking for.

The page you see when you access IOC depends on the workflow you use. Both predefined IOC workflows terminate in a host view, which contains a host profile for every host that meets your constraints. You can also create a custom

workflow that displays only the information that matches your specific needs. For more information, see Creating Custom Workflows on page 1916.

The following table describes some of the specific actions you can perform on an IOC workflow page. You can also perform the tasks described in the the Common Discovery Event Actions table on page 1451.

Indication of Compromise Actions

To...	You can...
learn more about the contents of the columns in the table	find more information in Understanding the Indications of Compromise Table on page 1483.
view the host profile for a compromised host	click the compromised host icon ( ) in the **IP Address** column.
mark selected IOC events resolved so they no longer appear in the list	select the check boxes next to the IOC events you want to edit, then click **Mark Resolved**. For more information, see Resolving Indications of Compromise on page 1405.
view details of events that triggered the IOC	click the view icon ( ) in the **First Seen** or **Last Seen** columns.

To view indications of compromise:

Access: Admin/Any Security Analyst

▶ Select **Analysis > Hosts > Indications of Compromise**.

The first page of the default indications of compromise (IOC) workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

TIP! If you are using a custom workflow that does not include the IOC table view, click **(switch workflow)**, then select **Indications of Compromise**.

Understanding the Indications of Compromise Table

License: FireSIGHT

The Sourcefire 3D System correlates various types of event data associated with hosts to determine whether a host on your monitored network is likely to be compromised by malicious means. These correlations appear, associated with the host, as indications of compromise (IOC). You can mark a host IOC as resolved, which removes that IOC tag from the host. A host can trigger multiple

IOC tags; you can view all IOC tags associated with a host in the Indications of Compromise section of the host profile. For more information on IOC data in the host profile, see Working with Indications of Compromise in the Host Profile on page 1402.

Descriptions of the fields in the IOC table follow below.

IP Address

The IP address associated with the host that triggered the IOC.

Category

Brief description of the type of compromise indicated, such as `Malware Executed` or `Impact 1 Attack`.

Event Type

Identifier associated with a specific Indication of Compromise (IOC), referring to the event that triggered it.

Description

Description of what the IOC means for the potentially compromised host, such as `This host may be under remote control` or `Malware has been executed on this host`.

First/Last Seen

The first (or most recent) date and time that events triggering a host's IOC occurred.

Searching for Indications of Compromise

LICENSE: FireSIGHT

You can search for specific indications of compromise (IOC) tags triggered on monitored hosts by using one of the predefined searches or by using your own search criteria. The predefined searches serve as examples and can provide quick access to important information about your network.

You may want to modify specific fields within the default searches to customize them for your network environment, then save them to reuse later. The fields you can use to retrieve data are described in Understanding the Indications of Compromise Table on page 1483.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.
- IP addresses may be specified using CIDR notation. For information on entering IPv4 and IPv6 addresses in the Sourcefire 3D System, see IP Address Conventions on page 63.
- Click the add object icon ( ) that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

To search for indications of compromise:

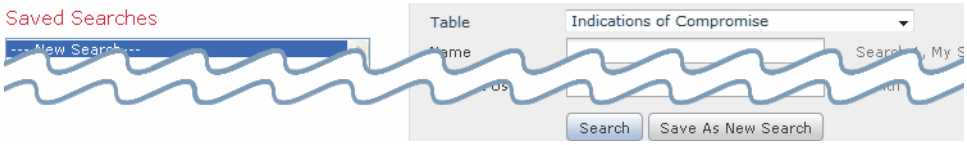
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Indications of Compromise**.

   The page reloads with the appropriate constraints.



> **TIP!** To search the database for a different kind of event, select it from the **Table** drop-down list.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, the Defense Center automatically creates one when you save the search.

4. Enter your search criteria in the appropriate fields, as described in Understanding the Indications of Compromise Table on page 1483. If you enter multiple criteria, the Defense Center returns only the records that match all the criteria. Click the add icon () that appears next to a search field to use an object as a search criterion.
5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search so that only you can use it.

   TIP! If you want to save a search as a restriction for custom user roles with restricted privileges, you **must** save it as a private search.

6. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in the default IOC workflow. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

Working with Servers

LICENSE: FireSIGHT

The Sourcefire 3D System collects information about all servers running on hosts on monitored network segments. The information that the system collects includes the name of the server, the application and network protocols used by the server, the vendor and version of the server, the IP address associated with the host running a server, and the port on which the server communicates.

When the system detects a server, it generates a discovery event unless the associated host has already reached its maximum number of servers. For more information, see Host Limits and Discovery Event Logging on page 1321. You can use the Defense Center web interface to view, search, and delete server events.

You can also base correlation rules on server events. For example, you could trigger a correlation rule when the system detects a chat server, such as ircd, running on one of your hosts.

Although you can configure the network discovery policy to add servers to the network map based on application data exported by NetFlow-enabled devices, the available information about these servers is limited. For more information, see

Differences Between NetFlow and FireSIGHT Data on page 1325.

See the following sections for more information:

- Viewing Servers on page 1487
- Understanding the Servers Table on page 1488
- Searching for Servers on page 1490
- Editing Server Identities on page 1416

Viewing Servers

LICENSE: FireSIGHT

You can use the Defense Center to view a table of detected servers. Then, you can manipulate the event view depending on the information you are looking for.

The page you see when you access servers differs depending on the workflow you use. All the predefined workflows terminate in a host view, which contains a host profile for every host that meets your constraints. You can also create a custom workflow that displays only the information that matches your specific needs. For more information, see Creating Custom Workflows on page 1916.

The Server Actions table below describes some of the specific actions you can perform on an servers workflow page. You can also perform the tasks described in the Common Discovery Event Actions table on page 1451.

Server Actions

TO...	YOU CAN...
learn more about the contents of the columns in the table	find more information in Understanding the Servers Table on page 1488.
edit server identities	select the check boxes next to the events for servers you want to edit, then click **Set Server Identity**. For more information, see Editing Server Identities on page 1416.

To view servers:

ACCESS: Admin/Any Security Analyst

▶ Select **Analysis > Hosts > Servers**.

The first page of the default servers workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

TIP! If you are using a custom workflow that does not include the table view of servers, click **(switch workflow)**, then select **Servers**.

Understanding the Servers Table

LICENSE: FireSIGHT

The Sourcefire 3D System collects information about servers running on hosts on monitored network segments.

Descriptions of the fields in the servers table follow below.

Although you can configure the network discovery policy to add servers to the network map based on data exported by NetFlow-enabled devices, the available information about these servers is limited. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

Last Used

The date and time the server was last used on the network or the date and time that the server was originally updated using the host input feature. The Last Used value is updated at least as often as the update interval you configured in the network discovery policy, as well as when the system detects a server information update. For information on setting the update interval, see Configuring Data Storage on page 1352.

IP Address

The IP address associated with the host running the server.

Port

The port where the server is running.

Protocol

The network or transport protocol used by the server.

Application Protocol

The application protocol, as indicated by one of the following:

- the name of the application protocol for the server
- `pending`, if the system cannot positively or negatively identify the server for one of several reasons
- `unknown`, if the system cannot identify the server based on known server fingerprints or if the server was added through host input and did not include the application protocol

Category, Tags, Risk, or Business Relevance for Application Protocols

The categories, tags, risk level, and business relevance assigned to the application protocol. These filters can be used to focus on a specific set of data.

For more information, see the Application Characteristics table on page 1317.

Vendor

One of:

- the server vendor as identified by the system, Nmap or another active source, or that you specified using the host input feature
- blank, if the system cannot identify its vendor based on known server fingerprints, or if the server was added to the network map using NetFlow data

Version

One of:

- the server version as identified by the system, Nmap or another active source, or that you specified using the host input feature
- blank, if the system cannot identify its version based on known server fingerprints, or if the server was added to the network map using NetFlow data

Web Application

The web application based on the payload content detected by the system in the http traffic. Note that if the system detects an application protocol of HTTP but cannot detect a specific web application, the system supplies a generic web browsing designation.

Category, Tags, Risk, or Business Relevance for Web Applications

The categories, tags, risk level, and business relevance assigned to the web application. These filters can be used to focus on a specific set of data.

For more information, see the Application Characteristics table on page 1317.

Hits

The number of times the server was accessed. For servers added using the host input feature, this value is always 0.

Source Type

One of the following values:

- User: *user_name*
- Application: *app_name*
- Scanner: *scanner_type* (Nmap or scanner added through network discovery configuration)
- FireSIGHT, FireSIGHT Port Match, or FireSIGHT Pattern Match, for servers detected by the Sourcefire 3D System
- NetFlow, for servers added to the network map based on NetFlow data

The system may reconcile data from multiple sources to determine the identity of a server; see Understanding Current Identities on page 1718.

Device

The name of the device that either detected the server or processed the NetFlow or host input data that added the server to the network map.

Current User

The user identity (username) of the currently logged in user on the host.

Note that when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Searching for Servers

License: FireSIGHT

You can search for specific servers that are running on monitored hosts by using one of the predefined searches or by using your own search criteria. The predefined searches serve as examples and can provide quick access to important information about your network.

You may want to modify specific fields within the default searches to customize them for your network environment, then save them to reuse later. The fields you can use to retrieve data are described in Understanding the Servers Table on page 1488.

When searching for servers, you should keep in mind that although you can configure the network discovery policy to add applications, including servers, to the network map based on data exported by NetFlow-enabled devices, the available information about these servers is limited. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.
- IP addresses may be specified using CIDR notation. For information on entering IPv4 and IPv6 addresses in the Sourcefire 3D System, see IP Address Conventions on page 63.
- Click the add object icon ( ) that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

To search for servers:

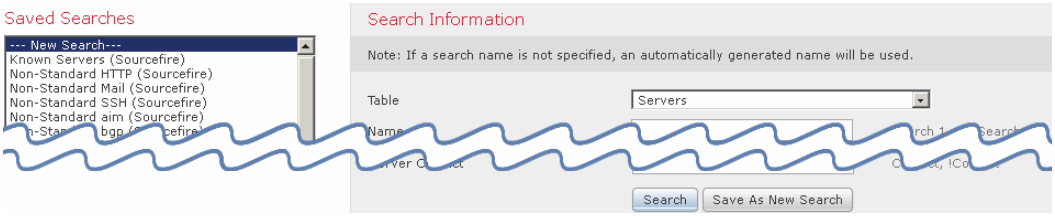
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Servers**.

   The page reloads with the appropriate constraints.



TIP! To search the database for a different kind of event, select it from the **Table** drop-down list.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, the Defense Center automatically creates one when you save the search.

4. Enter your search criteria in the appropriate fields. If you enter multiple criteria, the Defense Center returns only the records that match all the criteria. Click the add icon ( ) that appears next to a search field to use an object as a search criterion.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search so that only you can use it.

TIP! If you want to save a search as a restriction for custom user roles with restricted privileges, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in the default servers workflow. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

Working with Applications

LICENSE: FireSIGHT

When a monitored host connects to another host, the system can, in many cases, determine what application was used. The Sourcefire 3D System detects the use of many email, instant messaging, peer to peer, web applications, as well as other types of applications.

For each detected application, the system logs the IP address that used the application, the product, the version, and the number of times its use was detected. You can use the web interface to view, search, and delete application events. You can also update application data on a host or hosts using the host input feature.

If you know which applications are running on which hosts, you can use that knowledge to create host profile qualifications, which constrain the data you collect while building a traffic profile, and also can limit the conditions under which you want to trigger a correlation rule. You can also base correlation rules on the detection of application. For example, if you want your employees to use a specific mail client, you could trigger a correlation rule when the system detects a different mail client running on one of your hosts.

You should carefully read the release notes for each Sourcefire 3D System update as well as the advisories for each VDB update for information on updated detectors.

To collect and store application data for analysis, make sure that you enable application detection in your network discovery policy. For more information, see Understanding Discovery Data Collection on page 1304.

See the following sections for more information:

- Viewing Application Details on page 1498
- Understanding the Application Detail Table on page 1499
- Searching for Application Details on page 1501

Viewing Applications

learn more about the contents of the columns in the table	find more information in Understanding the Applications Table on page 1494.
open the Application Detail View for a specific application	click the application detail view icon ( ) next to a client, application protocol, or web application.

To view applications:

Access: Admin/Any Security Analyst

▶ Select **Analysis > Hosts > Application Details**.

The first page of the default application details workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

TIP! If you are using a custom workflow that does not include the table view of application details, click **(switch workflow)**, then select **Clients**.

Understanding the Applications Table

License: FireSIGHT

When a monitored host connects to another host, the Sourcefire 3D Systemcan, in many cases, determine what application was used. The system detects various web browsers or servers, email clients or servers, instant messengers, peer-to-peer applications, and so on. When the system detects traffic for a known client, application protocol, or web application, it logs information about the application and the host running it.

The Sourcefire 3D System classifies application data into three types: client, web application, and application protocol. The applications table provides a list combining all three types of detected applications on the appliance.

Descriptions of the fields in the applications table follow.

Application

The name of the detected application.

IP Address

The IP address associated with the host using the application.

Category

A general classification for the application that describes its most essential function. Each application belongs to at least one category.

Tag

Additional information about the application. Applications can have any number of tags, including none.

Risk

How likely the application is to be used for purposes that might be against your organization's security policy. An application's risk can range from `Very Low` to `Very High`.

Of Application Protocol Risk, Client Risk, and Web Application Risk, the highest of the three detected, when available, in the traffic that triggered the intrusion event.

Business Relevance

The likelihood that the application is used within the context of your organization's business operations, as opposed to recreationally. An application's business relevance can range from `Very Low` to `Very High`.

Of Application Protocol Business Relevance, Client Business Relevance, and Web Application Business Relevance, the lowest of the three detected, when available, in the traffic that triggered the intrusion event.

Current User

The user identity (username) of the currently logged in user on the host.

Note that when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Type

The type of application:

- **Application Protocols** represent communications between hosts.
- **Client Applications** represent software running on a host.
- **Web Applications** represent the content or requested URL for HTTP traffic.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Searching for Applications

LICENSE: FireSIGHT

You can search for hosts that are running specific clients, application protocols, or web applications. You may want to create searches customized for your network environment, then save them to reuse later.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.
- IP addresses may be specified using CIDR notation. For information on entering IPv4 and IPv6 addresses in the Sourcefire 3D System, see IP Address Conventions on page 63.
- Click the add object icon () that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

To search for applications:

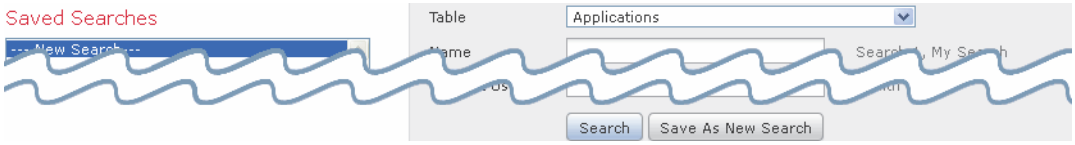
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Applications**.

   The page reloads with the appropriate constraints.



3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, the Defense Center automatically creates one when you save the search.

4. Enter your search criteria in the appropriate fields. If you enter multiple criteria, the Defense Center returns only the records that match all the criteria. Click the add icon ( ) that appears next to a search field to use an object as a search criterion.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search so that only you can use it.

   TIP! If you want to save a search as a restriction for custom user roles with restricted privileges, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in the default clients workflow. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

Viewing Application Details

LICENSE: FireSIGHT

You can use the Defense Center to view a table of detected application details. Then, you can manipulate the event view depending on the information you are looking for.

The page you see when you access application details differs depending on the workflow you use. There are two predefined workflows. You can also create a custom workflow that displays only the information that matches your specific needs. For more information, see Creating Custom Workflows on page 1916.

The Application Details Actions table below describes some of the specific actions you can perform on an application details workflow page. You can also perform the tasks described in the Common Discovery Event Actions table on

page 1451.

Application Details Actions

To...	You can...
learn more about the contents of the columns in the table	find more information in Understanding the Application Detail Table on page 1499.
open the Application Detail View for a specific application	click the application detail view icon ( ) next to a client.

To view application details:

Access: Admin/Any Security Analyst

▶ Select **Analysis > Hosts > Application Details**.

The first page of the default application details workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

TIP! If you are using a custom workflow that does not include the table view of application details, click **(switch workflow)**, then select **Clients**.

Understanding the Application Detail Table

License: FireSIGHT

When a monitored host connects to another host, the Sourcefire 3D Systemcan, in many cases, determine what application was used. The system detects various web browsers, email clients, instant messengers, peer-to-peer applications, and so on.

When the system detects traffic for a known client, application protocol, or web application, it logs information about the application and the host running it. Descriptions of the fields in the application details table follow.

Last Used

The time that the application was last used or the time that the application data was updated using the host input feature. The Last Used value is updated at least as often as the update interval you configured in the network discovery policy, as well as when the system detects an application information update. For information on setting the update interval, see Configuring Data Storage on page 1352.

IP Address

The IP address associated with the host using the application.

Client

The name of the application. Note that if the system detected an application protocol but could not detect a specific client, `client` is appended to the application protocol name to provide a generic name.

Version

The version of the application.

Category, Tags, Risk, or Business Relevance for Clients

The categories, tags, risk level, and business relevance assigned to the client. These filters can be used to focus on a specific set of data.

For more information, see Understanding Application Detection on page 1316.

Application Protocol

The application protocol used by the application. Note that if the system detected an application protocol but could not detect a specific client, `client` is appended to the application protocol name to provide a generic name.

Category, Tags, Risk, or Business Relevance for Application Protocols

The categories, tags, risk level, and business relevance assigned to the application protocol. These filters can be used to focus on a specific set of data.

For more information, see Understanding Application Detection on page 1316.

Web Application

The web application based on the payload content or URL detected by the system in the http traffic. Note that if the system detects an application protocol of `HTTP` but cannot detect a specific web application, the system supplies a generic web browsing designation here.

Category, Tags, Risk, or Business Relevance for Web Applications

The categories, tags, risk level, and business relevance assigned to the web application. These filters can be used to focus on a specific set of data.

For more information, see Understanding Application Detection on page 1316.

Hits

The number of times the system detected the application in use. For applications added using the host input feature, this value is always 0.

Device

The device that generated the discovery event containing the application detail.

Current User

The user identity (username) of the currently logged in user on the host.

Note that when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Searching for Application Details

License: FireSIGHT

You can search for hosts that are running specific clients, application protocols, or web applications. You may want to create searches customized for your network environment, then save them to reuse later.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.

- IP addresses may be specified using CIDR notation. For information on entering IPv4 and IPv6 addresses in the Sourcefire 3D System, see IP Address Conventions on page 63.
- Click the add object icon ( ) that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

To search for application details:

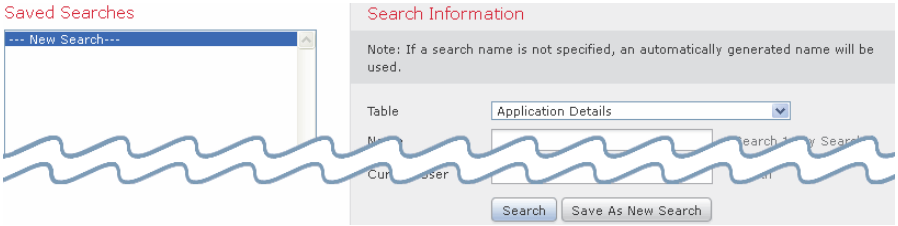
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Application Details**.

   The page reloads with the appropriate constraints.



TIP! To search the database for a different kind of event, select it from the **Table** drop-down list.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, the Defense Center automatically creates one when you save the search.

4. Enter your search criteria in the appropriate fields. If you enter multiple criteria, the Defense Center returns only the records that match all the criteria. Click the add icon ( ) that appears next to a search field to use an object as a search criterion.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search so that only you can use it.

TIP! If you want to save a search as a restriction for custom user roles with restricted privileges, you **must** save it as a private search.

6. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in the default clients workflow. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

Working with Sourcefire Vulnerabilities

LICENSE: FireSIGHT

The Sourcefire 3D System includes its own vulnerability tracking database which is used, in conjunction with the system's fingerprinting capability, to identify the vulnerabilities associated with the hosts on your network.

The operating systems, servers, and clients running on your hosts have different sets of associated vulnerabilities. You can deactivate vulnerabilities for a host after you patch the host or otherwise judge it immune to a vulnerability. You can use the Defense Center to track and review the vulnerabilities for each host.

Note that vulnerabilities for vendorless and versionless servers are not mapped unless the applications protocols used by the servers are mapped in the system policy. Vulnerabilities for vendorless and versionless clients cannot be mapped. For more information, see Mapping Vulnerabilities for Servers on page 2075.

For more information, see:

- Viewing Sourcefire Vulnerabilities on page 1503
- Understanding the Sourcefire Vulnerabilities Table on page 1505
- Deactivating Sourcefire Vulnerabilities on page 1507
- Searching for Sourcefire Vulnerabilities on page 1508

Viewing Sourcefire Vulnerabilities

LICENSE: FireSIGHT

You can use the Defense Center to view a table of vulnerabilities. Then, you can manipulate the event view depending on the information you are looking for.

The page you see when you access vulnerabilities differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of vulnerabilities. The table view contains a row for each vulnerability in the database, regardless of whether any of your detected hosts exhibit the vulnerabilities. The second page of the predefined workflow contains a row for

each vulnerability (that you have not deactivated) that applies to detected hosts on your network. The predefined workflow terminates in a vulnerability detail view, which contains a detailed description for every vulnerability that meets your constraints.

TIP! If you want to see the vulnerabilities that apply to a single host or set of hosts, perform a search for vulnerabilities, specifying an IP address or range of IP addresses for the hosts. For more information on searching for vulnerabilities, see Searching for Sourcefire Vulnerabilities on page 1508.

You can also create a custom workflow that displays only the information that matches your specific needs. For information on creating a custom workflow, see Creating Custom Workflows on page 1916.

The following table describes some of the specific actions you can perform on an vulnerabilities workflow page. You can also perform the tasks described in the Common Discovery Event Actions table on page 1451.

Vulnerability Actions

To...	You can...
learn more about the contents of the columns in the table	find more information in Understanding the Sourcefire Vulnerabilities Table on page 1505.
view the vulnerability details for a vulnerability	click the view icon ( ) in the SVID column. Alternatively, constrain on the vulnerability ID and drill down to the vulnerability details page. For more information, see Viewing Vulnerability Details on page 1429.
deactivate selected vulnerabilities so they are no longer used for intrusion impact correlation for currently vulnerable hosts	find more information in Deactivating Sourcefire Vulnerabilities on page 1507.
view the full text of a vulnerability title	right-click the title and select **Show Full Text**.

To view vulnerabilities:

ACCESS: Admin/Any Security Analyst

▶ Select **Analysis > Vulnerabilities > Vulnerabilities**.

The first page of the default vulnerabilities workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

TIP! If you are using a custom workflow that does not include the table view of vulnerabilities, click **(switch workflow)**, then select **Vulnerabilities**.

Understanding the Sourcefire Vulnerabilities Table

LICENSE: FireSIGHT

The Sourcefire 3D System includes its own vulnerability tracking database which is used, in conjunction with the system's fingerprinting capability, to identify the vulnerabilities associated with the hosts on your network.

The operating systems, servers, and clients running on your hosts have different sets of associated vulnerabilities. You can deactivate vulnerabilities for a host after you patch the host or otherwise judge it immune to a vulnerability. You can use the Defense Center to track and review the vulnerabilities for each host.

For more information on vulnerabilities, see Working with the Vulnerabilities Network Map on page 1383 and Working with Vulnerabilities in the Host Profile on page 1427.

Descriptions of the fields in the vulnerabilities table follow.

SVID

The Sourcefire vulnerability identification number that the system uses to track vulnerabilities.

Click the view icon ( ) to access the vulnerability details for the SVID. See Viewing Vulnerability Details on page 1429 for more information.

Bugtraq ID

The identification number associated with the vulnerability in the Bugtraq database. (http://www.securityfocus.com/bid/)

Snort ID

The identification number associated with the vulnerability in the Snort ID (SID) database. That is, if an intrusion rule can detect network traffic that exploits a particular vulnerability, that vulnerability is associated with the intrusion rule's SID.

Note that a vulnerability can be associated with more than one SID (or no SIDs at all). If a vulnerability is associated with more than one SID, the vulnerabilities table includes a row for each SID.

Title

The title of the vulnerability.

IP Address

The IP address associated with the host affected by the vulnerability.

Date Published

The date the vulnerability was published.

Vulnerability Impact

Displays the severity assigned to the vulnerability in the Bugtraq database on a scale of 0 to 10, with 10 being the most severe. The vulnerability impact is determined by the writer of the Bugtraq entry based on his or her best judgment and guided by SANS Critical Vulnerability Analysis (CVA) criteria.

Remote

Indicates whether the vulnerability is remotely exploitable.

Available Exploits

Indicates whether there are known exploits for the vulnerability.

Description

A brief description of the vulnerability.

Technical Description

A detailed technical description of the vulnerability.

Solution

Information about repairing the vulnerability.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Deactivating Sourcefire Vulnerabilities

LICENSE: FireSIGHT

Deactivate a vulnerability after you patch the hosts on your network or otherwise judge them immune. Deactivated vulnerabilities are not used for intrusion impact correlation. Note that if the system discovers a new host that is affected by that vulnerability, the vulnerability is considered valid (and is not automatically deactivated) for that host.

You can deactivate vulnerabilities within the vulnerabilities workflow **only** on a workflow page that shows vulnerabilities for specific hosts on your network, that is:

- on the second page of the default vulnerabilities workflow, **Vulnerabilities on the Network**, which shows only the vulnerabilities that apply to the hosts on your network
- on any page in a vulnerabilities workflow, custom or predefined, that you constrained based on IP address using a search.

Deactivating a vulnerability within a vulnerabilities workflow that is not constrained on IP addresses deactivates the vulnerability for *all* detected hosts on your network. To deactivate a vulnerability for a single host, you have three options:

- Use the network map.

  For more information, see Working with the Vulnerabilities Network Map on page 1383.
- Use the host's host profile.

  For more information, see Setting Vulnerabilities for Individual Hosts on page 1432.
- Constrain the vulnerabilities workflow based on the IP addresses of the host or hosts for which you want to deactivate vulnerabilities. For hosts with multiple associated IP addresses, this function applies only to the single, selected IP address of that host.

To constrain the view based on IP address, perform a search for vulnerabilities, specifying an IP address or range of IP addresses for the hosts for which you want to deactivate vulnerabilities. For more information on searching for vulnerabilities, see Searching for Sourcefire Vulnerabilities on page 1508.

To deactivate vulnerabilities:

ACCESS: Admin/Any Security Analyst

▶ On the Vulnerabilities on the Network page, select the check boxes next to vulnerabilities you want to deactivate, then click **Review**.

Searching for Sourcefire Vulnerabilities

LICENSE: FireSIGHT

You can search for vulnerabilities that affect the hosts on your network. You may want to create searches customized for your network environment, then save them to reuse later.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.
- IP addresses may be specified using CIDR notation. For information on entering IPv4 and IPv6 addresses in the Sourcefire 3D System, see IP Address Conventions on page 63.
- Click the add object icon () that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

Specific Search Criteria for Vulnerabilities

Note the following information specific to searching for vulnerabilities:

- Find Bugtraq ID numbers at http://www.securityfocus.com/bid.
- Enter `TRUE` to search for vulnerabilities that are exploited, or `FALSE` to exclude such vulnerabilities.

To search for vulnerabilities:

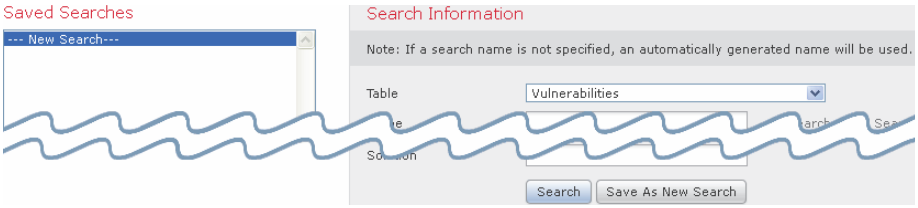
ACCESS: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Vulnerabilities**.

   The page reloads with the appropriate constraints.



3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields.

   If you enter multiple criteria, the search returns only the records that match all the criteria. Click the add icon ( ) that appears next to a search field to use an object as a search criterion.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search so that only you can use it.

   If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in the default vulnerabilities workflow. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

Working with Third-Party Vulnerabilities

LICENSE: FireSIGHT

The Sourcefire 3D System includes its own vulnerability tracking database which is used, in conjunction with the system's fingerprinting capability, to identify the vulnerabilities associated with the hosts on your network.

If your organization can write scripts or create command line import files to import network map data from third-party applications, you can import third-party

vulnerability data to augment the system's vulnerability data. For more information, see the *Sourcefire 3D System Host Input API Guide*.

To include imported data in impact correlations, you must map third-party vulnerability information to the operating system and application definitions in the database. You cannot map third-party vulnerability information to client definitions.

For more information, see:

- Viewing Third-Party Vulnerabilities on page 1510
- Understanding the Third-Party Vulnerabilities Table on page 1511
- Searching for Third-Party Vulnerabilities on page 1512

Viewing Third-Party Vulnerabilities

License: FireSIGHT

After you use the host input feature to import third-party vulnerability data, you can use the Defense Center to view a table of third-party vulnerabilities. Then, you can manipulate the event view depending on the information you are looking for.

The page you see when you access third-party vulnerabilities differs depending on the workflow you use. There are two predefined workflows. You can also create a custom workflow that displays only the information that matches your specific needs. For more information, see Creating Custom Workflows on page 1916.

The following table describes some of the specific actions you can perform on a third-party vulnerabilities workflow page. You can also perform the tasks described in the Common Discovery Event Actions table on page 1451.

Third-Party Vulnerability Actions

To...	You can...
learn more about the contents of the columns in the table	find more information in Understanding the Third-Party Vulnerabilities Table on page 1511.
view the vulnerability details for a third-party vulnerability	click the view icon ( ) in the SVID column. Alternatively, constrain on the vulnerability ID and drill down to the vulnerability details page. For more information, see Viewing Vulnerability Details on page 1429.

To view third-party vulnerabilities:

ACCESS: Admin/Any Security Analyst

- Select **Analysis > Vulnerabilities > Third-Party Vulnerabilities**.

  The first page of the default third-party vulnerabilities workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

TIP! If you are using a custom workflow that does not include the table view of third-party vulnerabilities, click **(switch workflow)**, then select **Vulnerabilities by Source** or **Vulnerabilities by IP Address**.

Understanding the Third-Party Vulnerabilities Table

LICENSE: FireSIGHT

When you import third-party vulnerability information using the host input feature, the system stores that information in its database. The fields in the third-party vulnerabilities table are described in the following table.

Vulnerability Source

The source of the third-party vulnerabilities, for example, QualysGuard or NeXpose.

Vulnerability ID

The ID number associated with the vulnerability for its source.

IP Address

The IP address associated with the host affected by the vulnerability.

Port

A port number, if the vulnerability is associated with a server running on a specific port.

Bugtraq ID

The identification number associated with the vulnerability in the Bugtraq database. (http://www.securityfocus.com/bid/)

CVE ID

The identification number associated with the vulnerability in MITRE's Common Vulnerabilities and Exposures (CVE) database (http://www.cve.mitre.org/).

SVID

The Sourcefire Vulnerability identification number that the system uses to track vulnerabilities

Click the view icon ( ) to access the vulnerability details for the SVID. See Viewing Vulnerability Details on page 1429 for more information.

Snort ID

The identification number associated with the vulnerability in the Snort ID (SID) database. That is, if an intrusion rule can detect network traffic that exploits a particular vulnerability, that vulnerability is associated with the intrusion rule's SID.

Note that a vulnerability can be associated with more than one SID (or no SIDs at all). If a vulnerability is associated with more than one SID, the vulnerabilities table includes a row for each SID.

Title

The title of the vulnerability.

Description

A brief description of the vulnerability.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Searching for Third-Party Vulnerabilities

LICENSE: FireSIGHT

You can search for third-party vulnerabilities that affect the hosts on your network. You may want to create searches customized for your network environment, then save them to reuse later.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.

- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.
- IP addresses may be specified using CIDR notation. For information on entering IPv4 and IPv6 addresses in the Sourcefire 3D System, see IP Address Conventions on page 63.
- Click the add object icon ( ) that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

Specific Search Criteria for Vulnerabilities

Note the following information specific to searching for vulnerabilities:

- Find Bugtraq ID numbers at http://www.securityfocus.com/bid.
- Enter TRUE to search for vulnerabilities that are exploited, or FALSE to exclude such vulnerabilities.

To search for third-party vulnerabilities:

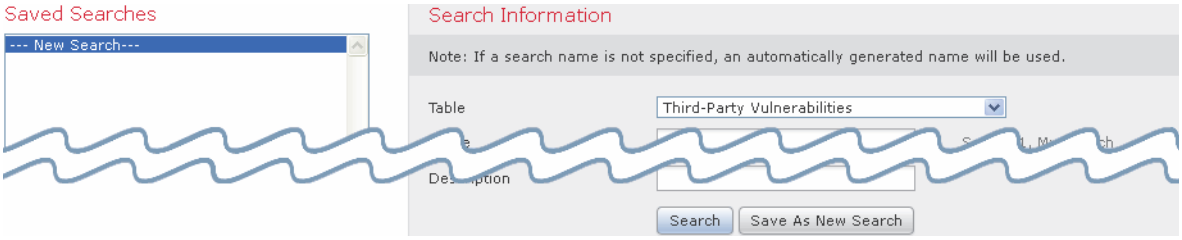
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Third-Party Vulnerabilities**.

   The page reloads with the appropriate constraints.



3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields.

   If you enter multiple criteria, the search returns only the records that match all the criteria. Click the add icon ( ) that appears next to a search field to use an object as a search criterion.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search so that only you can use it.

   If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in the default third-party vulnerabilities workflow. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

Working with Users

LICENSE: FireSIGHT

When either an Active Directory Agent or a managed device detects a user login for a user who is not already in the database, the user is added to the database, unless you have specifically restricted that login type (see Restricting User Logging on page 1343).

IMPORTANT! Although the system detects SMTP logins, the system does not record them unless there is already a user with a matching email address in the database; users are **not** added to the database based on SMTP logins.

The type of login that the system detected determines what information is stored about the new user, as described in the following table.

Login Types and User Data Stored

Login Type	User Data Stored
LDAP AIM Oracle SIP	• username • current IP address • login type (`aim`, `ldap`, `oracle`, or `sip`)
POP3 IMAP	• username • current IP address • email address • login type (`pop3` or `imap`)

If you configured Defense Center-LDAP server connections, the Defense Center queries the LDAP servers every five minutes and obtains metadata for the new users in the user database. At the same time, the Defense Center also queries the LDAP servers for updated information on users whose records in the Defense Center database are more than 12 hours old. It may take five to ten minutes for the Defense Center database to update with user metadata after the system detects a new user login. From the LDAP servers, the Defense Center obtains the following information and metadata about each user:

- LDAP username
- first and last names
- email address
- department
- telephone number

The number of users the Defense Center can store in its database depends on your FireSIGHT license. Note that AIM, Oracle, and SIP logins create duplicate user records because they are not associated with any of the user metadata that the system obtains from LDAP servers. To prevent overuse of user count because of duplicate user records from these protocols, disable logging of the protocols in the network discovery policy. For more information, see Restricting User Logging on page 1343.

You can search, view, and delete users from the database; you can also purge all users from the database. For more information, see the following sections:

- Viewing Users on page 1516
- Understanding the Users Table on page 1516
- Understanding User Details and Host History on page 1518
- Searching for Users on page 1520

Viewing Users

LICENSE: FireSIGHT

You can view a table of users, and then manipulate the event view depending on the information you are looking for.

The page you see when you access users differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of users that lists all detected users, and terminates in a user details page. The user details page provides information on every user that meets your constraints.

You can also create a custom workflow that displays only the information that matches your specific needs. For information on creating a custom workflow, see Creating Custom Workflows on page 1916.

For more information about the contents of the columns in the table, see Understanding the Users Table on page 1516.The following table, see describes some of the specific actions you can perform on an users workflow page. You can also perform the actions in the Common Discovery Event Actions table on page 1451.

To view users:

ACCESS: Admin/Any Security Analyst

▶ Select **Analysis > Users > Users**.

The first page of the default users workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

TIP! If you are using a custom workflow that does not include the table view of users, click **(switch workflow)**, then select **Users**.

Understanding the Users Table

LICENSE: FireSIGHT

When the system discovers a user, it collects data about that user and stores it in the database. Descriptions of the fields in the users table follow.

User

One of:

- the first name, last name, and username of the user as collected via the optional Defense Center-LDAP server connections
- the username only, if you have not configured Defense Center-LDAP server connections, or for users that the Defense Center cannot correlate with an LDAP record

The Defense Center also displays the protocol used to detect the user.

Note that because unsuccessful AIM login attempts are recorded, the Defense Center can store invalid AIM users (for example, if a user misspelled his or her username).

Current IP

The IP address associated with the host that the user is logged into. This field is blank if another authoritative user logs into the host with the same IP address after the user's login, unless the user is an authoritative user and the new user is a non-authoritative user. (The system associates the IP address with the last authoritative user that logged in with the host.) For more information on authoritative vs. non-authoritative users, see Users Database on page 1311.

First Name

The user's first name, as obtained from the optional Defense Center-LDAP server connections. This field is blank if:

- you have not configured a Defense Center-LDAP server connection
- the Defense Center cannot correlate the user in the Defense Center database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login)
- there is no first name associated with the user on your LDAP servers

Last Name

The user's last name, as obtained from the optional Defense Center-LDAP server connections. This field is blank if:

- you have not configured a Defense Center-LDAP server connection
- the Defense Center cannot correlate the user in the Defense Center database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login)
- there is no last name associated with the user on your LDAP servers

E-Mail

The user's email address. This field is blank if:

- the user was added to the database via an AIM login
- the user was added to the database via an LDAP login and there is no email address associated with the user on your LDAP servers

Department

The user's department, as obtained from the optional Defense Center-LDAP server connections. If there is no department explicitly associated with the user on your LDAP servers, the department is listed as whatever default group the server assigns. For example, on Active Directory, this is `Users (ad)`. This field is blank if:

- you have not configured a Defense Center-LDAP server connection
- the Defense Center cannot correlate the user in the Defense Center database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login)

Phone

The user's telephone number, as obtained from the optional Defense Center-LDAP server connections. This field is blank if:

- you have not configured a Defense Center-LDAP server connection
- the Defense Center cannot correlate the user in the Defense Center database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login)
- there is no telephone number associated with the user on your LDAP servers

User Type

The protocol used to detect the user. For example, for users added to the database when detects a POP3 login, the user type is `pop3`.

Count

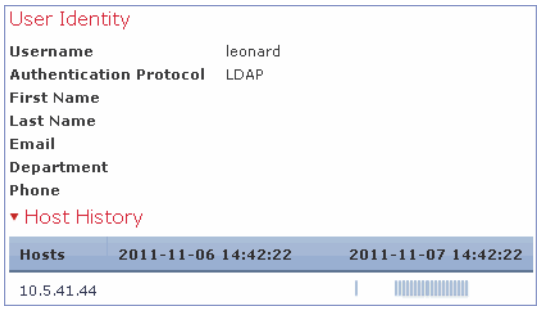
The number of users that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Understanding User Details and Host History

LICENSE: FireSIGHT

From any event view that associates user identity data with other kinds of events, as well as from a table view of users, you can display the User Identity pop-up

window to learn more about a specific user. User information also appears in the terminating page for users workflows.



The user data you see is the same as you would see in the table view of users; for more information, see Understanding the Users Table on page 1516.

The host history provides a graphic representation of the last twenty-four hours of the user's activity. A list of IP addresses of the hosts that the user logged into and logged off of approximates login and logout times with bar graphs. A typical user might log on to and off of multiple hosts in the course of a day. For example, periodic automated logins to a mail server would display as multiple short sessions, while longer logins (such as during working hours) display longer sessions.

Note that when a non-authoritative user login to a host is detected, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user login is detected for that host, only another authoritative user login changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control. If you configure capture of failed logins in the network discovery policy, the host history also includes hosts where the user failed to log in.

The data used to generate the host history is stored in the user history database, which by default stores 10 million user login events. If you do not see any data in the host history for a particular user, either that user is inactive, or you may need to increase the database limit. For more information, see Configuring Database Event Limits on page 2056.

To view user details and host history:

Access: Admin/Any Security Analyst

▶ You have two options:

- In any event view that lists users, click the user icon ( ) that appears next to a user identity.
- In any users workflow, click the Users terminating page.

User details appear.

Searching for Users

License: FireSIGHT

You can search for specific users. You may want to create searches customized for your network environment, then save them to reuse later.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.
- IP addresses may be specified using CIDR notation. For information on entering IPv4 and IPv6 addresses in the Sourcefire 3D System, see IP Address Conventions on page 63.
- Click the add object icon () that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

Specific User Search Criteria

For user type, valid search criteria are `ldap`, `pop3`, `imap`, and `aim`; because users are not added to the database based on SMTP logins, entering `smtp` will not return any results.

To search for users:

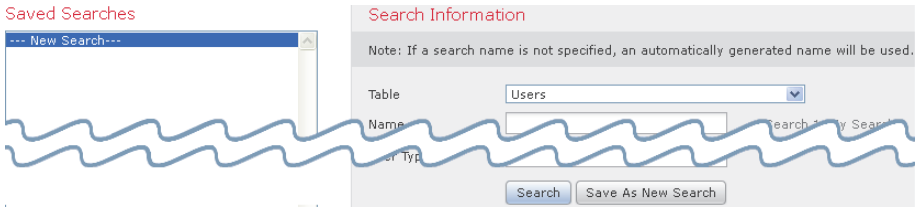
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Users**.

   The Users search page appears.



> **TIP!** To search the database for a different kind of event, select it from the **Table** drop-down list.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields. If you enter multiple criteria, the search returns only the records that match all the criteria.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

> **TIP!** If you want to save a search as a restriction for custom user roles with restricted privileges, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in the default users workflow. To use a different workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

Working with User Activity

LICENSE: FireSIGHT

The Sourcefire 3D System generates events that communicate the details of user activity on your network. Descriptions of the four types of user activity follow.

New User Identity

This event is generated when the system detects a user login for a user that is not in the database.

User Login

This event is generated when any of the following occur:

- an Active Directory Agent that you installed on an Active Directory server detects an LDAP login
- a managed device detects an LDAP, POP3, IMAP, SMTP, AIM, Oracle or SIP login

There are several points to keep in mind regarding user login events:

- SMTP logins are not recorded unless there is already a user with a matching email address in the database.
- Failed logins are only for LDAP, IMAP, and POP3, and only when detected in traffic. Users are not added to the detected users database as a result of a failed login, but the activity is optionally recorded in the user activity database, based on the user logging configuration in the network discovery policy.
- A user login is not recorded if you have specifically restricted its login type; see Restricting User Logging on page 1343.

Note that when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. In addition, when a non-authoritative user is the current user on a host, that user still cannot be used for user control.

Delete User Identity

This event is generated when you manually delete a user from the database.

User Identity Dropped: User Limit Reached

This event is generated when the system detects a user that is not in the database, but cannot add the user because you have reached the maximum number of users in the database as determined by your FireSIGHT license.

The total number of detected users the Defense Center can store depends on your FireSIGHT license. After you reach the licensed limit, in most cases the system stops adding new users to the database. To add new users, you must either manually delete old or inactive users from the database, or purge all users from the database.

However, the system favors authoritative users. If you have reached the limit and the system detects a login for a previously undetected authoritative user, the system deletes the non-authoritative user who has remained inactive for the longest time, and replaces it with the new authoritative user.

When the system detects user activity, it is logged to the database. You can view, search, and delete user activity; you can also purge all user activity from the database.

Whenever possible the Sourcefire 3D System correlates user activity with other types of events. For example, intrusion events can tell you the users who were logged into the source and destination hosts at the time of the event. This can tell you who owns the host that was targeted by an attack, or who initiated an internal attack or portscan.

You can also use user activity in correlation rules. Based on the type of user activity as well as other criteria that you specify, you can build correlation rules that, when used in a correlation policy, launch remediations and alert responses when network traffic meets your criteria. For more information on user activity, see Understanding User Data Collection on page 1306.

For more information, see the following sections:

- Viewing User Activity Events on page 1523
- Understanding the User Activity Table on page 1524
- Searching for User Activity on page 1525

Viewing User Activity Events

License: FireSIGHT

You can view a table of user activity, and then manipulate the event view depending on the information you are looking for.

The page you see when you access user activity differs depending on the workflow you use. You can use the predefined workflow, which includes the table view of user activity and terminates in a user details page, which contains user details for every user that meets your constraints. You can also create a custom workflow that displays only the information that matches your specific needs. For information on creating a custom workflow, see Creating Custom Workflows on page 1916.

For more information about the contents of the columns in the table, see Understanding the User Activity Table on page 1524.The following table, see describes some of the specific actions you can perform on an user activity workflow page. You can also perform the actions in the Common Discovery Event

Actions table on page 1451.

To view user activity:

Access: Admin/Any Security Analyst

- Select **Analysis > Users > User Activity**.

  The first page of the default user activity workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. If no events appear, you may need to adjust the time range; see Setting Event Time Constraints on page 1896.

TIP! If you are using a custom workflow that does not include the table view of user activity, click **(switch workflow)**, then select **User Activity**.

Understanding the User Activity Table

License: FireSIGHT

When the system detects user activity, it is logged to the database. Descriptions of the fields in the users table follow.

Time

The time that the system detected the user activity.

Event

The user activity type. For more information, see Working with User Activity on page 1522.

User

The user associated with the activity. At a minimum, this field contains a username and the protocol used to detect the user. If there is LDAP metadata on the user, this field may also contain the first name and last name of the user.

User Type

The protocol used to detect the user. For example, for users added to the database when the system detects a POP3 login, the user type is `pop3`.

IP Address

For User Login activity, the IP address involved in the login, which can be an IP address of the user's host (for LDAP, POP3, IMAP, and AIM logins), the server (for SMTP and Oracle logins), or the session originator (for SIP logins).

Note that an associated IP address does not mean the user is the current user for that IP address; when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user.

For other types of user activity, this field is blank.

Description

For Delete User Identity and User Identity Dropped activity, the username of the user who was deleted from the database or failed to be added to the database. For logins to network resources, `network login` is displayed. For other types of user activity, this field is blank.

Device

For user activity detected by a managed device, the name of the device. For other types of user activity, the managing Defense Center.

Count

The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Searching for User Activity

License: FireSIGHT

You can search for specific user activity. You may want to create searches customized for your network environment, then save them to reuse later.

General Search Syntax

The system displays examples of valid syntax next to each search field. When entering search criteria, keep the following points in mind:

- All fields accept negation (`!`).
- All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
- Many fields accept one or more asterisks (`*`) as wild cards.
- For some fields, you can specify `n/a` or `blank` in the field to identify events where information is not available for that field; use `!n/a` or `!blank` to identify the events where that field is populated.
- Most fields are case-insensitive.
- IP addresses may be specified using CIDR notation. For information on entering IPv4 and IPv6 addresses in the Sourcefire 3D System, see IP Address Conventions on page 63.

- Click the add object icon ( ) that appears next to a search field to use an object as a search criterion.

For detailed information on search syntax, including using objects in searches, see Searching for Events on page 1842.

To search for user activity:

Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Tables** drop-down menu, select **User Activity**.

   The User Activity search page appears.

TIP! To search the database for a different kind of event, select it from the **Table** drop-down list.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields. If you enter multiple criteria, the search returns only the records that match all the criteria. Click the add icon ( ) that appears next to a search field to use an object as a search criterion.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

TIP! If you want to save a search as a restriction for custom user roles with restricted privileges, you **must** save it as a private search.

6. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in the default user activity workflow, constrained by the current time range. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

CHAPTER 36

CONFIGURING CORRELATION POLICIES AND RULES

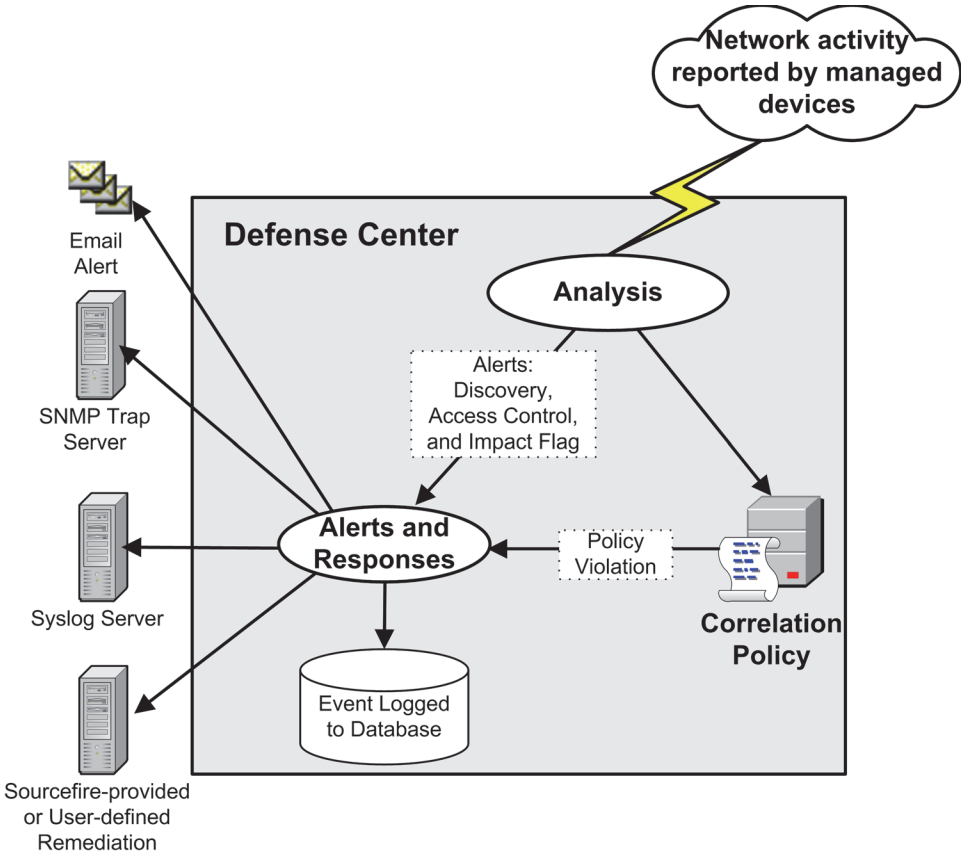
You can use the Sourcefire 3D System's *correlation* feature to build *correlation policies*, which are populated with *correlation rules* and *compliance white lists*, and that let you respond in real time to threats to your network. A correlation *policy violation* occurs when the activity on your network triggers either a correlation rule or white list.

A correlation rule triggers when a specific event generated by the Sourcefire 3D System either meets criteria that you specify, or when your network traffic deviates from your normal network traffic pattern as characterized in an existing traffic profile.

Compliance white lists, on the other hand, trigger when the system determines that a host on your network is running a prohibited operating system, client application (or client), application protocol, or protocol.

You can configure the Sourcefire 3D System to initiate responses to policy violations. Responses include simple alerts as well as various remediations (such as scanning a host). You can group responses so that the system launches multiple responses for each policy violation.

The following graphic illustrates the event notification and correlation process:



This chapter focuses on creating correlation rules, using those rules in policies, associating responses and response groups with those rules, and analyzing correlation events. For more information, see:

- Creating Rules for Correlation Policies on page 1530
- Managing Rules for Correlation Policies on page 1579
- Grouping Correlation Responses on page 1581
- Creating Correlation Policies on page 1584
- Managing Correlation Policies on page 1590
- Working with Correlation Events on page 1592

For information on creating compliance white lists and correlation responses (alerts and remediations), see:

- Using the Sourcefire 3D System as a Compliance Tool on page 1601
- Working with Alert Responses on page 571.
- Configuring Remediations on page 1677.

Creating Rules for Correlation Policies

LICENSE: FireSIGHT, Protection, URL Filtering, or Malware
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

Before you create a correlation policy, you should create correlation rules or compliance white lists (or both) to populate it.

IMPORTANT! This section describes how to create correlation rules. For information on creating compliance white lists, see Creating Compliance White Lists on page 1612.

A correlation rule triggers (and generates a correlation event) when your network traffic meets criteria that you specify. When you create correlation rules, you can use simple conditions or you can create more elaborate constructs by combining and nesting conditions and constraints.

You can further add to correlation rules in the following ways:

- Add a *host profile qualification* to constrain the rule using information from the host profile of a host involved in the triggering event.
- Add a *connection tracker* to a correlation rule so that after the rule's initial criteria are met, the system begins tracking certain connections. Then, a correlation event is generated only if the tracked connections meet additional criteria.
- Add a *user qualification* to a correlation rule to track certain users or groups of users. For example, you could constrain a correlation rule so that it triggers only when the identity of the source or destination user is a certain user or, for example, one from the marketing department.
- Add *snooze periods* and *inactive periods*. When a correlation rule triggers once, a snooze period causes that rule not to trigger again for a specified interval, even if the rule is violated again during the interval. After the snooze period has elapsed, the rule can trigger again (and start a new snooze period). During inactive periods, the correlation rule does not trigger.

WARNING! Evaluating complex correlation rules that trigger on frequently occurring events can degrade Defense Center performance. For example, a multi-condition rule that the Defense Center must evaluate against every connection logged by the system can cause resource overload.

The following table explains the licenses you must have to build effective correlation rules. If you do not have the appropriate licenses, correlation rules that use an unlicensed aspect of the Sourcefire 3D System do not trigger. For more

information on specific licenses, see License Types and Restrictions on page 2119.

License Requirements for Building Correlation Rules

TO...	YOU NEED THIS LICENSE...
trigger a correlation rule on an intrusion event	Protection
trigger a correlation rule on a discovery event, host input event, or user activity, or to add a host profile or user qualification to a correlation rule	FireSIGHT
trigger a correlation rule on a connection event or endpoint-based malware event, or to add a connection tracker to a rule	Any
trigger a correlation rule on a connection event with URL data, or build a connection tracker using URL data Note that neither Series 2 devices nor the DC500 Defense Center support URL filtering by category or reputation, and Series 2 devices do not support URL filtering by literal URL or URL group.	URL Filtering
trigger a correlation rule on a malware event based on network-based malware data or retrospective network-based malware data Note that neither Series 2 devices nor the DC500 Defense Center support network-based malware protection.	Malware

When you create either correlation rule trigger criteria, host profile qualifications, user qualifications, or connection trackers, the syntax varies but the mechanics remain consistent. For more information, See Understanding Rule Building Mechanics on page 1570.

To create a correlation rule:

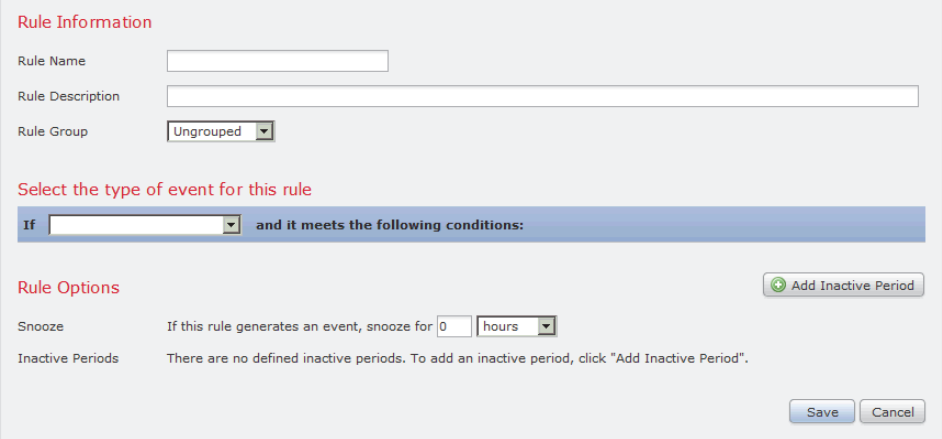
ACCESS: Admin/Discovery Admin

1. Select **Policies > Correlation**, then select the **Rule Management** tab.

   The Rule Management page appears.

2. Click **Create Rule**.

   The Create Rule page appears.



3. Provide basic rule information, such as the rule name, description, and group.

   See Providing Basic Rule Information on page 1533.

4. Specify the basic criteria on which you want the rule to trigger.

   See Specifying Correlation Rule Trigger Criteria on page 1533.

5. Optionally, add a host profile qualification to the rule.

   See Adding a Host Profile Qualification on page 1551.

6. Optionally, add a connection tracker to the rule.

   See Constraining Correlation Rules Using Connection Data Over Time on page 1556.

7. Optionally, add a user qualification to the rule.

   See Adding a User Qualification on page 1567.

8. Optionally, add an inactive period or snooze period (or both) to the rule.

   See Adding Snooze and Inactive Periods on page 1569.

9. Click **Save Rule**.

   The rule is saved. You can now use the rule within correlation policies or within other correlation rules that trigger on the same event type.

Providing Basic Rule Information

LICENSE: Any

You must give each correlation rule a name and, optionally, a short description. You can also place the rule in a rule group.

To provide basic rule information:

ACCESS: Admin/Discovery Admin

1. Select **Policies > Correlation**, then select the **Rule Management** tab.

   The Rule Management page appears.

2. Click **Create Rule**.

   The Create Rule page appears.

3. On the Create Rule page, in the **Rule Name** field, type a name for the rule.

4. In the **Rule Description** field, type a description for the rule.

5. Optionally, select a group for the rule from the **Rule Group** drop-down list.

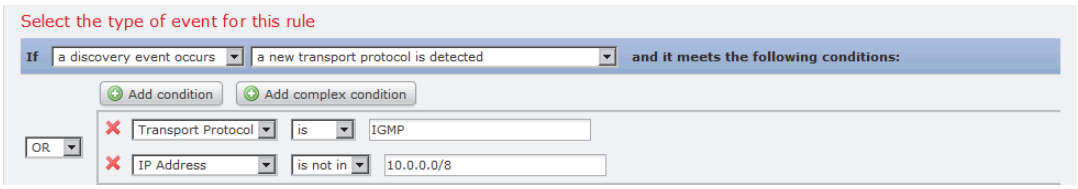
   For more information on rule groups, see Managing Rules for Correlation Policies on page 1579.

6. Continue with the procedure in the next section, Specifying Correlation Rule Trigger Criteria.

Specifying Correlation Rule Trigger Criteria

LICENSE: FireSIGHT, Protection, URL Filtering, or Malware
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

A simple correlation rule requires only that an event of a certain type occurs; you do not need to provide more specific conditions. For example, correlation rules based on traffic profile changes do not require any conditions at all. In contrast, correlation rules may be complex, with multiple nested conditions. For example, the rule shown in the following graphic comprises criteria that direct the rule to trigger if an IP address that is not in the 10.x.x.x subnet transmits an IGMP message.



To specify correlation rule trigger criteria:

Access: Admin/Discovery Admin

1. Select the type of event on which you want to base your rule.

   When you build a correlation rule, you must first select the type of event on which you want to base your rule. You have a few options under **Select the type of event for this rule**:

   - Select **an intrusion event occurs** to trigger your rule when a specific intrusion event occurs.
   - Select **a Malware event occurs** to trigger the rule when a specific malware event occurs.

     Note that because neither Series 2 devices nor the DC500 Defense Center support network-based malware protection, these appliances do not support triggering a correlation rule on a malware event based on network-based malware data or retrospective network-based malware data.
   - Select **a discovery event occurs** to trigger the rule when a specific discovery event occurs. When triggering a correlation rule on a discovery event, you must also choose the type of event you want to use. You can choose from a subset of the discovery events described in Understanding Discovery Event Types on page 1453; you cannot, for example, trigger a correlation rule on a hops change. You can, however, choose **there is any type of event** to trigger the rule when any kind of discovery event occurs.
   - Select **user activity is detected** to trigger the rule when a new user is detected or a user logs in to a host.
   - Select **a host input event occurs** to trigger the rule when a specific host input event occurs. When triggering a correlation rule on a host input event, you must also choose the type of event you want to use. You can choose from a subset of the events described in Understanding Host Input Event Types on page 1458.
   - Select **a connection event occurs** to trigger the rule when connection data meets specific criteria. When triggering a correlation rule on a connection event, you must also choose whether you want to use connection events that represent the beginning or the ending of the connection, or either.

     Note that because neither Series 2 devices nor the DC500 Defense Center support URL filtering by category or reputation, these appliances do not support triggering a correlation rule on a connection event with URL data, or building a connection tracker using URL data.
   - Select **a traffic profile changes** to trigger the correlation rule when network traffic deviates from your normal network traffic pattern as characterized in an existing traffic profile.

2. Specify the rule's conditions.

   The syntax you can use within correlation rule trigger criteria conditions varies depending on the base event you chose in step 1, but the mechanics are the same. For more information, see Understanding Rule Building Mechanics on page 1570.

   The syntax you can use to build conditions is described in the following sections:

   - Syntax for Intrusion Events on page 1536
   - Syntax for Malware Events on page 1538
   - Syntax for Discovery Events on page 1540
   - Syntax for User Activity Events on page 1543
   - Syntax for Host Input Events on page 1544
   - Syntax for Connection Events on page 1546
   - Syntax for Traffic Profile Changes on page 1549

   TIP! You can nest rules that share the base event type you specified in step 1. For example, if you create a new rule based on the detection of an open TCP port, the trigger criteria for the new rule could include **rule "MyDoom Worm" is true** and **rule "Kazaa (TCP) P2P" is true**.

3. Optionally, continue with the procedures in the following sections:

   - Adding a Host Profile Qualification on page 1551
   - Constraining Correlation Rules Using Connection Data Over Time on page 1556
   - Adding a User Qualification on page 1567
   - Adding Snooze and Inactive Periods on page 1569

   If you are finished building the correlation rule, continue with step 9 of the procedure in Creating Rules for Correlation Policies on page 1530 to save the rule.

Syntax for Intrusion Events

LICENSE: Protection

The Syntax for Intrusion Events table describes how to build a correlation rule condition when you choose an intrusion event as the base event.

Syntax for Intrusion Events

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Access Control Policy	Select one or more access control policies that use the intrusion policy that generated the intrusion event.
Access Control Rule Name	Type all or part of the name of the access control rule that uses the intrusion policy that generated the intrusion event.
Application Protocol	Select one or more application protocols associated with the intrusion event.
Application Protocol Category	Select one or more category of application protocol.
Classification	Select one or more classifications.
Client	Select one or more clients associated with the intrusion event.
Client Category	Select one or more category of client.
Destination IP, Source IP, or Source/Destination IP	Specify a single IP address, an address block, or a comma-separated list comprised of any of these. For information on using IP address notation and prefix lengths in the Sourcefire 3D System, see IP Address Conventions on page 63. Note that you cannot enter a comma-separated list if you select **is in** or **is not in** as the operator for the condition.
Destination Port/ICMP Code or Source Port/ ICMP Type	Type the port number or ICMP type for source traffic or the port number or ICMP type for destination traffic.
Device	Select one or more devices that may have generated the event.
Egress Interface or Ingress Interface	Select one or more interfaces.
Egress Security Zone or Ingress Security Zone	Select one or more security zones.

Syntax for Intrusion Events (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Generator ID	Select one or more preprocessors. See Using Advanced Settings in an Intrusion Policy on page 799 for more information about available preprocessors.
Impact Flag	Select the impact level assigned to the intrusion event. You select any of the following along with operators that specify `is`, `is not`, `is greater than`, and so on: • 0 — gray (Unknown) • 1 — red (Vulnerable) • 2 — orange (Potentially Vulnerable) • 3 — yellow (Currently Not Vulnerable) • 4 — blue (Unknown Target) **IMPORTANT!** Because there is no operating system information available for hosts added to the network map based on NetFlow data, the Defense Center cannot assign Vulnerable (level 1: red) impact levels for intrusion events involving those hosts, unless you use the host input feature to manually set the host operating system identity. For more information, see Using Impact Levels to Evaluate Events on page 688.
Inline Result	Select either: • **dropped**, to specify whether the packet was dropped in an inline, switched, or routed deployment • **would have dropped**, to specify whether the packet would have dropped if the intrusion policy had been set to drop packets in an inline, switched, or routed deployment Note that the system does not drop packets in a passive deployment, including when an inline set is in tap mode, regardless of the rule state or the drop behavior of the intrusion policy. For more information, see Setting Rule States on page 770, Setting Drop Behavior in an Inline Deployment on page 735, Configuring Passive Interfaces on page 312, and Tap Mode on page 321.
Intrusion Policy	Select one or more intrusion policies that generated the intrusion event.
IOC Tag	Select whether an IOC tag `is` or `is not` set as a result of the intrusion event.
Priority	Select the rule priority: **low**, **medium**, or **high**. For rule-based intrusion events, the priority corresponds to either the value of the `priority` keyword or the value for the `classtype` keyword. For other intrusion events, the priority is determined by the decoder or preprocessor.

Syntax for Intrusion Events (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Protocol	Type the name or number of the transport protocol as listed in http://www.iana.org/assignments/protocol-numbers.
Rule Message	Type all or part of the rule message.
Rule SID	Type a single Snort ID number (SID) or multiple SIDs separated by commas. **IMPORTANT!** If you choose **is in** or **is not in** as the operator, you cannot use the multi-selection pop-up window. You must type a comma-separated list of SIDs.
Rule Type	Specify whether the rule is or is not local. Local rules include custom standard text intrusion rules, standard text rules that you modified, and any new instances of shared object rules created when you saved the rule with modified header information. For more information, see Modifying Existing Rules on page 1214.
Username	Type the username of the user logged into the source host in the intrusion event.
VLAN ID	Type the innermost VLAN ID associated with the packet that triggered the intrusion event
Web Application	Select one or more web applications associated with the intrusion event.
Web Application Category	Select one or more category of web application.

Syntax for Malware Events

LICENSE: Any or Malware
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

The syntax for correlation rule conditions based on malware events depends on whether the event is reported by an endpoint-based malware agent, detected by a managed device, or detected by a managed device and retrospectively identified as malware.

Note that because neither Series 2 devices nor the DC500 Defense Center support network-based malware protection, these appliances do not support triggering a correlation rule on a malware event based on network-based malware data or retrospective network-based malware data.

The Syntax for Malware Events table describes how to build a correlation rule condition when you choose a malware event as the base event.

Syntax for Malware Events

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Application Protocol	Select one or more application protocols associated with the malware event.
Application Protocol Category	Select one or more category of application protocol.
Client	Select one or more clients associated with the malware event.
Client Category	Select one or more category of client.
Destination IP, Host IP, or Source IP	Specify a single IP address or address block. For information on using IP address notation in the Sourcefire 3D System, see IP Address Conventions on page 63.
Destination Port/ ICMP Code	Type the port number or ICMP code for destination traffic.
Disposition	Select either or both `Malware` or `Custom Detection`.
Event Type	Select one or more endpoint-based event types associated with the malware event. For more information, see Malware Event Types on page 1284.
File Name	Type the name of the file.
File Type	Select the type of file, for example, `PDF` or `MSEXE`.
File Type Category	Select one or more file type categories, for example, `Office Documents` or `Executables`.
IOC Tag	Select whether an IOC tag `is` or `is not` set as a result of the malware event.
SHA-256	Type or paste the SHA-256 hash value of the file.
Source Port/ICMP Type	Type the port number or ICMP type for source traffic.
Web Application	Select one or more web applications associated with the malware event.
Web Application Category	Select one or more category of web application.

Syntax for Discovery Events

LICENSE: FireSIGHT

If you base your correlation rule on a discovery event, you must first choose the type of event you want to use from a drop-down list. The following table lists the events you can choose as trigger criteria from the drop-down list, cross-referenced with their corresponding event types. For detailed descriptions of discovery event types, see Understanding Discovery Event Types on page 1453.

Correlation Rule Trigger Criteria vs. Discovery Event Types

SELECT THIS OPTION...	TO TRIGGER THE RULE ON THIS EVENT TYPE...
a client has changed	Client Update
a client timed out	Client Timeout
a host ip address is reused	DHCP: IP Address Reassigned
a host is deleted because the host limit was reached	Host Deleted: Host Limit Reached
a host is identified as a network device	Host Type Changed to Network Device
a host timed out	Host Timeout
a host's IP address has changed	DHCP: IP Address Changed
a NETBIOS name change is detected	NETBIOS Name Change
a new client is detected	New Client
a new IP host is detected	New Host
a new MAC address is detected	Additional MAC Detected for Host
a new MAC host is detected	New Host
a new network protocol is detected	New Network Protocol
a new transport protocol is detected	New Transport Protocol
a TCP port closed	TCP Port Closed

Correlation Rule Trigger Criteria vs. Discovery Event Types (Continued)

SELECT THIS OPTION...	TO TRIGGER THE RULE ON THIS EVENT TYPE...
a TCP port timed out	TCP Port Timeout
a UDP port closed	UDP Port Closed
a UDP port timed out	UDP Port Timeout
a VLAN tag was updated	VLAN Tag Information Update
an open TCP port is detected	New TCP Port
an open UDP port is detected	New UDP Port
the OS information for a host has changed	New OS
the OS or server identity for a host has a conflict	Identity Conflict
the OS or server identity for a host has timed out	Identity Timeout
there is any kind of event	any event type
there is new information about a MAC address	MAC Information Change
there is new information about a TCP server	TCP Server Information Update
there is new information about a UDP server	UDP Server Information Update

Note that you cannot trigger a correlation rule on hops changes, or when the system drops a new host due to reaching the licensed host limit. You can, however, choose **there is any type of event** to trigger the rule when any type of discovery event occurs.

After you choose the discovery event type, you can build correlation rule conditions as described in the Syntax for Discovery Events table below. Depending on the type of event you choose, you can build conditions using subsets of the criteria in the following table. For example, if you trigger your correlation rule when a new client is detected, you can build conditions based on

the IP or MAC address of the host, the client name, type, or version, and the device that detected the event.

Syntax for Discovery Events

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Application Protocol	Select one or more application protocols.
Application Protocol Category	Select one or more category of application protocol.
Application Port	Type the application protocol port number.
Client	Select one or more clients.
Client Category	Select one or more category of client.
Client Version	Type the version number of the client.
Device	Select one or more devices that may have generated the discovery event.
Hardware	Type the hardware model for the mobile device. For example, to match all Apple iPhones, type `iPhone`.
Host Type	Select one or more host types from the drop-down list. You can choose between a host or one of several types of network device.
IP Address or New IP Address	Type a single IP address or address block. For information on using IP address notation in the Sourcefire 3D System, see IP Address Conventions on page 63.
Jailbroken	Select **Yes** to indicate that the host in the event is a jailbroken mobile device or **No** to indicate that it is not.
MAC Address	Type all or part of the MAC address of the host. For example, if you know that devices from a certain hardware manufacturer have MAC addresses that begin with 0A:12:34, you could choose **begins with** as the operator, then type `0A:12:34` as the value.
MAC Type	Select whether the MAC address was **ARP/DHCP Detected**. That is, select whether the system positively identified the MAC address as belonging to the host (**is ARP/DHCP Detected**), or whether the system is seeing many hosts with that MAC address because, for example, there is a router between the managed device and the host (**is not ARP/DHCP Detected**).
MAC Vendor	Type all or part of the name of the MAC hardware vendor of the NIC used by the network traffic that triggered the discovery event.

Syntax for Discovery Events (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Mobile	Select **Yes** to indicate that the host in the event is a mobile device or **No** to indicate that it is not.
NETBIOS Name	Type the NetBIOS name of the host.
Network Protocol	Type the network protocol number as listed in http://www.iana.org/assignments/ethernet-numbers.
OS Name	Select one or more operating system names.
OS Vendor	Select one or more operating system vendors.
OS Version	Select one or more operating system versions.
Protocol or Transport Protocol	Type the name or number of the transport protocol as listed in http://www.iana.org/assignments/protocol-numbers.
Source	Select the source of the host input data (for operating system and server identity changes and timeouts).
Source Type	Select the type of the source for the host input data (for operating system and server identity changes and timeouts).
VLAN ID	Type the VLAN ID of the host involved in the event.
Web Application	Select a web application.

Syntax for User Activity Events

LICENSE: FireSIGHT

If you base your correlation rule on user activity, you must first choose the type of user activity you want to use from a drop-down list, either:

- a user logged into a host, or
- a new user identity was detected

After you choose the user activity type, you can build correlation rule conditions as described in the Syntax for User Activity table. Depending on the type of user activity you choose, you can build conditions using subsets of the criteria in the

following table; for correlation rules triggered on new user identity, you cannot specify an IP address.

Syntax for User Activity

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Device	Select one or more devices that may have detected the user activity.
IP Address	Type a single IP address or address block. For information on using IP address notation in the Sourcefire 3D System, see IP Address Conventions on page 63.
Username	Type a username.

Syntax for Host Input Events

LICENSE: FireSIGHT

If you base your correlation rule on a host input event, you must first choose the type of host input event you want to use from a drop-down list. The following table lists the events you can choose as trigger criteria from the drop-down list, cross-referenced with their corresponding host input event types. For detailed descriptions of host input event types, see Understanding Host Input Event Types on page 1458.

Correlation Rule Trigger Criteria vs. Host Input Event Types

SELECT THIS OPTION...	TO TRIGGER THE RULE ON THIS EVENT TYPE...
a client is added	Add Client
a client is deleted	Delete Client
a host is added	Add Host
a protocol is added	Add Protocol
a protocol is deleted	Delete Protocol
a scan result is added	Add Scan Result
a server definition is set	Set Server Definition
a server is added	Add Port
a server is deleted	Delete Port

Correlation Rule Trigger Criteria vs. Host Input Event Types (Continued)

SELECT THIS OPTION...	TO TRIGGER THE RULE ON THIS EVENT TYPE...
a vulnerability is marked invalid	Vulnerability Set Invalid
a vulnerability is marked valid	Vulnerability Set Valid
an address is deleted	Delete Host/Network
an attribute value is deleted	Host Attribute Delete Value
an attribute value is set	Host Attribute Set Value
an OS definition is set	Set Operating System Definition
host criticality is set	Set Host Criticality

You cannot trigger a correlation rule when you add, delete, or change the definition of a user-defined host attribute, or set a vulnerability impact qualification.

After you choose the host input event type, you can build correlation rule conditions as described in the Syntax for Host Input Events table below. Depending on the type of host input event you choose, you can build conditions using subsets of the criteria in the following table. For example, if you trigger your correlation rule when a client is deleted, you can build conditions based on the IP address of the host involved in the event, the source type of the deletion (manual,

third-party application, or scanner), and the source itself (a specific scanner type or user).

Syntax for Host Input Events

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
IP Address	Type a single IP address or address block. For information on using IP address notation in the Sourcefire 3D System, see IP Address Conventions on page 63.
Source	Select the source for the host input data.
Source Type	Select the type of the source for the host input data.

Syntax for Connection Events

LICENSE: Any

If you base your correlation rule on a connection event, you must first choose whether you want to evaluate events that represent the beginning or ending of the connection, or either the beginning or the end. After you choose the connection event type, you can build correlation rule conditions as described in Syntax for Connection Events on page 1546.

When you build rule conditions, you should make sure that your network traffic can trigger the rules. The information available for any individual connection or connection summary event depends on several factors, including the detection method, the logging method, and event type. For more information, see Information Available in Connection and Security Intelligence Events on page 597.

Syntax for Connection Events

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Access Control Policy	Select one or more access control policies that logged the connection.
Access Control Rule Action	Select one or more actions associated with the access control rule that logged the connection. **IMPORTANT!** Select **Monitor** to trigger correlation events when network traffic matches the conditions of any Monitor rule, regardless of the rule or default action that later handles the connection
Access Control Rule Name	Type all or part of the name of the access control rule that logged the connection. **IMPORTANT!** You can type the name of any Monitor rule whose conditions were matched by a connection, regardless of the rule or default action that later handled the connection.

Syntax for Connection Events (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Application Protocol	Select one or more application protocols associated with the connection.
Application Protocol Category	Select one or more category of application protocol.
Client	Select one or more clients.
Client Category	Select one or more category of client.
Client Version	Type the version number of the client.
Connection Duration	Type the duration of the connection event, in seconds.
Connection Type	Select whether you want to trigger the correlation rule based on whether the connection was detected by a Sourcefire managed device (**FireSIGHT**) or was exported by a NetFlow-enabled device (**NetFlow**).
Device	Select one or more devices that either detected the connection, or that processed the connection (for connection data exported by a NetFlow-enabled device).
Egress Interface or Ingress Interface	Select one or more interfaces.
Egress Security Zone or Ingress Security Zone	Select one or more security zones.
Initiator Bytes, Responder Bytes, or Total Bytes	Type one of: • the number of bytes transmitted (**Initiator Bytes**). • the number of bytes received (**Responder Bytes**). • the number of bytes both transmitted and received (**Total Bytes**).
Initiator IP, Responder IP, or Initiator/Responder IP	Specify a single IP address, an address block, or a comma-separated list comprised of any of these. For information on using IP address notation and prefix lengths in the Sourcefire 3D System, see IP Address Conventions on page 63.
Initiator Packets, Responder Packets, or Total Packets	Type one of: • the number of packets transmitted (**Initiator Packets**). • the number of packets received (**Responder Packets**). • the number of packets both transmitted and received (**Total Packets**)
Initiator Port/ICMP Type or Responder Port/ICMP Code	Type the port number or ICMP type for initiator traffic or the port number or ICMP code for responder traffic.

Syntax for Connection Events (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
IOC Tag	Select whether an IOC tag `is` or `is not` set as a result of the connection event.
NETBIOS Name	Type the NetBIOS name of the monitored host in the connection.
NetFlow Device	Select the IP address of the NetFlow-enabled device that exported the connection data you want to use to trigger the correlation rule. If you did not add any NetFlow-enabled devices to your deployment, the NetFlow Device drop-down list is blank.
Reason	Select one or more reasons associated with the connection event.
TCP Flags	Select a TCP flag that a connection event must contain in order to trigger the correlation rule. **IMPORTANT!** Only connection data exported by NetFlow-enabled devices contain TCP flags.
Transport Protocol	Type the transport protocol used by the connection: `TCP` or `UDP`.
URL	Type all or part of the URL visited in the connection.
URL Category	Select one or more URL categories for the URL visited in the connection.
URL Reputation	Select one or more URL reputation values for the URL visited in the connection.
Username	Type the username of the user logged into either host in the connection.
Web Application	Select one or more web applications associated with the connection.
Web Application Category	Select one or more category of web application.

Syntax for Traffic Profile Changes

LICENSE: Any

If you base your correlation rule on a traffic profile change, the rule triggers when network traffic deviates from your normal network traffic pattern as characterized in an existing traffic profile. For information on how to build a traffic profile, see Creating Traffic Profiles on page 1656.

You can trigger the rule based on either raw data or on the statistics calculated from the data. For example, you could write a rule that triggers if the amount of data traversing your network (measured in bytes) suddenly spikes, which could indicate an attack or other security policy violation. You could specify that the rule trigger if either:

- the number of bytes traversing your network spikes above a certain number of standard deviations above or below the mean amount of traffic

  Note that to create a rule that triggers when the number of bytes traversing your network falls outside a certain number of standard deviations (whether above or below), you must specify upper and lower bounds, as shown in the following graphic.

  To create a rule that triggers when the number of bytes traversing is greater than a certain number of standard deviations **above** the mean, use only the first condition shown in the graphic.

  To create a rule that triggers when the number of bytes traversing is greater than a certain number of standard deviations **below** the mean, use only the second condition.

- the number of bytes traversing your network spikes above a certain number of bytes

You can select the **use velocity data** check box (see Changing the Graph Type on page 605), to trigger the correlation rule based on rates of change between data points. If you wanted to use velocity data in the above example, you could specify that the rule triggers if either:

- the change in the number of bytes traversing your network spikes above or below a certain number of standard deviations above the mean rate of change
- the change in the number of bytes traversing your network spikes above a certain number of bytes

The following table describes how to build a condition in a correlation rule when you choose a traffic profile change as the base event. If your traffic profile uses connection data exported by NetFlow-enabled devices, see Differences Between NetFlow and FireSIGHT Data on page 1325 to learn about how the detection method can affect the data used to create your traffic profile.

Syntax for Traffic Profile Changes

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN TYPE...	AND THEN CHOOSE ONE OF THE FOLLOWING...
Number of Connections	the total number of connections detected **or** the number of standard deviations either above or below the mean that the number of connections detected must be in to trigger the rule	connections standard deviation(s)
Total Bytes, Initiator Bytes, or Responder Bytes	one of: • the total bytes transmitted (**Total Bytes**) • the number of bytes transmitted (**Initiator Bytes**) • the number of bytes received (**Responder Bytes**) **or** the number of standard deviations either above or below the mean that one of the above criteria must be in to trigger the rule	bytes standard deviation(s)

Syntax for Traffic Profile Changes (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN TYPE...	AND THEN CHOOSE ONE OF THE FOLLOWING...
Total Packets, Initiator Packets, or Responder Packets	one of: • the total packets transmitted (**Total Packets**) • the number of packets transmitted (**Initiator Packets**) • the number of packets received (**Responder Packets**) **or** the number of standard deviations either above or below the mean that one of the above criteria must be in trigger the rule	packets standard deviation(s)
Unique Initiators	the number of unique hosts that initiated sessions **or** the number of standard deviations either above or below the mean that the number of unique initiators detected must be to trigger the rule	initiators standard deviation(s)
Unique Responders	the number of unique hosts that responded to sessions **or** the number of standard deviations either above or below the mean that the number of unique responders detected must be to trigger the rule	responders standard deviation(s)

Adding a Host Profile Qualification

LICENSE: FireSIGHT

If you are using a connection, intrusion, discovery, user activity, or host input event to trigger your correlation rule, you can constrain the rule based on the host profile of a host involved in the event. This constraint is called a *host profile qualification*.

IMPORTANT! You **cannot** add a host profile qualification to a correlation rule that triggers on a malware event, traffic profile change, or on the detection of a new IP host.

For example, you could constrain a correlation rule so that it triggers only when a Microsoft Windows host is the target of the offending traffic, because only Microsoft Windows computers are vulnerable to the vulnerability the rule is written for. As another example, you could constrain a correlation rule so that it triggers only when the host is out of compliance with a white list.

To match against *implied* or generic clients, create a host profile qualification based on the application protocol used by the server responding to the client. When the client list on a host that acts as the initiator or source of a connection includes an application protocol name followed by **client**, that client may actually be an implied client. In other words, the system reports that client based on server response traffic that uses the application protocol for that client, not on detected client traffic.

For example, if the system reports **HTTPS client** as a client on a host, create a host profile qualification for **Responder Host** or **Destination Host** where **Application Protocol** is set to **HTTPS**, because **HTTPS client** is reported as a generic client based on the HTTPS server response traffic sent by the responder or destination host.

Note that to use a host profile qualification, the host must exist in the network map and the host profile property you want to use as a qualification must already be included in the host profile. For example, if you configure a correlation rule to trigger when an intrusion event is generated for a host running Windows, the rule only triggers if the host is already identified as Windows when the intrusion event is generated.

To add a host profile qualification:

Access: Admin/Discovery Admin

1. Select **Policies > Correlation**, then select the **Rule Management** tab.

   The Rule Management page appears.

2. Click **Create Rule**.

   The Create Rule page appears.

3. On the Create Rule page, click **Add Host Profile Qualification**.

   The Host Profile Qualification section appears.

TIP! To remove a host profile qualification, click **Remove Host Profile Qualification**.

4. Build the host profile qualification's conditions.

   You can create a single, simple condition, or you can create more elaborate constructs by combining and nesting conditions. See Understanding Rule Building Mechanics on page 1570 for information on how to use the web interface to build conditions.

   The syntax you can use to build conditions is described in Syntax for Host Profile Qualifications on page 1553.

5. Optionally, continue with the procedures in the following sections:
   - Constraining Correlation Rules Using Connection Data Over Time on page 1556
   - Adding a User Qualification on page 1567
   - Adding Snooze and Inactive Periods on page 1569

   If you are finished building the correlation rule, continue with step 9 of the procedure in Creating Rules for Correlation Policies on page 1530 to save the rule.

Syntax for Host Profile Qualifications

License: FireSIGHT

When you build a host profile qualification condition, you must first select the host you want to use to constrain your correlation rule. The host you can choose depends on the type of event you are using to trigger the rule, as follows:

- If you are using a connection event, select **Responder Host** or **Initiator Host**.
- If you are using an intrusion event, select **Destination Host** or **Source Host**.
- If you are using a discovery event, host input event, or user activity, select **Host**.

After you select the host type, you continue building your host profile qualification condition, as described in the Syntax for Host Profile Qualifications table.

Note that although you can configure the network discovery policy to add hosts to the network map based on data exported by NetFlow-enabled devices, the available information about these hosts is limited. For example, there is no operating system data available for these hosts, unless you provide it using the host input feature. In addition, if you use connection data exported by NetFlow-enabled devices, keep in mind that NetFlow records do not contain information about which host is the initiator and which is the responder. When the system processes NetFlow records, it uses an algorithm to determine this information based on the ports each host is using, and whether those ports are well-known. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

Syntax for Host Profile Qualifications

If you specify...	Select an operator, then...
Host Type	Select one or more host types. You can choose between a host or one of several types of network device.
NETBIOS Name	Type the NetBIOS name of the host.
Operating System > OS Name	Select one or more operating system names.

Syntax for Host Profile Qualifications (Continued)

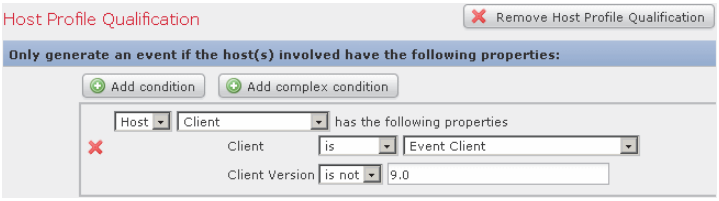
IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Operating System > OS Vendor	Select one or more operating system vendor names.
Operating System > OS Version	Select one or more operating system versions.
Hardware	Type the hardware model for the mobile device. For example, to match all Apple iPhones, type `iPhone`.
IOC Tag	Select one or more IOC tags. For more information on IOC tag types, see Understanding Indications of Compromise Types on page 1329.
Jailbroken	Select **Yes** to indicate that the host in the event is a jailbroken mobile device or **No** to indicate that it is not.
Mobile	Select **Yes** to indicate that the host in the event is a mobile device or **No** to indicate that it is not.
Network Protocol	Type the network protocol number as listed in http://www.iana.org/assignments/ethernet-numbers.
Transport Protocol	Type the name or number of the transport protocol as listed in http://www.iana.org/assignments/protocol-numbers.
Host Criticality	Select the host criticality: **None**, **Low**, **Medium**, or **High**. For more information on host criticality, see Working with the Predefined Host Attributes on page 1433.
VLAN ID	Type the VLAN ID associated with the host.
Application Protocol > Application Protocol	Select one or more application protocols.
Application Protocol > Application Port	Type the application protocol port number. If you are using an intrusion event to trigger the correlation rule, depending on the host you chose for the host profile qualification, this field is pre-populated with a port in the event: `dst_port` (for **Destination Host**) or `src_port` (for **Source Host**).
Application Protocol > Protocol	Select one or more protocols.
Application Protocol Category	Select a category.
Client > Client	Select one or more clients.

Syntax for Host Profile Qualifications (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Client > Client Version	Type the client version.
Client Category	Select a category.
Web Application	Select a web application.
Web Application Category	Select a category.
MAC Address > MAC Address	Type all or part of the MAC address of the host. For example, if you know that devices from a certain hardware have MAC addresses that begin with 0A:12:34, you could choose **begins with** as the operator, then type `0A:12:34` as the value.
MAC Address > MAC Type	Select whether the MAC type is **ARP/DHCP Detected**. That is, select whether the system positively identified the MAC address as belonging to the host (**is ARP/DHCP Detected**), whether the system is seeing many hosts with that MAC address because, for example, there is a router between the managed device and the host (**is not ARP/DHCP Detected**), or whether the MAC type is irrelevant (**is any**).
MAC Vendor > MAC Vendor	Type all or part of the name of the MAC hardware vendor of the host.
any available host attribute, including the default compliance white list host attribute	Specify the appropriate value, which depends on the type of host attribute you select: • If the host attribute type is `Integer`, enter an integer value in the range defined for the attribute. • If the host attribute type is `Text`, enter a text value. • If the host attribute type is `List`, select a valid list string. • If the host attribute type is `URL`, enter a URL value. For more information on host attributes, see Working with User-Defined Host Attributes on page 1434.

Note that you can often use event data when constructing a host profile qualification. For example, assume your correlation rule triggers when the system detects the use of Internet Explorer on one of your monitored hosts. Further assume that when you detect this use, you want to generate an event if the version of the browser is not the latest (for this example, assume the latest version is 9.0).

You could add a host profile qualification to this correlation rule so that the rule triggers only if the **Client** is the **Event Client** (that is, Internet Explorer), but the **Client Version** is not `9.0`.



Constraining Correlation Rules Using Connection Data Over Time

LICENSE: FireSIGHT

A *connection tracker* constrains a correlation rule so that after the rule's initial criteria are met (including host profile and user qualifications), the system begins tracking certain connections. The Defense Center generates a correlation event for the rule if the tracked connections meet additional criteria gathered over a time period that you specify.

If you are using a connection, intrusion, discovery, user activity, or host input event to trigger your correlation rule, you can add a connection tracker to the rule. You cannot add a connection tracker to a rule that triggers on a malware event or traffic profile change.

TIP! Connection trackers typically monitor very specific traffic and, when triggered, run only for a finite, specified time. Compare connection trackers with traffic profiles, which typically monitor a broad range of network traffic and run persistently; see Creating Traffic Profiles on page 1656.

There are two ways a connection tracker can generate an event, depending on how you construct the tracker:

Connection Trackers That Fire Immediately When Conditions Are Met

You can configure a connection tracker so that the correlation rule fires as soon as network traffic meets the tracker's conditions. When this happens, the system stops tracking connections for this connection tracker instance, even if the timeout period has not expired. If the same type of policy violation that triggered the correlation rule occurs again, the system creates a new connection tracker.

If, on the other hand time expires before network traffic meets the conditions in the connection tracker, the Defense Center does not generate a correlation event, and also stops tracking connections for that rule instance.

For example, a connection tracker can serve as a kind of event threshold by generating a correlation event only if a certain type of connection occurs more than a specific number of times within a specific time period. Or, you can generate a correlation event only if the system detects excessive data transfer after an initial connection.

Connection Trackers That Fire at The End of The Timeout Period

You can configure a connection tracker so that it relies on data collected over the entire timeout period, and therefore cannot fire until the end of the timeout period.

For example, if you configure a connection tracker to fire if you detect fewer than a certain number of bytes being transferred during a certain time period, the system waits until that time period passes and then generates an event if network traffic met that condition.

For more information, see the following sections:

- Adding a Connection Tracker on page 1558
- Syntax for Connection Trackers on page 1559
- Syntax for Connection Tracker Events on page 1563
- Example: Excessive Connections From External Hosts on page 1563
- Example: Excessive BitTorrent Data Transfers on page 1565

Adding a Connection Tracker

License: FireSIGHT

A connection tracker constrains a correlation rule so that after its initial criteria are met (including host profile and user qualifications), the system begins tracking certain connections. The Defense Center generates a correlation event for the rule if the tracked connections meet additional criteria gathered over a time period that you specify.

When you configure a connection tracker, you must specify:

- which connections you want to track
- the conditions that the connections you are tracking must meet for the Defense Center to generate a correlation event
- the maximum duration of the connection tracker, that is, the time period during which the conditions you specify must be met to generate a correlation event

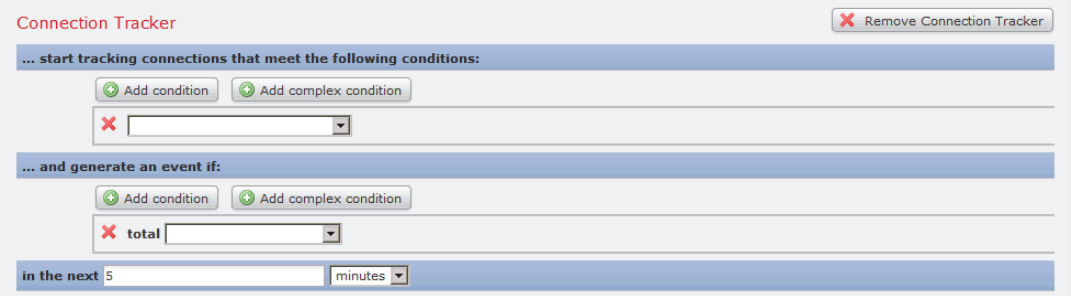
TIP! You can add a connection tracker to a simple correlation rule that requires only that any connection, intrusion, discovery, user identity, or host input event occurs.

To add a connection tracker:

Access: Admin/Discovery Admin

1. On the Create Rule page, click **Add Connection Tracker**.

   The Connection Tracker section appears.



TIP! To remove a connection tracker, click **Remove Connection Tracker**.

2. Specify which connections you want to track by setting connection tracker criteria.

   You can set connection tracker criteria by creating a single, simple condition, or you can create more elaborate constructs by combining and nesting conditions.

   See Understanding Rule Building Mechanics on page 1570 for information on how to use the web interface to build conditions. The syntax you can use to build connection tracker conditions is described in Syntax for Connection Trackers on page 1559.

3. Based on the connections you decided to track in step 2, describe when you want to generate a correlation event.

   You can create a single, simple condition that describes when you want to generate an event, or you can create more elaborate constructs by combining and nesting conditions.

   You must also specify the interval (in seconds, minutes, or hours) during which the conditions you specify must be met to generate a correlation event.

   See Understanding Rule Building Mechanics on page 1570 for information on how to use the web interface to build conditions. The syntax you can use to build connection tracker conditions is described in Syntax for Connection Tracker Events on page 1563.

4. Optionally, continue with the procedures in the following sections:

   - Adding a User Qualification on page 1567
   - Adding Snooze and Inactive Periods on page 1569

   If you are finished building the correlation rule, continue with step 9 of the procedure in Creating Rules for Correlation Policies on page 1530 to save the rule.

Syntax for Connection Trackers

LICENSE: Any

The Syntax for Connection Trackers table describes how to build a connection tracker condition that specifies the kind of connections you want to track.

You should keep in mind that connections detected by Sourcefire managed devices and connection data exported by NetFlow-enabled devices contain different information. For example, connections detected by managed devices do not contain TCP flag information. Therefore, if you want to specify that a connection event have a certain TCP flag to trigger a correlation rule, none of the connections detected by managed devices will trigger the rule.

As another example, NetFlow records do not contain information about which host in the connection is the initiator and which is the responder. When the system processes NetFlow records, it uses an algorithm to determine this information based on the ports each host is using, and whether those ports are well-known. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

Syntax for Connection Trackers

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Ingress Security Zone or Egress Security Zone	Select one or more security zones.
Device	Select one or more devices whose detected connections you want to track. If you want to track NetFlow connections, select the devices that process the connection data exported by your NetFlow-enabled devices.
Ingress Interface or Egress Interface	Select one or more interfaces.
Initiator IP, Responder IP, or Initiator/Responder IP	Type a single IP address or address block. For information on using IP address notation in the Sourcefire 3D System, see IP Address Conventions on page 63.
Initiator Port/ICMP Type or Responder Port/ICMP Code	Type the port number or ICMP type for initiator traffic or the port number or ICMP code for responder traffic.
IOC Tag	Select whether an IOC tag `is` or `is not` set.
Transport Protocol	Type the transport protocol used by the connection: `TCP` or `UDP`.
NETBIOS Name	Type the NetBIOS name of the monitored host in the connection.
Connection Type	Select whether you want to track connections based on how they were detected: by a Sourcefire managed device (**FireSIGHT**) or exported by a NetFlow-enabled device (**NetFlow**).
Connection Duration	Type the connection duration, in seconds.

Syntax for Connection Trackers (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
NetFlow Device	Select the IP address of the NetFlow-enabled device that exported the connections you want to track. If you did not add any NetFlow-enabled devices to your deployment, the NetFlow Device drop-down list is blank.
TCP Flags	Select the TCP flag that connections must contain in order to track them. **IMPORTANT!** Only connections exported by NetFlow-enabled devices contain TCP flag data.
Client	Select one or more clients.
Client Version	Type the version of the client.
Initiator Bytes, Responder Bytes, or Total Bytes	Type one of: • the number of bytes transmitted (**Initiator Bytes**) • the number of bytes received (**Responder Bytes**) • the number of bytes both transmitted and received (**Total Bytes**)
Initiator Packets, Responder Packets, or Total Packets	Type one of: • the number of packets transmitted (**Initiator Packets**) • the number of packets received (**Responder Packets**) • the number of packets both transmitted and received (**Total Packets**)
Username	Type the username of the user logged into either host in the connections you want to track.
Application Protocol	Select one or more application protocols.
Web Application	Select one or more web applications.
Access Control Policy	Select one or more access control policies that logged the connections you want to track.
Access Control Rule Name	Type all or part of the name of the access control rule that logged the connections you want to track. **IMPORTANT!** To track connections that match Monitor rules, type the name of the Monitor rule. The system tracks the connections, regardless of the rule or default action that later handles them.
Access Control Rule Action	Select one or more access control rule actions associated with the access control rule that logged the connections you want to track. **IMPORTANT!** Select **Monitor** to track connections that match the conditions of any Monitor rule, regardless of the rule or default action that later handles the connections.

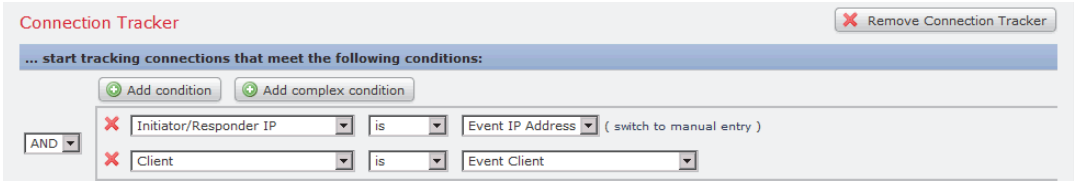
Syntax for Connection Trackers (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Reason	Select one or more reasons associated with the connections you want to track.
URL Category	Select one or more URL categories for the URL visited in the connections you want to track.
URL Reputation	Select one or more URL reputation values for the URL visited in the connections you want to track
URL	Type all or part of the URL visited in the connections you want to track.

Note that you can often use event data when constructing a connection tracker. For example, assume your correlation rule triggers when the system detects a new client on one of your monitored hosts; that is, the rule triggers when a system event whose base event type is **a new client is detected** is generated.

Further assume that when you detect this new client, you want to track connections involving the new client on the host where it was detected. Because the system knows the IP address of the host and the client name, you can build a simple connection tracker that tracks those connections.

In fact, when you add a connection tracker to this type of correlation rule, the connection tracker is populated with those default constraints; that is, the **Initiator/Responder IP** is set to the **Event IP Address** and the **Client** is set to the **Event Client**.



TIP! To specify that the connection tracker track connections for a specific IP address or block of IP addresses, click **switch to manual entry** to manually specify the IP. Click **switch to event fields** to go back to using the IP address in the event.

Syntax for Connection Tracker Events

LICENSE: Any

The Syntax for Connection Tracker Events table describes how to how to build a connection tracker condition that specifies when you want to generate a correlation event based on the connections you are tracking.

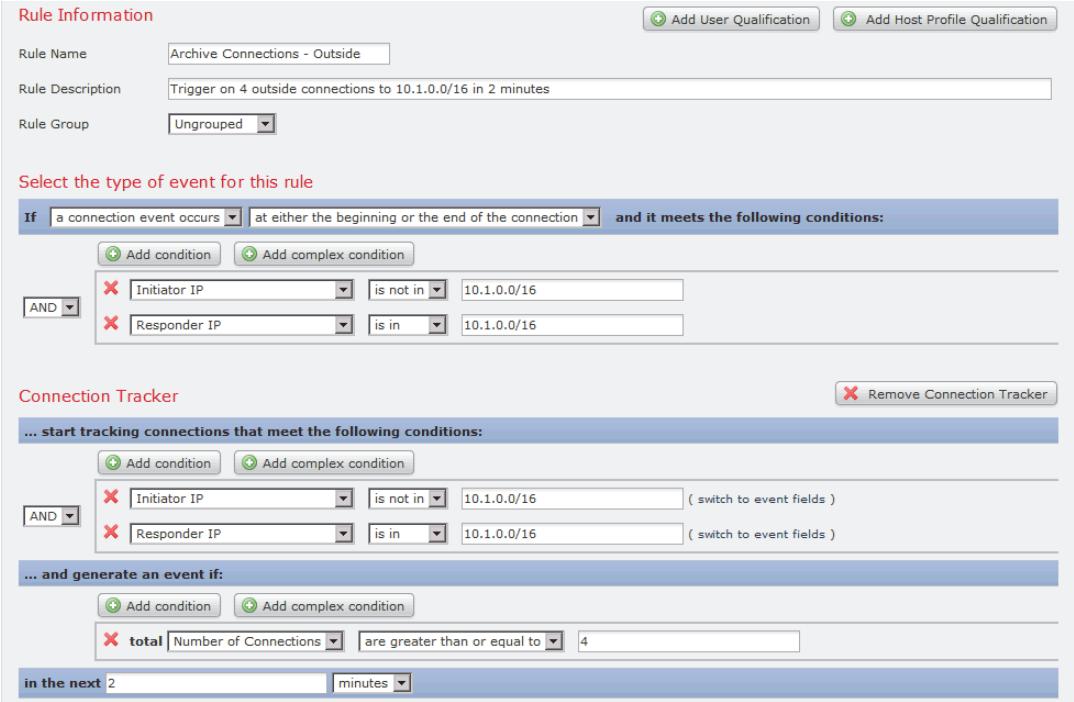
Syntax for Connection Tracker Events

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Number of Connections	Type the total number of connections detected.
Total Bytes, Initiator Bytes, or Responder Bytes	Type one of: • the total bytes transmitted (**Total Bytes**) • the number of bytes transmitted (**Initiator Bytes**) • the number of bytes received (**Responder Bytes**)
Total Packets, Initiator Packets, or Responder Packets	Type one of: • the total packets transmitted (**Total Packets**) • the number of packets transmitted (**Initiator Packets**) • the number of packets received (**Responder Packets**)
Unique Initiators or Unique Responders	Type one of: • the number of unique hosts that initiated sessions that were detected (**Unique Initiators**) • the number of unique hosts that responded to connections that were detected (**Unique Responders**)

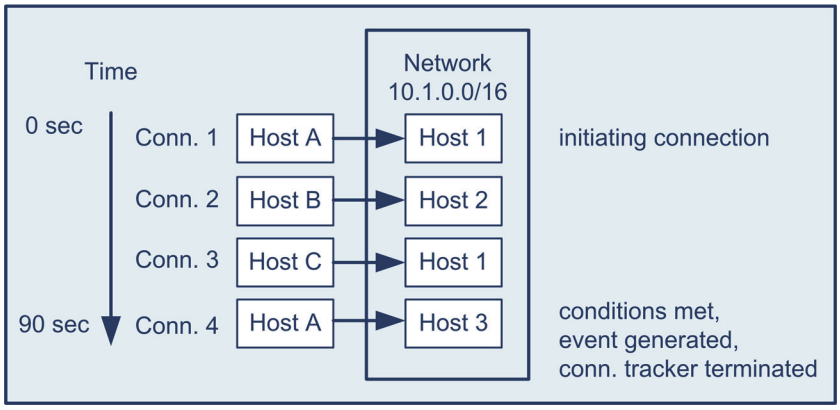
Example: Excessive Connections From External Hosts

Consider a scenario where you archive sensitive files on network 10.1.0.0/16, and where hosts outside this network typically do not initiate connections to hosts inside the network. An occasional connection initiated from outside the network might occur, but you have determined that when four or more connections are initiated within two minutes, there is cause for concern.

The rule shown in the following graphic specifies that when a connection occurs from outside the 10.1.0.0/16 network to inside the network, the system begins tracking connections that meet that criterion. The Defense Center then generates a correlation event if the system detects four connections (including the original connection) within two minutes that match that signature.



The following diagram shows how network traffic can trigger the above correlation rule.



In this example, the system detected a connection that met the basic conditions of the correlation rule, that is, the system detected a connection from a host outside the 10.1.0.0/16 network to a host inside the network. This created a connection tracker.

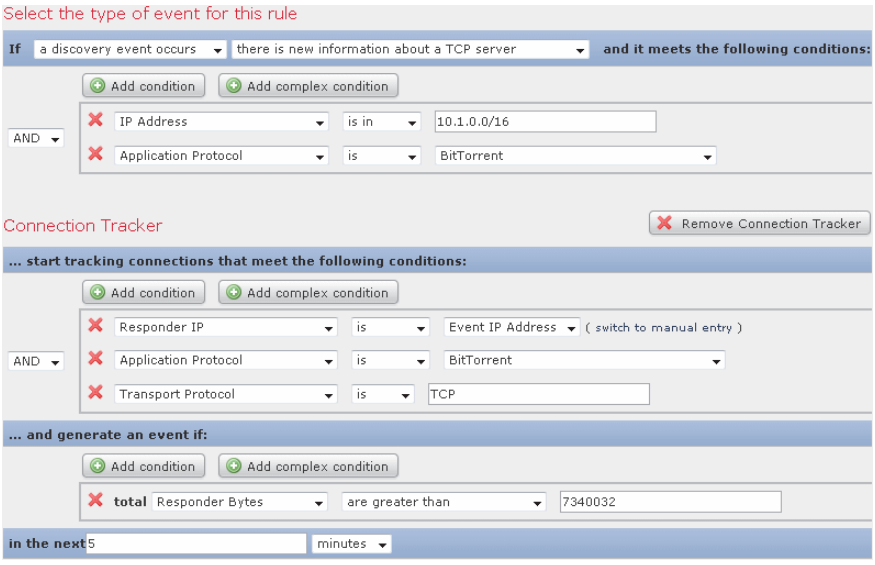
The connection tracker is processed in the following stages:

1. The system starts tracking connections when it detects a connection from Host A outside the network to Host 1 inside the network.
2. The system detects two more connections that match the connection tracker signature: Host B to Host 2 and Host C to Host 1.
3. The system detects a fourth qualifying connection when Host A connects to Host 3 within the two-minute time limit. The rule conditions are met.
4. The Defense Center generates a correlation event and the system stops tracking connections.

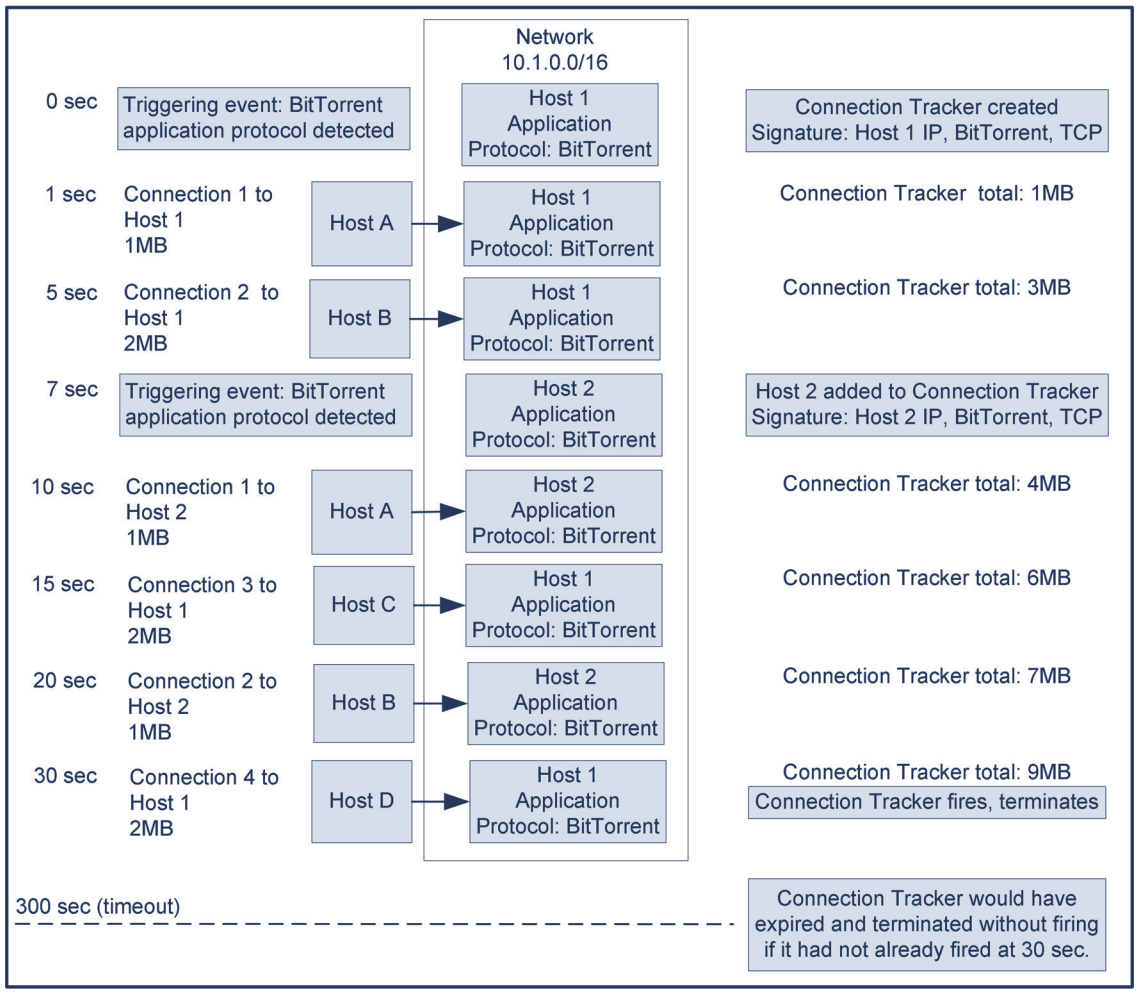
Example: Excessive BitTorrent Data Transfers

Consider a scenario where you want to generate a correlation event if the system detects excessive BitTorrent data transfers after an initial connection to any host on your monitored network.

The following graphic shows a correlation rule that triggers when the system detects the BitTorrent application protocol on your monitored network. The rule has a connection tracker that constrains the rule so that the rule triggers only if hosts on your monitored network (in this example, 10.1.0.0/16) collectively transfer more than 7MB of data (7340032 bytes) via BitTorrent in the five minutes following the initial policy violation.



The following diagram shows how network traffic can trigger the above correlation rule.



In this example, the system detected the BitTorrent TCP application protocol on two different hosts: Host 1 and Host 2. These two hosts transmitted data via BitTorrent to four other hosts: Host A, Host B, Host C, and Host D.

This connection tracker is processed in the following stages:

1. The system starts tracking connections at the 0-second marker when the system detects the BitTorrent application protocol on Host 1.

   Note that the connection tracker will expire if the system does not detect 7MB of BitTorrent TCP data being transmitted in the next 5 minutes (by the 300-second marker).

2. At 5 seconds, Host 1 has transmitted 3MB of data that matches the signature:
   - 1MB from Host 1 to Host A, at the 1-second marker (1MB total BitTorrent traffic counted towards fulfilling the connection tracker)
   - 2MB from Host 1 to Host B, at the 5-second marker (3MB total)
3. At 7 seconds, the system detects the BitTorrent application protocol on Host 2 and starts tracking BitTorrent connections for that host as well.
4. At 20 seconds, the system has detected additional data matching the signature being transmitted from both Host 1 and Host 2:
   - 1MB from Host 2 to Host A, at the 10-second marker (4MB total)
   - 2MB from Host 1 to Host C, at the 15-second marker (6MB total)
   - 1MB from Host 2 to Host B, at the 20-second marker (7MB total)

   Although Host 1 and Host 2 have now transmitted a combined 7MB of BitTorrent data, the rule does not trigger because the total number of bytes transmitted must be **more** than 7MB (**Responder Bytes are greater than 7340032**).

   At this point, if the system were to detect no additional BitTorrent transfers for the remaining 280 seconds in the tracker's timeout period, the tracker would expire and the Defense Center would not generate a correlation event.
5. However, at 30 seconds, the system detects another BitTorrent transfer:
   - 2MB from Host 1 to Host D at the 30-second marker (9MB total)

   The rule conditions are met.
6. The Defense Center generates a correlation event.

   The Defense Center also stops tracking connections for this connection tracker instance, even though the 5-minute period has not expired. If the system detects a new connection using the BitTorrent TCP application protocol at this point, it will create a new connection tracker.

   Note that the Defense Center generates the correlation event *after* Host 1 transmits the entire 2MB to Host D, because it does not tally connection data until the session terminates.

Adding a User Qualification

License: FireSIGHT

If you are using a connection, intrusion, discovery, or host input event to trigger your correlation rule, you can constrain the rule based on the identity of a user involved in the event. This constraint is called a *user qualification*. You **cannot** add a user qualification to a correlation rule that triggers on a traffic profile change or on the detection of user activity.

For example, you could constrain a correlation rule so that it triggers only when the identity of the source or destination user is one from the sales department.

To add a user identity qualification:

ACCESS: Admin/Discovery Admin

1. On the Create Rule page, click **Add User Qualification**.

   The User Identity Qualification section appears.

> **TIP!** To remove a user qualification, click **Remove User Qualification**.

2. Build the user qualification's conditions.

   You can create a single, simple condition, or you can create more elaborate constructs by combining and nesting conditions. See Understanding Rule Building Mechanics on page 1570 for information on how to use the web interface to build conditions.

   The syntax you can use to build conditions is described in Syntax for User Qualifications on page 1568.

3. Optionally, continue with Adding Snooze and Inactive Periods on page 1569.

   If you are finished building the correlation rule, continue with step 9 of the procedure in Creating Rules for Correlation Policies on page 1530 to save the rule.

Syntax for User Qualifications

LICENSE: FireSIGHT

When you build a user qualification condition, you must first select the identity you want to use to constrain your correlation rule. The identity you can choose depends on the type of event you are using to trigger the rule, as follows:

- If you are using a connection event, select **Identity on Initiator** or **Identity on Responder**.
- If you are using an intrusion event, select **Identity on Destination** or **Identity on Source**.
- If you are using a discovery event, select **Identity on Host**.
- If you are using a host input event, select **Identity on Host**.

After you select the user type, you continue building your user qualification condition, as described in the Syntax for User Qualifications table.

The Defense Center obtains certain information about users, including first and last names, department, telephone number, and email address, from an optional Defense Center-LDAP server connection; see Creating LDAP Connections with

the Defense Center on page 1357. This information may not be available for all users in the database.

Syntax for User Qualifications

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Username	Type the username of the user you want to use to constrain the correlation rule.
Authentication Protocol	Select an authentication protocol (or user type) protocol. This is the protocol that was used to detect the user.
First Name	Type the first name of the user you want to use to constrain the correlation rule.
Last Name	Type the last name of the user you want to use to constrain the correlation rule.
Department	Type the department of the user you want to use to constrain the correlation rule.
Phone	Type the telephone number of the user you want to use to constrain the correlation rule.
Email	Type the email address of the user you want to use to constrain the correlation rule.

Adding Snooze and Inactive Periods

LICENSE: Any

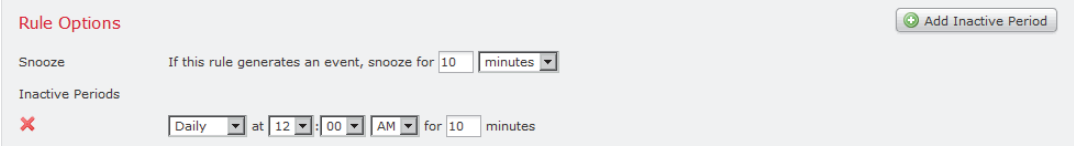
You can configure *snooze periods* in correlation rules. When a correlation rule triggers, a snooze period instructs the Defense Center to stop firing that rule for a specified interval, even if the rule is violated again during the interval. When the snooze period has elapsed, the rule can trigger again (and start a new snooze period).

For example, you may have a host on your network that should never generate traffic. A simple correlation rule that triggers whenever the system detects a connection involving that host may create multiple correlation events in a short period of time, depending on the network traffic to and from the host. To limit the number of correlation events exposing your policy violation, you can add a snooze period so that the Defense Center generates a correlation event only for the first connection (within a time period that you specify) that the system detects involving that host.

You can also set up inactive periods in correlation rules. During inactive periods, the correlation rule will not trigger. You can set up inactive periods to recur daily, weekly, or monthly. For example, you might perform a nightly Nmap scan on your

internal network to look for host operating system changes. In that case, you could set a daily inactive period on the affected correlation rules for the time and duration of your scan so that those rules do not trigger erroneously.

The following graphic shows a portion of a correlation rule that is configured with a snooze period and an inactive period.



To add a snooze period:

ACCESS: Admin/Discovery Admin

- On the Create Profile page, under **Rule Options**, specify the interval that the Defense Center should wait to trigger a rule again, after the rule triggers.

TIP! To remove a snooze period, specify an interval of **0** (seconds, minutes, or hours).

To add an inactive period:

ACCESS: Admin/Discovery Admin

1. On the Create Profile page, under **Rule Options**, click **Add Inactive Period**.
2. Using the drop-down lists and text field, specify when and how often you want the Defense Center to refrain from evaluating network traffic against the correlation rule.

TIP! To delete an inactive period, click the delete icon ( ) next to the inactive period you want to delete.

When you are finished adding snooze and inactive periods, continue with step 9 of the procedure in Creating Rules for Correlation Policies on page 1530 to save the rule.

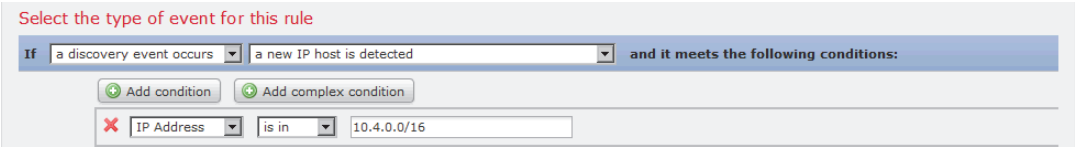
Understanding Rule Building Mechanics

LICENSE: Any

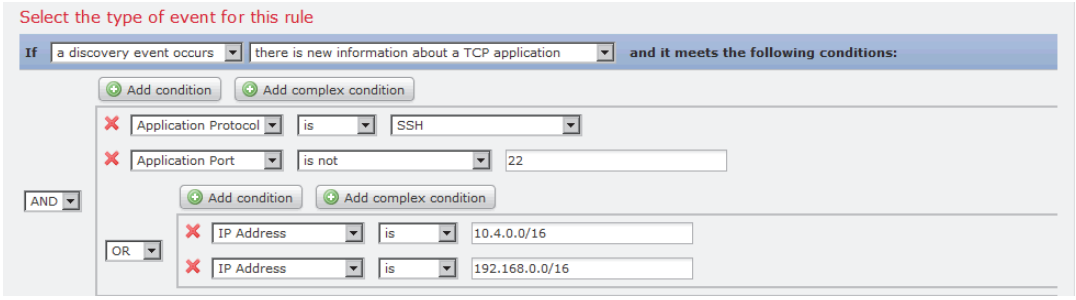
You build correlation rules, connection trackers, user qualifications, and host profile qualifications by specifying the conditions under which they trigger. You can create simple conditions, or you can create more elaborate constructs by combining and nesting conditions.

For example, if you want to generate a correlation event every time a new host is detected, you can create a very simple rule with no conditions, as shown in the following graphic.

If you wanted to further constrain the rule and generate an event only if that new host was detected on the 10.4.x.x network, you can add a single condition, as shown in the following graphic.



But the following rule, which detects SSH activity on a non-standard port on the 10.4.x.x network and the 192.168.x.x network, has four conditions, with the bottom two constituting a complex condition.



The syntax you can use within conditions varies depending on the element you are creating, but the mechanics are the same.

WARNING! Evaluating complex correlation rules that trigger on frequently occurring events can degrade Defense Center performance. For example, a multi-condition rule that the Defense Center must evaluate against every connection logged by the system can cause resource overload.

For more information on condition building, see:

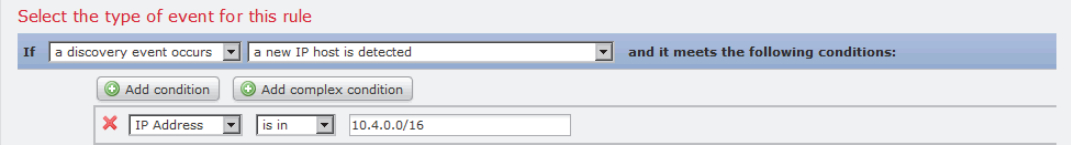
- Building a Single Condition on page 1572
- Adding and Linking Conditions on page 1574
- Using Multiple Values in a Condition on page 1577

Building a Single Condition

LICENSE: Any

Most conditions have three parts: a *category*, an *operator*, and a *value*; some conditions are more complex and contain several categories, each of which may have their own operators and values.

For example, the following correlation rule triggers if a new host is detected on the 10.4.x.x network. The category of the condition is **IP Address**, the operator is **is in**, and the value is `10.4.0.0/16`.



To build the correlation rule trigger criteria in the example above:

ACCESS: Admin/Discovery Admin

1. Begin building a correlation rule.

   For more information, see Creating Rules for Correlation Policies on page 1530.

2. On the Create Rule page, under **Select the type of event for this rule**, select **a discovery event occurs**, then select **a new IP host is detected** from the drop-down list.

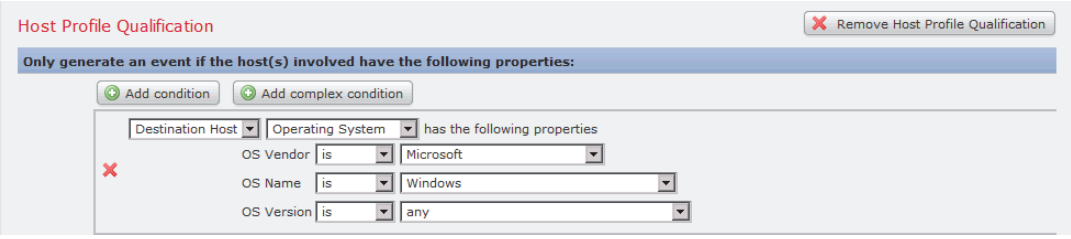
3. Start building the rule's single condition by selecting **IP Address** from the first (or *category*) drop-down list.

4. Select **is in** from the operator drop-down list that appears.

   TIP! When the category represents an IP address, choosing **is in** or **is not in** as the operator allows you to specify whether the IP address *is in* or *is not in* a block of IP addresses, as expressed in special notation such as CIDR. For information on using IP address notation in the Sourcefire 3D System, see IP Address Conventions on page 63.

5. Type `10.4.0.0/16` in the text field.

In contrast, the following host profile qualification is more complex; it constrains a correlation rule such that the rule triggers only if the host involved in the discovery event on which the rule is based is running a version of Microsoft Windows.



To build the host profile qualification in the example above:

Access: Admin/Discovery Admin

1. Build a correlation rule that triggers on an discovery event.

   For more information, see Creating Rules for Correlation Policies on page 1530.

2. On the Create Rule page, click **Add Host Profile Qualification**.

   The Host Profile Qualification section appears.

3. Under **Host Profile Qualification**, in the first condition, specify the host whose host profile you want to use to constrain your correlation rule.

   Because this host profile qualification is part of a correlation rule based on an discovery event, the only available category is **Host**.

4. Begin specifying the details of the operating system of the host by choosing the **Operating System** category.

   Three subcategories appear: **OS Vendor**, **OS Name**, and **OS Version**.

5. To specify that the host can be running any version of Microsoft Windows, use the same operator for all three subcategories: **is**.

6. Finally, specify the values for the subcategories.

   Select **Microsoft** as the value for **OS Vendor**, **Windows** as the value for **OS Name**, and leave **any** as the value for **OS Version**.

Note that the categories you can choose from depend on whether you are building correlation rule triggers, a host profile qualification, a connection tracker, or a user qualification. Within correlation rule triggers, the categories further depend on what kind of event is the basis for your correlation rule.

In addition, a condition's available operators depend on the category you choose. Finally, the syntax you can use to specify a condition's value depends on the

category and operator. Sometimes you must type the value in a text field. Other times, you can pick a value from a drop-down list.

IMPORTANT! Where the condition syntax allows you to pick a value from a drop-down list, you can often use multiple values from the list. For more information, see Using Multiple Values in a Condition on page 1577.

For more information on the syntax for building correlation rule trigger criteria, see:

- Syntax for Intrusion Events on page 1536
- Syntax for Malware Events on page 1538
- Syntax for Discovery Events on page 1540
- Syntax for User Activity Events on page 1543
- Syntax for Host Input Events on page 1544
- Syntax for Connection Events on page 1546
- Syntax for Traffic Profile Changes on page 1549

For more information on the syntax for building host profile qualifications, user qualifications, and connection trackers, see:

- Syntax for Host Profile Qualifications on page 1553
- Syntax for Connection Trackers on page 1559
- Syntax for Connection Tracker Events on page 1563
- Syntax for User Qualifications on page 1568

Adding and Linking Conditions

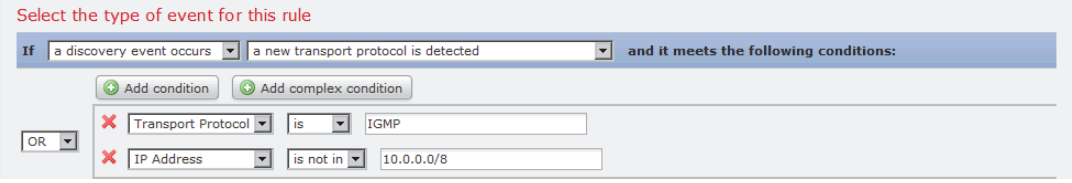
LICENSE: Any

You can create simple correlation rule triggers, connection trackers, host profile qualifications, and user qualifications, or you can create more elaborate constructs by combining and nesting conditions.

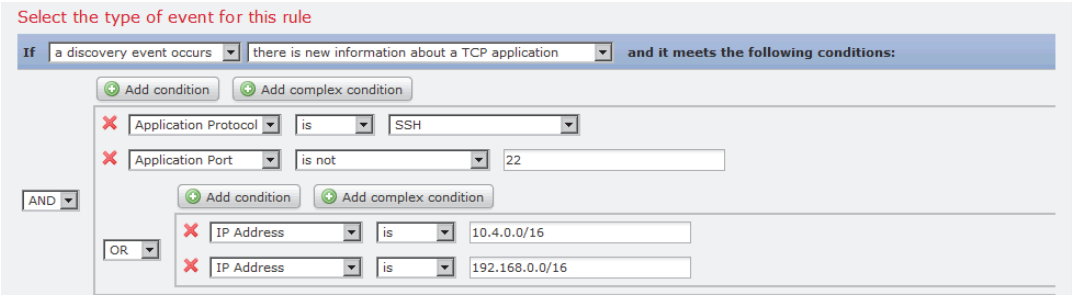
When your construct includes more than one condition, you must link them with an **AND** or an **OR** operator. Conditions on the same level are evaluated together:

- The **AND** operator requires that all conditions on the level it controls must be met.
- The **OR** operator requires that at least one of the conditions on the level it controls must be met.

For example, the following correlation rule trigger criteria contains two conditions, linked by **OR**. This means that the rule triggers if either condition is true, that is, if a host with an IP address is not in the 10.x.x.x subnet or if a host transmits an IGMP message.



In contrast, the following rule, which detects SSH activity on a non-standard port on the 10.4.x.x network and the 192.168.x.x network, has four conditions, with the bottom two constituting a complex condition.



This rule triggers if SSH is detected on a non-standard port; the first two conditions demand that the application protocol name is SSH and the port is not 22. The rule further requires that the IP address of the host involved in the event is in either the 10.4.x.x network or the 192.168.x.x network.

Logically, the rule is evaluated as follows:

```
(A and B and (C or D))
```

WHERE...	IS THE CONDITION THAT STATES...
A	Application Protocol is SSH
B	Application Port is not 22

WHERE...	IS THE CONDITION THAT STATES...
C	IP Address is in 10.4.0.0/8
D	IP Address is in 196.168.0.0/16

To add a single condition:

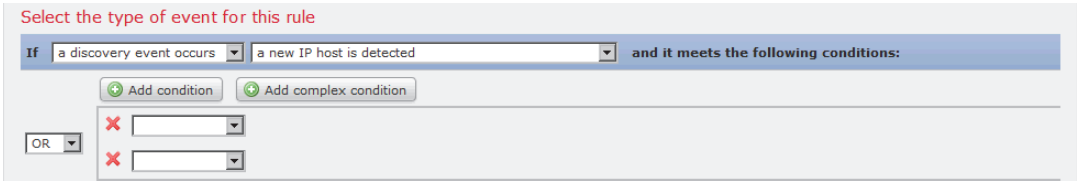
ACCESS: Admin/Discovery Admin

- To add a single condition, click **Add condition** above the current condition.

  A new condition is added below the current set of conditions, on the same level as the current set of conditions. By default, it is linked to the conditions on the same level with the **OR** operator, though you can change the operator to **AND**.

  For example, if you add a simple condition to the following rule:

  The result is:



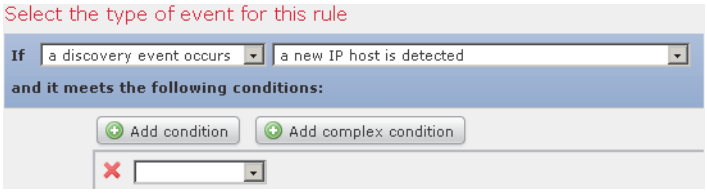
To add a complex condition:

Access: Admin/Discovery Admin

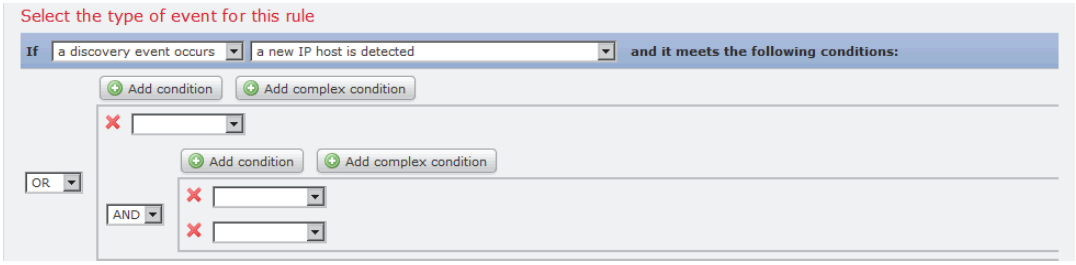
▶ Click **Add complex condition** above the current condition.

A complex condition is added below the current set of conditions. The complex condition comprises two subconditions, which are linked to each other with the opposite operator from the one used to link the conditions on the level above it.

For example, if you add a complex condition to the following rule:



The result is:



To link conditions:

Access: Admin/Discovery Admin

▶ Use the drop-down list to the left of a set of conditions. Choose:

- the **AND** operator to require that all conditions on the level it controls be met
- the **OR** operator to require that only one of the conditions on the level it controls be met

Using Multiple Values in a Condition

License: Any

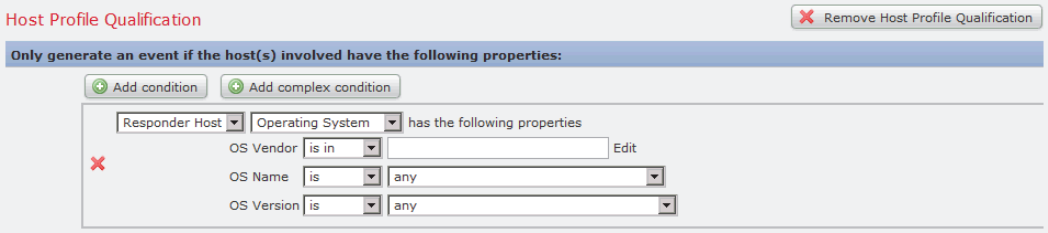
When you are building a condition, and the condition syntax allows you to pick a value from a drop-down list, you can often use multiple values from the list. For example, if you want to add a host profile qualification to a rule that requires that a host be running some flavor of UNIX, instead of constructing multiple conditions linked with the OR operator, use the following procedure.

To include multiple values in one condition:

Access: Admin/Discovery Admin

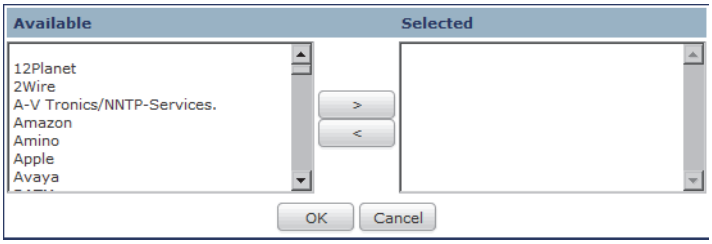
1. Build a condition, choosing **is in** or **is not in** as the operator.

   The drop-down list changes to a text field.



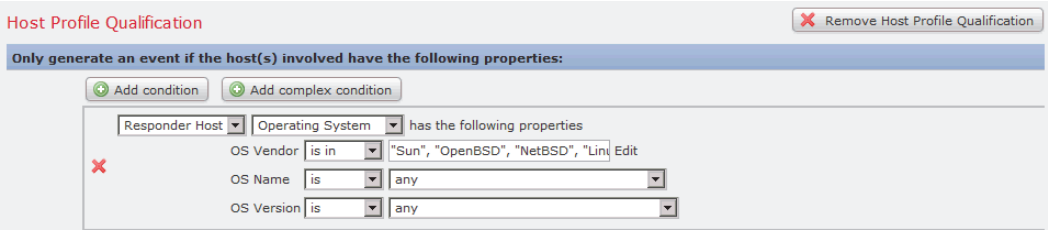
2. Click anywhere in the text field or on the **Edit** link.

   A pop-up window appears.



3. Under **Available**, use Ctrl or Shift while clicking to select multiple values. You can also click and drag to select multiple adjacent values.
4. Click the right arrow (**>**) to move the selected entries to **Selected**.
5. Click **OK**.

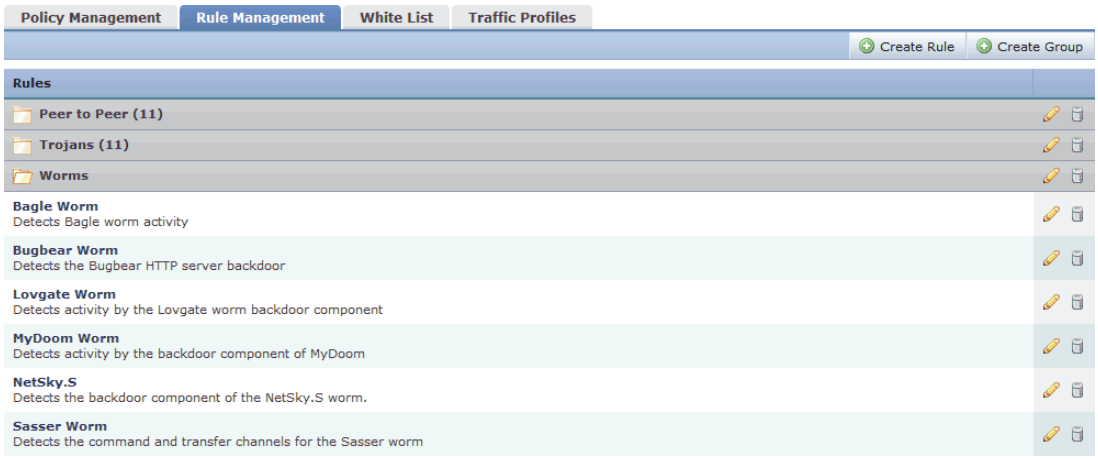
   The Create Rule page appears again. Your selections appear in the value field of your condition.



Managing Rules for Correlation Policies

LICENSE: Any

Use the Rule Management page to manage correlation rules used within correlation policies.



You can create, modify, and delete rules. You can also create rule groups to help you organize correlation rules. For more information on modifying rules, deleting rules, and creating rule groups, see:

- Modifying a Rule on page 1579
- Deleting a Rule on page 1580
- Creating a Rule Group on page 1580

For more information on creating rules, see Creating Rules for Correlation Policies on page 1530.

Modifying a Rule

LICENSE: Any

Use the following procedure to modify an existing correlation rule.

To modify an existing rule:

ACCESS: Admin/Discovery Admin

1. Select **Policies > Correlation**, then select the **Rule Management** tab.

   The Rule Management page appears.

2. If the rule is in a rule group, click the group name to expand the group.

3. Next to the rule you want to modify, click the edit icon ( ).

   The Create Rule page appears.

4. Make modifications as necessary and click **Save**.

   The rule is updated.

Deleting a Rule

LICENSE: Any

You cannot delete correlation rules that you are using in one or more correlation policies; you must first delete the rule from all policies in which it is included. For information on deleting a rule from a policy, see Editing a Correlation Policy on page 1591.

To delete an existing rule:

ACCESS: Admin/Discovery Admin

1. Select **Policies > Correlation**, then select the **Rule Management** tab.

   The Rule Management page appears.

2. If the rule is in a rule group, click the group name to expand the group.
3. Next to the rule you want to delete, click the delete icon ( ).
4. Confirm that you want to delete the rule.

   The rule is deleted.

Creating a Rule Group

LICENSE: Any

Create rule groups to help you organize correlation rules. The Sourcefire 3D System ships with many default rules, which are grouped according to function. For example, the Worms rule group comprises rules that detect activity by common worms. Note that rule groups exist only to help you organize correlation rules; you cannot assign a group of rules to a correlation policy. Instead, add each rule individually.

You can add a rule to an existing group when you create the rule. You can also modify an existing rule to add it to a group. For more information, see the following sections:

- Creating Rules for Correlation Policies on page 1530
- Modifying a Rule on page 1579

TIP! To delete a rule group, click the delete icon ( ) next to the group you want to delete. When you delete a rule group, rules that were in the group are **not** deleted. Rather, they merely become ungrouped

To create a rule group:

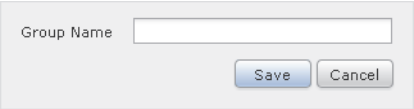
ACCESS: Admin/Discovery Admin

1. Select **Policies > Correlation**, then select the **Rule Management** tab.

   The Rule Management page appears.

2. Click **Create Group**.

   The Create Group page appears.



3. In the **Group Name** field, type a name for the group.
4. Click **Add Group**.

   The group is added.

Grouping Correlation Responses

LICENSE: Any

After you create alert responses and remediations, (see Working with Alert Responses on page 571 and Creating Remediations on page 1678), you can group them so that a policy violation triggers all of the responses within the group. Before you can assign response groups to correlation rules, you must create the groups on the Groups page.

The slider next to the group indicates whether the group is active. If you want to assign a response group to a rule within a correlation policy, you must activate it. You can sort response groups by state (active versus inactive) or alphabetically by name using the **Sort by** drop-down list.

See the following sections for more information:

- Creating a Response Group on page 1582
- Modifying a Response Group on page 1583
- Deleting a Response Group on page 1583
- Activating and Deactivating Response Groups on page 1583

Creating a Response Group

LICENSE: Any

You can place individual alerts and remediations in response groups, which can then be assigned to rules within correlation policies so that a group of alerts and remediations can be launched when a policy is violated. After a group has been assigned to rules in active policies, changes to the group and to alerts or remediations within the group are automatically applied to active policies.

To create a response group:

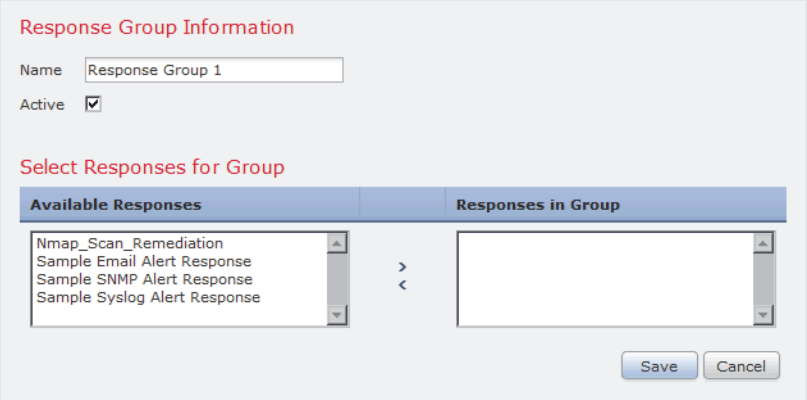
ACCESS: Admin

1. Select **Policies > Correlation**, then click **Groups**.

   The Groups page appears.

2. Click **Create Group**.

   The Response Group page appears.



3. In the **Name** field, type a name for the new group.
4. Select **Active** to activate the group so that you can use it in response to a correlation policy violation.
5. From the **Available Responses** list, select the alerts and remediations you want to include in the group.

   TIP! Hold down the Ctrl key while clicking to select multiple responses.

6. Click **>** to move alerts and remediations into the group.

   Conversely, you can select alerts and remediations from the **Responses in Group** list and click **<** to move the alerts out of the response group.

7. Click **Save**.

   The group is created.

Modifying a Response Group

LICENSE: Any

Use the following procedure to modify a response group.

To modify a response group:

ACCESS: Admin

1. Select **Policies > Correlation**, then click **Groups**.

   The Groups page appears.

2. Click the edit icon ( ) next to the group you want to modify.

   The Response Group page appears.

3. Make changes as needed and click **Save**.

   If the group is active and in use, the changes you made take effect immediately.

Deleting a Response Group

LICENSE: Any

You can delete a response group if it is not used in a correlation policy. Deleting a response group does **not** delete the responses in the group, just their association with each other.

To delete a response group:

ACCESS: Admin

1. Select **Policies > Correlation**, then click **Groups**.

   The Groups page appears.

2. Click the delete icon ( ) next to the group you want to delete.
3. Confirm that you want to delete the group.

   The group is deleted.

Activating and Deactivating Response Groups

LICENSE: Any

You can temporarily deactivate a response group without deleting it. This leaves the group on the system but does not launch it when a policy to which the group is assigned is violated. Note that if a response group is used in a correlation policy when you deactivate it, it is still considered in use even though it is deactivated; you cannot delete in-use response groups.

To activate or deactivate a response group:

ACCESS: Admin

1. Select **Policies > Correlation**, then click **Groups**.

   The Groups page appears.

2. Next to the response group you want to activate or deactivate, click the slider.

   If the group was activated, it is deactivated. If it was deactivated, it is activated.

Creating Correlation Policies

LICENSE: Any

After you create correlation rules or compliance white lists (or both), and, optionally, alert responses and remediations, you can use them to build correlation policies.

When your network traffic meets the criteria specified in a correlation rule or white list in an active policy, the Defense Center generates either a correlation event or white list event. It also launches any responses you assigned to the rule or white list. You can map each rule or white list to a single response or to a group of responses. If the network traffic triggers multiple rules or white lists, the Defense Center launches all the responses associated with each rule and white list.

For more information on creating the correlation rules, compliance white lists, and responses you can use to build a correlation policy, see the following sections:

- Creating Rules for Correlation Policies on page 1530
- Creating Compliance White Lists on page 1612
- Configuring External Alerting on page 569
- Configuring Remediations on page 1677

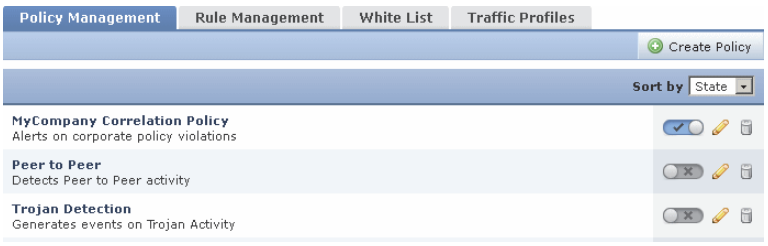
TIP! Optionally, create a skeleton policy and modify it later to add rules and responses.

To create a correlation policy:

Access: Admin/Discovery Admin

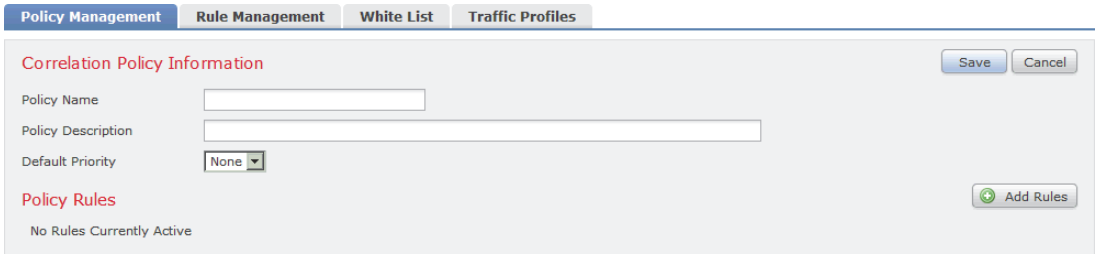
1. Select **Policies > Correlation**.

   The Policy Management page appears.



2. Click **Create Policy**.

   The Create Policy page appears.



3. Provide basic policy information, such as the name and description.

   See Providing Basic Policy Information on page 1586.

4. Add one or more rules or white lists to the correlation policy.

   See Adding Rules and White Lists to a Correlation Policy on page 1586.

5. Optionally, set rule and white list priorities.

   See Setting Rule and White List Priorities on page 1587.

6. Optionally, add responses to the rules or white lists you added.

   Adding Responses to Rules and White Lists on page 1588.

7. Click **Save**.

   The policy is saved.

IMPORTANT! You must activate the policy before it can generate correlation and white list events and launch responses to policy violations. For more information, see Managing Correlation Policies on page 1590.

Providing Basic Policy Information

LICENSE: Any

You must give each policy an identifying name. Optionally, you can add a short description to the policy.

You can also assign a user-defined priority to your policy. If your correlation policy is violated, the resultant correlation events display the priority value you assign to the policy (unless the rule that was triggered has its own priority).

IMPORTANT! Rule and white list priorities override policy priorities. For more information, see Adding Rules and White Lists to a Correlation Policy on page 1586.

To provide basic policy information:

ACCESS: Admin/Discovery Admin

1. On the Create Policy page, in the **Policy Name** field, type a name for the policy.
2. In the **Policy Description** field, type a description for the policy.
3. From the **Default Priority** drop-down list, select a priority for the policy.

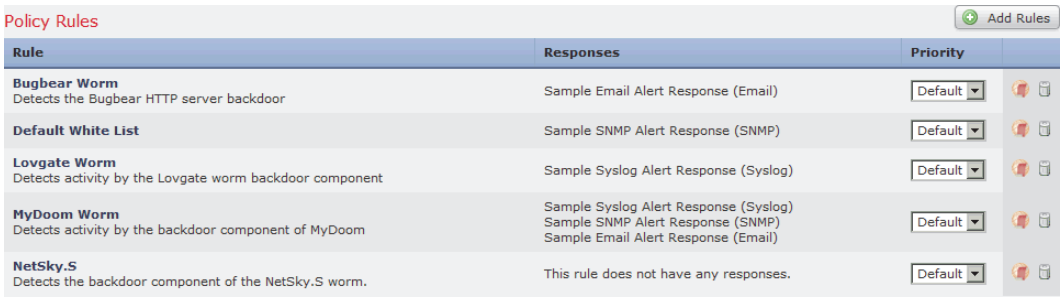
   You can select a priority value from 1 to 5, where 1 is highest and 5 is lowest. Or, you can select **None** to only use the priorities assigned to specific rules.
4. Continue with the procedure in the next section, Adding Rules and White Lists to a Correlation Policy on page 1586.

Adding Rules and White Lists to a Correlation Policy

LICENSE: Any

A correlation policy contains one or more correlation rules or white lists. When any rule or white list in a policy is violated, the system logs an event to the database. If you assigned one or more responses to the rule or white list, those responses are launched.

The following graphic shows a correlation policy composed of a compliance white list and a set of correlation rules, configured with a variety of responses.

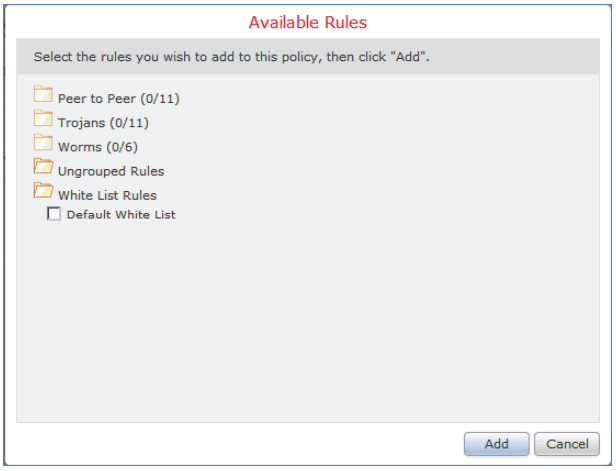


To add rules or white lists to a correlation policy:

Access: Admin/Discovery Admin

1. On the Create Policy page, click **Add Rules**.

   The Available Rules pop-up appears.



2. Click the appropriate folder name to expand it.
3. Select the rules and white lists that you want to use in the policy and click **Add**.

   The Create Policy page appears again. The rules and white lists you selected populate the policy.
4. Continue with the procedure in the next section, Setting Rule and White List Priorities on page 1587.

Setting Rule and White List Priorities

License: Any

You can assign a user-defined priority to each correlation rule or compliance white list in your correlation policy. If a rule or white list triggers, the resulting event

displays the priority you assign to the rule or white list. On the other hand, if you do not assign a priority value and the rule or white list triggers, the resulting event displays the priority value of the policy.

For example, consider a policy where the policy itself has a priority of 1 and its rules or white lists are set with the default priority, with the exception of one rule given a priority of 3. If the priority 3 rule triggers, the resulting correlation event shows 3 as its priority value. If other rules or white lists in the policy trigger, the resulting events show 1 as their priority values, retained from the policy's priority.

To set rule or white list priorities:

Access: Admin/Discovery Admin

1. On the Create Policy page, from the **Priority** list for each rule or white list, select a default priority. You can select:
   - a priority value from 1 to 5, where 1 is highest and 5 is lowest
   - **None**
   - **Default** to use the policy's default priority
2. Continue with the procedure in the next section, Adding Responses to Rules and White Lists on page 1588.

Adding Responses to Rules and White Lists

License: Any

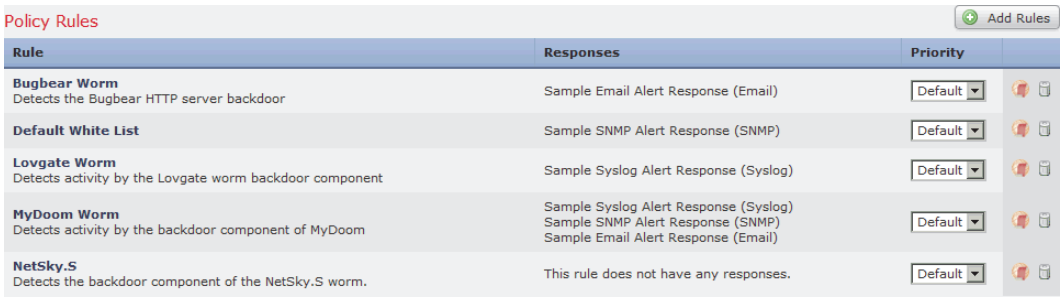
Within a correlation policy, you can map each rule or white list to a single response or to a group of responses. When any one of the rules or white lists in a policy is violated, the system logs an associated event to the database and launches the responses assigned to that rule or white list. If multiple rules or white lists within a policy trigger, the Defense Center launches the responses associated with each rule or white list.

For more information on creating responses and response groups, see:

- Configuring External Alerting on page 569
- Configuring Remediations on page 1677
- Grouping Correlation Responses on page 1581

IMPORTANT! Do **not** assign an Nmap remediation as a response to a correlation rule that triggers on a traffic profile change. The remediation will not launch.

The following graphic shows a correlation policy composed of a compliance white list and a set of correlation rules, configured with a variety of responses.

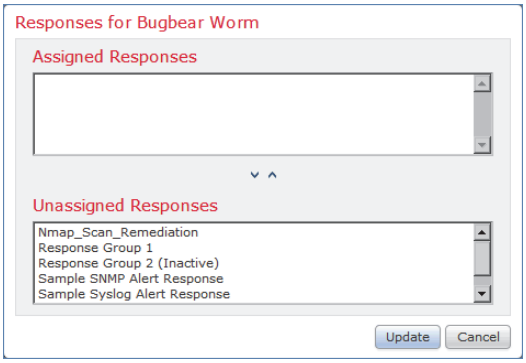


To add responses to rules and white lists:

Access: Admin/Discovery Admin

1. On the Create Policy page, next to a rule or white list where you want to add responses, click the responses icon ( ).

   A pop-up window appears.



2. Under **Unassigned Responses**, select the response, multiple responses, or response group you want to launch when the rule or white list triggers, and click the up arrow.

TIP! Hold down the Ctrl key while clicking to select multiple responses.

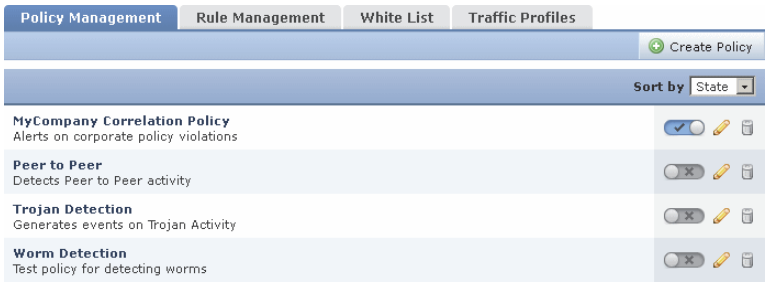
3. Click **Update**.

   The Create Policy page appears again. The responses you specified are added to the rule or white list.

Managing Correlation Policies

LICENSE: Any

You manage correlation policies on the Policy Management page. You can create, modify, sort, activate, deactivate, and delete policies.



The slider next to the policy indicates whether the group is active. If you want the policy to generate correlation events and white list events, you must activate it. You can sort policies by state (active versus inactive) or alphabetically by name using the **Sort by** drop-down list.

If an active correlation policy contains a compliance white list, the following actions do **not** delete the host attribute associated with the white list, nor do they change that host attribute's values:

- deactivating the policy
- modifying the policy to remove the white list
- deleting the policy

That is, hosts that were compliant when you performed the action still appear as compliant on the host attributes network map, and so on. To delete the host attribute, you must delete its corresponding white list.

To update the white list compliance of the hosts on your network, you must either reactivate the correlation policy (if you deactivated it) or add the white list to another active correlation policy (if you deleted the white list from a correlation policy or deleted the policy itself). Note that the reevaluation of the white list that occurs when you do this does **not** generate white list events and therefore does not trigger any responses you associated with the white list. For more information on compliance white lists, see Using the Sourcefire 3D System as a Compliance Tool on page 1601.

For more information on managing correlation policies, see:

- Activating and Deactivating Correlation Policies on page 1591
- Editing a Correlation Policy on page 1591
- Deleting a Correlation Policy on page 1591

For information on creating new policies, see Creating Correlation Policies on page 1584.

Activating and Deactivating Correlation Policies

License: Any

Use the following procedure to either activate or deactivate a correlation policy.

To activate or deactivate a policy:

Access: Admin/Discovery Admin

1. Select **Policies > Correlation**.

   The Policy Management page appears.

2. Next to the policy you want to activate or deactivate, click the slider.

   If the policy was active, it is deactivated. If it was deactivated, it is activated.

Editing a Correlation Policy

License: Any

Use the following procedure to modify a correlation policy.

To edit a policy:

Access: Admin/Discovery Admin

1. Select **Policies > Correlation**.

   The Policy Management page appears.

2. Click the edit icon ( ) next to the policy.

   The Create Policy page appears. See Creating Correlation Policies on page 1584 for information on the various configurations you can change. To remove a rule or white list from a correlation policy, on the Create Policy page, click the delete icon ( ) next to the rule or white list you want to remove.

3. Make changes as needed and click **Save**.

   The policy is changed. If the policy is active, the changes you made take effect immediately.

Deleting a Correlation Policy

License: Any

Use the following procedure to delete a correlation policy.

To delete a policy:

Access: Admin/Discovery Admin

1. Select **Policies > Correlation**.

   The Policy Management page appears.

2. Click the delete icon ( ) next to the policy you want to delete.

   The policy is deleted.

Working with Correlation Events

LICENSE: Any

When a correlation rule within an active correlation policy triggers, the Defense Center generates a correlation event and logs it to the database. For information on configuring the number of correlation events saved in the database, see Configuring Database Event Limits on page 2056.

IMPORTANT! When a compliance white list within an active correlation policy triggers, the Defense Center generates a white list event. For more information, see Working with White List Events on page 1643.

For more information, see the following sections:

- Viewing Correlation Events on page 1592
- Understanding the Correlation Events Table on page 1595
- Searching for Correlation Events on page 1597

Viewing Correlation Events

LICENSE: Any

You can view a table of correlation events, then manipulate the event view depending on the information you are looking for.

The page you see when you access correlation events differs depending on the workflow you use. You can use the predefined workflow, which includes the table view of correlation events. You can also create a custom workflow that displays only the information that matches your specific needs. For information on creating a custom workflow, see Creating Custom Workflows on page 1916.

The Correlation Event Actions table below describes some of the specific actions you can perform on an correlation events workflow page.

Correlation Event Actions

To...	You can...
view the host profile for an IP address	click the host profile icon that appears next to the IP address.
view user profile information	click the user icon ( ) that appears next to the user identity. For more information, see Understanding User Details and Host History on page 1518.
sort and constrain events on the current workflow page	find more information in Sorting Drill-Down Workflow Pages on page 1910.
navigate within the current workflow page	find more information in Navigating to Other Pages in the Workflow on page 1911.
navigate between pages in the current workflow, keeping the current constraints	click the appropriate page link at the top left of the workflow page. For more information, see Using Workflow Pages on page 1889.
learn more about the columns that appear	find more information in Understanding the Correlation Events Table on page 1595.
modify the time and date range for displayed events	find more information in see Setting Event Time Constraints on page 1896. Note that events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.

Correlation Event Actions (Continued)

To...	You can...
drill down to the next page in the workflow, constraining on a specific value	use one of the following methods: • on a drill-down page that you created in a custom workflow, click a value within a row. Note that clicking a value within a row in a table view constrains the table view and does **not** drill down to the next page. • To drill down to the next workflow page constraining on some users, select the check boxes next to the users you want to view on the next workflow page, then click **View**. • To drill down to the next workflow page keeping the current constraints, click **View All**. **TIP!** Table views always include "Table View" in the page name. For more information, see Constraining Events on page 1905.
delete correlation events from the system	use one of the following methods: • To delete some events, select the check boxes next to the events you want to delete, then click **Delete**. • To delete all events in the current constrained view, click **Delete All**, then confirm you want to delete all the events.
navigate to other event views to view associated events	find more information in Navigating Between Workflows on page 1911.

To view correlation events:

Access: Admin/Any Security Analyst

▶ Select **Analysis > Correlation > Correlation Events**.

The first page of the default correlation events workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. If no events appear, you may need to adjust the time range; see Setting Event Time Constraints on page 1896.

TIP! If you are using a custom workflow that does not include the table view of correlation events, click **(switch workflow)**, then select **Correlation Events**.

Understanding the Correlation Events Table

LICENSE: Any

When a correlation rule triggers, the Defense Center generates a correlation event. The fields in the correlation events table are described in the following table.

Correlation Event Fields

FIELD	DESCRIPTION
Time	The date and time that the correlation event was generated.
Impact	The impact level assigned to the correlation event based on the correlation between intrusion data, discovery data, and vulnerability information. For more information, see Using Impact Levels to Evaluate Events on page 688.
Inline Result	One of: • a black down arrow, indicating that the system dropped the packet that triggered the intrusion rule • a gray down arrow, indicating that the system would have dropped the packet in an inline, switched, or routed deployment if you enabled the **Drop when Inline** intrusion policy option • blank, indicating that the triggered intrusion rule was not set to Drop and Generate Events Note that the system does not drop packets in a passive deployment, including when an inline set is in tap mode, regardless of the rule state or the drop behavior of the intrusion policy. For more information, see Setting Rule States on page 770, Setting Drop Behavior in an Inline Deployment on page 735, Configuring Passive Interfaces on page 312, and Tap Mode on page 321.
Source IP or Destination IP	The IP address of the source or destination host in the event that triggered the policy violation.
Source User or Destination User	The name of the user logged in to the source or destination host in the event that triggered the policy violation
Source Port/ICMP Type or Destination Port/ ICMP Code	The source port or ICMP type for the source traffic or the destination port or ICMP code for destination traffic associated with the event that triggered the policy violation.
Description	The description of the correlation event. The information in the description depends on how the rule was triggered. For example, if the rule was triggered by an operating system information update event, the new operating system name and confidence level appears.

Correlation Event Fields (Continued)

Field	Description
Policy	The name of the policy that was violated.
Rule	The name of the rule that triggered the policy violation.
Priority	The priority specified by the policy or rule that triggered the policy violation.
Src Host Criticality or Dst Host Criticality	The user-assigned host criticality of the source or destination host involved in the correlation event: `None`, `Low`, `Medium`, or `High`. Note that only correlation events generated by rules based on discovery events, host input events, or connection events contain a source host criticality. For more information on host criticality, see Working with the Predefined Host Attributes on page 1433.
Ingress Security Zone or Egress Security Zone	The ingress or egress security zone in the intrusion or connection event that triggered the policy violation.
Device	The name of the device that generated the event that triggered the policy violation.
Ingress Interface or Egress Interface	The ingress or egress interface in the intrusion or connection event that triggered the policy violation.
Count	The number of events that match the information that appears in each row. Note that the **Count** field appears only after you apply a constraint that creates two or more identical rows.

For more information on displaying the correlation events table, see the following:

- Viewing Correlation Events on page 1592
- Searching for Correlation Events on page 1597

Searching for Correlation Events

LICENSE: Any

You can search for specific correlation events. You may want to create searches customized for your network environment, then save them to reuse later. The following table describes the search criteria you can use.

Correlation Event Search Criteria

FIELD	SEARCH CRITERIA RULES
Policy	Type the name of the correlation policy you want to search for.
Rule	Type the name of the correlation rule you want to search for.
Description	Type all or part of the correlation event description. The information in the description depends on the event that caused the rule to trigger.
Priority	Specify the priority of the correlation event, which is determined by the priority of either the triggered rule or the violated correlation policy. Enter **none** for no priority. For information on setting correlation rule and policy priorities, see Providing Basic Policy Information on page 1586 and Setting Rule and White List Priorities on page 1587.
Source IP Destination IP, or Source/Destination IP	Specify the IP address of the source, destination, or source or destination hosts in the event that triggered the policy violation. You can specify a single IP address or address block, or a comma-separated list of either or both. You can also use negation. See Specifying IP Addresses in Searches on page 1848 for more information.
Source User or Destination User	Specify the user logged in to the source or destination host in the event that triggered the policy violation.
Source Port/ICMP Type or Destination Port/ICMP Code	Specify the source port or ICMP type for source traffic or destination port or ICMP code for destination traffic associated with the event that triggered the policy violation.
Impact	Specify the impact flag assigned to the correlation event. Valid case-insensitive values are `Impact 0`, `Impact Level 0`, `Impact 1`, `Impact Level 1`, `Impact 2`, `Impact Level 2`, `Impact 3`, `Impact Level 3`, `Impact 4`, and `Impact Level 4`. Do not use impact icon colors or partial strings (for example, do not use `blue`, `level 1`, or `0`). For more information, see Using Impact Levels to Evaluate Events on page 688.

Correlation Event Search Criteria (Continued)

Field	Search Criteria Rules
Inline Result	For policy violations triggered by intrusion events, type either: • `dropped`, to specify whether the packet was dropped in an inline, switched, or routed deployment • `would have dropped`, to specify whether the packet would have dropped if the intrusion policy had been set to drop packets in an inline, switched, or routed deployment Note that the system does not drop packets in a passive deployment, including when an inline set is in tap mode, regardless of the rule state or the drop behavior of the intrusion policy. For more information, see Setting Rule States on page 770, Setting Drop Behavior in an Inline Deployment on page 735, and Tap Mode on page 321.
Source Host Criticality or Destination Host Criticality	Specify the host criticality of the source or destination host involved in the policy violation: `None`, `Low`, `Medium`, or `High`. Note that only correlation events generated by rules based on discovery events, host input events, or connection events contain a source host criticality. For more information on host criticality, see Working with the Predefined Host Attributes on page 1433.
Ingress Security Zone, Egress Security Zone, or Ingress/Egress Security Zone	Specify the ingress, egress, or ingress or egress security zone in the intrusion or connection event that triggered the policy violation.
Device	Type the name, group name, or IP address of the device that generated the event that triggered the policy violation. See Managing Devices on page 232, Editing Assigned Device Names on page 288, and Managing Device Groups on page 259.
Ingress Interface or Egress Interface	Specify the ingress or egress interface in the intrusion or connection event that triggered the policy violation.

To search for correlation events:

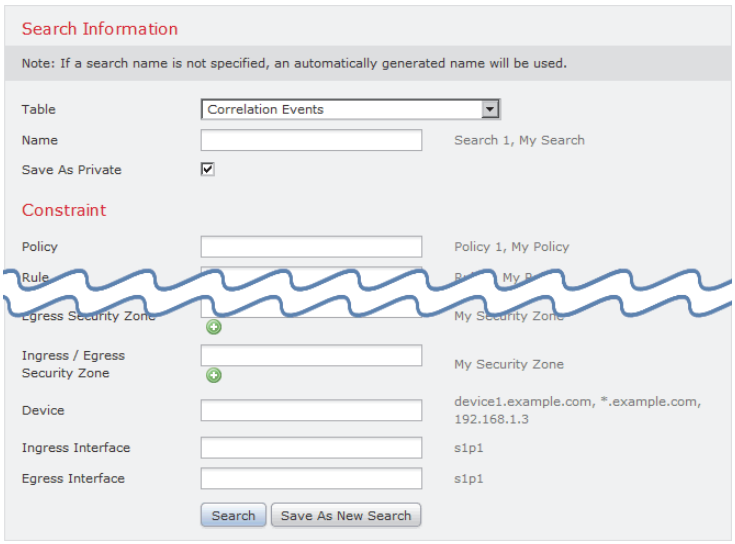
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Correlation Events**.

   The page reloads with the appropriate constraints.



3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields, as described in the Correlation Event Search Criteria table:

   - All fields accept negation (`!`).
   - All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
   - Many fields accept one or more asterisks (*) as wild cards.
   - Specify `n/a` in any field to identify events where information is not available for that field; use `!n/a` to identify the events where that field is populated.
   - Click the add object icon ( ) that appears next to a search field to use an object as a search criterion.

   For more information on search syntax, including using objects in searches, see Searching for Events on page 1842.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

   If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in the default correlation events workflow, constrained by the current time range. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**) so that you can run it at a later time.

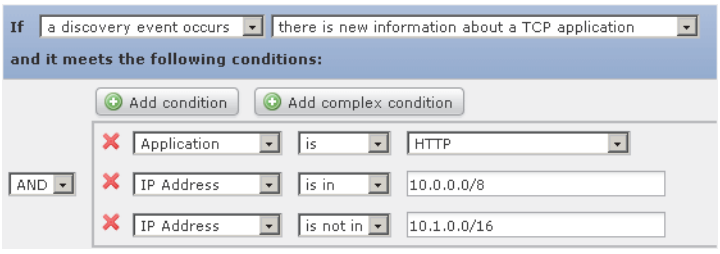
CHAPTER 37

USING THE SOURCEFIRE 3D SYSTEM AS A COMPLIANCE TOOL

A *compliance white list* (or *white list*) is a set of criteria that allows you to specify the operating systems, applications, and protocols that are allowed to run on a specific subnet, and automatically generate an event if a host on the subnet violates the white list. For example, your security policy might state that while your web servers are allowed to run HTTP, none of the other hosts on your network are. You could create a white list that evaluates your entire network, excluding your web farm, to determine which hosts are running HTTP.

Note that you could create a correlation rule that performs this function by configuring the rule so that it triggers when:

- the system discovers new information about an application protocol
- the application protocol name is http
- the IP address of the host involved in the event is not in your web farm



However, correlation rules, which provide you with a more flexible way of alerting you and responding to policy violations on your network, are more complex to configure and maintain than white lists. Correlation rules are also wider in scope, allowing you to generate a correlation event when one of many types of event meets any criteria that you specify. On the other hand, white lists are specifically

meant to help you evaluate the operating systems, application protocols, clients, web applications, and protocols that are running on your network and whether that violates your organization's policies.

You can create custom white lists that meet your specific needs, or you can use the default white list created by the Sourcefire Vulnerability Research Team (VRT) that contains recommended settings for allowed operating systems, application protocols, clients, web applications, and protocols. You may also want to customize the default white list for your network environment.

If you add a white list to an active correlation policy, when the system detects that a host is violating the white list, the system logs a white list event — which is a special kind of correlation event — to the database. Further, you can configure the system to trigger responses (remediations and alerts) automatically when it detects a white list violation.

IMPORTANT! Although you can configure the network discovery policy to add hosts and application protocols to the network map based on data exported by NetFlow-enabled devices, the available information about these hosts and application protocols is limited. For example, there is no operating system data available for these hosts, unless you provide it using the host input feature. This may affect the way you build compliance white lists. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

Because the system creates a host attribute for each host that indicates whether it is in compliance with any white lists you create, you can obtain an at-a-glance summary of the compliance of your network. In just a few seconds, you can determine exactly which hosts in your organization are running HTTP in violation of your policy, and take appropriate action.

Then, using the correlation feature, you can configure the system to alert you whenever a host that is not in your web farm starts running HTTP.

In addition, the system allows you to use host profiles to determine whether an individual host is violating any of the white lists you have configured, and in which way it is violating the white list. The Sourcefire 3D System also includes workflows that allow you to view each of the individual white list violations, as well as the number of violations per host.

Finally, you can use the dashboard to monitor recent system-wide compliance activity, including white list events and summary views of the overall white list compliance of your network.

For more information on creating and managing compliance white lists and on interpreting white list events and violations, see the following sections:

- Understanding Compliance White Lists on page 1603
- Creating Compliance White Lists on page 1612
- Managing Compliance White Lists on page 1634
- Working with Shared Host Profiles on page 1635

- Working with White List Events on page 1643
- Working with White List Violations on page 1650

In addition, see the following chapters and sections for more information:

- Creating Correlation Policies on page 1584 explains how to create and configure correlation policies that include compliance white lists, and explains how to assign responses and priorities to the white lists.
- Using Host Profiles on page 1394 explains how to use a host's profile to determine whether it is violating any white lists.
- Using Dashboards on page 73 explains how to obtain an at-a-glance view of your current system status, including white list compliance activity.

Understanding Compliance White Lists

LICENSE: FireSIGHT

A *compliance white list* is a set of criteria that specify the operating systems, clients, application protocols, web applications, and protocols that are allowed to run on your network. You can create custom white lists that meet your specific needs, or you can use the default white list created by the VRT that contains recommended settings.

Custom white list criteria can be simple; you can specify that only hosts running a certain operating system are allowed. Your criteria can also be complex; you can specify that while all operating systems are allowed, only hosts running a certain operating system are allowed to run a certain application protocol on a specific port.

White lists comprise two main parts: *targets* and *host profiles*. The targets are the specific hosts that are evaluated by the white list, while the host profiles specify the operating systems, clients, application protocols, web applications, and protocols that are allowed to run on the targets.

After you create a white list and add it to an active correlation policy, the system evaluates the white list's targets against its host profiles to determine whether the targets are in compliance with the white list. After this initial evaluation, the system generates a *white list event* when it detects that a valid target is violating the white list.

For more information, see the following sections:

- Understanding White List Targets on page 1604 explains how white lists only target the hosts that you specify.
- Understanding White List Host Profiles on page 1605 explains the different kinds of profiles that describe which clients, application protocols, web applications, and protocols are allowed to run on your network.

- Understanding White List Evaluations on page 1609 explains how the system evaluates the hosts on your network against white lists, and how you can tell which hosts are in compliance and which are not.
- Understanding White List Violations on page 1610 explains how the system detects and notifies you of white list violations.

Understanding White List Targets

LICENSE: FireSIGHT

When you create a white list, you first specify the portions of your network it applies to. You can use a white list to evaluate all the hosts on your monitored network, or you can restrict the white list to evaluate only certain network segments or even individual hosts. You can further restrict the white list so that it evaluates only hosts that have a certain host attribute or that belong to a certain VLAN. A host that is eligible to be evaluated by a white list is called a *valid target* (or *target*). A valid target:

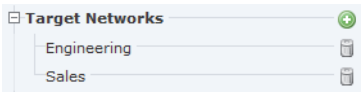
- must be in one of the IP address blocks you specify. You can also exclude blocks of IP addresses.
- must have at least one of the host attributes you specify.

  For example, you could configure a white list to evaluate only hosts that have a high host criticality. For information on host attributes, including host criticality, see Working with User-Defined Host Attributes on page 1434 and Working with the Predefined Host Attributes on page 1433.
- must belong to one of the VLANs you specify.

If a host does not meet all of these criteria, it is not evaluated against the white list, regardless of whether its host profile is in violation of the white list.

If your white list contains more than one target, a host must meet the criteria specified in only one of them to be considered valid. For example, if you create a target that includes the 10.10.x.x network and one that excludes the 10.10.x.x network, a host in that network is considered a valid target. Note that if your white list does not contain any targets, none of the hosts on your network will be evaluated against the white list.

The target networks for your white list are listed on the left of the Create White List page.



Note that the default white list uses targets of 0.0.0.0/0 and ::/0, which represent the entire monitored network. If you choose to use this white list, you can leave the target network as-is or modify it to reflect your network environment.

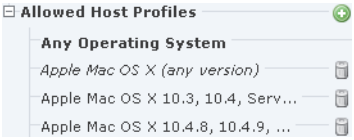
For information on creating white list targets, see Configuring Compliance White List Targets on page 1616.

Understanding White List Host Profiles

LICENSE: FireSIGHT

After you specify which targets the white list evaluates, the next step is to configure *host profiles*. Host profiles in a white list specify which operating systems, clients, application protocols, web applications, and protocols are allowed to run on the target hosts.

There are three kinds of host profiles you can configure in a white list: global host profiles, host profiles for specific operating systems, and shared host profiles. Each type of host profile appears differently when you are creating a white list.



The following table explains how to identify and access the different kinds of host profiles.

Accessing Compliance White List Host Profiles

TO VIEW...	UNDER ALLOWED HOST PROFILES, CLICK...
the global host profile for the white list	**Any Operating System**
a host profile for a specific operating system	a host profile name that is listed in plain text rather than italics
a shared host profile used by the white list	a host profile name that is listed in italics

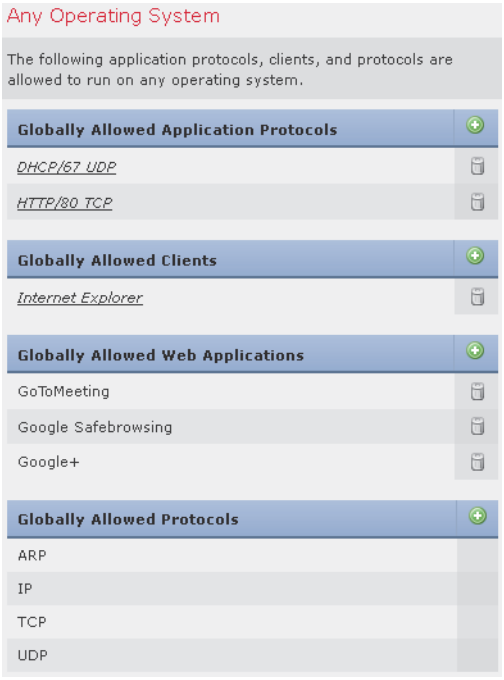
For more information, see the following sections:

- Understanding the Global Host Profile on page 1606
- Understanding Host Profiles for Specific Operating Systems on page 1606
- Understanding Shared Host Profiles on page 1608

Understanding the Global Host Profile

License: FireSIGHT

Every white list contains a global host profile, which specifies the application protocols, clients, web applications, and protocols that are allowed to run on target hosts, regardless of the host's operating system.



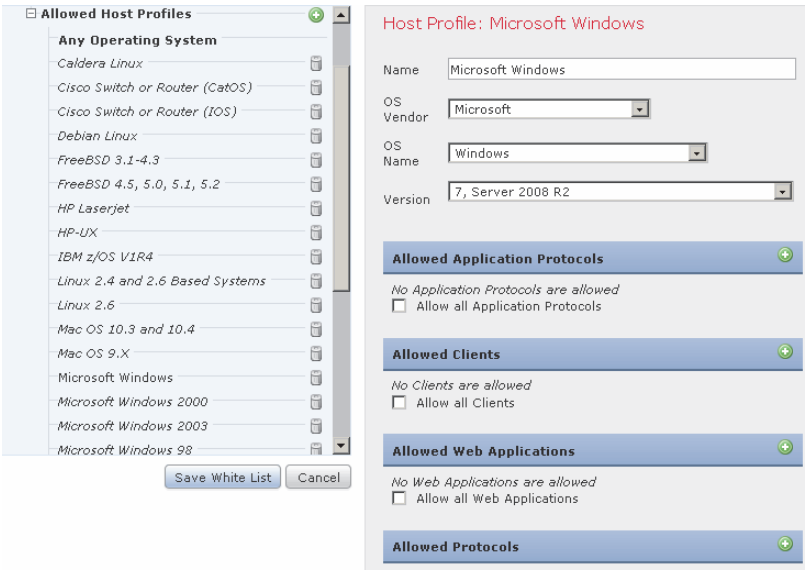
For example, instead of editing multiple Microsoft Windows and Linux host profiles to allow Internet Explorer, you can configure the global host profile to allow it regardless of the operating system on which it was detected. Note that the ARP, IP, TCP, and UDP protocols are always allowed to run on every host; you cannot disallow them. For more information, see Configuring the Global Host Profile on page 1620.

Understanding Host Profiles for Specific Operating Systems

License: FireSIGHT

You must create one host profile for each operating system you want to allow on your network. To disallow an operating system on your network, do not create a host profile for that operating system. For example, to make sure that all the

hosts on your network are running Microsoft Windows, configure the white list to only contain host profiles for that operating system.



When you create a host profile for an operating system, you can also require that it have a particular version. For example, you could require that compliant hosts run Windows 7 or Server 2008 R2.

After you create a host profile for a particular operating system, you can specify the application protocols, clients, web applications, and protocols that are allowed to run on target hosts running that operating system. For example, you could allow SSH to run on Linux hosts on port 22. You could also restrict the particular vendor and version to OpenSSH 4.2.

Note that unidentified hosts remain in compliance with all white lists until they are identified. You can, however, create a white list host profile for unknown hosts.

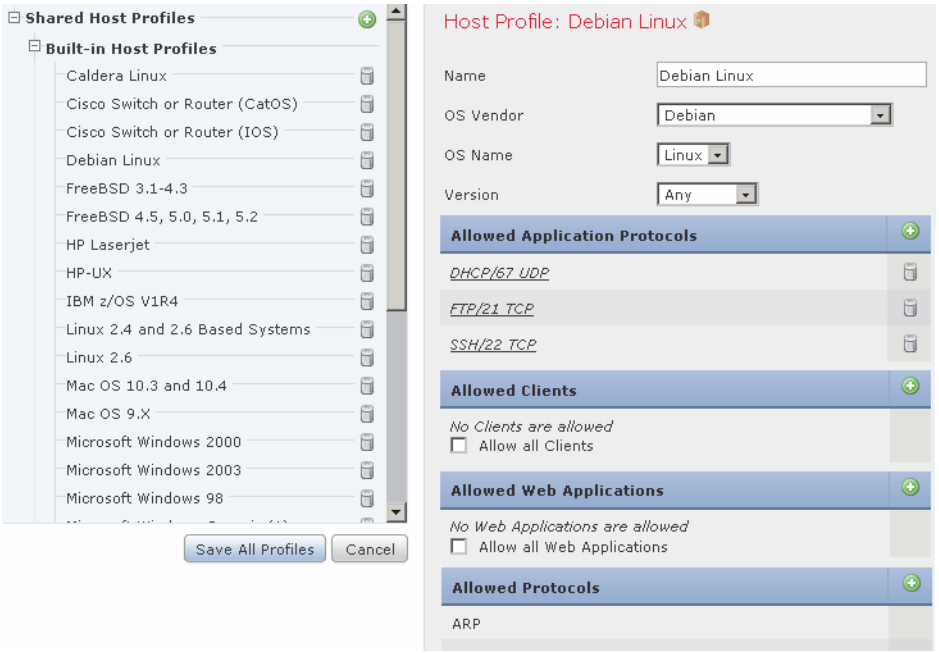
IMPORTANT! Unidentified hosts are not the same as unknown hosts. *Unidentified* hosts are hosts about which the system has not yet gathered enough information to identify their operating systems. *Unknown* hosts are hosts whose traffic has been analyzed by the system, but whose operating systems do not match any of the known fingerprints.

For more information, see Creating Host Profiles for Specific Operating Systems on page 1621.

Understanding Shared Host Profiles

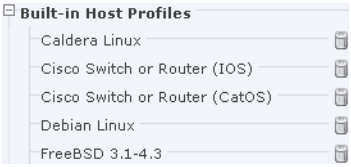
LICENSE: FireSIGHT

Shared host profiles are tied to specific operating systems, but you can use each shared host profile in more than one white list. That is, if you create multiple white lists but want to use the same host profile to evaluate hosts running a particular operating system across the white lists, use a shared host profile.



For example, if you have offices worldwide and you want to create a separate white list for each location, but always want to use the same profile for all hosts running Apple Mac OS X, you can create a shared profile for that operating system and use it in all your white lists.

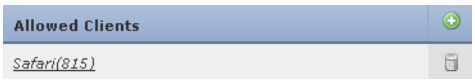
The default white list represents recommended "best practices" settings for allowed operating systems, clients, application protocols, web applications, and protocols. This white list uses a special category of shared host profiles, called *built-in host profiles*.



Note that built-in host profiles are marked with the built-in host profile icon ( ).

Built-in host profiles use built-in application protocols, protocols, and clients. You can use these elements as-is in both the default white list and in any custom

white list that you create or you can modify them to suit your needs. They are displayed in italics within the built-in host profile and in any other host profile that uses them.



Keep in mind that like all shared host profiles, if you modify a built-in host profile, it affects every white list that uses it. Likewise, if you modify a built-in application protocol, protocol, or client, it affects every white list that uses it.

For more information on shared host profiles, Working with Shared Host Profiles on page 1635.

Understanding White List Evaluations

LICENSE: FireSIGHT

After you create white list host profiles and save the white list, you can add the white list to a correlation policy, just as you would a correlation rule. For more information, see Configuring Correlation Policies and Rules on page 1528.

After you activate the correlation policy, the system evaluates the targets of the white list against the white list criteria.You can then use the host attributes network map to gain an overall view of the white list compliance of the hosts on your network.

Every host on the network is assigned a host attribute that has the same name as the white list. This host attribute has one of the following values:

- **Compliant**, for valid targets that are compliant with the white list
- **Non-Compliant**, for valid targets that violate the white list
- **Not Evaluated**, for invalid targets and hosts that have not yet been evaluated for any reason

Note that if your network is large and the system is in the process of evaluating all the valid targets in the network map against the white list, targets that have not yet been evaluated are marked as `Not Evaluated`. As the system completes its processing, more hosts move from `Not Evaluated` to either `Compliant` or `Non-Compliant`. The system can evaluate approximately 100 hosts per second.

Additionally, a host may be marked as `Not Evaluated` if the system has insufficient information to determine whether the host is in compliance. For example, this may occur if the system has detected a new host but has not yet

gathered relevant information on the operating system, clients, application protocols, web applications, or protocols running on the host.

IMPORTANT! If you change or delete a host attribute from a host and that change or deletion means that the host is no longer a valid target, the host changes from either `Compliant` or `Non-Compliant` to `Not Evaluated`.

For more information on host attributes, see Working with the Host Attributes Network Map on page 1385.

Understanding White List Violations

LICENSE: FireSIGHT

After the initial white list evaluation, the system generates a *white list event* when it detects that a valid target is violating the white list. White list events are a special kind of correlation event, and are logged to the Defense Center correlation event database. You can view white list events in a workflow, or search for specific white list events. For more information, see Working with White List Events on page 1643.

White list violations occur when the system generates an event that indicates that a host is out of compliance. Similarly, discovery events may indicate that a previously non-compliant host is now compliant, although the system does **not** generate a white list event when this occurs.

The following events can change the compliance of a host:

- the system detects a change in a host's operating system
- the system detects an identity conflict for a host's operating system or an application protocol on the host
- the system detects a new TCP server port (for example, a port used by SMTP or web servers) active on a host, or a new UDP server running on a host
- the system detects a change in a discovered TCP or UDP server running on a host, for example, a version change due to an upgrade
- the system detects a new client running on a host
- the system drops a client from its database due to inactivity
- the system detects a new web application running on a host
- the system drops a web application from a host profile due to inactivity
- the system detects that a host is communicating with a new network protocol, such as Novell Netware or IPv6, or a new transport protocol, such as ICMP or EGP
- the system detects a new mobile device that is jailbroken
- the system detects that a TCP or UDP port has closed or timed out on a host

In addition, you can trigger a compliance change for a host by using the host input feature or the host profile to:

- add a client, protocol, or server to a host
- delete a client, protocol, or server from a host
- set the operating system definition for a host
- change a host attribute for a host so that the host is no longer a valid target

For example, if your white list specifies that only Microsoft Windows hosts are allowed on your network, and the system detects that the host is now running Mac OS X, the system generates a white list event. In addition, the host attribute associated with the white list changes its value from `Compliant` to `Non-Compliant` for that host.

For the host in this example to come back into compliance, one of the following must occur:

- you edit the white list so that the Mac OS X operating system is allowed
- you manually change the operating system definition of the host to Microsoft Windows
- the system detects that the operating system has changed back to Microsoft Windows

In any case, the host attribute associated with the white list changes its value from `Non-Compliant` to `Compliant` for that host.

As another example, if your compliance white list disallows the use of FTP, and you then delete FTP from the application protocols network map or from an event view, hosts running FTP become compliant. However, if the system detects the application protocol again, the system generates a white list event and the hosts become non-compliant.

Note that if the system generates an event that contains insufficient information for the white list, the white list does not trigger. For example, consider a scenario where your white list specifies that you allow only TCP FTP traffic on port 21. Then, the system detects that port 21, using the TCP protocol, has become active on one of the white list targets, but the system is unable to determine whether the traffic is FTP. In this scenario, the white list does not trigger until either the system identifies the traffic as something other than FTP traffic or you use the host input feature to designate the traffic as non-FTP traffic.

IMPORTANT! During the initial evaluation of a white list, the system does **not** generate white list events for non-compliant hosts. If you want to generate white list events for all non-compliant targets, you must purge the Defense Center database. This causes the hosts on your network and their associated clients, application protocols, web applications, and protocols to be rediscovered, which may trigger white list events. For more information, see Purging Discovery Data from the Database on page 2319.

Finally, you can configure the system to trigger responses automatically when it detects a white list violation. Responses include remediations (such as running an Nmap scan), alerts (email, SNMP, and syslog alerts), or combination of alerts and remediations. For more information, see Adding Responses to Rules and White Lists on page 1588.

Creating Compliance White Lists

LICENSE: FireSIGHT

When you create a white list, you can survey either your entire network or a specific network segment. Surveying the network populates the white list with one host profile for each operating system that the system has detected on the network segment. By default, these host profiles allow all of the clients, application protocols, web applications, and protocols that the system has detected on the applicable operating systems.

Then, you must specify the targets of the white list. You can configure a white list to evaluate all the hosts on your monitored network, or you can restrict the white list to evaluate only certain network segments or even individual hosts. You can further restrict the white list so that it evaluates only hosts that have a certain host attribute or that belong to a certain VLAN. If you surveyed your network, by default the network segment that you surveyed represents the white list targets. You can edit or delete the surveyed network, or you can add new targets.

Next, create host profiles that represent compliant hosts. Host profiles in a white list specify which operating systems, clients, application protocols, web applications, and protocols are allowed to run on the target hosts. You can configure the global host profile, edit the host profiles created by any network survey your performed, as well as add new host profiles, and add and edit shared host profiles.

Finally, save the white list and add it to an active correlation policy. The system begins evaluating the target hosts for compliance, generating white list events when a host violates the white list, and triggering any responses you have configured to white list violations. For a more detailed introduction to compliance white lists, see Understanding Compliance White Lists on page 1603.

TIP! You can also create a white list from a table view of hosts. For more information, see Creating a Compliance White List Based on Selected Hosts on page 1472.

To create a compliance white list:

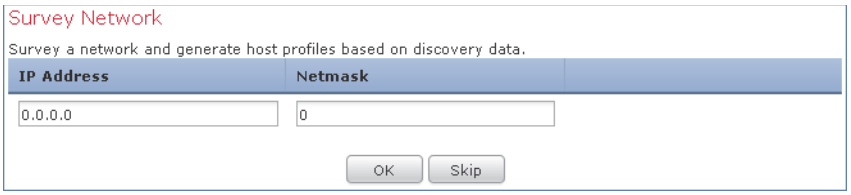
ACCESS: Admin

1. Select **Policies > Correlation**, then click **White List**.

   The White List page appears.

2. Click **New White List**.

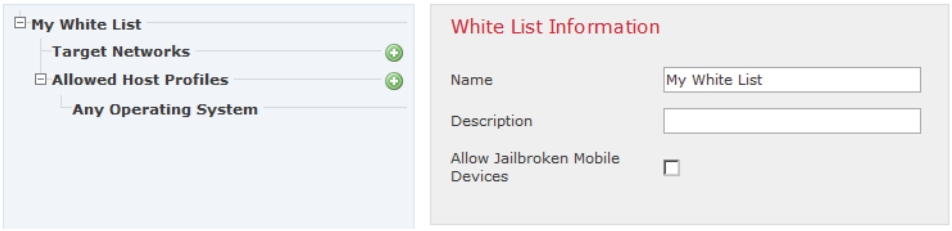
   The Survey Network page appears.



3. Optionally, survey your network:

   - To survey your network, see Surveying Your Network on page 1614.
   - To create a white list without surveying your network, click **Skip** and continue with the next step.

   The Create White List page appears.



4. In the **Name** field, type a name for the new white list.
5. In the **Description** field, type a short description of the white list.
6. To allow jailbroken mobile devices on your network, enable **Allow Jailbroken Mobile Devices**. To cause all jailbroken devices evaluated by the white list to generate a white list violation, disable the option.
7. Specify the targets for the white list. You can edit or delete the targets created by a network survey as well as add new targets. Optionally, further restrict targets based on host attributes or VLAN ID. For more information, see Configuring Compliance White List Targets on page 1616.
8. Create host profiles that represent compliant hosts. You can configure the global host profile, edit the host profiles created by a network survey, as well as add new host profiles and add and edit shared host profiles. For more information, see Configuring Compliance White List Host Profiles on page 1620.
9. Click **Save White List** to save your white list.

   The white list is saved. You can now add it to an active correlation policy to begin evaluating the target hosts for compliance, generating white list events when a host violated the white list, and, optionally triggering responses to white list violations. For more information, see Creating Correlation Policies on page 1584.

Surveying Your Network

LICENSE: FireSIGHT

When you begin creating a compliance white list, you can survey either your entire network or a specific network segment.

Surveying your network gathers data from the database about the application protocols, clients, web applications, and protocols running on the different detected operating systems. Then, the system creates one host profile within the white list for each detected operating system. By default, these host profiles allow all of the detected clients, application protocols, web applications, and protocols that the system has detected on each applicable operating systems.

This creates a baseline white list so that you do not have to manually create and configure multiple host profiles. After you survey your network, you can then edit or delete the host profiles that the survey created to suit your needs; you can also add any other host profiles you might need.

Note that you can survey your network at any time during the white list creation process. This can add additional allowed clients, application protocols, web applications, and protocols to the host profiles that already exist, and can create additional host profiles if the survey detects hosts running operating systems that were not detected during the initial survey. If you resurvey your network within a white list that is used within an active correlation policy, and the survey changes either your targets or host profiles, the target hosts are re-evaluated when you save the white list. Although this re-evaluation may bring some hosts into compliance, it does not generate any white list events.

To begin creating a compliance white list by surveying your network:

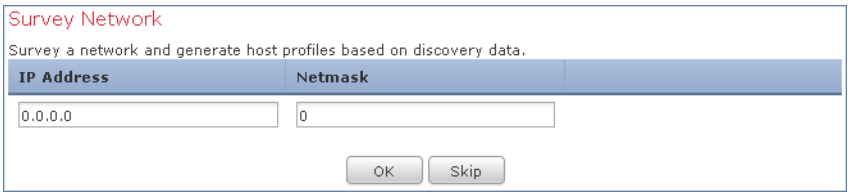
ACCESS: Admin

1. Select **Policies > Correlation**, then click **White List**.

   The White List page appears.

2. Click **New White List**.

   The Survey Network page appears.



3. Do you want to survey your network?
   - If **yes**, continue with the next step.
   - If **no**, click **Skip**.

     The Create White List page appears and displays a blank white list. Continue with the procedure in the next section, Providing Basic White List Information.

4. In the **IP Address** and **Netmask** fields, enter the IP address and network mask (in special notation such as CIDR) that represent the hosts you want to survey.

   Make sure to specify a network that you configured the system to monitor in the network discovery policy. For information on using IP address notation in the Sourcefire 3D System, see IP Address Conventions on page 63.

   TIP! To survey the entire monitored network, use the default values of `0.0.0.0/0` and `::/0`.

5. Click **OK**.

   The Create White List page appears.

   The white list is pre-populated; its targets are the hosts in the network you surveyed and its allowed host profiles are those of the targets.

6. To survey additional networks, click **Target Network** and repeat steps 4 and 5 for each additional network you want to survey.

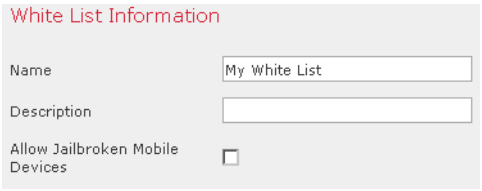
   Surveying an additional network can add additional allowed clients, application protocols, web applications, and protocols to the host profiles that already exist, and can create additional host profiles if the survey detects hosts running operating systems that were not detected during the initial survey. Surveying an additional network also adds a target to the white list that represents the hosts in the network segment that you surveyed. You can then edit or delete this target.

7. Continue with the next section, Providing Basic White List Information.

Providing Basic White List Information

LICENSE: FireSIGHT

You must give each white list a name, and, optionally, a short description. In addition, you can choose whether jailbroken mobile devices should cause a white list violation.



To provide basic white list information:

ACCESS: Admin

1. In the **Name** field, type a name for the new white list.
2. In the **Description** field, type a short description of the white list.
3. To allow jailbroken mobile devices on your network, enable **Allow Jailbroken Mobile Devices**. To cause all jailbroken devices evaluated by the white list to generate a white list violation, disable the option.
4. Continue with the next section, Configuring Compliance White List Targets.

Configuring Compliance White List Targets

LICENSE: FireSIGHT

When you create a compliance white list, you must specify the portions of your network it applies to. You can use a white list to evaluate all the hosts on your monitored network, or you can restrict the white list to evaluate only certain network segments or even individual hosts. You can further restrict the white list so that it evaluates only hosts that have a certain host attribute or that belong to a certain VLAN. A host that is eligible to be evaluated by a white list is called a *target*. For a more detailed introduction to white list targets, see Understanding White List Targets on page 1604.

When you are finished creating compliance white list targets, continue with Configuring Compliance White List Host Profiles on page 1620.

IMPORTANT! If you change or delete a host attribute from a host and that modification means that the host is no longer a valid target, the host is no longer evaluated by the white list and is considered neither compliant nor non-compliant.

For information on how to modify and delete targets, see:

- Modifying Existing Targets on page 1619
- Deleting Existing Targets on page 1619

When you create a target for a compliance white list, you specify the criteria a host must meet to be evaluated against the white list. A valid target:

- must be in one of the IP address blocks you specify. You can also exclude blocks of IP addresses.
- must have at least one of the host attributes you specify.
- must belong to one of the VLANs you specify.

Note that if you add a target to a white list that is used by an active correlation policy, after you save the white list, the new target hosts are evaluated for compliance. However, this evaluation does not generate white list events.

To create a compliance white list target:

Access: Admin

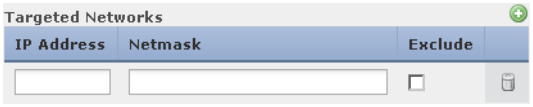
1. On the Create White List Page, next to **Target Networks**, click the add icon ( ).

   The settings for the new target appear.

   TIP! You can also create a new target by surveying a network segment. On the Create White List page, click **Target Network**, then follow steps 4 and 5 in Surveying Your Network on page 1614. The new target is created and is named according to the IP addresses you specified. Click the target you just created and continue with the rest of this procedure to rename the target, add or exclude additional networks, and add host attribute or VLAN restrictions.

2. In the **Name** field, type a name for the new target.

3. Target a specific set of IP addresses by clicking the add icon ( ) next to **Targeted Networks**.



4. In the **IP Address** and **Netmask** fields, enter the IP address and network mask (in special notation, such as CIDR) that represent the hosts you want to target or exclude from targeting.

   You should make sure that you specify a network that you configured the system to monitor in your network discovery policy. For information on using IP address notation in the Sourcefire 3D System, see IP Address Conventions on page 63.

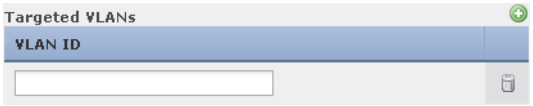
   TIP! To target the entire monitored network, use `0.0.0.0/0` and `::/0`.

5. If you want to exclude the network from monitoring, select **Exclude**.
6. To add additional networks, repeat steps 4 and 5.
7. Target hosts that have a specific host attribute by clicking **Add** next to **Targeted Host Attributes**.

8. From the **Attribute** and **Value** drop-down lists, specify the host attribute.
9. To add additional host attributes, repeat steps 7 and 8.

   A host must have at least one of the host attributes you specify to be evaluated against the white list.

10. Target hosts that belong to a specific VLAN by clicking **Add** next to **Targeted VLANs**.



11. In the **VLAN ID** field, specify the VLAN IDs of the hosts you want to evaluate against the white list. This can be any integer between 0 and 4095 for 802.1q VLANs.

12. To add additional VLAN IDs, repeat steps 10 and 11.

    The host must be a member of one of the VLANs you specify to be evaluated against the white list.

> **TIP!** To remove a network, host attribute restriction, or VLAN restriction, click the delete icon ( ) next to the element you want to delete.

Modifying Existing Targets

LICENSE: FireSIGHT

After you modify a target, you must save the white list for your changes to take effect. Note that if you modify a target in a white list that is used by an active correlation policy, after you save the white list, any new target hosts are evaluated for compliance. However, this evaluation does not generate white list events. In addition, the system changes the white list host attribute of previously valid targets to `Not Evaluated`.

To modify an existing target:

ACCESS: Admin

1. On the Create White List page, under **Targets**, click the target you want to modify.

   The settings for the target appear.

2. Make changes as needed.

   You can rename the target, add or exclude additional networks, and add host attribute or VLAN restrictions. For more information, see Configuring Compliance White List Targets on page 1616.

Deleting Existing Targets

LICENSE: FireSIGHT

After you delete a target, you must save the white list for your changes to take effect. Note that if you delete a target from a white list that is used by an active correlation policy, the system changes the white list host attribute of previously valid targets to `Not Evaluated`.

To delete a white list target:

ACCESS: Admin

1. Next to the target you want to delete, click the delete icon ( ).
2. When prompted, confirm that you want to delete the target.

   The target is deleted.

Configuring Compliance White List Host Profiles

LICENSE: FireSIGHT

Host profiles in a compliance white list specify which operating systems, clients, application protocols, web applications, and protocols are allowed to run on the target hosts. There are three kinds of host profiles you can configure in a white list:

- global host profiles, which specify the application protocols, clients, web applications, and protocols that are allowed to run on target hosts, regardless of the host's operating system
- host profiles for specific operating systems, which specify not only which operating systems are allowed to run on your network, but also the application protocols, clients, web applications, and protocols that are allowed to run on those operating systems
- shared host profiles, which function exactly like the host profiles for specific operating systems, except they are not tied to a single white list; you can use them across multiple white lists

For a more detailed introduction to compliance white list host profiles, see Understanding White List Host Profiles on page 1605.

When you are finished creating compliance white list host profiles, you can add the white list to an active correlation policy to begin evaluating the target hosts for compliance, generating white list events when a host violated the white list, and optionally, triggering responses based on white list violations.

For information on how to create, modify, and delete compliance white list host profiles, see:

- Configuring the Global Host Profile on page 1620
- Creating Host Profiles for Specific Operating Systems on page 1621
- Adding a Shared Host Profile to a Compliance White List on page 1629
- Modifying Existing Host Profiles on page 1630
- Deleting Existing Host Profiles on page 1633

Configuring the Global Host Profile

LICENSE: FireSIGHT

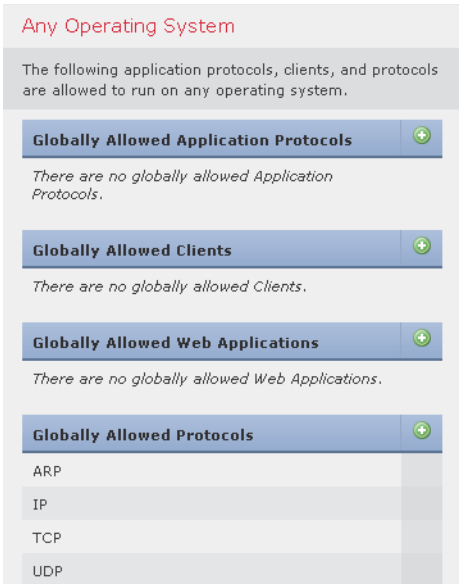
Every white list contains a global host profile, which specifies the application protocols, clients, web applications, and protocols that are allowed to run on target hosts, regardless of the host's operating system. For a more detailed introduction to the global host profile, see Understanding the Global Host Profile on page 1606.

To configure the global host profile:

Access: Admin

1. On the Create White List page, under **Allowed Host Profiles**, click **Any Operating System**.

   The settings for the global host profile appear.



2. To specify the application protocols you want to allow, follow the directions in Adding an Application Protocol to a Host Profile on page 1623.
3. To specify the clients you want to allow, follow the directions in Adding a Client to a Host Profile on page 1625.
4. To specify the web applications you want to allow, follow the directions in Adding a Web Application to a Host Profile on page 1627.
5. To specify the protocols you want to allow, follow the directions in Adding a Protocol to a Host Profile on page 1628.

   Note that ARP, IP, TCP, and UDP are always allowed.

Creating Host Profiles for Specific Operating Systems

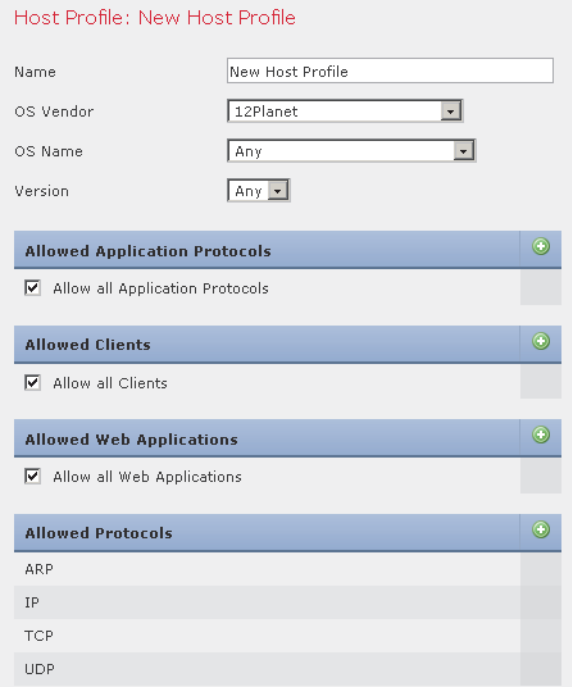
License: FireSIGHT

Host profiles for specific operating systems indicate not only which operating systems are allowed to run on your network, but also the application protocols, clients, web applications, and protocols that are allowed to run on those operating systems. For a more detailed introduction, see Understanding Host Profiles for Specific Operating Systems on page 1606.

To create a new compliance white list host profile for a specific operating system:

Access: Admin

1. Next to **Allowed Host Profiles**, click the add icon ( ).
   The settings for the new host profile appear.



2. In the **Name** field, type a descriptive name for the host profile.
3. From the **OS Vendor**, **OS Name**, and **Version** drop-down lists, pick the operating system and version for which you want to create a host profile.
4. Specify the application protocols you want to allow. You have three options:
   - To allow all application protocols, leave the **Allow all Application Protocols** check box selected.
   - To allow no application protocols, clear the **Allow all Application Protocols** check box.
   - To allow specific application protocols, follow the directions in Adding an Application Protocol to a Host Profile on page 1623.
5. Specify the clients you want to allow. You have three options:
   - To allow all clients, leave the **Allow all Clients** check box selected.
   - To allow no clients, clear the **Allow all Clients** check box.
   - To allow specific clients, follow the directions in Adding a Client to a Host Profile on page 1625.

6. Specify the web applications you want to allow. You have three options:
   - To allow all web applications, leave the **Allow all Web Applications** check box selected.
   - To allow no web applications, clear the **Allow all Web Applications** check box.
   - To allow specific web applications, follow the directions in Adding a Web Application to a Host Profile on page 1627.
7. Specify the protocols you want to allow.

   To add a protocol, next to **Allowed Protocols**, follow the directions in Adding a Protocol to a Host Profile on page 1628. Note that ARP, IP, TCP, and UDP are always allowed.

Adding an Application Protocol to a Host Profile

License: FireSIGHT

You can configure a compliance white list, using either a shared host profile or a host profile that belongs to a single white list, to allow certain application protocols to run on specific operating systems. You can also configure a white list to allow certain application protocols to run on any valid target; these are called globally allowed application protocols.

For any allowed application protocol, you can either specify the type of application protocol that you want to allow — FTP and SSH are examples of application protocol types — or you can allow a custom application protocol by specifying an application protocol type of **any**. You must also specify the protocol the allowed application protocol uses (TCP or UDP). You can allow the application protocol on any port, or restrict it to a port that you specify.

Optionally, you can require that the application protocol server have a specific vendor or version. For example, you could allow SSH to run on Linux hosts on port 22. You could also restrict the particular vendor and version to OpenSSH 4.2.

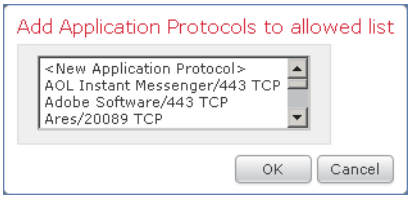
To add an application protocol to a compliance white list host profile:

Access: Admin

1. While you are creating or modifying a white list host profile, click the add icon ( )next to **Allowed Application Protocols** (or next to **Globally Allowed Application Protocols** if you are modifying the Any Operating System host profile).

   A pop-up window appears. The application protocols listed are:

   - application protocols that you created within the white list
   - application protocols that existed in the network map when you surveyed your networks as described in Surveying Your Network on page 1614
   - application protocols that are used by other host profiles in the white list, which may include built-in application protocols created by the VRT for use in the default white list

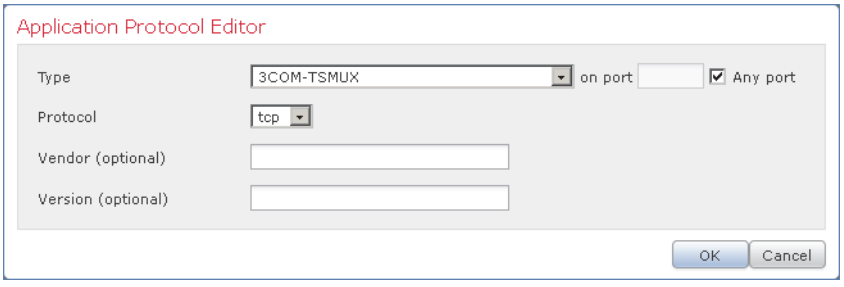


2. You have two options:

   - To add an application protocol already in the list, select it and click **OK**. Use Ctrl or Shift while clicking to select multiple application protocols. You can also click and drag to select multiple adjacent application protocols.

     The application protocol is added. Note that if you added a built-in application protocol, its name appears in italics. You can skip the rest of the procedure, or optionally, to change any of the application protocol's values (such as the port or protocol), click the application protocol you just added to display the application protocol editor.
   - To add a new application protocol, select **<New Application Protocol>** and click **OK**.

     The application protocol editor appears.



3. From the **Type** drop-down list, select the application protocol type. For custom application protocols, select **any**.
4. Specify the application protocol port. You have two options:
   - To allow the application protocol to run on any port, check the **Any port** check box.
   - To allow the application protocol to run only on a specific port, type the port number in the **port** field.
5. From the **Protocol** drop-down list, select the protocol: **TCP** or **UDP**.
6. Optionally, in the **Vendor** and **Version** fields, specify a vendor and version for the application protocol.

   If you do not specify a vendor or version, the white list allows all vendors and versions as long as the type and protocol match. Note that if you restrict the vendor and version, you must make sure to specify them exactly as they would appear in an event view or in the application protocols network map.
7. Click **OK**.

   The application protocol is added. Note that you must save the white list for your changes to take effect.

   If you added an application protocol to a white list that is used by an active correlation policy, after you save the white list, the target hosts are re-evaluated. Although this re-evaluation may bring some hosts into compliance, it does not generate any white list events.

Adding a Client to a Host Profile

License: FireSIGHT

You can configure a compliance white list, using either a shared host profile or a host profile that belongs to a single white list, to allow certain client applications to run on specific operating systems. You can also configure a white list to allow certain clients to run on any valid target; these are called globally allowed clients.

Optionally, you can require that the client be a specific version. For example, you could allow only Microsoft Internet Explorer 8.0 to run on Microsoft Windows hosts.

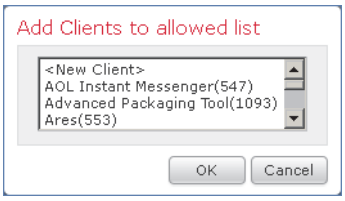
To add a client to a compliance white list host profile:

Access: Admin

1. While you are creating or modifying a white list host profile, click the add icon ( ) next to **Allowed Clients** (or next to **Globally Allowed Clients** if you are modifying the Any Operating System host profile).

   A pop-up window appears. The clients listed are:

   - clients that you created within the white list
   - clients that were running on hosts in the network map when you surveyed your networks as described in Surveying Your Network on page 1614
   - clients that are used by other host profiles in the white list, which may include built-in clients created by the VRT for use in the default white list

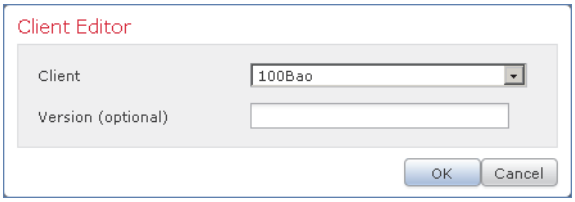
   


2. You have two options:

   - To add a client already in the list, select it and click **OK**. Use Ctrl or Shift while clicking to select multiple clients. You can also click and drag to select multiple adjacent clients.

     The client is added. Note that if you added a built-in client, its name appears in italics. You can skip the rest of the procedure, or optionally, to change any of the client's values (such as its version), click the client you just added to display the client editor.
   - To add a new client, select **<New Client>** and click **OK**.

     The client editor appears.

3. From the **Client** drop-down list, select the client.
4. Optionally, in the **Version** field, specify a version for the client.

   If you do not specify a version, the white list allows all versions as long as the name matches. Note that if you restrict the version, you must specify it exactly as it would appear in a table view of clients.
5. Click **OK**.

   The client is added. Note that you must save the white list for your changes to take effect.

   If you added a client to a white list that is used by an active correlation policy, after you save the white list, the target hosts are re-evaluated. Although this re-evaluation may bring some hosts into compliance, it does not generate any white list events.

Adding a Web Application to a Host Profile

License: FireSIGHT

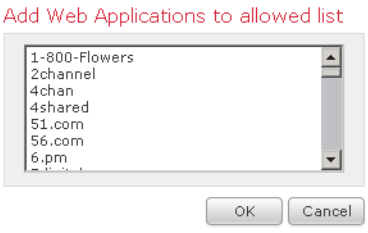
You can configure a compliance white list, using either a shared host profile or a host profile that belongs to a single white list, to allow certain web applications to run on specific operating systems. You can also configure a white list to allow certain web applications to run on any valid target; these are called globally allowed web applications.

To add a web application to a compliance white list host profile:

Access: Admin

1. While you are creating or modifying a white list host profile, click the add icon ( ) next to **Allowed Web Applications** (or next to **Globally Allowed Web Applications** if you are modifying the Any Operating System host profile).

   A pop-up window appears, listing all web applications detected by the system.



2. Select a web application and click **OK**. Use Ctrl or Shift while clicking to select multiple web applications. You can also click and drag to select multiple adjacent web applications.

   The web application is added. Note that you must save the white list for your changes to take effect.

   If you added a web application to a white list that is used by an active correlation policy, after you save the white list, the target hosts are re-evaluated. Although this re-evaluation may bring some hosts into compliance, it does not generate any white list events.

Adding a Protocol to a Host Profile

License: FireSIGHT

You can configure a compliance white list, using either a shared host profile or a host profile that belongs to a single white list, to allow certain protocols to run on specific operating systems. You can also configure a white list to allow certain protocols to run on any valid target; these are called globally allowed protocols. Note that ARP, IP, TCP, and UDP are always allowed to run on any host; you cannot disallow them.

For any allowed protocol, you must specify its type (Network or Transport) and number.

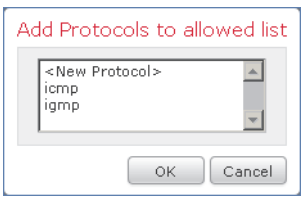
To add a protocol to a compliance white list host profile:

Access: Admin

1. While you are creating or modifying a white list host profile, click the add icon () next to **Allowed Protocols** (or next to **Globally Allowed Protocols** if you are modifying the Any Operating System host profile).

   A pop-up window appears. The protocols listed are:

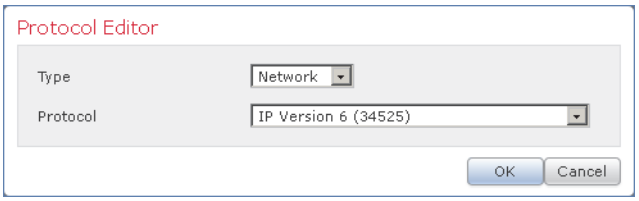
   - protocols that you created within the white list
   - protocols that were running on hosts in the network map when you surveyed your networks as described in Surveying Your Network on page 1614
   - protocols that are used by other host profiles in the white list, which may include built-in protocols created by the VRT for use in the default white list



2. You have two options:
   - To add a protocol already in the list, select it and click **OK**. Use Ctrl or Shift while clicking to select multiple protocols. You can also click and drag to select multiple adjacent protocols.

     The protocol is added. Note that if you added a built-in protocol, its name appears in italics. You can skip the rest of the procedure, or optionally, to change any of the protocol's values (such as the type or number) click the protocol you just added to display the protocol editor.
   - To add a new protocol, select **<New Protocol>** and click **OK**.

     The protocol editor appears.



3. From the **Type** drop-down list, select the protocol type: **Network** or **Transport**.
4. Specify the protocol. You have two options:
   - Select a protocol from the drop-down list.
   - Select **Other (manual entry)** to specify a protocol that is not in the list. For network protocols, type the appropriate number as listed in http://www.iana.org/assignments/ethernet-numbers/. For transport protocols, type the appropriate number as listed in http://www.iana.org/assignments/protocol-numbers/.
5. Click **OK**.

   The protocol is added. Note that you must save the white list for your changes to take effect.

   If you added a protocol to a white list that is used by an active correlation policy, after you save the white list, the target hosts are re-evaluated. Although this re-evaluation may bring some hosts into compliance, it does not generate any white list events.

Adding a Shared Host Profile to a Compliance White List

License: FireSIGHT

Shared host profiles are also tied to specific operating systems, but you can use them across white lists. That is, if you create multiple white lists but want to use the same host profile to evaluate hosts running a particular operating system across the white lists, use a shared host profile.

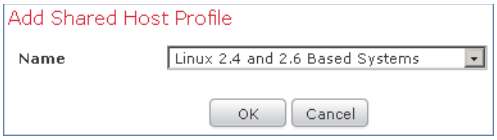
You can add any of the built-in shared host profiles to your compliance white lists, or you can add shared host profiles that you created. For more information, see Understanding Shared Host Profiles on page 1608 and Creating Shared Host Profiles on page 1636.

To add a shared host profile to a compliance white list:

ACCESS: Admin

1. On the Create White List page, click **Add Shared Host Profile**.

   The Add Shared Host Profile page appears.



2. From the **Name** drop-down list, select the shared host profile you want to add to your white list, and click **OK**.

   The shared host profile is added to your white list and the Create White List page appears again. The shared host profile's name appears in italics under Allowed Host Profiles.

TIP! You can edit a shared host profile from within a white list that uses it by clicking on the profile name under Allowed Host Profiles. For more information, see Modifying Existing Host Profiles on page 1630.

Modifying Existing Host Profiles

LICENSE: FireSIGHT

After you modify a host profile within a compliance white list, you must save the white list for your changes to take effect.

If a host profile you modify belongs to a white list used in an active correlation policy, modifying the profile may bring hosts into or out of compliance but does **not** generate white list events. Further, modifying a shared host profile affects every white list that uses it. This may bring hosts into or out of compliance not only in the white list you are working with, but in other white lists as well.

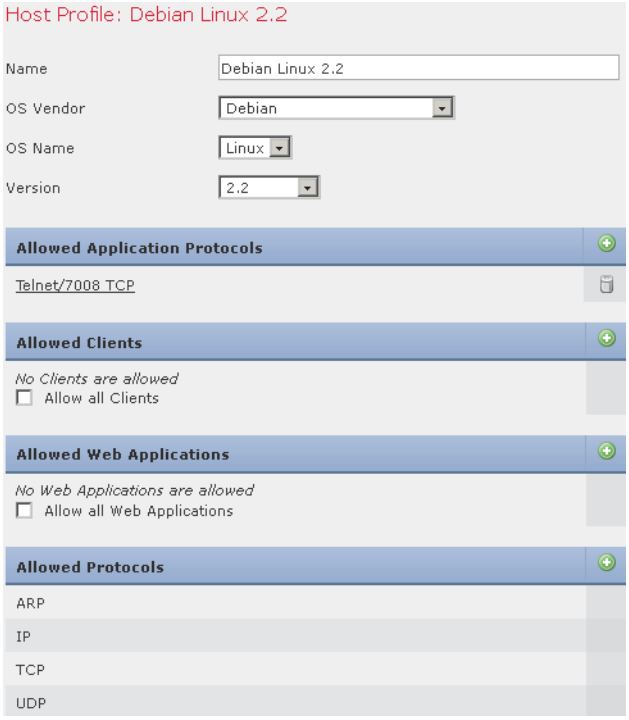
TIP! As with other shared host profiles, you can edit the built-in host profiles used by the default white list. You can also reset them to their factory defaults. For more information, see Resetting Built-In Host Profiles to Their Factory Defaults on page 1642.

To modify an existing host profile:

Access: Admin

1. On the Create White List page, click the name of the host profile you want to modify.

   The settings for the host profile appear. Note that if you are editing a shared host profile, an **Edit** link appears next to the name of the host profile. If you are editing a built-in host profile, the built-in host profile icon ( ) also appears.



2. You have two options:

   - If you are modifying a shared host profile, click **Edit**.

     A pop-up window appears. Make changes as needed as described in the table below. Click **Save All Profiles** to save the profile, then click **Done** to close the pop-up window.

     For more information editing shared host profiles, see Modifying a Shared Host Profile on page 1638.

   - If you are modifying either the white list's global host profile or a host profile for a specific operating system, perform one of the actions described in the procedures below.

To rename the host profile:

Access: Admin

- Type a new name in the **Name** field.

To change the operating system for the host profile:

Access: Admin

- Select the new operating system and version from the **OS Vendor**, **OS Name**, and **Version** drop-down lists.

  If you change these values, you may also want to rename the host profile. Note that a white list's global host profile has no operating system associated with it, so you cannot change it.

To add an application protocol:

Access: Admin

- Follow the directions in Adding an Application Protocol to a Host Profile on page 1623.

To add a client:

Access: Admin

- Follow the directions in Adding a Client to a Host Profile on page 1625.

To add a web application:

Access: Admin

- Follow the directions in Adding a Web Application to a Host Profile on page 1627.

To add a protocol:

Access: Admin

- Follow the directions in Adding a Protocol to a Host Profile on page 1628.

To allow all application protocols:

Access: Admin

- Under **Allowed Application Protocols**, select the **Allow all Application Protocols** check box.

  Note that the check box does not appear until you delete any application protocols you have previously allowed.

To allow all clients:

Access: Admin

- Under **Allowed Clients**, select the **Allow all Clients** check box.

  Note that the check box does not appear until you delete any clients you have previously allowed.

To allow all web applications:

Access: Admin

- Under **Allowed Web Applications**, select the **Allow all Web Applications** check box.

  Note that the check box does not appear until you delete any web applications you have previously allowed.

To modify an application protocol, client, web application, or protocol:

Access: Admin

- Click the element you want to modify.

  For more information on the properties you can change, see:

  - Adding an Application Protocol to a Host Profile on page 1623
  - Adding a Client to a Host Profile on page 1625
  - Adding a Protocol to a Host Profile on page 1628

IMPORTANT! The changes you make to an application protocol, client, web application, or protocol are reflected in every host profile that uses that element.

To delete an application protocol, client, web application, or protocol:

Access: Admin

- Next to the element you want to delete, click the delete icon ( ).

To survey your network:

Access: Admin

- Click **Survey Network**. Surveying your network can add additional allowed clients, application protocols, and protocols to the host profiles that already exist, and can create additional host profiles if the survey detects hosts running operating systems that were not detected during any initial survey. For more information, see Surveying Your Network on page 1614.

Deleting Existing Host Profiles

License: FireSIGHT

After you delete a host profile from a compliance white list, you must save the white list for your changes to take effect. Note that deleting a shared host profile removes it from the white list, but does not delete the profile or remove it from any other white lists that use it. You cannot delete a white list's global host profile.

If the host profile you delete belongs to one or more white lists used in an active correlation policy, deleting the profile may force hosts out of compliance, but does **not** generate white list events.

To delete a compliance white list host profile:

Access: Admin

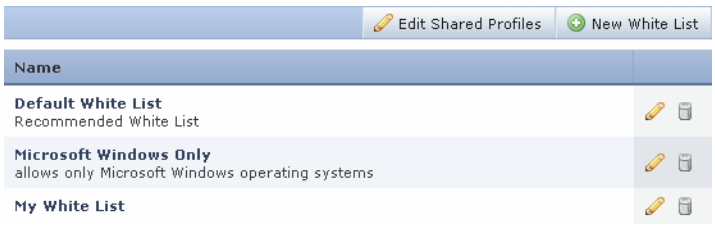
1. On the Create White List page, next to the host profile you want to delete, click the delete icon ( ).
2. When prompted, confirm that you want to delete the host profile.

   The host profile is deleted.

Managing Compliance White Lists

License: FireSIGHT

Use the White List page to manage compliance white lists. You can create, modify, and delete white lists, including the default white list. You can also edit any shared host profiles you have created, as well as the built-in shared host profiles, and add new shared host profiles.



For more information, see:

- Creating Compliance White Lists on page 1612
- Modifying a Compliance White List on page 1634
- Deleting a Compliance White List on page 1635
- Working with Shared Host Profiles on page 1635

Modifying a Compliance White List

License: FireSIGHT

When you modify a compliance white list that is included in an active correlation policy, the system re-evaluates the target hosts. Note that the system does **not** generate white list events — and therefore does not trigger any responses you associated with the white list — during this re-evaluation, even if the white list is included in an active correlation policy and a previously compliant host becomes non-compliant with the updated white list.

To modify an existing compliance white list:

Access: Admin

1. Select **Policies > Correlation**, then click **White List**.
   The White List page appears.
2. Next to the white list you want to modify, click the edit icon ( ).
   The Create White List page appears.
3. Make modifications as necessary and click **Save White List**.
   The white list is updated.

Deleting a Compliance White List

License: FireSIGHT

You cannot delete a compliance white list that you are using in one or more correlation policies; you must first delete the white list from all policies where it is used. For information on deleting a white list from a policy, see Editing a Correlation Policy on page 1591.

Deleting a white list also removes the host attribute associated with the white list from all hosts on your network.

To delete an existing compliance white list:

Access: Admin

1. Select **Policies > Correlation**, then click **White List**.
   The White List page appears.
2. Next to the white list you want to delete, click the delete icon ( ).
   The white list is deleted.

Working with Shared Host Profiles

License: FireSIGHT

Shared host profiles specify which operating systems, clients, application protocols, web applications, and protocols are allowed to run on target hosts across multiple white lists. That is, if you create multiple white lists but want to use the same host profile to evaluate hosts running a particular operating system across the white lists, use a shared host profile. Note that the default white list uses a special category of shared host profiles, called *built-in host profiles*.

For a more detailed introduction to shared host profiles, see Understanding Shared Host Profiles on page 1608.

You can create, modify, and delete shared host profiles. In addition, if you modify or delete any of the built-in shared host profiles, or modify or delete any of the

built-in application protocols, protocols, or clients, you can reset them to their factory defaults. For more information, see:

- Creating Shared Host Profiles on page 1636
- Modifying a Shared Host Profile on page 1638
- Deleting a Shared Host Profile on page 1642
- Resetting Built-In Host Profiles to Their Factory Defaults on page 1642

After you create a shared host profile, you can add it to multiple white lists. For more information, see Adding a Shared Host Profile to a Compliance White List on page 1629.

Creating Shared Host Profiles

License: FireSIGHT

Create a shared host profile if you want to use the same host profile to evaluate hosts running a particular operating system across multiple white lists.

TIP! You can also create a shared host profile for your compliance white lists using the host profile of a specific host. For more information, see Creating a White List Host Profile from a Host Profile on page 1425.

To create a shared host profile:

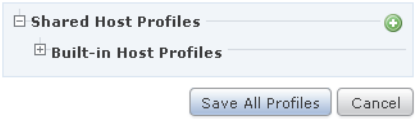
Access: Admin

1. Select **Policies > Correlation**, then click **White List**.

   The White List page appears.

2. Click **Edit Shared Profiles**.

   The Edit Shared Profiles page appears.



3. Optionally, survey your network.

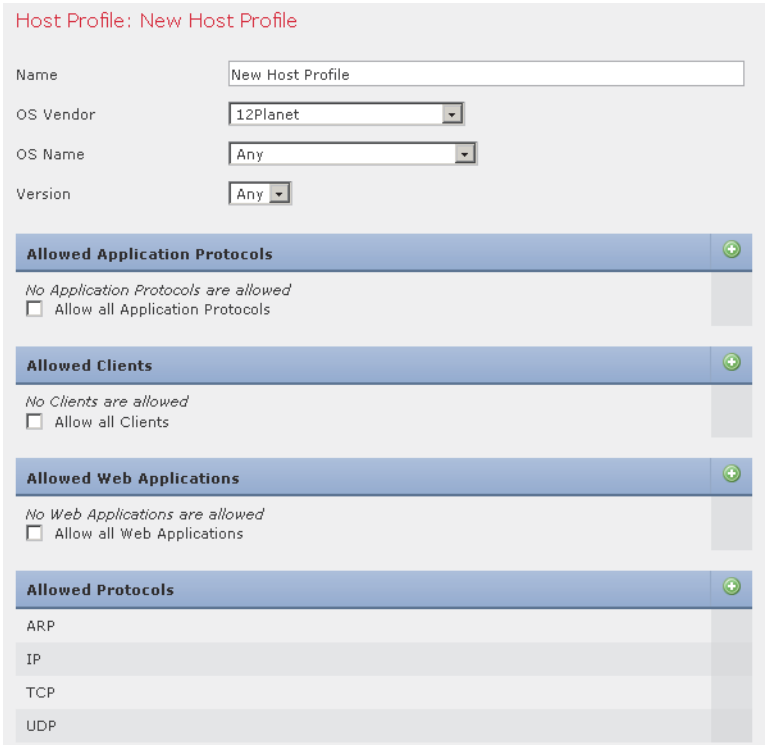
   Surveying your network creates several baseline shared white lists based on the data the system has accumulated about your network. This saves you from manually creating and configuring multiple shared host profiles. You have two options:

   - To survey your network, click **Survey Network**. For more information, see Surveying Your Network on page 1614.

     The system creates one or more baseline shared host profiles. You can edit or delete these shared host profiles as described in Modifying a Shared Host Profile on page 1638 and Deleting a Shared Host Profile on page 1642. To add any other shared host profiles you might need, continue with the next step.
   - To skip surveying your network, continue with the next step.

4. Next to **Shared Host Profiles**, click the add icon ( ).

   The settings for the new shared host profile appear.



5. In the **Name** field, type a descriptive name for the shared host profile.
6. From the **OS Vendor**, **OS Name**, and **Version** drop-down lists, pick the operating system and version for which you want to create a shared host profile.

7. Specify the application protocols you want to allow. You have three options:
   - To allow all application protocols, select the **Allow all Application Protocols** check box.
   - To allow no application protocols, leave the **Allow all Application Protocols** check box cleared.
   - To allow specific application protocols, next to **Allowed Application Protocols**, follow the directions in Adding an Application Protocol to a Host Profile on page 1623.
8. Specify the clients you want to allow. You have three options:
   - To allow all clients, select the **Allow all Clients** check box.
   - To allow no clients, leave the **Allow all Clients** check box cleared.
   - To allow specific clients, follow the directions in Adding a Client to a Host Profile on page 1625.
9. Specify the web applications you want to allow. You have three options:
   - To allow all web applications, select the **Allow all Web Applications** check box.
   - To allow no web applications, leave the **Allow all Web Applications** check box cleared.
   - To allow specific web applications, follow the directions in Adding a Web Application to a Host Profile on page 1627.
10. Specify the protocols you want to allow.

    To add a protocol, next to **Allowed Protocols**, follow the directions in Adding a Protocol to a Host Profile on page 1628. Note that ARP, IP, TCP, and UDP are always allowed.
11. Click **Save all Profiles** to save your changes.

    The shared host profile is created. You can now add the shared host profile to any compliance white list.

Modifying a Shared Host Profile

License: FireSIGHT

Modifying a shared host profile changes the profile for all the white lists it belongs to. For the white lists that use the shared host profile and are also used in an active correlation policy, modifying a shared host profile may bring hosts into or out of compliance, but does **not** generate white list events.

To modify a shared host profile:

Access: Admin

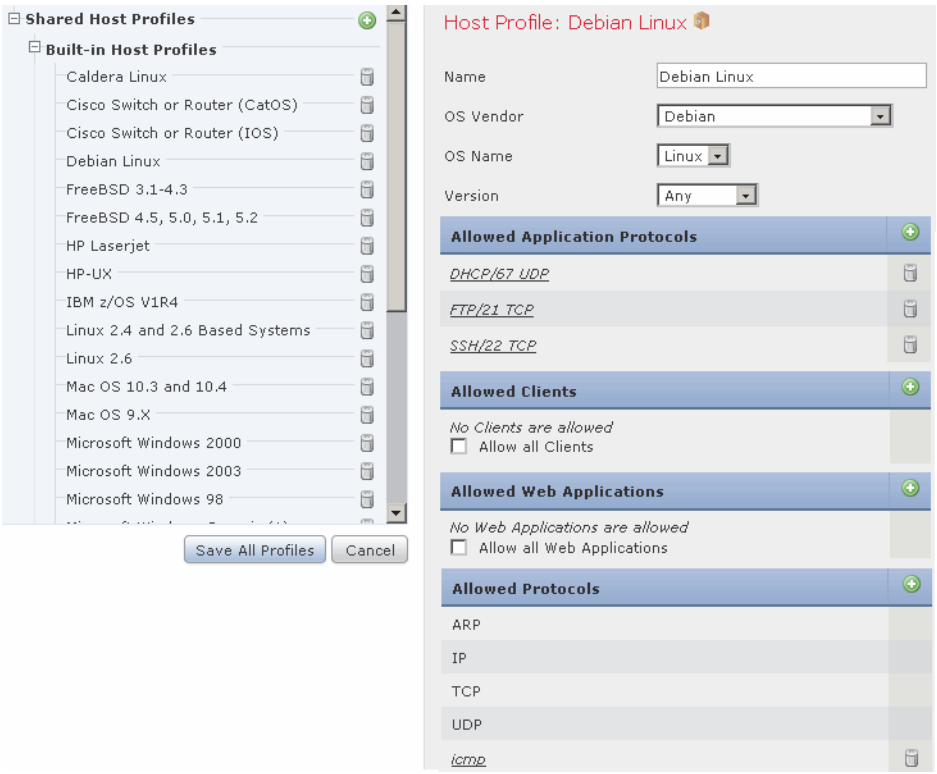
1. Select **Policies > Correlation**, then click **White List**.
   The White List page appears.
2. Click **Edit Shared Profiles**.
   The Edit Shared Profiles page appears.

3. Do you want to edit one of the built-in shared host profiles?
   - If yes, expand **Built-in Host Profiles** to display those host profiles.

   - If no, continue with the next step.

4. Click the name of the shared host profile you want to modify.

   The host profile appears.



5. Perform any of the actions described in the table below.

To...	You can...
rename the host profile	type a new name in the **Name** field.
change the operating system	select the new operating system and version from the **OS Vendor**, **OS Name**, and **Version** drop-down lists. If you change these values, you may also want to rename the host profile.
add an application protocol	follow the directions in Adding an Application Protocol to a Host Profile on page 1623.
add a client	follow the directions in Adding a Client to a Host Profile on page 1625.
add a web application	follow the directions in Adding a Web Application to a Host Profile on page 1627.

To...	You can...
add a protocol	follow the directions in Adding a Protocol to a Host Profile on page 1628.
allow all application protocols	under **Allowed Application Protocols**, select the **Allow all Application Protocols** check box. Note that the check box does not appear until you delete any application protocols you have previously allowed.
allow all clients	under **Allowed Clients**, select the **Allow all Clients** check box. Note that the check box does not appear until you delete any clients you have previously allowed.
allow all web applications	under **Allowed Web Applications**, select the **Allow all Web Applications** check box. Note that the check box does not appear until you delete any clients you have previously allowed.
modify an application protocol, client, web application, or protocol	click the element you want to modify. For more information on the properties you can change, see: • Adding an Application Protocol to a Host Profile on page 1623 • Adding a Client to a Host Profile on page 1625 • Adding a Web Application to a Host Profile on page 1627 • Adding a Protocol to a Host Profile on page 1628 **IMPORTANT!** The changes you make to an application protocol, client, or protocol are reflected in every host profile that uses that element.
delete an application protocol, client, web application, or protocol	next to the element you want to delete, click the delete icon ( ).
survey your network	click **Survey Network**. Surveying your network can add additional allowed clients, application protocols, web applications, and protocols to the host profiles that already exist, and can create additional host profiles if the survey detects hosts running operating systems that were not detected during any initial survey. For more information, see Surveying Your Network on page 1614.

6. Click **Save all Profiles** to save your changes.

   The shared host profile is saved.

Deleting a Shared Host Profile

LICENSE: FireSIGHT

If the shared host profile you delete belongs to one or more white lists used in an active correlation policy, deleting the profile may force hosts out of compliance, but does **not** generate white list events.

TIP! If you delete a built-in shared host profile that is used by the default white list, you can restore it by resetting the built-in profiles to their factory defaults. For more information, see Resetting Built-In Host Profiles to Their Factory Defaults on page 1642.

To delete a shared host profile:

ACCESS: Admin

1. Select **Policies > Correlation**, then click **White List**.

   The White List page appears.

2. Click **Edit Shared Profiles**.

   The Edit Shared Profiles page appears.

3. Do you want to delete one of the built-in shared host profiles?
   - If yes, expand **Built-in Host Profiles** to display those host profiles.
   - If no, continue with the next step.

4. Next to the shared host profile you want to delete, click the delete icon ( ).

   Confirm that you want to delete the shared host profile.

5. Click **Save all Profiles** to save your changes.

   The shared host profile is deleted and removed from all compliance white lists that use it.

Resetting Built-In Host Profiles to Their Factory Defaults

LICENSE: FireSIGHT

The default white list uses a special category of shared host profiles, called *built-in host profiles*. Built-in host profiles use built-in application protocols, protocols, and clients. You can use any these elements as-is in both the default white list and in any custom white list that you create, or you can modify them to suit your needs. For more information, see Understanding Shared Host Profiles.

If you make changes to the built-in profiles, application protocols, protocols, web applications, or clients that you need to undo, you can reset to factory defaults. When you reset to factory defaults, the following things occur:

- **All** built-in host profiles, application protocols, protocols, and clients that you modified are reset to their factory defaults.
- **All** built-in host profiles, application protocols, protocols, and clients that you deleted are restored.
- **All** white lists (including the default white list) that are used by active correlation policies and that used any of the reset built-in host profiles, application protocols, protocols, or clients are re-evaluated. Although this re-evaluation may change the compliance of some hosts into compliance, it does not generate any white list events.

To reset built-in host profiles, application protocols, protocols, and clients:

Access: Admin

1. Select **Policies > Correlation**, then click **White List**.

   The White List page appears.

2. Click **Edit Shared Profiles**.

   The Edit Shared Profiles page appears.

3. Click **Built-in Host Profiles**.

   The Built-in Host Profiles page appears.

4. Click **Reset to Factory Defaults**.
5. Confirm that you want to reset to factory defaults by clicking **OK**.

   All built-in host profiles, application protocols, protocols, and clients are reset to factory defaults. Any white list that is used by an active correlation policy and that used any of the reset built-in host profiles, application protocols, protocols, or clients is re-evaluated.

Working with White List Events

License: FireSIGHT

When the system generates a discovery event that indicates that a host is out of compliance with a white list that is included in an activated correlation policy, a white list event is generated. White list events are a special kind of correlation

event, and are logged to the correlation event database. You can search, view, and delete white list events.

TIP! For information on configuring the number of events saved in the database, see Configuring Database Event Limits on page 2056. Note that white list events are stored in the correlation event database.

For more information, see the following sections:

- Viewing White List Events on page 1644
- Understanding the White List Events Table on page 1646
- Searching for Compliance White List Events on page 1647

Viewing White List Events

LICENSE: FireSIGHT

You can use the Defense Center to view a table of compliance white list events. Then, you can manipulate the event view depending on the information you are looking for.

The page you see when you access white list events differs depending on the workflow you use. You can use the predefined workflow, which includes the table view of white list events. You can also create a custom workflow that displays only the information that matches your specific needs. For information on creating a custom workflow, see Creating Custom Workflows on page 1916.

The following table describes some of the specific actions you can perform on an white list events workflow page.

Compliance White List Event Actions

TO...	YOU CAN...
view the host profile for a host	click the host profile icon ( ) that appears next to the IP address.
view user profile information	click the user icon ( )that appears next to the user identity. For more information, see Understanding User Details and Host History on page 1518.
sort and constrain events on the current workflow page	find more information in Sorting Drill-Down Workflow Pages on page 1910.
navigate within the current workflow page	find more information in Navigating to Other Pages in the Workflow on page 1911.

Compliance White List Event Actions (Continued)

TO...	YOU CAN...
navigate between pages in the current workflow, keeping the current constraints	click the appropriate page link at the top left of the workflow page. For more information, see Using Workflow Pages on page 1889.
learn more about the columns that appear	find more information in Understanding the White List Events Table on page 1646.
modify the time and date range for displayed events	find more information in see Setting Event Time Constraints on page 1896.
drill down to the next page in the workflow, constraining on a specific value	use one of the following methods: • on a drill-down page that you created in a custom workflow, click a value within a row. Note that clicking a value within a row in a table view constrains the table view and does **not** drill down to the next page. • To drill down to the next workflow page constraining on some users, select the check boxes next to the users you want to view on the next workflow page, then click **View**. • To drill down to the next workflow page keeping the current constraints, click **View All**. **TIP!** Table views always include "Table View" in the page name. For more information, see Constraining Events on page 1905.
delete white list events from the system	use one of the following methods: • To delete some events, select the check boxes next to the events you want to delete, then click **Delete**. • To delete all events in the current constrained view, click **Delete All**, then confirm you want to delete all the events.
navigate to other event views to view associated events	find more information in Navigating Between Workflows on page 1911.

To view compliance white list events:

ACCESS: Admin/Any Security Analyst/Discovery Admin

▶ Select **Analysis > Correlation > White List Events**.

The first page of the default white list events workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**.by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. If no events appear, you may need to adjust the time range; see Setting Event Time Constraints on page 1896.

Understanding the White List Events Table

LICENSE: FireSIGHT

You can use the correlation policy feature to build *correlation policies* that let the system respond in real time to threats on your network. Correlation policies describe the type of activity that constitutes a policy violation, which include compliance white list violations. For more information on correlation policies, see Configuring Correlation Policies and Rules on page 1528.

When a compliance white list is violated, the system generates a white list event. The fields in the white list events table are described in the following table.

Compliance White List Event Fields

FIELD	DESCRIPTION
Time	The date and time that the white list event was generated.
IP Address	The IP address of the non-compliant host.
User	The identity of any known user logged in to the non-compliant host.
Port	The port, if any, associated with the event that triggered an application protocol white list violation (a violation that occurred as a result of a non-compliant application protocol). For other types of white list violations, this field is blank.

Description	A description of how the white list was violated. For example:
	`Client "AOL Instant Messenger" is not allowed.`
	
	Violations that involve an application protocol indicate the application protocol name and version, as well as the port and protocol (TCP or UDP) it is using. If you restrict prohibitions to a particular operating system, the description includes the operating system name. For example:
	`Server "ssh / 22 TCP ( OpenSSH 3.6.1p2 )" is not allowed on Operating System "Linux Linux 2.4 or 2.6".`

Policy	The name of the correlation policy that was violated, that is, the correlation policy that includes the white list.
White List	The name of the white list.
Priority	The priority specified by the policy or white list that triggered the policy violation. For information on setting correlation rule and policy priorities, see Providing Basic Policy Information on page 1586 and Setting Rule and White List Priorities on page 1587.

Compliance White List Event Fields (Continued)

Field	Description
Host Criticality	The user-assigned host criticality of the host that is out of compliance with the white list: `None`, `Low`, `Medium`, or `High`. For more information on host criticality, see Working with the Predefined Host Attributes on page 1433.
Device	The name of the managed device that detected the white list violation.
Count	The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Searching for Compliance White List Events

License: FireSIGHT

You can search for specific compliance white list events. You may want to create searches customized for your network environment, then save them to re-use later. The following table describes the search criteria you can use.

Compliance White List Event Search Criteria

Field	Search Criteria Rules
Policy	Enter the name of a correlation policy to return all events caused by violations of white lists included in that policy.
White List	Enter the name of a white list to return all events caused by violations of that white list.
Description	Enter the white list event description.
Priority	Specify the priority of the white list event, which is determined either by the priority of the white list in a correlation policy or by the priority of the correlation policy itself. Note that the white list priority overrides the priority of its policy. Enter **none** for no priority. For information on setting correlation rule and policy priorities, see Providing Basic Policy Information on page 1586 and Setting Rule and White List Priorities on page 1587.
IP Address	Specify an IP address of a host that has become non-compliant with a white list.

Compliance White List Event Search Criteria (Continued)

Field	Search Criteria Rules
User	Specify the identity of the user logged in to a host that has become non-compliant with a white list.
Port	Specify the port, if any, associated with the discovery event that triggered an application protocol white list violation (a violation that occurred as a result of a non-compliant application protocol).
Host Criticality	Specify the host criticality of the source host involved in the white list event: `None`, `Low`, `Medium`, or `High`. For more information on host criticality, see Working with the Predefined Host Attributes on page 1433.
Device	Type the name of the device or device group that detected the white list violation.

To search for compliance white list events:

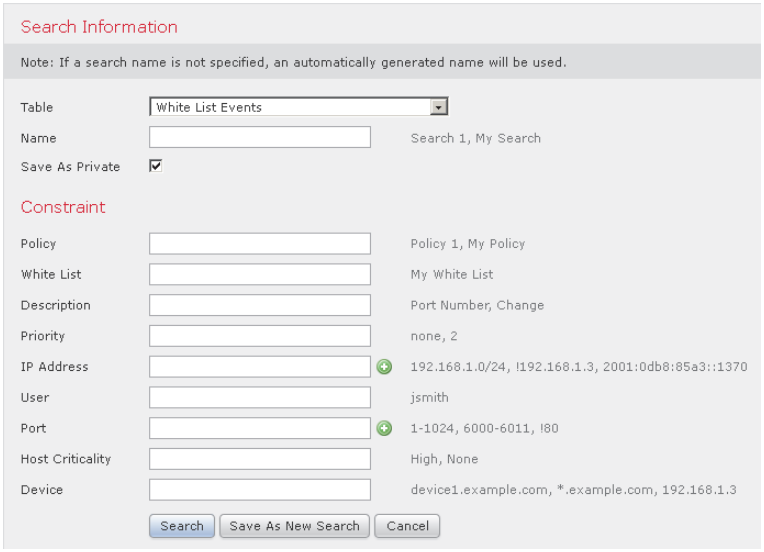
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **White List Events**.

   The page reloads with the appropriate constraints.



3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields, as described in the Compliance White List Event Search Criteria table on page 1647, and keeping in mind the following additional points:

   - All fields accept negation (`!`).
   - All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
   - Many fields accept one or more asterisks (*) as wild cards.
   - Specify `n/a` in any field to identify events where information is not available for that field; use `!n/a` to identify the events where that field is populated.
   - Click the add object icon () that appears next to a search field to use an object as a search criterion.

   For more information on search syntax, including using objects in searches, see Searching for Events on page 1842.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

   If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in the default white list events workflow, constrained by the current time range. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

Working with White List Violations

LICENSE: FireSIGHT

The system keeps track of the ways in which hosts on your network violate the compliance white lists in active correlation policies. You can search and view these records.

For more information, see the following sections:

- Viewing White List Violations on page 1650
- Understanding the White List Violations Table on page 1652
- Searching for White List Violations on page 1653

Viewing White List Violations

LICENSE: FireSIGHT

You can use the Defense Center to view a table of white list violations. Then, you can manipulate the event view depending on the information you are looking for. The page you see when you access white list violations differs depending on the workflow you use. There are two predefined workflows:

- The Host Violation Count workflow provides a series of pages that list all the hosts that violate at least one white list. The first page sorts the hosts based on the number of violations per host, with the hosts with the greatest number of violations at the top of the list. If a host violates more than one white list, there is a separate row for each violated white list. The workflow also contains a table view of white list violations that lists all violations with the most recently detected violation at the top of the list. Each row in the table contains a single detected violation.
- The White List Violations workflow includes a table view of white list violations that lists all violations with the most recently detected violation at the top of the list. Each row in the table contains a single detected violation.

Both predefined workflows terminate in a host view, which contains a host profile for every host that meets your constraints. You can also create a custom workflow that displays only the information that matches your specific needs. For more information, see Creating Custom Workflows on page 1916.

The following table describes some of the specific actions you can perform on a white list violations workflow page.

Compliance White List Violations Actions

To...	You can...
view the host profile for a host	click the host profile icon () that appears next to the IP address.
sort and constrain events on the current workflow page	find more information in Sorting Drill-Down Workflow Pages on page 1910.
navigate within the current workflow page	find more information in Navigating to Other Pages in the Workflow on page 1911.
navigate between pages in the current workflow, keeping the current constraints	click the appropriate page link at the top left of the workflow page. For more information, see Using Workflow Pages on page 1889.
learn more about the columns that appear	find more information in Understanding the White List Violations Table on page 1652.
drill down to the next page in the workflow	use one of the following methods: • To drill down to the next workflow page constraining on a specific value, click a value within a row. Note that this only works on drill-down pages. Clicking a value within a row in a table view constrains the table view and does **not** drill down to the next page. • To drill down to the next workflow page constraining on some events, select the check boxes next to the events you want to view on the next workflow page, then click **View**. • To drill down to the next workflow page keeping the current constraints, click **View All**. **TIP!** Table views always include "Table View" in the page name. For more information, see Constraining Events on page 1905.
navigate to other event views to view associated events	find more information in Navigating Between Workflows on page 1911.

To view compliance white list violations:

Access: Admin/Any Security Analyst/Discovery Admin

▶ Select **Analysis > Correlation > White List Violations**.

The first page of the default white list violations workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

Understanding the White List Violations Table

LICENSE: FireSIGHT

You can use the correlation policy feature to build *correlation policies* that let the system respond in real time to threats on your network. Correlation policies describe the type of activity that constitutes a policy violation, which include compliance white list violations. For more information on correlation policies, see Configuring Correlation Policies and Rules on page 1528.

When a compliance white list is violated, the system records the violation. Note that you can not set event time constraints in the table view because the table view displays only the current host violations on your network. The fields in the white list violations table are described in the Compliance White List Violation Fields table.

Compliance White List Violation Fields

FIELD	DESCRIPTION
Time	The date and time that the white list violation was detected.
IP Address	The relevant IP address of the non-compliant host.
Type	The type of white list violation, that is, whether the violation occurred as a result of a non-compliant: • operating system (**os**) • application protocol (**server**) • client (**client**) • protocol (**protocol**) • web application (**web**)
Information	Any available vendor, product, or version information associated with the white list violation. For example, if you have a white list that allows only Microsoft Windows hosts, the Information field describes the operating systems of the hosts that are not running Microsoft Windows. For protocols that violate a white list, the Information field also indicates whether the violation is due to a network or transport protocol.
Port	The port, if any, associated with the event that triggered an application protocol white list violation (a violation that occurred as a result of a non-compliant application protocol). For other types of white list violations, this field is blank.
Protocol	The protocol, if any, associated with the event that triggered an application protocol white list violation (a violation that occurred as a result of a non-compliant application protocol). For other types of white list violations, this field is blank.

Compliance White List Violation Fields (Continued)

Field	Description
White List	The name of the white list that was violated.
Count	The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Searching for White List Violations

License: FireSIGHT

You can search for specific compliance white list violations. You may want to create searches customized for your network environment, then save them to re-use later. The following table describes the search criteria you can use.

Compliance White List Violations Search Criteria

Field	Search Criteria Rules
Time	Specify the date and time that the white list was violated.
IP Address	Specify an IP address of a host that has become non-compliant with a white list.
White List	Enter the name of a white list to return all violations from that white list.
Type	Enter the type of white list violation: • enter `os` (or `operating system`) to search for violations based on operating systems • enter `server` to search for violations based on application protocols • enter `client` to search for violations based on clients • enter `protocol` to search for violations based on protocols • enter `web application` to search for violations based on web applications
Information	Enter white list violation information.

Compliance White List Violations Search Criteria (Continued)

Field	Search Criteria Rules
Port	Specify the port, if any, associated with the discovery event that triggered an application protocol white list violation (a violation that occurred as a result of a non-compliant application protocol).
Protocol	Specify the protocol, if any, associated with the discovery event that triggered an application protocol white list violation (a violation that occurred as a result of a non-compliant application protocol).

To search for compliance white list violations:

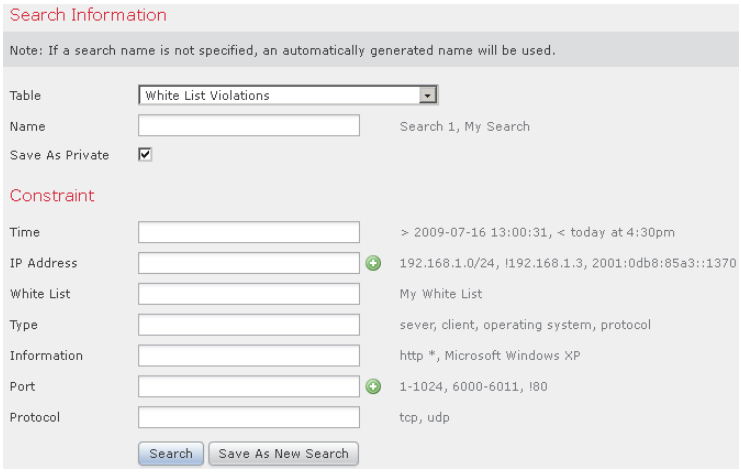
Access: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **White List Violations**.

   The page reloads with the appropriate constraints.



3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields, as described in the Compliance White List Event Search Criteria table on page 1647, and keeping in mind the following additional points:
   - All fields accept negation (`!`).
   - All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
   - Many fields accept one or more asterisks (*) as wild cards.
   - Specify `n/a` in any field to identify events where information is not available for that field; use `!n/a` to identify the events where that field is populated.
   - Click the add object icon () that appears next to a search field to use an object as a search criterion.

   For more information on search syntax, including using objects in searches, see Searching for Events on page 1842.
5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

   If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.
6. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in the default white list violations workflow. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

CHAPTER 38
CREATING TRAFFIC PROFILES

A traffic profile is just that—a profile of the traffic on your network, based on connection data collected over a time span that you specify. You can use connection data collected by your devices, the connection data exported by any or all of your NetFlow-enabled devices, or both.

After you create a traffic profile, you can detect abnormal network traffic by evaluating new traffic against your profile, which presumably represents normal network traffic.

Keep in mind that the Sourcefire 3D System uses connection data to create traffic profiles and trigger correlation rules based on traffic profile changes. You cannot include connections that you do not log to the Defense Center database in traffic profiles. The system uses only end-of-connection data to populate connection summaries (see Understanding Connection Summaries on page 587), which the system then uses to create connection graphs and traffic profiles. Therefore, if you want to create and use traffic profiles, make sure you log connection events at the end of connections.

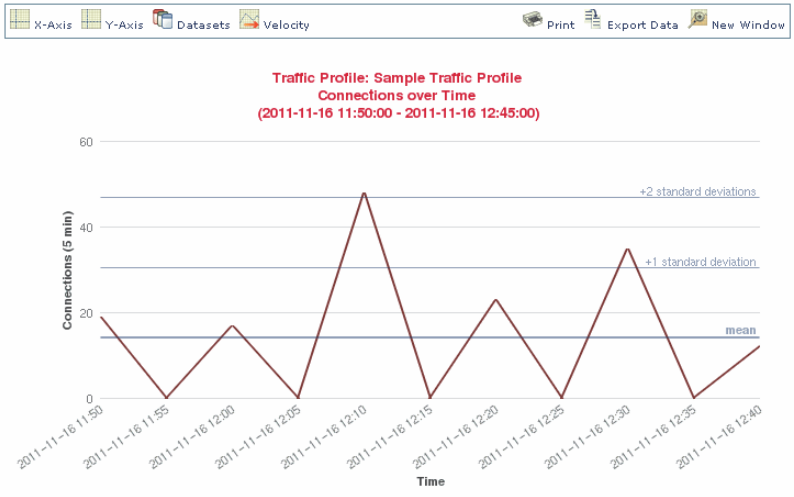
The time span used to collect data to build your traffic profile is called the profiling time window (PTW). The PTW is a sliding window; that is, if your PTW is one week (the default), your traffic profile includes connection data collected over the last week. You can change the PTW to be as short as an hour or as long as several weeks.

When you first activate a traffic profile, it collects and evaluates connection data according to the criteria you have set, for a learning period equal in time to the PTW. The Defense Center does not evaluate rules you have written against the traffic profile until the learning period is complete.

You can create profiles using all the traffic on a monitored network segment, or you can create more targeted profiles using criteria based on the data in the connection events. For example, you could set the profile conditions so that the traffic profile only collects data where the detected session uses a specific port, protocol, or application. Or, you could add a host profile qualification to the traffic profile to collect data only for hosts that exhibit a host criticality of **high**.

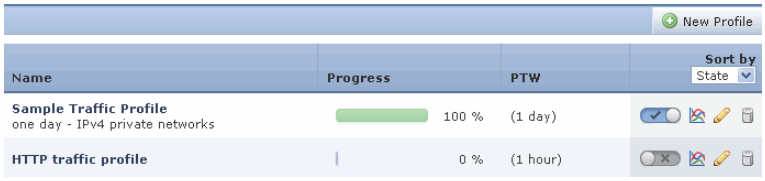
Finally, when you create a traffic profile, you can specify inactive periods—periods in which connection data do not affect profile statistics and rules written against the profile do not trigger. You can also change how often the traffic profile aggregates and calculates statistics on collected connection data.

The following graphic shows a traffic profile with a PTW of one day and a sampling rate of five minutes.



After you create and activate a traffic profile and its learning period is complete, you can create correlation rules that trigger when you detect anomalous traffic. For example, you could write a rule that triggers if the amount of data traversing your network (measured in packets, KBytes, or number of connections) suddenly spikes to three standard deviations above the mean amount of traffic, which could indicate an attack or other security policy violation. Then, you could include that rule in a correlation policy to alert you of the traffic spike or to perform a remediation in response. For information on using traffic profiles to detect abnormal network traffic, see Creating Rules for Correlation Policies on page 1530.

You create traffic profiles on the Traffic Profiles page.



The slider icon next to each profile indicates whether the profile is active. If you want to base a correlation rule on a traffic profile change, you must activate the profile. If the slider icon is blue with a check mark, the profile is active. If it is gray with an x, the profile is inactive. For more information, see Activating and Deactivating Traffic Profiles on page 1666.

The progress bar shows the status of the traffic profile's learning period. When the progress bar reaches 100%, correlation rules written against the profile will trigger.

TIP! You can sort traffic profiles by state (active versus inactive) or alphabetically by name using the **Sort by** drop-down list.

For more information, see:

- Providing Basic Profile Information on page 1658
- Specifying Traffic Profile Conditions on page 1659
- Adding a Host Profile Qualification on page 1661
- Setting Profile Options on page 1664
- Saving a Traffic Profile on page 1666
- Activating and Deactivating Traffic Profiles on page 1666
- Editing a Traffic Profile on page 1667
- Understanding Condition-Building Mechanics on page 1668

Providing Basic Profile Information

LICENSE: FireSIGHT

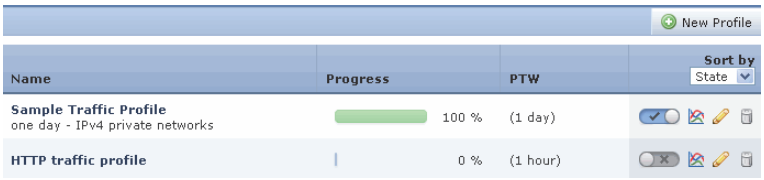
When you create a traffic profile, you must give it a name and, optionally, a short description.

To begin creating a traffic profile:

ACCESS: Admin/Discovery Admin

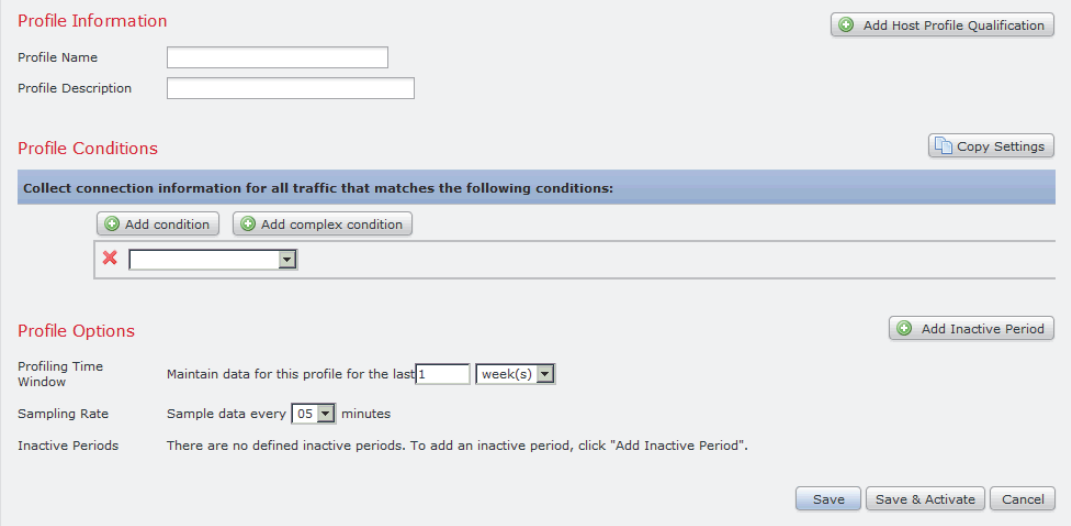
1. Select **Policies > Correlation**, then click **Traffic Profiles**.

   The Traffic Profiles page appears.



2. Click **New Profile**.

   The Create Profile page appears.



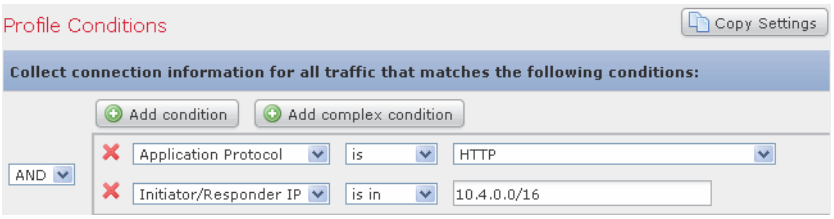
3. In the **Profile Name** field, type a name of up to 255 characters for the new traffic profile.
4. In the **Profile Description** field, type a short description of up to 255 characters of the new traffic profile.
5. Continue with Specifying Traffic Profile Conditions.

Specifying Traffic Profile Conditions

LICENSE: FireSIGHT

Profile conditions constrain the kinds of connection data you want the traffic profile to track. A simple traffic profile that profiles all the traffic on a monitored network segment has no conditions. In contrast, traffic profiles can be complex, with multiple nested conditions.

For example, the traffic profile conditions in the following graphic collects HTTP connections on the 10.4.x.x subnet.



You build traffic profile conditions in the **Profile Conditions** section of the Create Profile page. See Understanding Condition-Building Mechanics on page 1668 for information on building conditions. Also, the syntax you can use to build

conditions is fully described in Syntax for Traffic Profile Conditions on page 1660.

TIP! If you want to use the settings from an existing traffic profile, click **Copy Settings** and, in the pop-up window, select the traffic profile you want to use and click **Load**.

Syntax for Traffic Profile Conditions

LICENSE: FireSIGHT

The Syntax for Profile Conditions table describes how to build a traffic profile condition.

Keep in mind that NetFlow records do not contain information about which host in the connection is the initiator and which is the responder. When the system processes NetFlow records, it uses an algorithm to determine this information based on the ports each host is using, and whether those ports are well-known. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

Syntax for Profile Conditions

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Initiator IP, Responder IP, or Initiator/Responder IP	Use a specific IP address or CIDR notation to specify a range of IP addresses. See Specifying IP Addresses in Searches on page 1848 for a description of the syntax allowed for IP addresses. Note, however, that you **cannot** use the `local` or `remote` keywords to specify IP addresses that are or are not in the networks you are monitoring.
Responder Port/ ICMP Code	Type the port number or ICMP code.
Transport Protocol	Type `TCP` or `UDP` as the transport protocol.
Connection Type	Specify in the traffic profile whether you want to use connection data collected by your Sourcefire devices or by NetFlow-enabled devices. If you do not specify a connection type, the traffic profile includes both.
NetFlow Device	Select the NetFlow-enabled device whose data you want to use to create the traffic profile. If you did not add any NetFlow-enabled devices to your deployment (using the local configuration), the NetFlow Device drop-down list is blank.

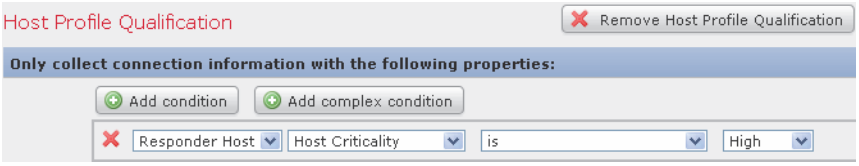
Syntax for Profile Conditions (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Application Protocol	Select an application protocol name from the drop-down list of available protocols.
Client	Select a client name from the drop-down list of available clients.
Web Application	Select a web application name from the drop-down list of available web applications.

Adding a Host Profile Qualification

LICENSE: FireSIGHT

You can constrain any traffic profile with information from the host profile of the tracked hosts. This constraint is called a *host profile qualification*. For example, as shown in the following graphic, you could collect connection data only for hosts that are assigned a host criticality of **high**.



To use a host profile qualification, the host must exist in the database and the host profile property you want to use as a qualification must already be included in the host profile. For example, if you configure a correlation policy rule to trigger when an intrusion event is generated on a host running Windows, the rule only triggers if the host is already identified as Windows when the intrusion event is generated.

To add a host profile qualification:

ACCESS: Admin/Discovery Admin

1. On the Create Profile page, click **Add Host Profile Qualification**.

   The Host Profile Qualification section appears.

2. Build the host profile qualification's conditions.

   You can create a single, simple condition, or you can create more elaborate constructs by combining and nesting conditions. See Understanding Condition-Building Mechanics on page 1668 for information building conditions.

   The syntax you can use to build conditions is described in Syntax for Host Profile Qualifications on page 1662.

TIP! To remove a host profile qualification, click **Remove Host Profile Qualification**.

Syntax for Host Profile Qualifications

License: FireSIGHT

When you build a host profile qualification condition, you must first select the host you want to use to constrain your traffic profile. You can select either **Responder Host** or **Initiator Host**. After you select the host role, continue building your host profile qualification condition, as described in the Syntax for Host Profile Qualifications table.

Although you can configure the network discovery policy to add hosts to the network map based on data exported by NetFlow-enabled devices, the available information about these hosts is limited. For example, there is no operating system data available for these hosts, unless you provide it using the host input feature. In addition, if your traffic profile uses connection data exported by NetFlow-enabled devices, keep in mind that NetFlow records do not contain information about which host in the connection is the initiator and which is the responder. When the system processes NetFlow records, it uses an algorithm to determine this information based on the ports each host is using, and whether those ports are well-known. For more information, see Differences Between NetFlow and FireSIGHT Data on page 1325.

To match against *implied* or generic clients, create a host profile qualification based on the application protocol used by the server responding to the client. When the client list on a host that acts as the initiator or source of a connection includes an application protocol name followed by **client**, that client may actually be an implied client. In other words, the system reports that client based on server response traffic that uses the application protocol for that client, not on detected client traffic.

For example, if the system reports **HTTPS client** as a client on a host, create a host profile qualification for **Responder Host** where **Application Protocol** is set to **HTTPS**,

because HTTPS client is reported as a generic client based on the HTTPS server response traffic sent by the responder or destination host.

Syntax for Host Profile Qualifications

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
Host Type	Select one or more host types from the drop-down list. You can choose between a normal host or one of several types of network device.
NETBIOS Name	Type the NetBIOS name of the host.
Operating System > OS Vendor	Select one or more operating system vendor names from the drop-down list.
Operating System > OS Name	Select one or more operating system names from the drop-down list.
Operating System > OS Version	Select one or more operating system versions from the drop-down list.
Network Protocol	Type the network protocol number as listed in http://www.iana.org/assignments/ethernet-numbers.
Transport Protocol	Type the name or number of the transport protocol as listed in http://www.iana.org/assignments/protocol-numbers.
Host Criticality	Select the host criticality from the list that appears. You can select **None**, **Low**, **Medium**, or **High**. For more information on host criticality, see Working with the Predefined Host Attributes on page 1433.
VLAN ID	Type the VLAN ID number of the host.
Application Protocol> Application Protocol	Select an application protocol from the drop-down list.
Application Protocol > Application Port	Type the application protocol port number.
Application Protocol > Protocol	Select the protocol from the drop-down list.
Client > Client	Select a client from the drop-down list.
Client > Client Version	Type the client version.
Web Application	Select a client from the drop-down list.

Syntax for Host Profile Qualifications (Continued)

IF YOU SPECIFY...	SELECT AN OPERATOR, THEN...
MAC Address > MAC Address	Type all or part of the MAC address of the host.
MAC Address > MAC Type	Select whether the MAC type is **ARP/DHCP Detected**. That is, select whether the system positively identified the MAC address as belonging to the host (**is ARP/DHCP Detected**), whether the system is seeing many hosts with that MAC address because, for example, there is a router between the device and the host (**is not ARP/DHCP Detected**), or whether the MAC type is irrelevant (**is any**).
MAC Vendor	Type all or part of the MAC vendor of hardware used by the host.
any available host attribute, including the default compliance white list host attribute	Specify the appropriate value, which depends on the type of host attribute you select: • If the host attribute type is Integer, enter an integer value in the range defined for the attribute. • If the host attribute type is Text, and enter a text value. • If the host attribute type is List, select a valid list string from the drop-down list. • If the host attribute type is URL, enter a URL value. For more information on host attributes, see Working with User-Defined Host Attributes on page 1434.

Setting Profile Options

LICENSE: FireSIGHT

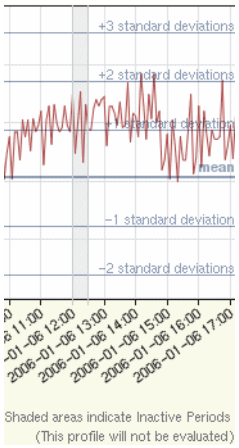
The profiling time window (PTW) is the sliding time window, equal in length to the learning period, that the Sourcefire 3D System uses to calculate statistics for the traffic profile. The default PTW is one week, but you can change it to be as short as an hour or as long as several weeks.

Also, traffic profiles are based on aggregated connection data. By default, traffic profiles generate statistics on connection events generated by the system over five-minute intervals. However, you can set this sampling rate anywhere between the default five minutes and one hour.

Keep in mind that you should set your PTW and sampling rate so that your traffic profiles contain enough data to be statistically meaningful. For example, a PTW of one day with a sampling rate of one hour would only contain 24 data points, which may not be enough for accurate analysis of network traffic patterns.

TIP! Your PTW should include at least 100 data points.

You can also set up inactive periods in traffic profile. For example, consider a network infrastructure where all the workstations are backed up at midnight every night. The backup takes about 30 minutes and spikes the network traffic. In that case, you might want to set up a recurring inactive period for your traffic profile to coincide with the scheduled backups. During inactive periods, the traffic profile collects data (so you can see the traffic on the traffic profile graphs), but that data is not used when calculating profile statistics. You can set up inactive periods to recur daily, weekly, or monthly. Inactive periods can be as short as five minutes or as long as one hour. Traffic profile graphs plotted over time show inactive periods as a shaded region.



Access: Admin/Discovery Admin

Follow the directions in the Profile Options table to set profile options.

Profile Options

To...	You can...
change the profiling time window	in the **Profiling Time Window** field, type the number of hours, days, or weeks. Then choose **hour(s)**, **day(s)**, or **week(s)** from the drop-down list.
change the sampling rate	select the rate from the **Sampling Rate** drop-down list.

Profile Options (Continued)

To...	You can...
add an inactive period	click **Add Inactive Period**. Then, using the drop-down lists, specify when and how often you want the traffic profile to refrain from collecting data.
delete an inactive period	click **Delete** next to the inactive period you want to delete.

Saving a Traffic Profile

License: FireSIGHT

Use the following procedure to save a traffic profile.

To save a traffic profile:

Access: Admin/Discovery Admin

▶ You have two options:

- To save the profile without activating it, click **Save**.
- To save the profile and start collecting data immediately, click **Save & Activate**.

Activating and Deactivating Traffic Profiles

License: FireSIGHT

When you want it to begin profiling the traffic on a monitored network segment, you must activate a traffic profile.

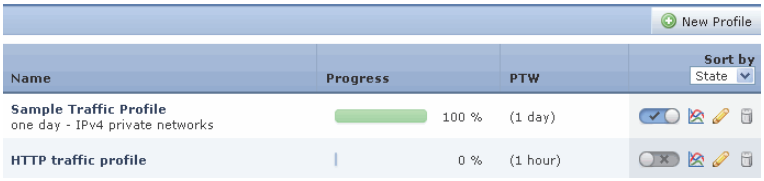
Deactivate a profile when you want it to stop collecting and evaluating connection data. Rules written against deactivated traffic profiles do not trigger. In addition, deactivating a traffic profile deletes all data collected and aggregated by the profile. If you later reactivate a deactivated traffic profile, you must wait the length of its PTW before rules written against it will trigger.

To activate or deactivate a traffic profile:

Access: Admin/Discovery Admin

1. Select **Policies > Correlation**, then click **Traffic Profiles**.

   The Traffic Profiles page appears.



2. You have two options:
   - To activate an inactive traffic profile, click **Activate** next to the profile.
   - To deactivate an active traffic profile, click **Deactivate** next to the profile. Confirm that you want to deactivate the profile by clicking **OK**.

Editing a Traffic Profile

License: FireSIGHT

You cannot substantially edit an active traffic profile; if the traffic profile is active you can only change its name and description. To edit a traffic profile's conditions options, you must first deactivate it. Note that deactivating a traffic profile deletes all the data it has collected.

For more information on activating and deactivating traffic profiles, see Activating and Deactivating Traffic Profiles on page 1666.

To edit a traffic profile:

Access: Admin/Discovery Admin

1. Select **Policies > Correlation**, then click **Traffic Profiles**.

   The Traffic Profiles page appears.

2. Next to the traffic profile you want to edit, click **Edit**.

   The Create Profile page appears.

3. Make changes to the profile and click **Save**.

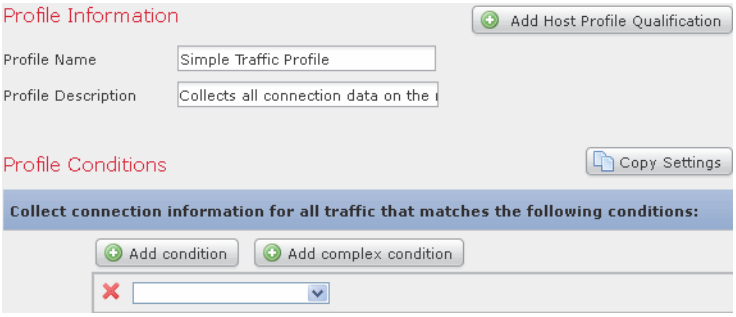
   Your profile is updated.

Understanding Condition-Building Mechanics

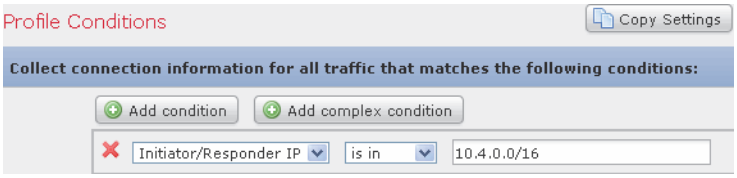
LICENSE: FireSIGHT

You build traffic profiles by specifying the conditions they use to collect data. You can create either simple conditions or more elaborate constructs with nested conditions.

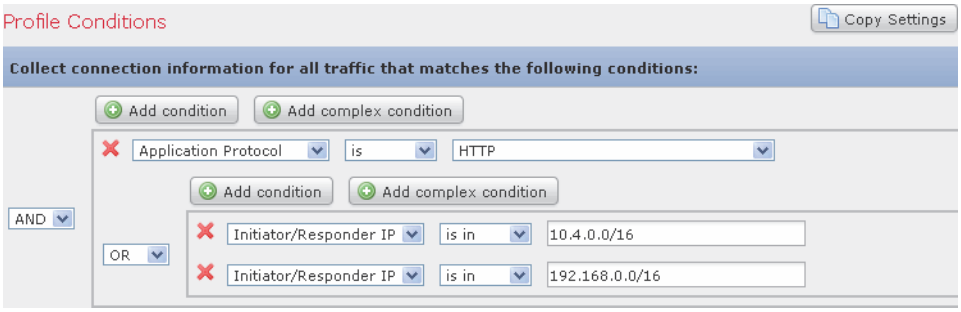
For example, if you want to create a traffic profile that collects data for your entire monitored network segment, you can create a very simple profile with no conditions, as shown in the following graphic.



If you wanted to constrain the profile and collect data only for the 10.4.x.x network, you can add a single condition, as shown in the following graphic.



But the following traffic profile, which collects HTTP activity on the 10.4.x.x network and the 192.168.x.x network, has three conditions, with the last constituting a complex condition.



The syntax you can use within conditions varies depending on the element you are creating, but the mechanics are the same. For more information, see:

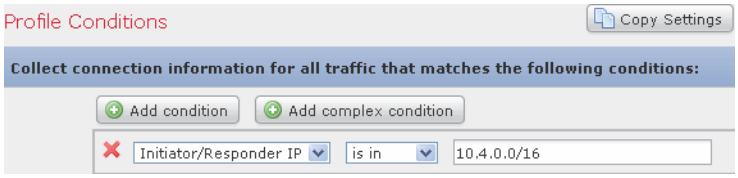
- Building a Single Condition on page 1669
- Adding and Linking Conditions on page 1671
- Using Multiple Values in a Condition on page 1674

Building a Single Condition

LICENSE: FireSIGHT

Most conditions have three parts: a category, an operator, and a value. Some conditions are more complex and contain several categories, each of which may have their own operators and values.

For example, the following traffic profile collects information on the 10.4.x.x network. The category of the condition is **Initiator/Responder IP**, the operator is **is in**, and the value is `10.4.0.0/16`.



The following steps explain how to build this traffic profile condition.

To build a single condition:

ACCESS: Admin/Discovery Admin

1. Select **Policies > Correlation**, then click **Traffic Profiles**.

   The Traffic Profiles page appears.

2. Click **New Profile**.

   The Create Profile page appears.

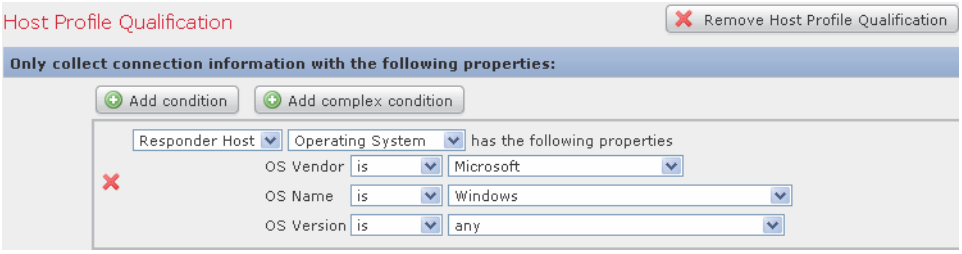
3. Under **Profile Conditions**, begin building the profile's single condition by selecting **Initiator/Responder IP** from the first (category) drop-down list.

4. Select **is in** from the second (operator) drop-down list.

TIP! When the category represents an IP address, choosing **is in** or **is not in** as the operator allows you to specify whether the IP address *is in* or *is not in* a range of IP addresses, as expressed in CIDR notation. For information on using CIDR notation in the Sourcefire 3D System, see IP Address Conventions on page 63.

5. Type `10.4.0.0/16` in the text field.

In contrast, the following host profile qualification is more complex; it constrains a traffic profile such that it collects connection data only if the responding host in the detected connection is running a version of Microsoft Windows.



The following steps explain how to build this host profile qualification.

To build this host profile qualification:

Access: Admin/Discovery Admin

1. Select **Policies > Correlation**, then click **Traffic Profiles**.

   The Traffic Profiles page appears.

2. Click **New Profile**.

   The Create Profile page appears.

3. Click **Add Host Profile Qualification**.

4. Under **Host Profile Qualification**, in the first condition, specify the host whose information you want to collect.

   In this example, select **Responder Host** because we only want information on responding hosts in a connection.

5. Begin specifying the details of the operating system of the host by choosing the **Operating System** category.

   Three subcategories appear: **OS Vendor**, **OS Name**, and **OS Version**.

6. To specify that the host can be running any version of Microsoft Windows, use the same operator for all three subcategories: **is**.

7. Finally, specify the values for the subcategories.

   Select **Microsoft** as the value for **OS Vendor**, **Windows** as the value for **OS Name**, and leave **any** as the value for **OS Version**.

Note that the categories you can choose from depend on whether you are building traffic profile conditions or a host profile qualification. In addition, a condition's available operators depend on the category you choose. Finally, the syntax you can use to specify a condition's value depends on the category and operator. Sometimes you must type the value in a text field. Other times, you can pick a value from a drop-down list.

IMPORTANT! Where the condition syntax allows you to pick a value from a drop-down list, you can often use multiple values from the list. For more information, see Using Multiple Values in a Condition on page 1674.

For information on the syntax for building traffic profile conditions and host profile qualifications, see:

- Syntax for Traffic Profile Conditions on page 1660
- Syntax for Host Profile Qualifications on page 1662

Adding and Linking Conditions

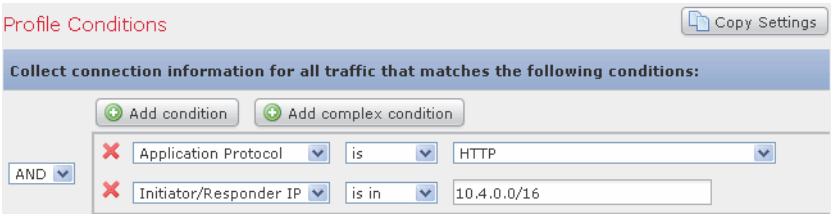
LICENSE: FireSIGHT

You can create simple traffic profile conditions and host profile qualifications, or you can create more elaborate constructs by combining and nesting conditions.

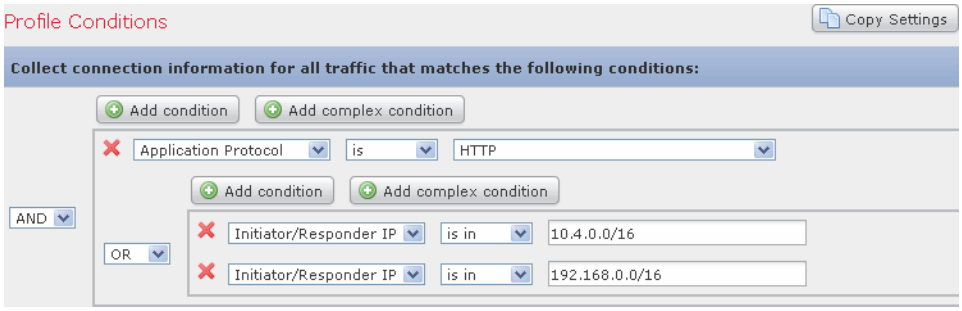
When your construct includes more than one condition, you must link them with an **AND** or an **OR** operator. Conditions on the same level are evaluated together:

- The **AND** operator requires that all conditions on the level it controls must be met.
- The **OR** operator requires that at least one of the conditions on the level it controls must be met.

For example, the following traffic profile contains two conditions linked by **AND**. This means that the traffic profile collects connection data only if both conditions are true. In this example, it collects HTTP connections for all hosts with IP addresses in the 10.4.x.x subnet.



In contrast, the following traffic profile, which collects connection data for HTTP activity in either the 10.4.x.x network or the 192.168.x.x network, has three conditions, with the last constituting a complex condition.



Logically, the above traffic profile is evaluated as follows:

```
(A and (B or C))
```

WHERE...	IS THE CONDITION THAT STATES...
A	Application Protocol Name is HTTP
B	IP Address is in 10.4.0.0/16
C	IP Address is in 192.168.0.0/16

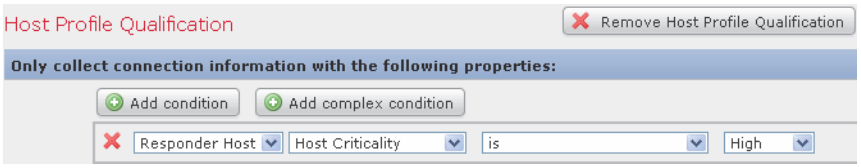
To add a single condition:

ACCESS: Admin/Discovery Admin

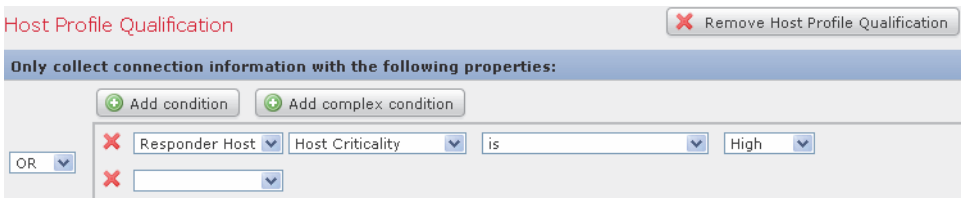
▶ To add a single condition, click **Add condition** above the current condition.

A new condition is added to the same logical level as the current set of conditions. By default, it is linked to the conditions on its level with the **OR** operator, though you can change the operator to **AND**.

For example, if you add a simple condition to the following host profile qualification:



The result is:



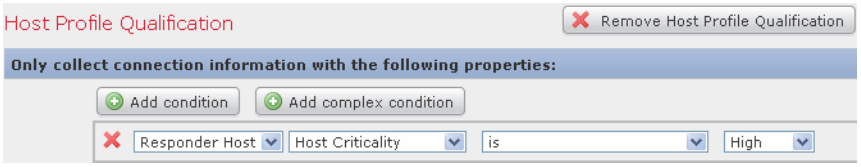
To add a complex condition:

Access: Admin/Discovery Admin

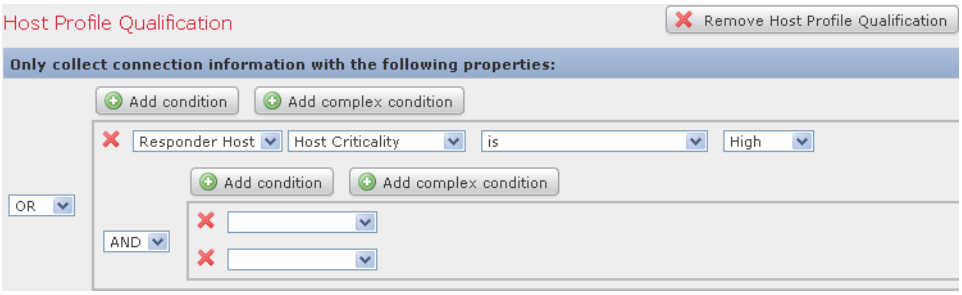
▶ Click **Add complex condition** above the current condition.

A complex condition is added below the current set of conditions. The complex condition comprises two subconditions, which are linked to each other with the opposite operator from the one used to link the conditions on the level above it.

For example, if you add a complex condition to the following host profile qualification:



The result is:



To link conditions:

Access: Admin/Discovery Admin

▶ Use the drop-down list to the left of a set of conditions:

- To require that all conditions on the level that the operator controls are met, select **AND**.
- To require that only one of the conditions on the level that the operator controls is met, select **OR**.

Using Multiple Values in a Condition

LICENSE: FireSIGHT

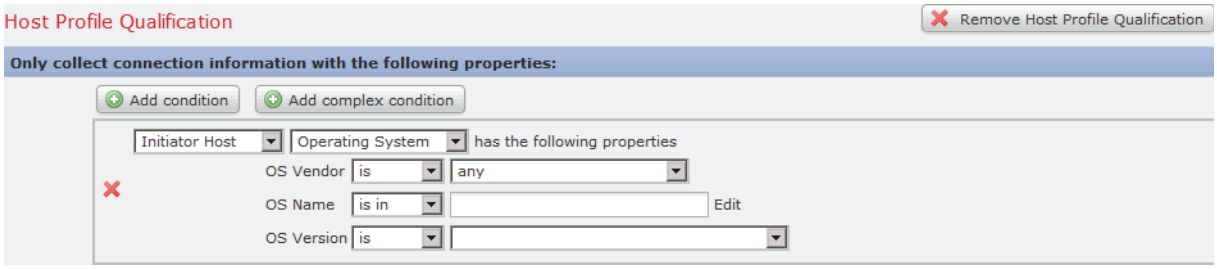
When you are building a condition, and the condition syntax allows you to pick a value from a drop-down list, you can often use multiple values from the list. For example, if you want to add a host profile qualification to a traffic profile that requires that a host be running some flavor of UNIX, instead of constructing multiple conditions linked with the OR operator, use the following procedure.

To include multiple values in one condition:

ACCESS: Admin/Discovery Admin

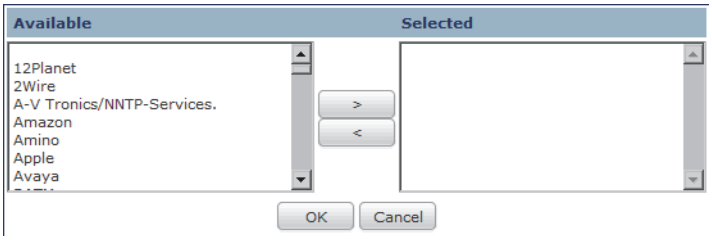
1. Build a condition, choosing **is in** or **is not in** as the operator.

   The drop-down list changes to a text field.



2. Click anywhere in the text field or on the **Edit** link.

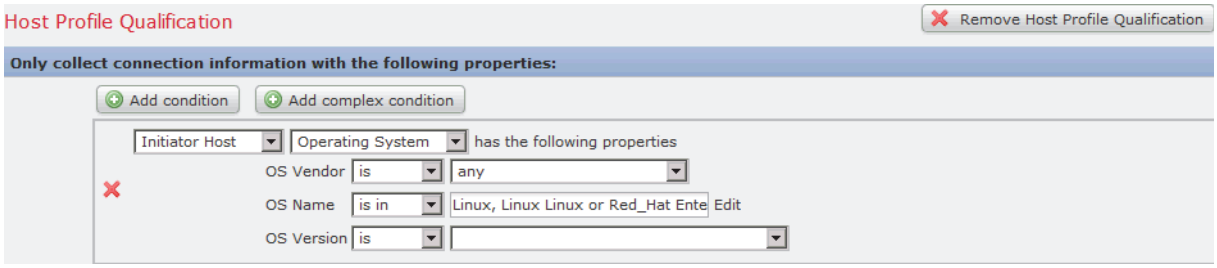
   A pop-up window appears.



3. Under **Available**, use Ctrl or Shift while clicking to select multiple values. You can also click and drag to select multiple adjacent values.
4. Click the right arrow (**>**) to move the selected entries to **Selected**.

5. Click **OK**.

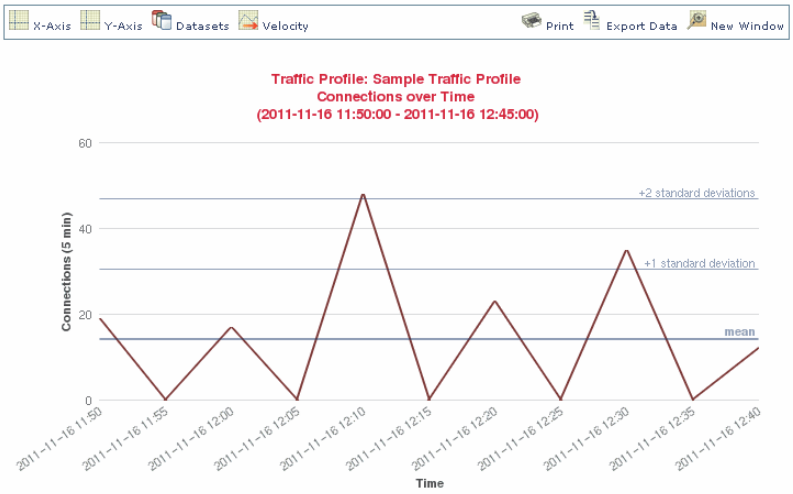
   Your selections appear in the value field of your condition on the Create Profile page.



Viewing Traffic Profiles

LICENSE: FireSIGHT

Because traffic profiles are based on connection data, you can view graphs of traffic profiles. The following graphic shows a traffic profile with a PTW of one week, a sampling rate of five minutes, and a daily half-hour inactive period from midnight to 12:30 AM.



You can perform almost all the same actions on traffic profile graphs that you can perform on connection data graphs. However, because traffic profiles are based on aggregated data (connection summaries), you cannot examine the individual connection events on which the graphs are based. In other words, you cannot drill down to a connection data table view from a traffic profile graph. See Viewing Connection and Security Intelligence Data on page 602 for more information. In addition, traffic profiles appear as detached graphs. For more information, see Detaching Connection Graphs on page 616.

In addition, traffic profile graphs plotted over time show the mean (average) y-axis value as a bold horizontal line. Graphs over time also plot the values of the first four standard deviations above and below the mean, assuming that network traffic is distributed normally. By default, these statistics are calculated over the

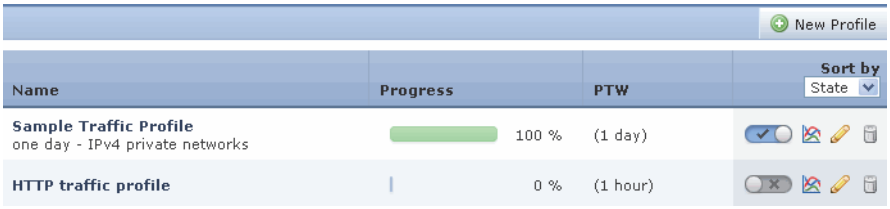
PTW, but if you alter the time settings for a graph, the Defense Center recalculates the statistics. Rules written against traffic profile statistics, however, are always evaluated against the statistics for the PTW.

To view a traffic profile graph for a traffic profile:

Access: Admin/Discovery Admin

1. Select **Policies > Correlation**, then click **Traffic Profiles**.

   The Traffic Profiles page appears.



2. Next to the traffic profile for which you want to view the graph, click the graph icon ( ).

   The graph for the traffic profile appears in a separate browser window.

CHAPTER 39
CONFIGURING REMEDIATIONS

When a correlation policy violation occurs, you can configure the Sourcefire 3D System to initiate one or multiple responses, which include remediations (such as running an Nmap scan) and various types of alerts.

The most basic kind of response you can launch is an alert. Alerts notify you, via email, a SNMP trap server, or syslog, of a policy violation. For information on creating alerts, see Configuring External Alerting on page 569.

Another kind of response you can launch is a remediation. A remediation is a program that the Defense Center runs when your network traffic violates a correlation policy. The Sourcefire 3D System ships with predefined remediations, which perform actions such as blocking a host at the firewall or router when it violates a policy or scanning the host.

When the Defense Center launches a remediation, it generates a remediation status event. You can search, view, and delete remediation status events, as you would any other event.

The Sourcefire 3D System also provides a flexible API that allows you to create custom remediation modules to respond to correlation policy violations. For example, if you are running a Linux-based firewall, you could write and upload a remediation module that dynamically updates the `iptables` file on the Linux server so that traffic violating a correlation policy is blocked. For more information about writing your own remediation modules, refer to the *Sourcefire Remediation API Guide*.

IMPORTANT! You must use a Defense Center to configure and use remediations.

For more information, see:

- Creating Remediations on page 1678
- Working with Remediation Status Events on page 1704

Creating Remediations

LICENSE: FireSIGHT

In addition to alerts, which are simple notifications of a correlation policy violation, you can also configure responses called *remediations*. Remediations are programs that the Defense Center runs when a correlation policy is violated. These programs use information provided in the event that triggered the violation to perform a specific action.

The Sourcefire 3D System ships with several predefined remediation modules:

- The Cisco IOS Null Route module, which, if you are running Cisco routers that use Cisco IOS® Version 12.0 or higher, allows you to dynamically block traffic sent to an IP address or network that violates a correlation policy.

  See Configuring Remediations for Cisco IOS Routers on page 1680 for more information.
- The Cisco PIX Shun module, which, if you are running Cisco PIX® Firewall Version 6.0 or higher, allows you to dynamically block traffic sent from an IP address that violates a correlation policy.

  See Configuring Remediations for Cisco PIX Firewalls on page 1689 for more information.
- The Nmap Scanning module, which allows you to actively scan specific targets to determine operating systems and servers running on those hosts.

  See Configuring Nmap Remediations on page 1694 for more information.
- The Set Attribute Value module, which allows you to set a host attribute on a host where a correlation event occurs.

  See Configuring Set Attribute Remediations on page 1700.

You can create multiple instances for each remediation module, where each instance represents a connection to a specific appliance. For example, if you have four Cisco IOS routers where you want to send remediations, you should configure four instances of the Cisco IOS remediation module.

When you create an instance, you specify the configuration information necessary for the Defense Center to establish a connection with the appliance. Then, for each configured instance, you add remediations that describe the actions you want the appliance to perform when a policy is violated.

After they are configured, you can add remediations to what are called response groups, or you can assign the remediations specifically to rules within correlation policies. When the system executes these remediations, it generates a remediation status event, which includes details such as the remediation name, the policy and rule that triggered it, and the exit status message. For more information on these events, see Working with Remediation Status Events on page 1704.

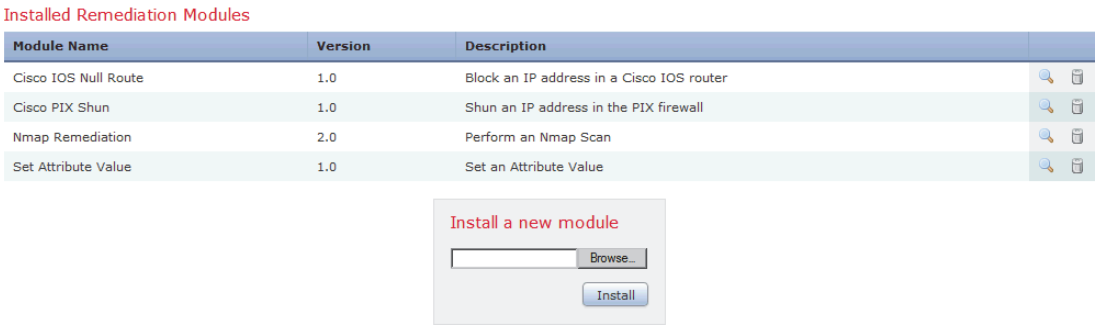
In addition to the default modules that Sourcefire provides, you can write custom remediation modules that perform other specific tasks when policy violations trigger. Refer to the *Sourcefire Remediation API Guide* for more information about writing your own remediation modules and installing them on the Defense Center. If you are installing a custom module, you can use the Modules page to install, view, and delete new modules.

To install a new module on the Defense Center:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Modules**.

   The Modules page appears.



2. Click **Browse** to navigate to the location where you saved the file that contains the custom remediation module (refer to the *Sourcefire Remediation API Guide* for more information).
3. Click **Install**.

   The custom remediation module installs.

To view or delete a module from the Defense Center:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Modules**.

   The Modules page appears.

2. Perform one of the following actions:

   - Click **View** to view the module.

     The Module Detail page appears.

   - Click **Delete** next to the module you want to delete. You **cannot** delete default modules provided by Sourcefire.

     The remediation module is deleted.

Configuring Remediations for Cisco IOS Routers

License: FireSIGHT

Sourcefire provides a Cisco IOS Null Route remediation module that allows you to block a single IP address or an entire block of addresses using Cisco's "null route" command when a correlation policy is violated. This forwards all traffic sent to the host or network listed as the source or destination host in the event that violated the correlation policy to the router's NULL interface, causing it to be dropped (note that this will not block traffic sent **from** the violating host or network).

The Cisco IOS Null Route remediation module supports Cisco routers running Cisco IOS 12.0 and higher. You must have level 15 administrative access to the router to execute Cisco IOS remediations.

IMPORTANT! A destination-based remediation only works if you configure it to launch when a correlation rule that is based on a connection event or intrusion event triggers. Discovery events only transmit source hosts.

WARNING! When a Cisco IOS remediation is activated, there is no timeout period. To remove the blocked IP address or network from the router, you must manually clear the routing change from the router itself.

To create remediations for routers running Cisco IOS:

ACCESS: Admin/Discovery Admin

1. Enable Telnet on the Cisco router.

   Refer to the documentation provided with your Cisco router or IOS software for more information about enabling Telnet.

2. On the Defense Center, add a Cisco IOS Null Route instance for each Cisco IOS router you plan to use with the Defense Center.

   See Adding a Cisco IOS Instance on page 1681 for the procedures.

3. Create specific remediations for each instance, based on the type of response you want to elicit on the router when correlation policies are violated.

   Each available remediation type is described in the following sections:

   - Cisco IOS Block Destination Remediations on page 1683
   - Cisco IOS Block Destination Network Remediations on page 1685
   - Cisco IOS Block Source Remediations on page 1686
   - Cisco IOS Block Source Network Remediations on page 1687

4. Begin assigning Cisco IOS remediations to specific correlation policy rules.

Adding a Cisco IOS Instance

LICENSE: FireSIGHT

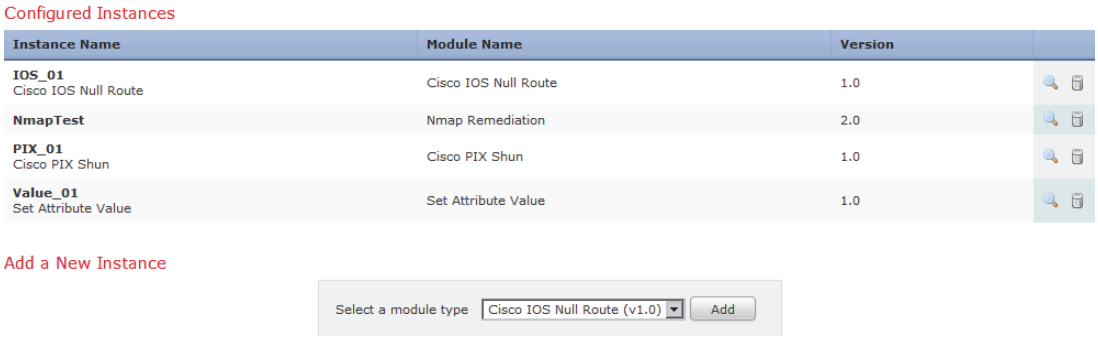
After you configure Telnet access on the Cisco IOS router (refer to the documentation provided with your Cisco router or IOS software for more information about enabling Telnet access), you can add an instance to the Defense Center. If you have multiple routers where you want to send remediations, you must create a separate instance for each router.

To add a Cisco IOS instance:

ACCESS: Admin/Discovery Admin

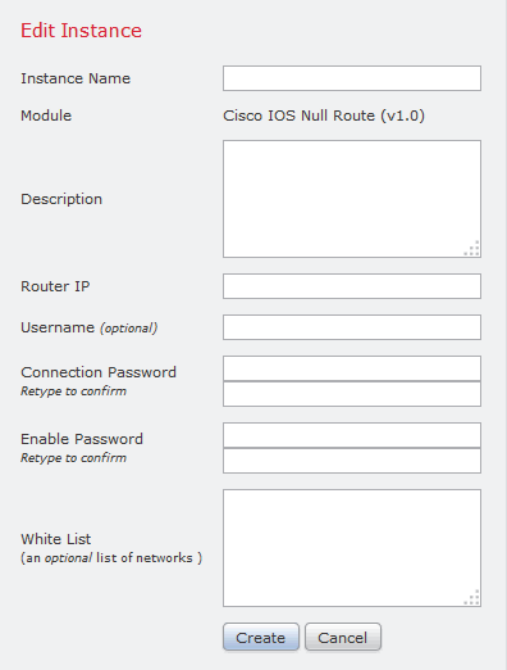
1. Select **Policies > Actions > Instances**.

   The Instances page appears.



2. From the **Add a New Instance** list, select **Cisco IOS Null Route (v1.0)** and click **Add**.

   The Edit Instance page appears.



3. In the **Instance Name** field, enter a name for the instance.

   The name you choose should contain no spaces or special characters and should be descriptive. For example, if you intend to connect more than one Cisco IOS router, you will have multiple instances, so you may want to choose a name such as `IOS_01` and `IOS_02`.

4. In the **Router IP** field, enter the IP address of the Cisco IOS router you want to use for the remediation.

5. In the **Username** field, enter the Telnet user name for the router. This user must have level 15 administrative access on the router.

6. In the **Connection Password** fields, enter the Telnet user's user password. The password entered in both fields must match.

7. In the **Enable Password** fields, enter the Telnet user's enable password. This is the password used to enter privileged mode on the router. The password entered in both fields must match.

8. In the **White List** field, enter IP addresses that you want to exempt from the remediation, one per line. You can also use CIDR notation or a specific IP address. For example, the following white list would be accepted by the system:

   ```
   10.1.1.152
   172.16.1.0/24
   ```

   Note that this white list is not associated with any compliance white lists you have created. For information on using CIDR notation in the Sourcefire 3D System, see IP Address Conventions on page 63.

9. Click **Create**.

   The instance is created and remediations appear in the Configured Remediations section of the page. You must add specific remediations for them to be used by correlation policies. See the following sections for more information:

   - Cisco IOS Block Destination Remediations on page 1683
   - Cisco IOS Block Destination Network Remediations on page 1685
   - Cisco IOS Block Source Remediations on page 1686
   - Cisco IOS Block Source Network Remediations on page 1687

Cisco IOS Block Destination Remediations

LICENSE: FireSIGHT

The Cisco IOS Block Destination remediation allows you to block traffic sent from the router to the destination host in a correlation event.

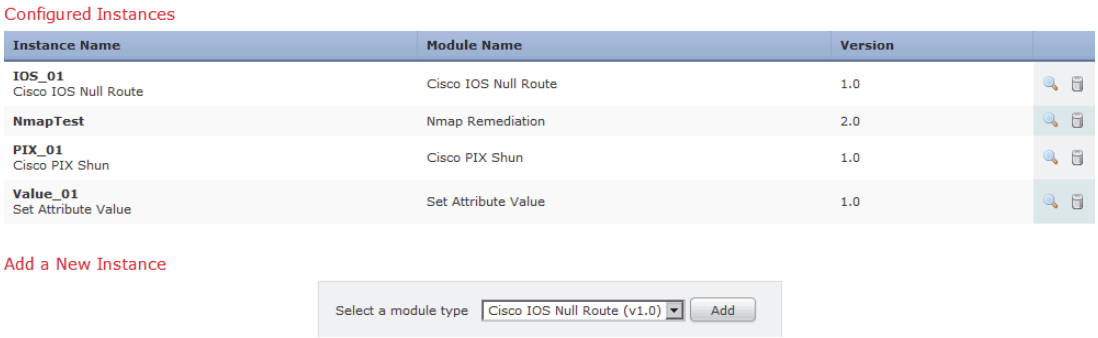
IMPORTANT! Do **not** use this remediation as a response to a correlation rule that is based on a discovery event; discovery events only transmit a source host and not a destination host. You can use this remediation in response to correlation rules that are based on connection events or intrusion events.

To add the remediation:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Instances**.

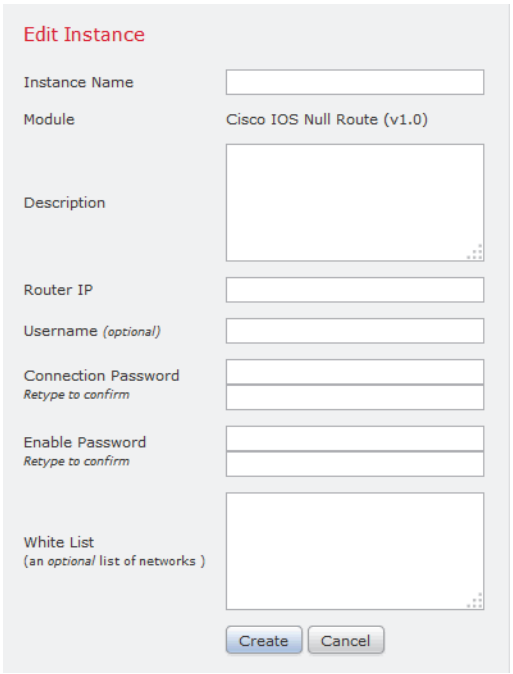
   The Instances page appears.



2. Next to the instance where you want to add the remediation, click the view icon ( ).

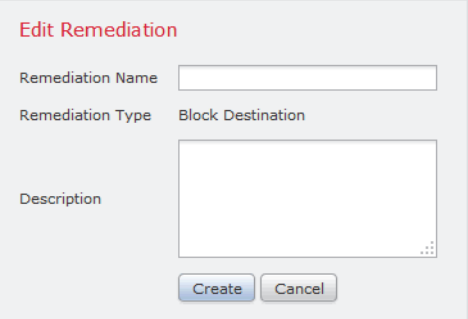
   If you have not yet added an instance, see Adding a Cisco IOS Instance on page 1681.

   The Edit Instance page appears.



3. In the **Configured Remediations** section, select **Block Destination** and click **Add**.

   The Edit Remediation page appears.



4. In the **Remediation Name** field, enter a name for the remediation.

   The name you choose cannot contain spaces or special characters and should be descriptive. For example, if you have multiple Cisco IOS router instances and multiple remediations for each instance, you may want to specify a name such as `IOS_01_BlockDest`.

5. Optionally, in the **Description** field, enter a description of the remediation.

6. Click **Create**, then click **Done**.

   The remediation is added.

Cisco IOS Block Destination Network Remediations

License: FireSIGHT

The Cisco IOS Block Destination Network remediation allows you to block any traffic sent from the router to the network of the destination host in a correlation event.

IMPORTANT! Do **not** use this remediation as a response to a correlation rule that is based on a discovery event; discovery events only transmit a source host and not a destination host. You can use this remediation in response to correlation rules that are based on connection events or intrusion events.

To add the remediation:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Instances**.

   The Instances page appears.

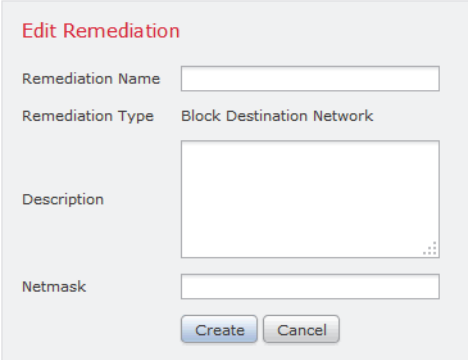
2. Next to the instance where you want to add the remediation, click **View**.

   If you have not yet added an instance, see Adding a Cisco IOS Instance on page 1681.

   The Edit Instance page appears.

3. In the **Configured Remediations** section, select **Block Destination Network** and click **Add**.

   The Edit Remediation page appears.



4. In the **Remediation Name** field, enter a name for the remediation.

   The name you choose cannot contain spaces or special characters and should be descriptive. For example, if you have multiple Cisco IOS router instances and multiple remediations for each instance, you may want to specify a name such as `IOS_01_BlockDestNet`.

5. Optionally, in the **Description** field, enter a description of the remediation.

6. In the **Netmask** field, enter the subnet mask or use CIDR notation to describe the network that you want to block traffic to.

   For example, to block traffic to an entire Class C network when a single host triggered a rule (this is not recommended), use `255.255.255.0` or `24` as the netmask.

   As another example, to block traffic to 30 addresses that include the triggering IP address, specify `255.255.255.224` or `27` as the netmask. In this case, if the IP address `10.1.1.15` triggers the remediation, all IP addresses between `10.1.1.1` and `10.1.1.30` are blocked. To block only the triggering IP address, leave the field blank, enter `32`, or enter `255.255.255.255`.

7. Click **Create**, then click **Done**.

   The remediation is added.

Cisco IOS Block Source Remediations

License: FireSIGHT

The Cisco IOS Block Source remediation allows you to block any traffic sent from the router to the source host included in a correlation event that violates a correlation policy. The source host is the source IP address in the connection event or intrusion event upon which the correlation rule is based, or the host IP address in a discovery event.

To add the remediation:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Instances**.

   The Instances page appears.

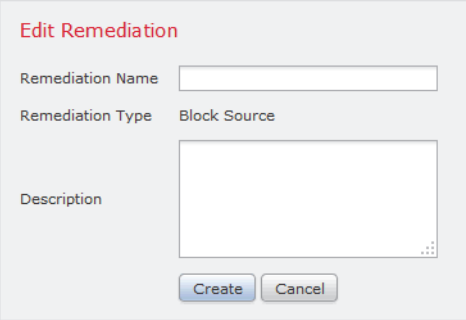
2. Next to the instance where you want to add the remediation, click **View**.

   If you have not yet added an instance, see Adding a Cisco IOS Instance on page 1681.

   The Edit Instance page appears.

3. In the **Configured Remediations** section, select **Block Source** and click **Add**.

   The Edit Remediation page appears.



4. In the **Remediation Name** field, enter a name for the remediation.

   The name you choose cannot contain spaces or special characters and should be descriptive. For example, if you have multiple Cisco IOS router instances and multiple remediations for each instance, you may want to specify a name such as `IOS_01_BlockSrc`.

5. Optionally, in the **Description** field, enter a description of the remediation.

6. Click **Create**, then click **Done**.

   The remediation is added.

Cisco IOS Block Source Network Remediations

License: FireSIGHT

The Cisco IOS Block Source Network remediation allows you to block any traffic sent from the router to the network of the source host in a correlation event. The source host is the source IP address in the connection event or intrusion event upon which the correlation rule is based, or the host IP address in a discovery event.

To add the remediation:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Instances**.

   The Instances page appears.

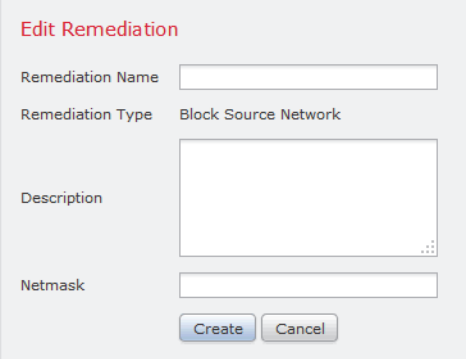
2. Next to the instance where you want to add the remediation, click **View**.

   If you have not yet added an instance, see Adding a Cisco IOS Instance on page 1681.

   The Edit Instance page appears.

3. In the **Configured Remediations** section, select **Block Source Network** and click **Add**.

   The Edit Remediation page appears.



4. In the **Remediation Name** field, enter a name for the remediation.

   The name you choose should contain no spaces or special characters and should be descriptive. For example, if you have multiple Cisco IOS router instances and multiple remediations for each instance, you may want to specify a name such as `IOS_01_BlockSourceNet`.

5. Optionally, in the **Description** field, enter a description of the remediation.

6. In the **Netmask** field, enter the subnet mask or CIDR notation that describes the network that you want to block traffic to.

   For example, to block traffic to an entire Class C network when a single host triggered a rule (this is not recommended), use `255.255.255.0` or `24` as the netmask.

   As another example, to block traffic to 30 addresses that include the triggering IP address, specify `255.255.255.224` or `27` as the netmask. In this case, if the IP address `10.1.1.15` triggers the remediation, all IP addresses between `10.1.1.1` and `10.1.1.30` are blocked. To block only the triggering IP address, leave the field blank, enter `32`, or enter `255.255.255.255`.

7. Click **Create**, then click **Done**.

   The remediation is added.

Configuring Remediations for Cisco PIX Firewalls

License: FireSIGHT

Sourcefire provides a Cisco PIX Shun remediation module that allows you to block an IP address or network using Cisco's "shun" command. This blocks all traffic sent from either the source or destination host that violated the correlation policy and closes all current connections (note that this will not block traffic sent through the firewall *to* the host).

The Cisco PIX Shun remediation module supports Cisco PIX Firewall 6.0 and higher. You must have level 15 administrative access or higher to launch Cisco PIX remediations.

IMPORTANT! A destination-based remediation only works if you configure it to launch when a correlation rule that is based on a connection event or intrusion event triggers. Discovery events only transmit source hosts.

WARNING! When a Cisco PIX remediation is activated, no timeout period is used. To unblock the IP address or network, you must manually remove the rule from the firewall.

To create remediations for Cisco PIX firewalls:

Access: Admin/Discovery Admin

1. Enable Telnet or SSH (Sourcefire recommends SSH) on the firewall.

   Refer to the documentation provided with your Cisco PIX firewall for more information about enabling SSH or Telnet.

2. On the Defense Center, add a Cisco PIX Shun instance for each Cisco PIX firewall you plan to use with the Defense Center.

   See Adding a Cisco PIX Instance on page 1690 for the procedures.

3. Create specific remediations for each instance, based on the type of response you want to elicit on the firewall when correlation policies are violated.

   The available remediation types are described in the following sections:

   - Cisco PIX Block Destination Remediations on page 1691
   - Cisco PIX Block Source Remediations on page 1693

4. Begin assigning Cisco PIX remediations to specific correlation policy rules.

Adding a Cisco PIX Instance

License: FireSIGHT

After you configure SSH or Telnet on the Cisco PIX firewall, you can add an instance to the Defense Center. If you have multiple firewalls you want to send remediations to, you must create a separate instance for each firewall.

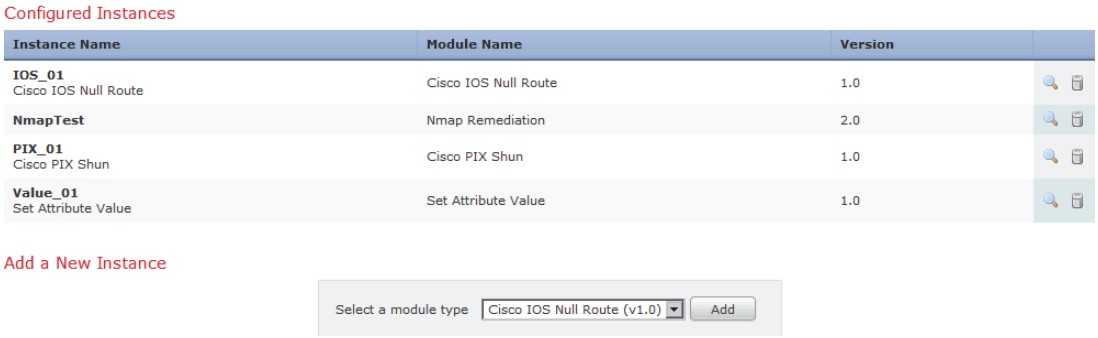
IMPORTANT! Sourcefire recommends that you use an SSH connection instead of a Telnet connection. Data transmitted using SSH is encrypted, making it much more secure than Telnet.

To add a Cisco PIX instance:

Access: Admin/Discovery Admin

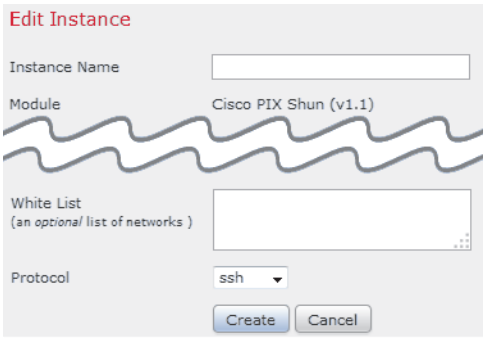
1. Select **Policies > Actions > Instances**.

   The Instances page appears.



2. From the **Add a New Instance** list, select **Cisco PIX Shun** and click **Add**.

   The Edit Instance page appears.



3. In the **Instance Name** field, type a name for the instance.

   The name you choose cannot contain spaces or special characters and should be descriptive. For example, if you intend to connect more than one Cisco firewall, you will have multiple instances, so you may want to choose a name such as `PIX_01`, `PIX_02`, and so on.

4. Optionally, type a description for the instance in the **Description** field.
5. In the **PIX IP** field, enter the IP address of the Cisco PIX firewall you want to use for the remediation.
6. If you require a specific username other than the default (`pix`), type it in the **Username** field.
7. In the **Connection Password** fields, enter the password required to connect to the firewall using SSH or Telnet. The password entered in both fields must match.
8. In the **Enable Password** fields, enter the SSH or Telnet enable password. This is the password used to enter privileged mode on the firewall. The password entered in both fields must match.
9. In the **White List** field, enter IP addresses that you want to exempt from the remediation, one on each line. You can also use CIDR notation or a specific IP address. For example, the following white list is accepted by the system:

   ```
   10.1.1.152
   172.16.1.0/24
   ```

   Note that this white list is not associated with any compliance white lists you have created. For information on using CIDR notation in the Sourcefire 3D System, see IP Address Conventions on page 63.
10. From the **Protocol** list, select the method you want to use to connect to the firewall.
11. Click **Create**.

    The instance is created and remediations appear in the Configured Remediations section of the page. You must add specific remediations for them to be used in correlation policies. See the following sections for more information:

    - Cisco PIX Block Destination Remediations on page 1691
    - Cisco PIX Block Source Remediations on page 1693

Cisco PIX Block Destination Remediations

LICENSE: FireSIGHT

The Cisco PIX Block Destination remediation allows you to block traffic sent from the destination host in a correlation event.

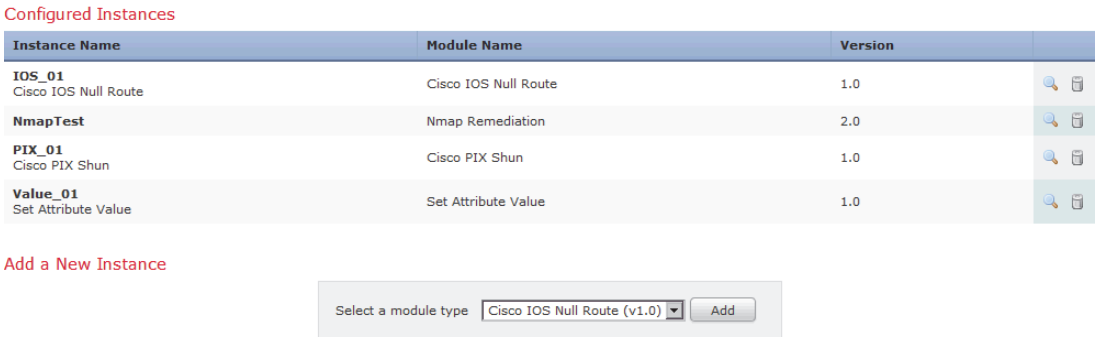
IMPORTANT! Do **not** use this remediation as a response to a correlation rule that is based on a discovery event; discovery events only transmit a source host and not a destination host. You can use this remediation in response to correlation rules that are based on connection events or intrusion events.

To add the remediation:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Instances**.

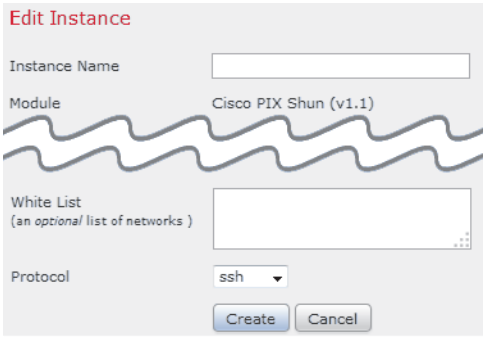
   The Instances page appears.



2. Next to the instance where you want to add the remediation, click **View**.

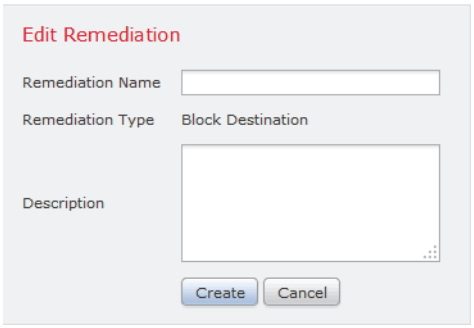
   If you have not yet added an instance, see Adding a Cisco PIX Instance on page 1690.

   The Edit Instance page appears.



3. In the **Configured Remediations** section, select **Block Destination** and click **Add**.

   The Edit Remediation page appears.



4. In the **Remediation Name** field, enter a name for the remediation.

   The name you choose cannot contain spaces or special characters and should be descriptive. For example, if you have multiple Cisco PIX firewall instances and multiple remediations for each instance, you may want to specify a name such as `PIX_01_BlockDest`.

5. Optionally, in the **Description** field, enter a description of the remediation.

6. Click **Create**, then click **Done**.

   The remediation is added.

Cisco PIX Block Source Remediations

License: FireSIGHT

The Cisco PIX Block Source remediation allows you to block any traffic sent from the source host included in the event that violates a correlation policy. The source host is the source IP address in the connection event or intrusion event upon which the correlation rule is based, or the host IP address in a discovery event.

To add the remediation:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Instances**.

   The Instances page appears.

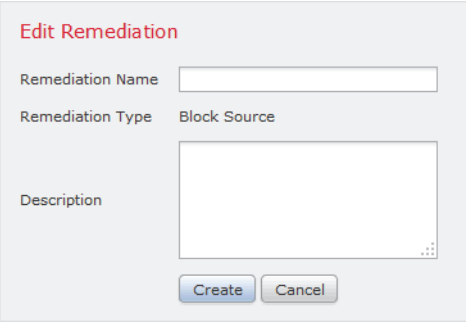
2. Next to the instance where you want to add the remediation, click **View**.

   If you have not yet added an instance, see Adding a Cisco PIX Instance on page 1690.

   The Edit Instance page appears.

3. In the **Configured Remediations** section, select **Block Source** and click **Add**.

   The Edit Remediation page appears.



4. In the **Remediation Name** field, enter a name for the remediation.

   The name you choose cannot contain spaces or special characters and should be descriptive. For example, if you have multiple Cisco PIX firewall instances and multiple remediations for each instance, you may want to specify a name such as `PIX_01_BlockSrc`.

5. Optionally, in the **Description** field, enter a description of the remediation.

   The remediation is added.

Configuring Nmap Remediations

LICENSE: FireSIGHT

You can respond to a correlation event by scanning the host where the triggering event occurred. You can choose to scan only the port from the event that triggered the correlation event.

To set up Nmap scanning in response to a correlation event, you must first create an Nmap scan instance, then add an Nmap scan remediation. You can then configure Nmap scanning as responses to violations of rules within the policy.

See the following sections:

- Adding an Nmap Scan Instance on page 1694
- Nmap Scan Remediations on page 1696

Adding an Nmap Scan Instance

LICENSE: FireSIGHT

You can set up a separate scan instance for each Nmap module that you want to use to scan hosts on your network for operating system and server information. You can set up scan instances for the local Nmap module on your Defense Center and for any managed devices you want to use to run scans remotely. The results of each scan are always stored on the Defense Center where you configure the scan, even if you run the scan from a remote managed device. To prevent accidental or malicious scanning of mission-critical hosts, you can create a blacklist for the instance to indicate the hosts that should never be scanned with the instance.

Note that you cannot add a scan instance with the same name as any existing scan instance.

To create a scan instance:

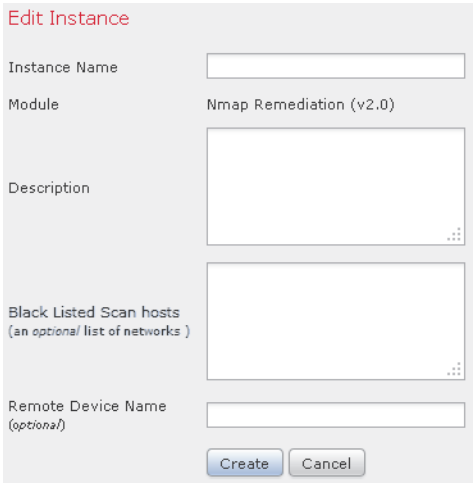
ACCESS: Admin/Discovery Admin

1. Select **Policies > Actions > Instances**.

   The Instances page appears.

2. Select **Nmap Remediation (v1.0)** from the **Add a module type** drop-down list and click **Add**.

   The Edit Instance page appears.



3. In the **Instance Name** field, enter a name that includes 1 to 63 alphanumeric characters, with no spaces and no special characters other than underscore (_) and dash (-).
4. In the **Description** field, specify a description that includes 0 to 255 alphanumeric characters, including spaces and special characters.
5. Optionally, in the **Black Listed Scan hosts** field, specify any hosts or networks that should *never* be scanned with this scan instance, using the following syntax:
   - For IPv6 hosts, an exact IP address (for example, `2001:DB8::fedd:eeff`)
   - For IPv4 hosts, an exact IP address (for example, `192.168.1.101`) or an IP address block using CIDR notation (for example, `192.168.1.0/24` scans the 254 hosts between `192.168.1.1` and `192.168.1.254`, inclusive)

   If you specifically target a scan to a host that is in a blacklisted network, that scan will not run. For information on using CIDR notation in the Sourcefire 3D System, see IP Address Conventions on page 63.
6. Optionally, to run the scan from a remote managed device instead of the Defense Center, specify the name or IP address of the managed device in the **Remote Device Name** field.
7. Click **Create**.

   The scan instance is created.

Nmap Scan Remediations

License: FireSIGHT

You can define the settings for an Nmap scan by creating an Nmap remediation. An Nmap remediation can be used as a response in a correlation policy, run on demand, or scheduled to run at a specific time. In order for the results of an Nmap scan to appear in the network map, the scanned host must already exist in the network map. Note that NetFlow, the host input feature, and the system itself can add hosts to the network map.

For more information on the specific settings in an Nmap remediation, see Understanding Nmap Remediations on page 1765.

Note that Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host for operating system and server data using Nmap, you may want to set up regularly scheduled scans to keep any Nmap-supplied operating system and server data up-to-date. For more information, see Automating Nmap Scans on page 2013. Also note that if the host is deleted from the network map, any Nmap scan results for that host are discarded.

For general information about Nmap functionality, refer to the Nmap documentation at http://insecure.org.

To create a Nmap remediation:

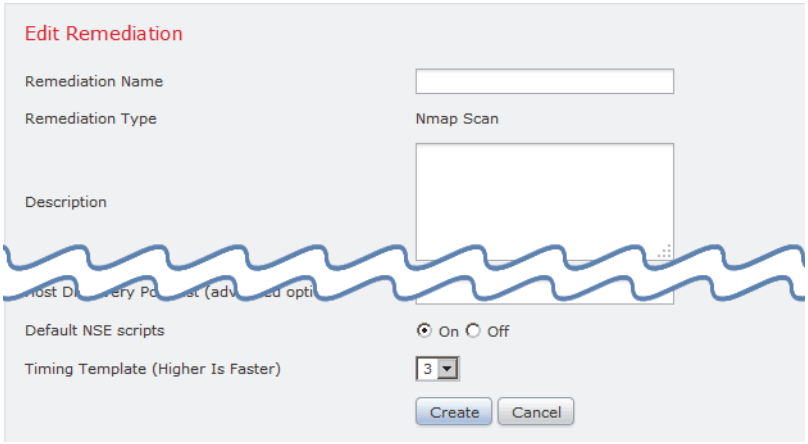
Access: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.

   The Nmap Scanners page appears.

2. Click **Add Remediation** next to the scan instance where you want to add a remediation.

   The Edit Remediation page appears.



3. In the **Remediation Name** field, type a name for the remediation that includes 1 to 63 alphanumeric characters, with no spaces and no special characters other than underscore (_) and dash (-).
4. In the **Description** field, type a description for the remediation that includes 0 to 255 alphanumeric characters, including spaces and special characters.
5. If you plan to use this remediation in response to a correlation rule that triggers on an intrusion event, a connection event, or a user event, configure the **Scan Which Address(es) From Event?** option.
   - Select **Scan Source and Destination Addresses** to scan the hosts represented by the source IP address and the destination IP address in the event.
   - Select **Scan Source Address Only** to scan the host represented by the event's source IP address.
   - Select **Scan Destination Address Only** to scan the host represented by the event's destination IP address.

   If you plan to use this remediation in response to a correlation rule that triggers on a discovery event or a host input event, by default the remediation scans the IP address of the host involved in the event; you do not need to configure this option.

IMPORTANT! Do **not** assign a Nmap remediation as a response to a correlation rule that triggers on a traffic profile change.

6. Configure the **Scan Type** option:
   - To scan quickly in stealth mode on hosts where the `admin` account has raw packet access or where IPv6 is not running, by initiating TCP connections but not completing them, select **TCP Syn Scan**.
   - To scan by using a system `connect()` call, which can be used on hosts where the `admin` account on your Defense Center does not have raw packet access or where IPv6 is running, select **TCP Connect Scan**.
   - To send an ACK packet to check whether ports are filtered or unfiltered, select **TCP ACK Scan**.
   - To send an ACK packet to check whether ports are filtered or unfiltered but also determine whether a port is open or closed, select **TCP Window Scan**.
   - To identify BSD-derived systems using a FIN/ACK probe, select **TCP Maimon Scan**.
7. Optionally, to scan UDP ports in addition to TCP ports, select **On** for the **Scan for UDP ports** option.

   TIP! A UDP portscan takes more time than a TCP portscan. To speed up your scans, leave this option disabled.

8. If you plan to use this remediation in response to correlation policy violations, configure the **Use Port From Event** option:
   - Select **On** to scan the port in the correlation event, rather than the ports you specify in step 12.

     If you scan the port in the correlation event, note that the remediation scans the port on the IP addresses that you specified in step 8. These ports are also added to the remediation's dynamic scan target.
   - Select **Off** to scan only the ports you will specify in step 12.
9. If you plan to use this remediation in response to correlation policy violations and want to run the scan using the appliance running the detection engine that detected the event, configure the **Scan from reporting detection engine** option:
   - To scan from the appliance running the reporting detection engine, select **On**.
   - To scan from the appliance configured in the remediation, select **Off**.
10. Configure the **Fast Port Scan** option:
    - To only scan ports listed in the `nmap-services` file located in the `/var/sf/nmap/share/nmap/nmap-services` directory on the managed device that does the scanning, ignoring other port settings, select **On**.
    - To scan all TCP ports, select **Off**.

11. In the **Port Ranges and Scan Order** field, type the ports you want to scan by default, using Nmap syntax, in the order you want to scan those ports.

    Specify values from 1 to 65535. Separate ports using commas or spaces. You can also use a hyphen to indicate a port range. When scanning for both TCP and UDP ports, preface the list of TCP ports you want to scan with a T and the list of UDP ports with a U. For example, to scan ports 53 and 111 for UDP traffic, then scan ports 21-25 for TCP traffic, enter `U:53,111,T:21-25`.

    Note that the **Use Port From Event** option overrides this setting when the remediation is launched in response to a correlation policy violation, as described in step 8.

12. To probe open ports for server vendor and version information, configure **Probe open ports for vendor and version information:**
    - Select **On** to scan open ports on the host for server information to identify server vendors and versions.
    - Select **Off** to continue using server information for the host.

13. If you choose to probe open ports, set the number of probes used by selecting a number from the **Service Version Intensity** drop-down list:
    - To use more probes for higher accuracy with a longer scan, select a higher number.
    - To use fewer probes for less accuracy with a faster scan, select a lower number.

14. To scan for operating system information, configure **Detect Operating System** settings:
    - Select **On** to scan the host for information to identify the operating system.
    - Select **Off** to continue using operating system information for the host.

15. To determine whether or not host discovery occurs and whether port scans are only run against available hosts, configure **Treat All Hosts As Online**:
    - To skip the host discovery process and run a port scan on every host in the target range, select **On**.
    - To perform host discovery using the settings for **Host Discovery Method** and **Host Discovery Port List** and skip the port scan on any host that is not available, select **Off**.

16. Select the method to be used when Nmap tests to see if a host is present and available:
    - To send an empty TCP packet with the SYN flag set and elicit an RST response on a closed port or a SYN/ACK response on an open port on available hosts, select **TCP SYN**.

      Note that this option scans port 80 by default and that TCP SYN scans are less likely to be blocked by a firewall with stateful firewall rules.

- To send an empty TCP packet with the ACK flag set and elicit an RST response on available hosts, select **TCP ACK.**

  Note that this option scans port 80 by default and that TCP ACK scans are less likely to be blocked by a firewall with stateless firewall rules.
- To send a UDP packet to elicit port unreachable responses from closed ports on available hosts, select **UDP**. This option scans port 40125 by default.

17. If you want to scan a custom list of ports during host discovery, type a list of ports appropriate for the host discovery method you selected, separated by commas, in **Host Discovery Port List**.
18. Configure the **Default NSE Scripts** option to control whether to use the default set of Nmap scripts for host discovery and server, operating system, and vulnerability discovery:
    - To run the default set of Nmap scripts, select **On**.
    - To skip the default set of Nmap scripts, select **Off**.

    See http://nmap.org/nsedoc/categories/default.html for the list of default scripts.
19. To set the timing of the scan process, select a timing template number; select a higher number for a faster, less comprehensive scan and a lower number for a slower, more comprehensive scan.
20. Click **Save**, then click **Done**.

    The remediation is created.

Configuring Set Attribute Remediations

LICENSE: FireSIGHT

You can respond to a correlation event by setting a host attribute value on the host where the triggering event occurred. For text host attributes, you can choose to use the description from the event as the attribute value. For more information on host attributes, see Working with the Predefined Host Attributes on page 1433 and Working with User-Defined Host Attributes on page 1434.

To configure setting an attribute value in response to a correlation event, you must first create a set attribute instance, then add a set attribute remediation. You can then configure attribute value updates as responses to violations of rules within the policy.

For more information, see the following sections:

- Adding a Set Attribute Value Instance on page 1701
- Set Attribute Value Remediations on page 1702

Adding a Set Attribute Value Instance

LICENSE: FireSIGHT

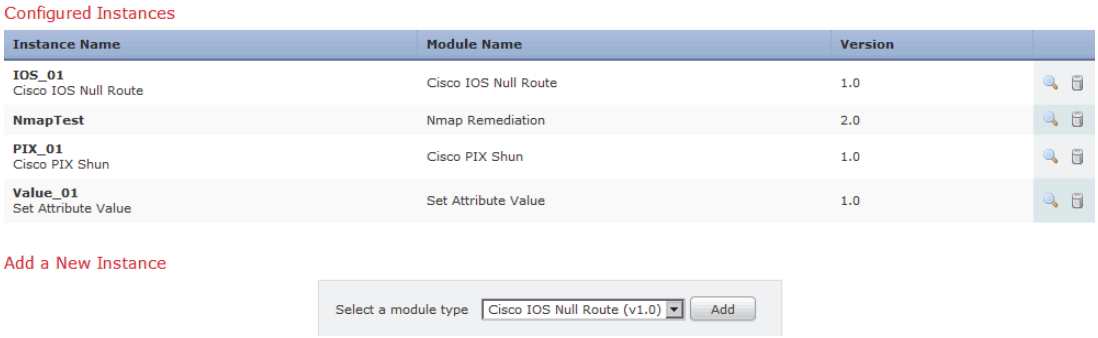
You can set up an instance to set attribute values in response to correlation rule violations.

To create a set attribute instance:

ACCESS: Admin/Discovery Admin

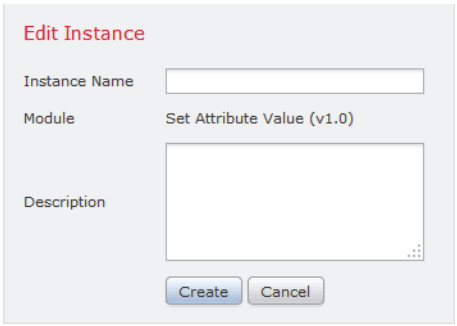
1. Select **Policies > Actions > Instances**.

   The Instances page appears.



2. Select **Set Attribute Value (v1.0)** from the **Add a module type** drop-down list and click **Add**.

   The Edit Instance page appears.



3. In the **Instance Name** field, enter a name that includes 1 to 63 alphanumeric characters, with no spaces and no special characters other than underscore (_) and dash (-).
4. In the **Description** field, specify a description that includes 0 to 255 alphanumeric characters, including spaces and special characters.
5. Click **Create**.

   The instance is created.

Set Attribute Value Remediations

License: FireSIGHT

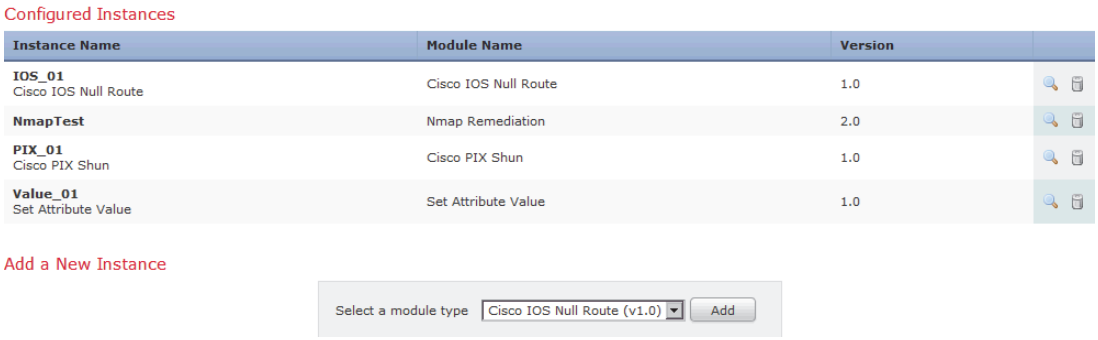
You can create a set attribute value remediation for each attribute value you want to be able to set in response to a correlation rule violation. If the attribute you want to set is a text attribute, you can set the remediation to use the description from the event as the attribute value.

To create a set attribute value remediation:

Access: Admin/Discovery Admin

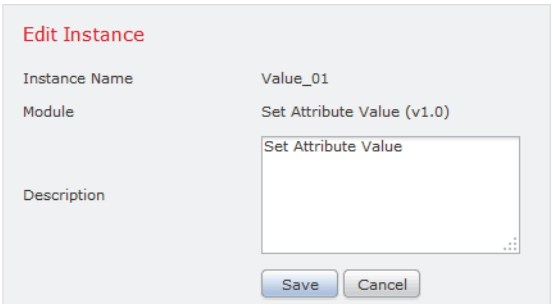
1. Select **Policies > Actions > Instances**.

   The Instances page appears.



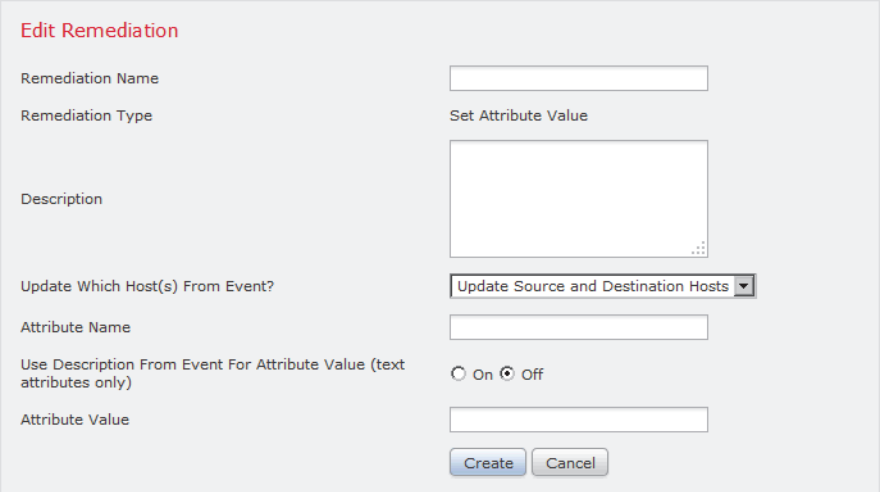
2. Click **View** next to the scan instance where you want to add a remediation.

   The Edit Instance page appears.



3. Select **Set Attribute Value** from the **Add a new remediation of type** drop-down list.

   The Edit Remediation page appears.



4. In the **Remediation Name** field, type a name for the remediation that includes 1 to 63 alphanumeric characters, with no spaces and no special characters other than underscore (_) and dash (-).
5. In the **Description** field, type a description for the remediation that includes 0 to 255 alphanumeric characters, including spaces and special characters.
6. If you plan to use this remediation in response to a correlation rule that triggers on an intrusion event, user event, or a connection event, configure the **Update Which Host(s) From Event** option.
   - Select **Update Source and Destination Hosts** to update the attribute value on the hosts represented by the source IP address and the destination IP address in the event.
   - Select **Update Source Host Only** to update the attribute value on the host represented by the event's source IP address.
   - Select **Update Destination Host Only** to update the attribute value on the host represented by the event's destination IP address.

   If you plan to use this remediation in response to a correlation rule that triggers on a discovery event or host input event, by default the remediation scans the IP address of the host involved in the event; you do not need to configure this option.

7. Configure the **Use Description From Event For Attribute Value (text attributes only)** option:
   - To use the description from the event as the attribute value, select **On**.
   - To use the Attribute Value setting for the remediation as the attribute value, select **Off**.
8. If you are not planning to use the event description, type the attribute value you want to set in the **Attribute Value** field.
9. Click **Save**, then click **Done**.

   The remediation is created.

Working with Remediation Status Events

LICENSE: FireSIGHT

When a remediation triggers, a remediation status event is generated. These events are logged to the database and can be viewed on the Remediation Status page. You can search, view, and delete remediation status events.

For more information, see:

- Setting Event Time Constraints on page 1896
- Searching for Remediation Status Events on page 1709

Viewing Remediation Status Events

LICENSE: FireSIGHT

The page you see when you access remediation status events differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of remediations. The table view contains a row for each remediation status event. You can also create a custom workflow that displays only the information that matches your specific needs. For information on creating a custom workflow, see Creating Custom Workflows on page 1916.

The Remediation Status Actions table below describes some of the specific actions you can perform on a remediation status events workflow page.

Remediation Status Actions

To...	You can...
learn more about the columns that appear	find more information in Understanding the Remediation Status Table on page 1707.
modify the time and date range for displayed events	see Setting Event Time Constraints on page 1896. Note that events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This can occur even if you configured a sliding time window for the appliance.
sort and constrain the events	see Constraining Events on page 1905 and Sorting Drill-Down Workflow Pages on page 1910.
temporarily use a different workflow	click **(switch workflow)** by the workflow title. For more information, see Selecting Workflows on page 1885.
navigate to the correlation events view to see associated events	click **Correlation Events**. For more information, see Navigating Between Workflows on page 1911.
bookmark the current page so that you can quickly return to it	click **Bookmark This Page**. For more information, see Using Bookmarks on page 1913.
navigate to the bookmark management page	click **View Bookmarks**. For more information, see Using Bookmarks on page 1913.
generate a report based on the data in the table view	click **Report Designer**. For more information, see Creating a Report Template from an Event View on page 1797.

Remediation Status Actions (Continued)

To...	You can...
drill down to the next page in the workflow, constraining on a specific value	use one of the following methods: • on a drill-down page that you created in a custom workflow, click a value within a row. Note that clicking a value within a row in a table view constrains the table view and does **not** drill down to the next page. • To drill down to the next workflow page constraining on some users, select the check boxes next to the users you want to view on the next workflow page, then click **View**. • To drill down to the next workflow page keeping the current constraints, click **View All**. **TIP!** Table views always include "Table View" in the page name. For more information, see Constraining Events on page 1905.
delete remediation status events from the system	use one of the following methods: • To delete some events, select the check boxes next to events you want to delete, then click **Delete**. • To delete all events in the current constrained view, click **Delete All**, then confirm you want to delete all the events.
search for remediation status events	click **Search**. For more information, see Searching for Remediation Status Events on page 1709.

To view remediation status events:

Access: Admin

▶ Select **Analysis > Correlation > Status**.

The first page of the default remediations workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. If no events appear, you may need to adjust the time range; see Setting Event Time Constraints on page 1896.

TIP! If you are using a custom workflow that does not include the table view of remediations, click **(switch workflow)** menu by the workflow title, then select **Remediation Status**.

Working with Remediation Status Events

LICENSE: FireSIGHT

You can change the layout of the event view or constrain the events in the view by a field value.

When you disable a column, it is disabled for the duration of your session (unless you add it back later). Note that when you disable the first column, the Count column is added.

Clicking a value within a row in a table view constrains the table view and does not drill down to the next page.

TIP! Table views always include "Table View" in the page name.

For more information, see the following topics:

- Constraining Events on page 1905.
- Using Compound Constraints on page 1908.
- Sorting Drill-Down Workflow Pages on page 1910.
- Understanding the Remediation Status Table on page 1707

Understanding the Remediation Status Table

LICENSE: FireSIGHT

You can configure the Defense Center to launch a variety of responses to policy violations and to discovery events. These responses include remediations, such as blocking a host at the firewall or router when it violates a policy. When a remediation triggers, a remediation status event is generated and logged to the database. For more information on remediations, see Configuring Remediations on page 1677.

The fields in the remediation status table are described in the Remediation Status Fields table.

Remediation Status Fields

FIELD	DESCRIPTION
Policy	The name of the correlation policy that was violated and triggered the remediation.
Remediation Name	The name of the remediation that was launched.

Remediation Status Fields (Continued)

Field	Description
Result Message	A message that describes what happened when the remediation was launched. Status messages include: • Successful completion of remediation • Error in the input provided to the remediation module • Error in the remediation module configuration • Error logging into the remote device or server • Unable to gain required privileges on remote device or server • Timeout logging into remote device or server • Timeout executing remote commands or servers • The remote device or server was unreachable • The remediation was attempted but failed • Failed to execute remediation program • Unknown/unexpected error **IMPORTANT!** If custom remediation modules are installed, you may see additional status messages that are implemented by the custom module.
Rule	The name of the rule that triggered the remediation.
Time	The date and time that the Defense Center launched the remediation
Count	The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

To display the table view of remediation status events:

Access: Admin

▶ Select **Analysis > Correlation > Status**.

The table view appears. For information on working with remediation status events, see Working with Remediation Status Events on page 1704.

TIP! If you are using a custom workflow that does not include the table view of remediation status events, click **(switch workflow)** by the workflow title, then click **Remediation Status**.

Searching for Remediation Status Events

LICENSE: FireSIGHT

You can search for remediation status events to determine when and if a particular remediation was launched. You may want to create searches customized for your network environment, then save them to reuse later. The search criteria you can use are described in the Remediation Status Search Criteria table.

Remediation Status Search Criteria

SEARCH FIELD	DESCRIPTION
Result Message	Enter the **exact** name of the result message (a message that describes what happened when the remediation was launched) you want to match. Valid status messages are: • Successful completion of remediation • Error in the input provided to the remediation module • Error in the remediation module configuration • Error logging into the remote device or server • Unable to gain required privileges on remote device or server • Timeout logging into remote device or server • Timeout executing remote commands or servers • The remote device or server was unreachable • The remediation was attempted but failed • Failed to execute remediation program • Unknown/unexpected error **IMPORTANT!** If you installed custom remediation modules, you may be able to enter additional status messages implemented by the custom module.
Time	Specify the date and time the Defense Center launched the remediation. See Specifying Time Constraints in Searches on page 1847 for the syntax for entering time.
Remediation Name	Enter the exact name of the remediation that was launched. This is the name you specified when you created the remediation.
Policy	Enter the name of the correlation policy that triggered the remediation.
Rule	Enter the name of the correlation rule that triggered the remediation.

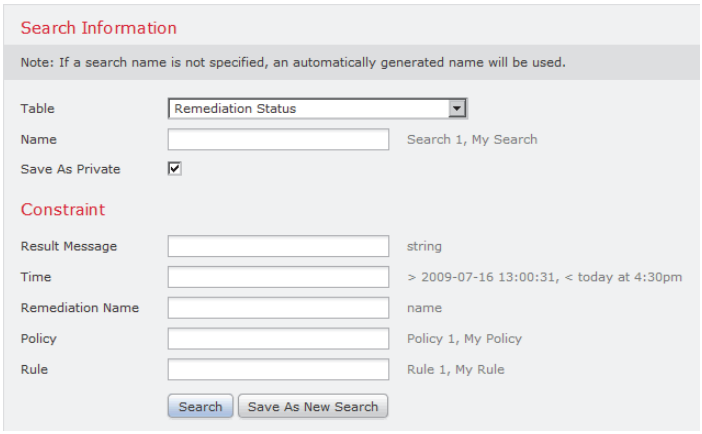
For more information on searching, including how to load and delete saved searches, see Searching for Events on page 1842.

To search for remediation status events:

Access: Admin

1. Select **Analysis & Reporting > Searches > Remediation Status**.

   The Remediation Status search page appears.



TIP! To search the database for a different kind of event, select it from the **Table** drop-down list.

2. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is automatically created when you save the search.

3. Enter your search criteria in the appropriate fields, as described in the Remediation Status Search Criteria table. If you enter multiple criteria, the search returns only the records that match all the criteria.

4. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

TIP! If you want to save a search as a restriction for restricted event analyst users, you **must** save it as a private search.

5. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in the default remediation status workflow, constrained by the current time range. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

CHAPTER 40
ENHANCING NETWORK DISCOVERY

The information about your network traffic collected by the Sourcefire 3D System is most valuable to you when the system can correlate this information to identify the hosts on your network that are most vulnerable and most important.

As an example, if you have several devices on your network running a customized version of SuSE Linux, the system cannot identify that operating system and so cannot map vulnerabilities to the hosts. However, knowing that the system has a list of vulnerabilities for SuSE Linux, you may want to create a custom fingerprint for one of the hosts that can then be used to identify the other hosts running the same operating system. You can include a mapping of the vulnerability list for SuSE Linux in the fingerprint to associate that list with each host that matches the fingerprint.

The system also allows you to input host data from third-party systems directly into the network map, using the host input feature. However, third-party operating system or application data does not automatically map to vulnerability information. If you want to see vulnerabilities and perform impact correlation for hosts using third-party operating system, server, and application protocol data, you must map the vendor and version information from the third-party system to the vendor and version listed in the vulnerability database (VDB). You also may want to maintain the host input data on an ongoing basis. Note that even if you map application data to Sourcefire 3D System vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

If the system cannot identify application protocols running on hosts on your network, you can create user-defined application protocol detectors that allow the system to identify the applications based on a port or a pattern. You can also

import, activate, and deactivate certain application detectors to further customize the application detection capability of the Sourcefire 3D System.

You can also replace detection of operating system and application data using scan results from the Nmap active scanner or augment the vulnerability lists with third-party vulnerabilities. The system may reconcile data from multiple sources to determine the identity for an application. For more information on how the system does this, see Understanding Current Identities on page 1718. For more information on active scanning, see Configuring Active Scanning on page 1764.

For more information, see the following sections:

- Assessing Your Detection Strategy on page 1713
- Enhancing Your Network Map on page 1716
- Using Custom Fingerprinting on page 1720
- Working with Application Detectors on page 1735
- Importing Host Input Data on page 1752

Assessing Your Detection Strategy

LICENSE: FireSIGHT

Before you make any changes to the system's default detection capabilities, you should analyze what hosts are not being identified correctly and why, so you can decide what solution to implement. Use the following as a guide for your decision:

- Are Your Managed Devices Correctly Placed? on page 1713
- Do Unidentified Operating Systems Have a Unique TCP Stack? on page 1714
- Can the Sourcefire 3D System Identify All Applications? on page 1715
- Have You Applied Patches that Fix Vulnerabilities? on page 1715
- Do You Want to Track Third-Party Vulnerabilities? on page 1715

Are Your Managed Devices Correctly Placed?

LICENSE: FireSIGHT

If network devices such as load balancers, proxy servers, or NAT devices reside between the managed device and the unidentified or misidentified host, place a managed device closer to the misidentified host rather than using custom fingerprinting. Sourcefire does not recommend using custom fingerprinting in this scenario.

Do Unidentified Operating Systems Have a Unique TCP Stack?

LICENSE: FireSIGHT

If the system misidentifies a host, you should investigate why the host is misidentified to help you decide between creating and activating a custom fingerprint or substituting Nmap or host input data for discovery data.

WARNING! If you encounter misidentified hosts, contact your support representative before creating custom fingerprints.

If a host is running an operating system that is not detected by the system by default and does not share identifying TCP stack characteristics with existing detected operating systems, you should create a custom fingerprint.

For example, if you have a customized version of Linux with a unique TCP stack that the system cannot identify, you would benefit from creating a custom fingerprint, which allows the system to identify the host and continuing monitoring it, rather than using scan results or third-party data, which require you to actively update the data yourself on an ongoing basis.

Note that many open source Linux distributions use the same kernel, and as such, the system identifies them using the Linux kernel name. If you create a custom fingerprint for a Red Hat Linux system, you may see other operating systems (such as Debian Linux, Mandrake Linux, Knoppix, and so on) identified as Red Hat Linux, because the same fingerprint matches multiple Linux distributions.

You should not use a fingerprint in every situation. For example, a modification may have been made to a host's TCP stack so that it resembles or is identical to another operating system. For example, an Apple Mac OS X host is altered, making its fingerprint identical to a Linux 2.4 host, causing the system to identify it as Linux 2.4 instead of Mac OS X. If you create a custom fingerprint for the Mac OS X host, it may cause all legitimate Linux 2.4 hosts to be erroneously identified as Mac OS X hosts. In this case, if Nmap correctly identifies the host, you could schedule regular Nmap scans for that host.

If you import data from a third-party system using host input, you must map the vendor, product, and version strings that the third party uses to describe servers and application protocols to the Sourcefire definitions for those products. For more information, see Managing Third-Party Product Mappings on page 1754. Note that even if you map application data to Sourcefire 3D System vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

The system may reconcile data from multiple sources to determine the current identity for an operating system or application. For more information on how the system does this, see Understanding Current Identities on page 1718.

For Nmap data, you can schedule regular Nmap scans. For host input data, you can regularly run the Perl script for the import or the command line utility.

However, note that active scan data and host input data may not be updated with the frequency of discovery data.

Can the Sourcefire 3D System Identify All Applications?

LICENSE: FireSIGHT

If a host is correctly identified by the system but has unidentified applications, you can create a user-defined detector to provide the system with port and pattern matching information to help identify the application. For more information, see Creating a User-Defined Application Protocol Detector on page 1738.

Have You Applied Patches that Fix Vulnerabilities?

LICENSE: FireSIGHT

If the system correctly identifies a host but does not reflect applied fixes, you can use the host input feature to import patch information. When you import patch information, you must map the fix name to a fix in the database. For more information, see Mapping Third-Party Product Fixes on page 1757.

Do You Want to Track Third-Party Vulnerabilities?

LICENSE: FireSIGHT

If you have vulnerability information from a third-party system that you want to use for impact correlation, you can map the third-party vulnerability identifiers for servers and application protocols to vulnerability identifiers in the Sourcefire database and then import the vulnerabilities using the host input feature. For more information on using the host input feature, see the *Sourcefire 3D System Host Input API Guide*. For more information on mapping third-party vulnerabilities, see Mapping Third-Party Vulnerabilities on page 1759. Note that even if you map application data to Sourcefire 3D System vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

Enhancing Your Network Map

LICENSE: FireSIGHT

The Sourcefire 3D System builds the network map using data it detects by passively analyzing traffic. It also uses data added through active sources such as the host input feature and the Nmap scanner. Understanding how the system decides which data to use for an application or operating system identity can help you decide how best to augment the system's passive detection capabilities with active input sources.

For more information, see the following topics:

- Understanding Passive Detection on page 1716
- Understanding Active Detection on page 1717
- Understanding Current Identities on page 1718
- Understanding Identity Conflicts on page 1719

Understanding Passive Detection

LICENSE: FireSIGHT

Passive detection is the detection of host operating system, client, and application information through analysis of traffic passively collected by the system. The system uses information in the VDB to help it identify your network assets.

If the system cannot identify an operating system on a host, you can manually determine it and then create a custom server or client fingerprint to help the system recognize that operating system on other hosts with similar operating system characteristics.

The system uses all collected passive fingerprints for a host operating system to create a *derived fingerprint*. The system creates derived fingerprints by applying a formula which calculates the most likely identity using the confidence value of each collected fingerprint and the amount of corroborating fingerprint data between identities. Common elements are identified between identities.

If you use user-defined application detectors on your network, you can augment the system's application detection capabilities by creating custom detectors that provide the system with the information it needs to identify those applications. NetFlow can also add passively detected application information to the network map.

Note that the system does not use application protocol and operating system data that it classified as *unknown* because it is unable to interpret the data. The managed device reports the identity to the Defense Center as **unknown** and the identity data is not used to derive fingerprints.

Understanding Active Detection

LICENSE: FireSIGHT

Active detection is addition, to the network map, of data collected by active sources, such as host operating system and application information. For example, you can use the Nmap scanner to actively scan the hosts that you target on your network. Nmap discovers operating systems and applications on hosts.

In addition, the host input feature allows you to actively add *host input data* to the network map. There are two different categories of host input data:

- You can modify a host's operating system or application identity through the Sourcefire 3D System user interface. Data added through the interface is *user input data*.
- You can also import data using a command line utility. Imported data is *host import input data*.

The system retains one identity for each active source. When you run an Nmap scan instance, for example, the results of the previous scan are replaced with the new scan results. However, if you run an Nmap scan and then replace those results with data from a client whose results are imported through the command line, the system retains both the identities from the Nmap results and the identities from the import client. Then the system uses the priorities set in the system policy to determine which active identity to use as the current identity.

Note that user input is considered one source, even if it comes from different users. As an example, if UserA sets the operating system through the host profile, and then UserB changes that definition through the host profile, the definition set by UserB is retained, and the definition set by UserA is discarded. In addition, note that user input overrides all other active sources and is used as the current identity if it exists.

Understanding Current Identities

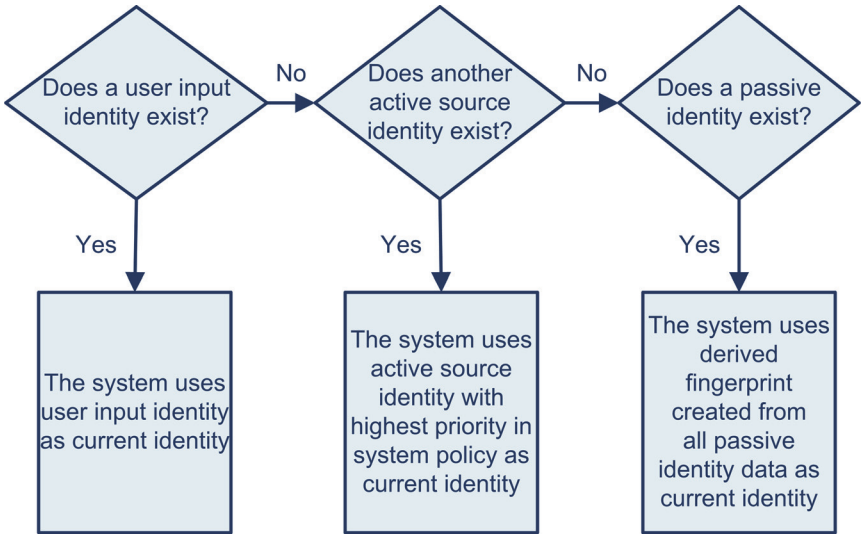
LICENSE: FireSIGHT

The *current identity* for an application or an operating system on a host is the identity that the system finds most likely to be correct.

The system uses the current identity for an operating system or application for the following purposes:

- to assign vulnerabilities to a host
- for impact assessment
- when evaluating correlation rules written against operating system identifications, host profile qualifications, and compliance white lists
- for display in the Hosts and Servers table views in workflows
- for display in the host profile
- to calculate the operating system and application statistics on the Discovery Statistics page

The system uses source priorities to determine which active identity should be used as the current identity for an application or operating system.



For example, if a user sets the operating system to Windows 2003 Server on a host, Windows 2003 Server is the current identity. Attacks which target Windows 2003 Server vulnerabilities on that host are given a higher impact, and the vulnerabilities listed for that host in the host profile include Windows 2003 Server vulnerabilities.

The database may retain information from several sources for the operating system or for a particular application on a host.

The system treats an operating system or application identity as the current identity when the source for the data has the highest source priority. Possible sources have the following priority order:

1. user
2. scanner and application (set in the network discovery policy)
3. managed devices
4. NetFlow

Note that a new higher priority application identity will not override a current application identity if it has less detail than the current identity.

In addition, note that when an identity conflict occurs, the resolution of the conflict depends on settings in the network discovery policy or on your manual resolution, as described in Understanding Identity Conflicts on page 1719.

Understanding Identity Conflicts

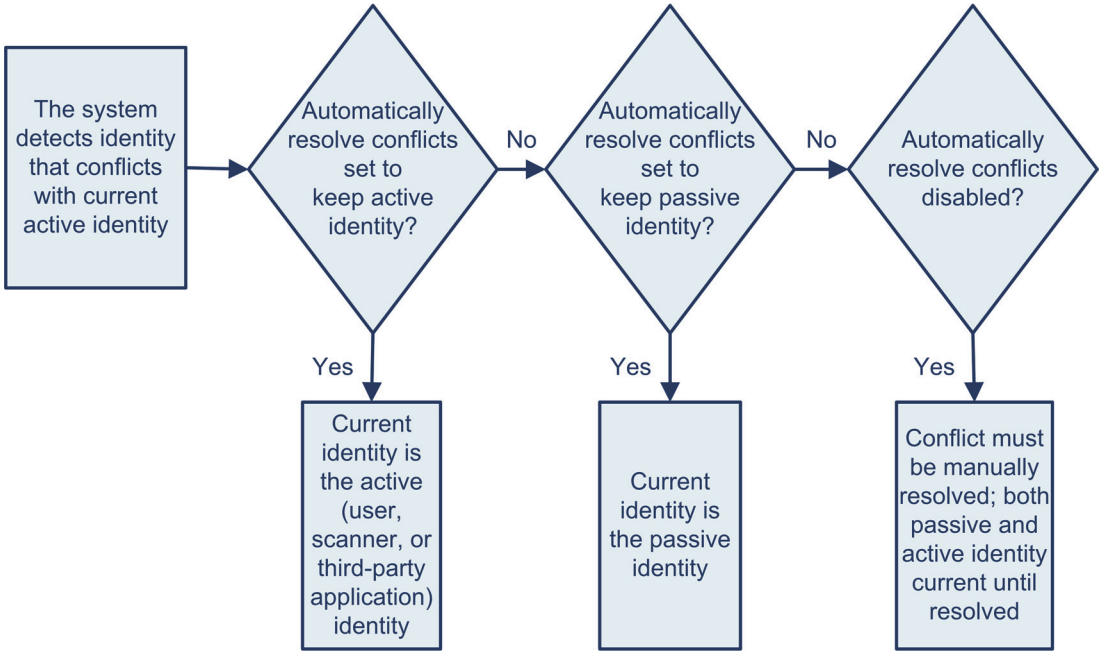
LICENSE: FireSIGHT

An *identity conflict* occurs when the system reports a new passive identity that conflicts with the current active identity and previously reported passive identities. For example, the previous passive identity for an operating system is reported as Windows 2000, then an active identity of Windows XP becomes current. Next, the system detects a new passive identity of Ubuntu Linux 8.04.1. The Windows XP and the Ubuntu Linux identities are in conflict.

When an identity conflict exists for the identity of the host's operating system or one of the applications on the host, the system lists both conflicting identities as current and uses both for impact assessment until the conflict is resolved.

A user with Administrator privileges can resolve identity conflicts automatically by choosing to always use the passive identity or always use the active identity.

Unless you disable automatic resolution of identity conflicts, identity conflicts are always automatically resolved.



A user with Administrator privileges can also configure the system to generate an event when an identity conflict occurs. That user can then set up a correlation policy with a correlation rule that uses an Nmap scan as a correlation response. When an event occurs, Nmap scans the host to obtain updated host operating system and application data.

Using Custom Fingerprinting

LICENSE: FireSIGHT

The Sourcefire 3D System includes operating system *fingerprints* that the system uses to identify the operating system on each host it detects. However, sometimes the system cannot identify a host operating system or misidentifies it because no fingerprints exist that match the operating system. To correct this problem, you can create a *custom fingerprint,* which provides a pattern of operating system characteristics unique to the unknown or misidentified operating system, to supply the name of the operating system for identification purposes.

If the system cannot match a host's operating system, it cannot identify the vulnerabilities for the host, because the system derives the list of vulnerabilities for each host from its operating system fingerprint. For example, if the system detects a host running Microsoft Windows, the system has a stored Microsoft Windows vulnerability list that it adds to the host profile for that host based on the detected Windows operating system.

As an example, if you have several devices on your network running a new beta version of Microsoft Windows, the system cannot identify that operating system and so cannot map vulnerabilities to the hosts. However, knowing that the system has a list of vulnerabilities for Microsoft Windows, you may want to create a custom fingerprint for one of the hosts that can then be used to identify the other hosts running the same operating system. You can include a mapping of the vulnerability list for Microsoft Windows in the fingerprint to associate that list with each host that matches the fingerprint.

When you create a custom fingerprint, you can add a customized display of operating system information, and you can select the operating system vendor, product name, and product version for the operating system which the system should use as a model for the vulnerability list for the fingerprint. The Defense Center lists the set of vulnerabilities associated with that fingerprint for any hosts running the same operating system. If the custom fingerprint you create does not have any vulnerabilities mappings in it, the system uses the fingerprint to assign the custom operating system information you provide in the fingerprint. When the system sees new traffic from a host that has already been detected and currently resides in the network map, the system updates the host with the new fingerprint information. the system also uses the new fingerprint to identify any new hosts with that operating system the first time they are detected.

Before attempting to fingerprint a host, you should determine why the host is not being identified correctly to decide whether custom fingerprinting is a viable solution. For more information, see Assessing Your Detection Strategy on page 1713.

You can create two types of fingerprints with the system:

- Client fingerprints, which identify operating systems based on the SYN packet that the host sends when it connects to a TCP application running on another host on the network.

  See Fingerprinting Clients on page 1722 for information about how to obtain a client fingerprint for a host.

- Server fingerprints, which identify operating systems based on the SYN-ACK packet that the host uses to respond to an incoming connection to a running TCP application.

  See Fingerprinting Servers on page 1727 for information about how to obtain a server fingerprint for a host.

After creating fingerprints, you must activate them before the system can associate them with hosts. See Managing Fingerprints on page 1732 for more information.

IMPORTANT! If both a client and server fingerprint match the same host, the client fingerprint is used.

Fingerprinting Clients

LICENSE: FireSIGHT

Client fingerprints identify operating systems based on the SYN packet a host sends when it connects to a TCP application running on another host on the network.

If the Defense Center does not have direct contact with monitored hosts, you can specify a device that is managed by the Defense Center and is closest to the host you intend to fingerprint when specifying client fingerprint properties.

Before you begin the fingerprinting process, obtain the following information about the host you want to fingerprint:

- The number of network hops between the host and the Defense Center or the device you use to obtain the fingerprint. (Sourcefire strongly recommends that you directly connect the Defense Center or the device to the same subnet that the host is connected to.)
- The network interface (on the Defense Center or the device) that is connected to the network where the host resides.
- The actual operating system vendor, product, and version of the host.
- Access to the host in order to generate client traffic.

To obtain a client fingerprint for a host:

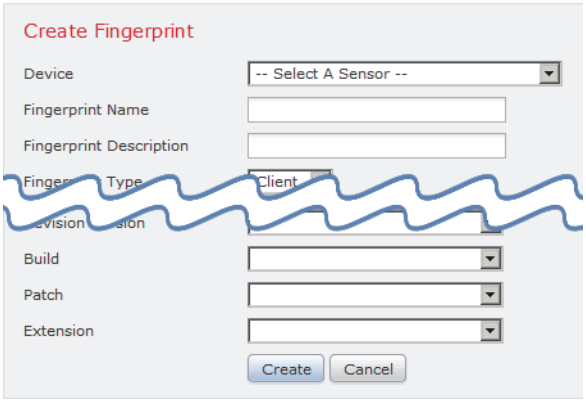
ACCESS: Admin/Discovery Admin

1. Select **Policies** > **Network Discovery**, then click **Custom Operating Systems**.

   The Custom Fingerprint page appears.

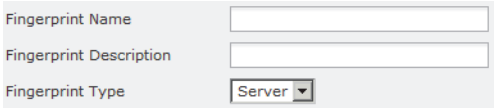
2. Click **Create Fingerprint**.

   The Create Fingerprint page appears.



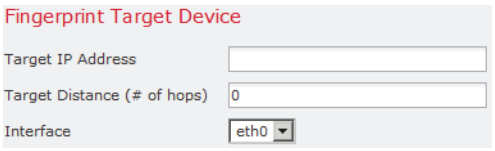
3. From the **Device** drop-down list, select the Defense Center or the device that you want to use to collect the fingerprint.

4. In the **Fingerprint Name** field, type an identifying name for the fingerprint.



5. In the **Fingerprint Description** field, type a description for the fingerprint.
6. From the **Fingerprint Type** list, select **Client**.
7. In the **Target IP Address** field, type an IP address of the host you want to fingerprint. Note that the fingerprint will only be based on traffic to and from the host IP address you specify, not any of the host's other IP addresses (if it has any).

WARNING! You can capture IPv6 fingerprints only with appliances running Version 5.2 and later of the Sourcefire 3D System. These appliances must have IPv6 capability enabled. For information on enabling IPv6 on managed devices and Defense Centers, see Configuring Network Settings on page 2088.



8. In the **Target Distance** field, enter the number of network hops between the host and the device that you selected in step 3 to collect the fingerprint.

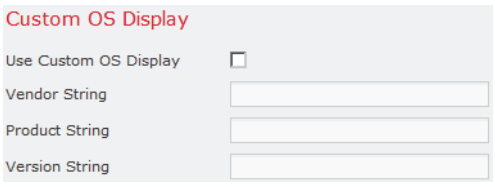
   WARNING! This must be the actual number of physical network hops to the host, which may or may not be the same as the number of hops detected by the system.

9. From the **Interface** list, select the network interface that is connected to the network segment where the host resides.

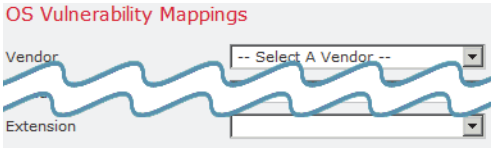
   WARNING! Sourcefire recommends that you do **not** use the sensing interface on a managed device for fingerprinting for several reasons. First, fingerprinting does not work if the sensing interface is on a span port. Also, if you use the sensing interface on a device, the device stops monitoring the network for the amount of time it takes to collect the fingerprint. You can, however, use the management interface or any other available network interfaces to perform fingerprint collection. If you do not know which interface is the sensing interface on your device, refer to the *Installation Guide* for the specific model you are using to fingerprint.

10. If you want to display custom information in the host profile for fingerprinted hosts (or if the host you want to fingerprint does not reside in the OS Vulnerability Mappings section), select **Use Custom OS Display** in the Custom OS Display section and provide the values you want to display in host profiles for the following:

    - In the **Vendor String** field, type the operating system's vendor name. For example, the vendor for Microsoft Windows would be Microsoft.
    - In the **Product String** field, type the operating system's product name. For example, the product name for Microsoft Windows 2000 would be Windows.
    - In the **Version String** field, type the operating system's version number. For example, the version number for Microsoft Windows 2000 would be 2000.



11. In the OS Vulnerability Mappings section, select the operating system, product, and versions you want to use for vulnerability mapping.



For example, if you want your custom fingerprint to assign the list of vulnerabilities from Redhat Linux 9 to matching hosts, select **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the major version.

TIP! When creating a fingerprint, you assign a single vulnerability mapping for the fingerprint. After the fingerprint is created and activated, you can add additional vulnerability mappings for other versions of the operating system. See Editing an Active Fingerprint on page 1735 for more information.

You must specify a Vendor and Product name in this section if you want to use the fingerprint to identify vulnerabilities for matching hosts or if you do not assign custom operating system display information. To map vulnerabilities for all versions of an operating system, specify only the vendor and product name. For example, to add all versions of the Palm OS, you would select **PalmSource, Inc.** from the **Vendor** list, **Palm OS** from the **Product** list, and leave all other lists at their default settings.

IMPORTANT! Not all options in the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** drop-down lists may apply to the operating system you choose. In addition, if no definition appears in a list that matches the operating system you want to fingerprint, you can leave these values empty. Be aware that if you do not create any OS vulnerability mappings in a fingerprint, the system cannot use the fingerprint to assign a vulnerabilities list with hosts identified by the fingerprint.

12. Click **Create**.

    The Custom Fingerprint status page reappears. The status page refreshes every ten seconds until it receives data from the host in question.

    TIP! When you click **Create**, the status briefly shows `New`, then switches to `Pending`, where it remains until traffic is seen for the fingerprint, then the status switches to `Ready`.

13. Using the IP address you specified as the target IP address, access the host you are trying to fingerprint and initiate a TCP connection to the appliance.

    For example, access the web interface of the Defense Center from the host you want to fingerprint or SSH into the Defense Center from the host. If you are using SSH, use the following command:

    `ssh -b` *`localIPv6address DCmanagementIPv6address`*

    where *`localIPv6address`* is the IPv6 address specified in step 7 that is currently assigned to the host and *`DCmanagementIPv6address`* is the management IPv6 address of the Defense Center.

    The Custom Fingerprint page should then reload with a "Ready" status.

    IMPORTANT! To create an accurate fingerprint, traffic **must** be seen by the appliance collecting the fingerprint. If you are connected through a switch, traffic to a system other than the appliance may not be seen by the system.

14. After the fingerprint is created, you must activate it before the Defense Center can use it to identify hosts. See Managing Fingerprints on page 1732 for more information.

Fingerprinting Servers

LICENSE: FireSIGHT

Server fingerprints identify operating systems based on the SYN-ACK packet that the host uses to respond to an incoming connection to a running TCP application. Before you begin, you should obtain the following information about the host you want to fingerprint:

- The number of network hops between the host and the appliance you use to obtain the fingerprint. Sourcefire strongly recommends that you directly connect an unused interface on the appliance to the same subnet that the host is connected to.
- The network interface (on the appliance) that is connected to the network where the host resides.
- The actual operating system vendor, product, and version of the host.
- An IP address that is not currently in use and is authorized on the network where the host is located.

TIP! If the Defense Center does not have direct contact with monitored hosts, you can specify a managed device that is closest to the host you intend to fingerprint when specifying server fingerprint properties.

To obtain a server fingerprint for a host:

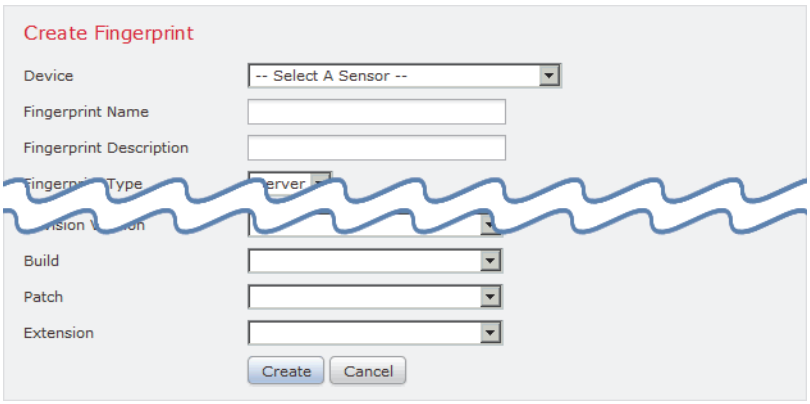
ACCESS: Admin/Discovery Admin

1. Select **Policies** > **Network Discovery,** then click **Custom Operating Systems**.

   The Custom Fingerprint page appears.

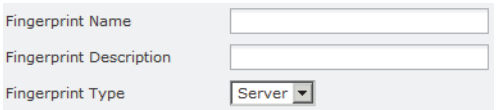
2. Click **Create Fingerprint**.

   The Create Fingerprint page appears.



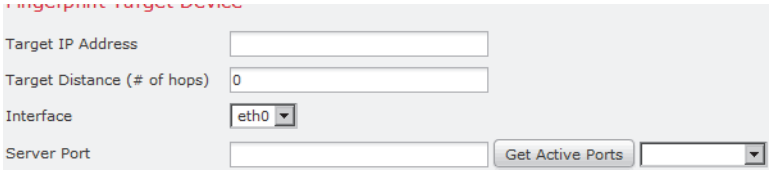
3. From the **Device** list, select the Defense Center or the managed device that you want to use to collect the fingerprint.

4. In the **Fingerprint Name** field, type an identifying name for the fingerprint.



5. In the **Fingerprint Description** field, type a description for the fingerprint.
6. From the **Fingerprint Type** list, select **Server**.

   Server fingerprinting options appear.



7. In the **Target IP Address** field, type an IP address of the host you want to fingerprint. Note that the fingerprint will only be based on traffic to and from the host IP address you specify, not any of the host's other IP addresses (if it has any).

WARNING! You can capture IPv6 fingerprints only with appliances running Version 5.2 and later of the Sourcefire 3D System.

8. In the **Target Distance** field, enter the number of network hops between the host and the device that you selected in step 3 to collect the fingerprint.

   WARNING! This must be the actual number of physical network hops to the host, which may or may not be the same as the number of hops detected by the system.

9. From the **Interface** list, select the network interface that is connected to the network segment where the host resides.

   WARNING! Sourcefire recommends that you do **not** use the sensing interface on a managed device for fingerprinting for several reasons. First, fingerprinting does not work if the sensing interface is on a span port. Also, if you use the sensing interface on a device, the device stops monitoring the network for the amount of time it takes to collect the fingerprint. You can, however, use the management interface or any other available network interfaces to perform fingerprint collection. If you do not know which interface is the sensing interface on your device, refer to the *Installation Guide* for the specific model you are using to fingerprint.

10. Click **Get Active Ports**.

    If the system has detected any open ports on the host, they appear in the drop-down list.

11. In the **Server Port** field, type the port that you want the device selected to collect the fingerprint to initiate contact with, or select a port from the **Get Active Ports** drop-down list.

    You can use any server port that you know is open on the host (for instance, 80 if the host is running a web server).

12. In the **Source IP Address** field, type an IP address that should be used to attempt to communicate with the host.

You should use a source IP address that is authorized for use on the network but is not currently being used, for example, a DHCP pool address that is currently not in use. This prevents you from temporarily knocking another host offline while you create the fingerprint.

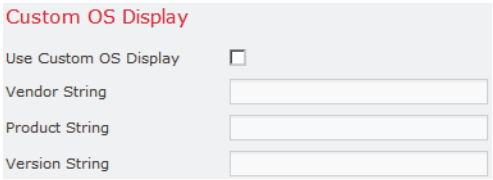
In addition, you should exclude that IP address from monitoring in your network discovery policy while you create the fingerprint. Otherwise, the network map and discovery event views will be cluttered with inaccurate information about the host represented by that IP address. For more information, see Understanding Discovery Data Collection on page 1304.

13. In the **Source Subnet Mask** field, type the subnet mask for the IP address you are using.

14. If the **Source Gateway** field appears, enter the default gateway IP address that should be used to establish a route to the host.

The **Source Gateway** field appears if the target distance (number of hops) is 1 or higher and you are using an interface other than the management interface to connect to the network where the host resides.

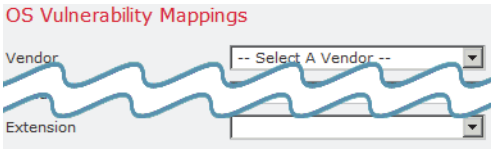
15. If you want to display custom information in the host profile for fingerprinted hosts or if the fingerprint name you want to use does not exist in the OS Definition section, select **Use Custom OS Display** in the Custom OS Display section.



Provide the values you want to appear in host profiles for the following:

- In the **Vendor String** field, type the operating system's vendor name. For example, the vendor for Microsoft Windows would be Microsoft.
- In the **Product String** field, type the operating system's product name. For example, the product name for Microsoft Windows 2000 would be Windows.
- In the **Version String** field, type the operating system's version number. For example, the version number for Microsoft Windows 2000 would be 2000.

16. In the OS Vulnerability Mappings section, select the operating system, product, and versions you want to use for vulnerability mapping. For example, if you want your custom fingerprint to assign the list of vulnerabilities from Redhat Linux 9 to matching hosts, select **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.



TIP! When creating a fingerprint, you assign a single vulnerability mapping for the fingerprint. After the fingerprint is created and activated, you can add additional vulnerability mappings for other versions of the operating system. See Editing an Active Fingerprint on page 1735 for more information.

You must specify a Vendor and Product name in this section if you want to use the fingerprint to identify vulnerabilities for matching hosts or if you do not assign custom operating system display information. To map vulnerabilities for all versions of an operating system, specify only the vendor and product name. For example, to add all versions of the Palm OS, you would select **PalmSource, Inc.** from the **Vendor** list, **Palm OS** from the **Product** list, and leave all other lists at their default settings.

IMPORTANT! Not all options in the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** drop-down lists may apply to the operating system you choose. In addition, if no definition appears in a list that matches the operating system you want to fingerprint, you can leave these values empty. Be aware that if you do not create any OS vulnerability mappings in a fingerprint, the system cannot use the fingerprint to assign a vulnerabilities list with hosts identified by the fingerprint.

17. Click **Create**.
18. The Custom Fingerprint status page appears. It reloads every ten seconds and should reload with a "Ready" status.

IMPORTANT! If the target system stops responding during the fingerprinting process, the status shows an `ERROR: No Response` message. If you see this message, submit the fingerprint again. Wait three to five minutes (the time period may vary depending on the target system), click the edit icon ( ) to access the Custom Fingerprint page, and then click **Create**.

19. After the fingerprint is created, activate it and, optionally, add vulnerability mappings. See Managing Fingerprints on page 1732 for more information.

Managing Fingerprints

LICENSE: FireSIGHT

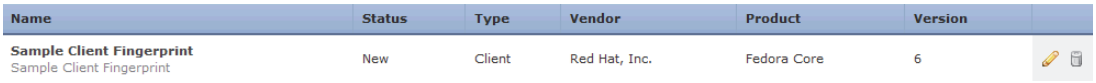
You can activate, deactivate, delete, view, and edit custom fingerprints. When creating a fingerprint, you assign a single vulnerability mapping for the fingerprint. For more information on creating a fingerprint, see Fingerprinting Clients on page 1722 and Fingerprinting Servers on page 1727. After the fingerprint is created and activated, you can edit the fingerprint to make changes or add vulnerability mappings.

To access the Custom Fingerprints page:

ACCESS: Admin/Discovery Admin

▶ Select **Policies** > **Network Discovery**, then click **Custom Operating Systems**.

The Custom Fingerprint page appears.



If the system is awaiting data to create a fingerprint, it automatically refreshes the page every 10 seconds until the fingerprint is created.

See the following sections for more information:

- Activating Fingerprints on page 1732
- Deactivating Fingerprints on page 1733
- Deleting Fingerprints on page 1733
- Editing Fingerprints on page 1734

Activating Fingerprints

LICENSE: FireSIGHT

After creating a custom fingerprint, you must activate it before the system can use it to identify hosts. After the new fingerprint is activated, the system uses it to re-identify previously discovered hosts and discover new hosts.

To activate a fingerprint:

ACCESS: Admin/Discovery Admin

1. Select **Policies** > **Network Discovery**, then click **Custom Operating Systems**.

   The Custom Fingerprint page appears.

2. Click the slider next to the fingerprint you want to activate.

IMPORTANT! The activate option is only available if the fingerprint you created is valid. If the slider is not available, try creating the fingerprint again.

The Defense Center activates the fingerprint and propagates it to all managed devices. The icon next to the fingerprint name changes to indicate that the fingerprint is active.

Deactivating Fingerprints

LICENSE: FireSIGHT

If you want to stop using a fingerprint, you can deactivate it. Deactivating a fingerprint causes a fingerprint to no longer be used, but allows it to remain on the system. When you deactivate a fingerprint, the operating system is marked as unknown for hosts that use the fingerprint. If the hosts are detected again and match a different active fingerprint, they are then identified by that active fingerprint.

Deleting a fingerprint removes it from the system completely. After deactivating a fingerprint, you can delete it.

To deactivate an active fingerprint:

ACCESS: Admin/Discovery Admin

1. Select **Policies** > **Network Discovery**, then click **Custom Operating Systems**.

   The Custom Fingerprint page appears.

2. Click the slider next to the active fingerprint you want to deactivate.

   The Defense Center deactivates the fingerprint and propagates the deactivation to all managed devices.

Deleting Fingerprints

LICENSE: FireSIGHT

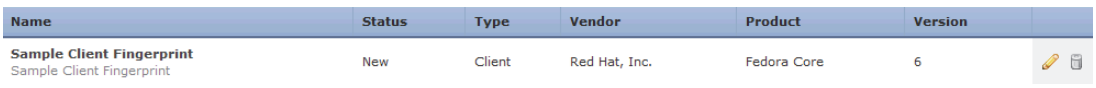
If you no longer have use for a fingerprint, you can delete it from the system. Note that you must deactivate fingerprints before you can delete them.

To delete a fingerprint:

ACCESS: Admin/Discovery Admin

1. Select **Policies** > **Network Discovery**, then click **Custom Operating Systems**.

   The Custom Fingerprint page appears.



2. If the fingerprints you want to delete are active, click the slider icon next to each one to deactivate it.
3. Click the delete icon ( ) next to the fingerprint you want to delete.
4. Click **OK** to confirm that you want to delete the fingerprint.

   The fingerprint is deleted.

Editing Fingerprints

License: FireSIGHT

After you create a fingerprint, you can view or edit it. This allows you to make changes and resubmit the fingerprint or add additional vulnerability mappings to it. You can modify fingerprints whether they are active or inactive, but depending on a fingerprint's state, the things that can be modified differ.

If a fingerprint is *inactive*, you can modify all elements of the fingerprint and resubmit it to the Defense Center. This includes all properties you specified when creating the fingerprint, such as fingerprint type, target IP addresses and ports, vulnerability mappings, and so on. When you edit an inactive fingerprint and submit it, it is resubmitted to the system and, if it is a client fingerprint, you must resend traffic to the appliance before activating it. Note that you can select only a single vulnerability mapping for an inactive fingerprint. After you activate the fingerprint, you can map additional operating systems and versions to its vulnerabilities list.

If a fingerprint is *active*, you can modify the fingerprint name, description, custom operating system display, and map additional vulnerabilities to it.

For more information, see the following sections:

- Editing an Inactive Fingerprint on page 1734
- Editing an Active Fingerprint on page 1735

Editing an Inactive Fingerprint

License: FireSIGHT

If a fingerprint is inactive, you can modify its properties and resubmit it to the system. This includes making changes such as the type of fingerprint to use, the target system to fingerprint, and so on.

To edit inactive fingerprints:

Access: Admin/Discovery Admin

1. Select **Policies** > **Network Discovery**, then click **Custom Operating Systems**.

   The Custom Fingerprint page appears.
2. Click the edit icon ( ) next to the fingerprint you want to edit.

   The Edit Custom Fingerprint page appears.

3. Make changes to the fingerprint as necessary:
   - If you are modifying a client fingerprint, see Fingerprinting Clients on page 1722 for more information about the options you can configure.
   - If you are modifying a server fingerprint, see Fingerprinting Servers on page 1727 for more information about the options you can configure.
4. Click **Save** to resubmit the fingerprint.

IMPORTANT! If you modified a client fingerprint, remember to send traffic from the host to the appliance gathering the fingerprint.

Editing an Active Fingerprint

LICENSE: FireSIGHT

When a fingerprint is active, you can change its name, description, and display label. In addition, you can manage vulnerability mappings, including adding and deleting vulnerability mappings.

To edit active fingerprints:

ACCESS: Admin/Discovery Admin

1. Select **Policies** > **Network Discovery**, then click **Custom Operating Systems**.

   The Custom Fingerprint page appears.
2. Click the edit icon ( ) next to the fingerprint you want to edit.

   The Edit Custom Fingerprint Product Mappings page appears.
3. Modify the fingerprint name, description, and custom OS display, if necessary.
4. If you want to delete a vulnerability mapping, click **Delete** next to the mapping in the Pre-Defined OS Product Maps section of the page.
5. If you want to add additional operating systems for vulnerability mapping, select the **Product** and, if applicable, the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** and then click **Add OS Definition**.

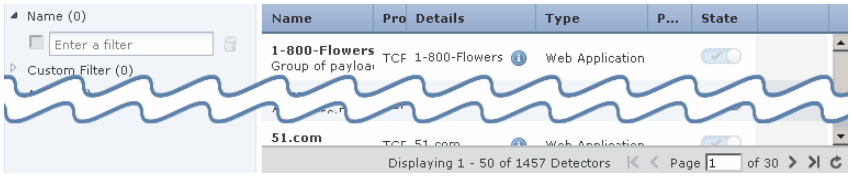
   The vulnerability mapping is added to the Pre-Defined OS Product Maps list.
6. Click **Save** to save your changes.

Working with Application Detectors

LICENSE: FireSIGHT

When the Sourcefire 3D System analyzes IP traffic, it uses detectors to identify the commonly used applications on your network. You use the Detectors page

(**Policies > Application Detectors**) to customize the detection capability of the Sourcefire 3D System.



The page provides information about each detector, including:

- the name of the detector
- the protocol (TCP, UDP, or both) of traffic that the detector inspects
- whether the type of the detector is application protocol, client, web application, or internal detector
- for port-based application detectors, the port used by the application traffic
- details regarding the detected application, including the name, description, risk, business relevance, tags, and categories associated with the application detected by the detector
- the state (active or inactive) of the detector

The system uses only active detectors to analyze application traffic.

You may notice that the listed detectors have different properties. For example, you can view the settings for some detectors but not others. Similarly, you can delete some detectors but not others. This is because there are several different types of Sourcefire-provided detectors, as described in the following sections.

Sourcefire-Provided Internal Detectors

Internal detectors are application detectors that are only delivered with updates to the Sourcefire 3D System. Internal detectors detect client, web application, or application protocol traffic, depending on the detector, but they are categorized as internal detectors rather than one of the other types because they are built-in detectors and cannot be deactivated.

Internal detectors are always on; you cannot deactivate, delete, or otherwise configure them. Examples of internal detectors are the Built-in Amazon detector and the Built-in AppleTalk detector.

Sourcefire-Provided Client Detectors

Sourcefire-provided *client detectors*, which detect client traffic, are delivered via VDB updates but may also be provided with updates to the Sourcefire 3D System. These detectors may also be provided by Sourcefire Professional Services as an importable detector.

You can activate and deactivate client detectors according to the needs of your organization. VDB updates may also activate or deactivate client detectors. You can export a client detector only if you import it.

The Google Earth and Immunet detectors are examples of client detectors.

Sourcefire-Provided Web Application Detectors

Sourcefire-provided *web application detectors*, which detect web applications in payloads of HTTP traffic, are delivered via VDB updates but may also be provided with updates to the Sourcefire 3D System.

You can activate and deactivate web application detectors according to the needs of your organization. VDB updates may activate or deactivate web application detectors. Examples of web application detectors are the Blackboard and LiveJournal detectors.

Sourcefire-Provided Application Protocol (Port) Detectors

Port-based application protocol detectors, provided by Sourcefire, are based on detection of network traffic on well-known ports. These detectors are delivered via VDB updates but may also be provided with updates to the Sourcefire 3D System or provided by Sourcefire Professional Services as an importable detector.

You can activate and deactivate application protocol detectors according to the needs of your organization. You can also view a detector definition to use it as the basis for a custom detector. VDB updates may activate or deactivate application protocol detectors.

The chargen and finger detectors are examples of port detectors.

Sourcefire-Provided Application Protocol (FireSIGHT) Detectors

FireSIGHT-based application protocol detectors, provided by Sourcefire, are based on detection of network traffic using FireSIGHT application fingerprints. These detectors are delivered via VDB updates but may also be provided with updates to the Sourcefire 3D System.

You can activate and deactivate application protocol detectors according to the needs of your organization. VDB updates may activate or deactivate Sourcefire-provided application protocol detectors. Examples of FireSIGHT-based application protocol detectors are the Jabber and Steam detectors.

Application Protocol (Pattern) Detectors

Pattern-based application detectors are based on detection of patterns in packets from network traffic. These detectors can be provided by Sourcefire Professional Services as an importable detector or created by you. This allows you to enhance the system's detection capabilities with new pattern-based detectors without updating the Sourcefire 3D System as a whole.

You can activate and deactivate application protocol detectors according to the needs of your organization.

You have full control over imported and user-defined detectors; you can activate, deactivate, edit, import, export, and delete them. An example of a pattern-based detector is a user-defined detector using a pattern in the packet header to detect traffic for a custom application.

Keep in mind that the detector list may change depending on the version of the Sourcefire 3D System and the VDB you have installed, as well as on any individual detectors you may have imported or created. You should carefully read the release notes for each Sourcefire 3D System update as well as the advisories for each VDB update for information on updated detectors.

For more information, see:

- Understanding Application Detection on page 1316
- Creating a User-Defined Application Protocol Detector on page 1738
- Managing Detectors on page 1745

Creating a User-Defined Application Protocol Detector

LICENSE: FireSIGHT

If you use custom applications on your network, you can create user-defined application protocol detectors that provide the system with the information it needs to identify those applications. You can base application protocol detection on the port or ports used by application traffic, patterns within the traffic, or on both ports and patterns.

For example, if you expect traffic for a custom application protocol to use port 1180, you can create an application protocol detector that detects traffic on that port. As another example, if you know that the header for any packet containing application protocol traffic has a string of `ApplicationName` in it, you can create a detector that registers the ASCII string of `ApplicationName` as a pattern to match.

You can only create user-defined application detectors for application protocols, not for clients or for web applications. Note that client sessions must include a response from the server for application detection to occur.

WARNING! When you create and activate a new application detector, a short pause in traffic flow and processing may occur on your managed devices, which may also cause a few packets to pass uninspected.

User-defined application protocol detectors must use either a port or a pattern match; you cannot create a detector that uses neither, even if you base the detector on an existing detector. You can also create a detector that uses both

criteria; this increases the likelihood of correctly identifying traffic for that application protocol.

TIP! If you have already created a detector on another Defense Center, you can export it and then import it onto this Defense Center. You can then edit the imported detector to suit your needs. You can export and import user-defined detectors as well as detectors provided by Sourcefire Professional Services. However, you **cannot** export or import any other type of Sourcefire-provided detectors. For more information, see Importing and Exporting Configurations on page 2308.

To create a user-defined application protocol detector:

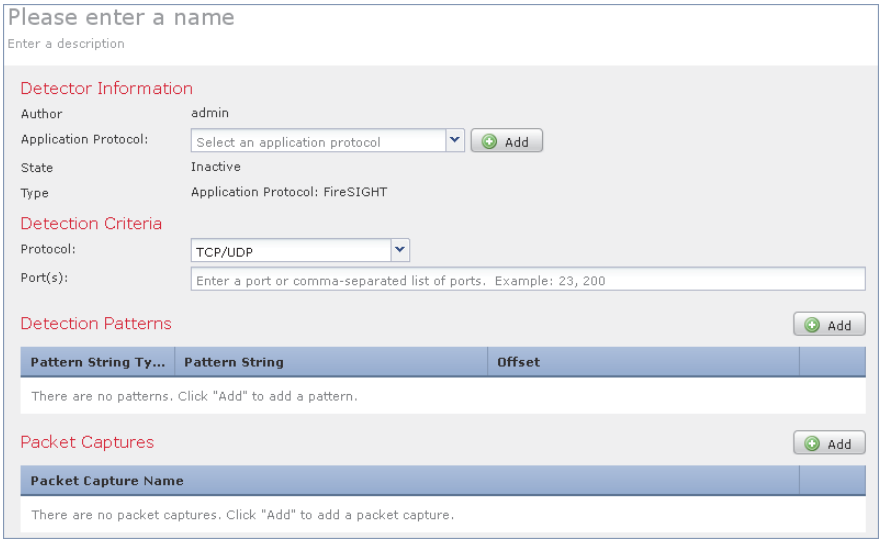
Access: Admin/Discovery Admin

1. Select **Policies > Application Detectors**.

   The Detectors page appears.

2. Click **Create Detector**.

   The Create Detector page appears.



3. Provide basic detector information, such as the detector name and description.

   See Providing Basic Application Protocol Detector Information on page 1740.

4. Optionally, create a user-defined application for the detector.

   See Creating a User-Defined Application on page 1741.

5. Provide detection criteria, including the protocol of traffic the detector should inspect and the port that the traffic uses.

   See Specifying Detection Criteria for Application Protocol Detectors on page 1742.

6. Optionally, configure the detector to inspect traffic for matches to one or more patterns that occurs in traffic for that application protocol.

   See Adding Detection Patterns to an Application Protocol Detector on page 1743.

7. Optionally, test the new detector against the contents of one or more PCAP files.

   See Testing an Application Protocol Detector Against Packet Captures on page 1745.

8. Click **Save**.

   The application protocol detector is saved.

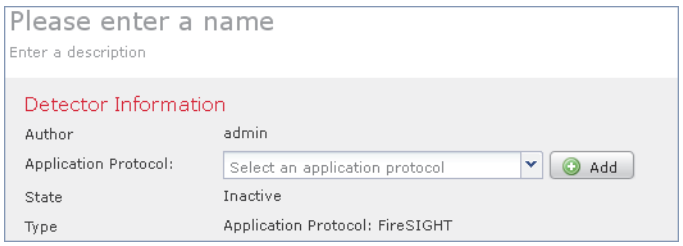
IMPORTANT! You must activate the detector before the system can use it to analyze application protocol traffic. For more information, see Activating and Deactivating Detectors on page 1750. Note that if you include the application in an access control rule, the detector is automatically activated and cannot be deactivated while in use.

Providing Basic Application Protocol Detector Information

LICENSE: FireSIGHT

You must give each user-defined application protocol detector a name, as well as identify the application protocol you want to detect. Optionally, you can provide a brief description of the detector.

In addition to the information you provide, the Defense Center indicates whether the detector is active or inactive, and whether the detector is a port or pattern detector. If a detector identifies application protocol traffic by port and pattern, the Sourcefire 3D System considers it a pattern detector.



If you are editing an existing detector, the Defense Center also displays the detector's author. If you created a user-defined application protocol detector, you are the author. You are also the author for any detector that you import or that you edit and save.

To provide basic application protocol detector information:

ACCESS: Admin/Discovery Admin

1. On the Create Detector page, in the **Please enter a name** field, type a name for the detector.

   Detector names must be unique within the protocol for the traffic you are inspecting. That is, you can create a TCP detector and a UDP detector with the same name, but you cannot create two TCP detectors with the same name.

2. Identify the application protocol you want to detect. You have the following options:

   - If you are creating a detector for an existing application protocol (for example, if you want to detect a particular application protocol on a non-standard port), select the application protocol from the **Application Protocol** drop-down list. Continue with the procedure in Specifying Detection Criteria for Application Protocol Detectors on page 1742.
   - If you are creating a detector for a custom application, continue with the procedure in the next section, Creating a User-Defined Application.

Creating a User-Defined Application

LICENSE: FireSIGHT

You can create a user-defined application to identify a custom application on your network. You can also create custom categories and custom tags to describe the application. Applications, categories, and tags created here are available in access control rules and in the application filter object manager as well.

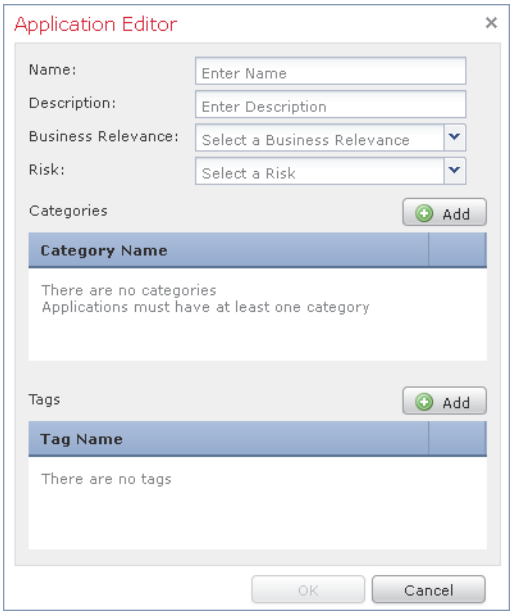
For more information on application detection, including a discussion of application protocols and the categories, tags, risk levels, and business relevance used to describe them, see Understanding Application Detection on page 1316.

To create a user-defined application:

Access: Admin/Discovery Admin

1. On the Create Detector page, click **Add**.

   The Application Editor pop-up window appears.



2. Type a **Name** for the custom application.
3. Type a **Description** for the custom application.
4. Select a **Business Relevance**.
5. Select a **Risk**.
6. Click **Add** next to Categories to add a category and type a new category name or select an existing category from the **Categories** drop-down list.
7. Optionally, click **Add** next to Tags to add a tag and type a new tag name or select an existing tag from the **Tags** drop-down list.

   Click **OK** to return to the Create Detector page.
8. Continue with the procedure in the next section, Specifying Detection Criteria for Application Protocol Detectors.

Specifying Detection Criteria for Application Protocol Detectors

License: FireSIGHT

When creating a user-defined application protocol detector, you must specify the protocol of traffic (TCP, UDP, or both) the detector should inspect. Optionally, you can specify a port that the traffic uses.

Note that if you do not specify a port, you must configure the detector to inspect traffic for matches to one or more patterns, as described in Adding Detection Patterns to an Application Protocol Detector on page 1743.

To specify detection criteria for an application protocol detector:

Access: Admin/Discovery Admin

1. On the Create Detector page, from the **Protocol** drop-down list, select the protocol for traffic the detector should inspect.

   Detectors can inspect TCP, UDP, or TCP and UDP traffic.

2. Optionally, to identify application protocol traffic based on the port it uses, type a port from 1 to 65535 in the **Port(s)** field. To use multiple ports, separate them by commas.

3. You have the following options:

   - If you want to configure the application protocol detector to inspect traffic for matches to one or more patterns that occurs in traffic for that application protocol, continue with the procedure in the next section, Adding Detection Patterns to an Application Protocol Detector.
   - If you want to test the new detector against the contents of one or more PCAP files, skip to Testing an Application Protocol Detector Against Packet Captures on page 1745.
   - If you are done creating the detector, click **Save**.

     The application protocol detector is saved.

   Note that you must activate the detector before the system can use it to analyze application protocol traffic. For more information, see Activating and Deactivating Detectors on page 1750.

Adding Detection Patterns to an Application Protocol Detector

License: FireSIGHT

If you know that the header for any packet containing application protocol traffic contains a particular pattern string, you can configure a user-defined application protocol detector to search for that pattern.

Application protocol detectors can search for ASCII or hexadecimal patterns, using any offset. You can also configure detectors to search for multiple patterns; in that case the application protocol traffic must match all of the patterns for the detector to positively identify the application protocol.

Note that if you do not specify a pattern, you must configure the detector to inspect traffic that uses one or more ports, as described in Specifying Detection Criteria for Application Protocol Detectors on page 1742.

To add a detection pattern to an application protocol detector:

Access: Admin/Discovery Admin

1. On the Create Detector page, in the **Detection Patterns** section, click **Add**.

   The Add Pattern pop-up window appears.

2. Specify the pattern type you want to detect: **Ascii** or **Hex**.
3. Type a string of the type you specified in the **Pattern String** field.
4. Optionally, specify where in a packet the system should begin searching for the pattern; this is called the offset.

   Type the offset (in bytes from the beginning of the packet payload) in the **Offset** field.

   Because packet payloads start at byte 0, calculate the offset by subtracting 1 from the number of bytes you want to move forward from the beginning of the packet payload. For example, to look for the pattern in the fifth bit of the packet, type 4 in the **Offset** field.
5. Optionally, repeat steps 1 to 4 to add additional patterns.

TIP! To delete a pattern, click the delete icon ( ) next to the pattern you want to delete.

6. You have the following options:
   - If you want to test the new detector against the contents of one or more PCAP files, continue with the procedure in the next section, Testing an Application Protocol Detector Against Packet Captures.
   - If you are done creating the detector, click **Save**.

     The application protocol detector is saved.

IMPORTANT! You must activate the detector before the system can use it to analyze application protocol traffic. For more information, see Activating and Deactivating Detectors on page 1750.

Testing an Application Protocol Detector Against Packet Captures

License: FireSIGHT

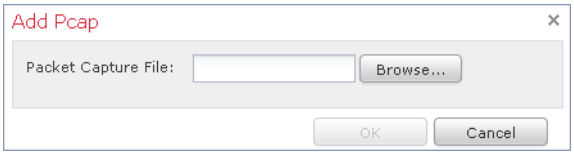
If you have a packet capture (PCAP) file that contains packets with traffic from the application protocol you want to detect, you can test a user-defined application protocol detector against that PCAP file. Note that PCAP files must be 32KB or smaller; if you try to test your detector against a larger PCAP file, the Defense Center automatically truncates it.

To test an application protocol detector against a PCAP file:

Access: Admin/Discovery Admin

1. On the Create Detector page, in the **Packet Captures** section, click **Add**.

   A pop-up window appears.



2. Browse to the PCAP file and click **OK**.

   The PCAP file appears in the Packet Captures file list.

3. To test your detector against the contents of the PCAP file, click the evaluate icon next to the PCAP file.

   A message appears, indicating whether the test succeeded.

4. Optionally, repeat steps 1 to 3 to test the detector against additional PCAP files.

TIP! To delete a PCAP file, click the delete icon ( ) next to the file you want to delete.

5. To save the detector, click **Save**.

IMPORTANT! You must activate the detector before the system can use it to analyze application protocol traffic. For more information, see Activating and Deactivating Detectors on page 1750.

Managing Detectors

License: FireSIGHT

You view and manage detectors on the Detectors page.

From the Detectors page, you can:

- view details about the application the detector identifies
- sort, filter, and browse the list of detectors
- view a list of the Sourcefire-provided internal detectors
- view the properties of the Sourcefire-provided application protocol port detectors, and optionally save copies as new, user-defined detectors that you can modify
- create, modify, delete, and export user-defined application protocol detectors
- delete and export any application protocol detectors you individually imported
- activate and deactivate user-defined, imported, or Sourcefire-provided web application, client, and application protocol detectors

Note that you cannot modify or delete internal or Sourcefire-provided application protocol, client, or web application detectors and cannot deactivate internal detectors.

For more information, see:

- Viewing Detector Details on page 1746
- Sorting the Detector List on page 1747
- Filtering the Detector List on page 1747
- Navigating to Other Detector Pages on page 1750
- Activating and Deactivating Detectors on page 1750
- Modifying Application Detectors on page 1751
- Deleting Detectors on page 1752

Viewing Detector Details

License: FireSIGHT

You can view more detail on a detector from the application detectors list.

To view application detector details:

Access: Admin/Discovery Admin

- Click the information icon ( ) in the **Details** column.

  The information pop-up window for the detector appears.

  For more information on risk, business relevance, tags, and categories, see Understanding Application Detection on page 1316.

Sorting the Detector List

License: FireSIGHT

By default, the Detectors page lists detectors alphabetically by name. An up (▲) or down arrow next to a column heading indicates that the page is sorted by that column in that direction.

To sort detectors:

Access: Admin/Discovery Admin

- On the Detectors page, click the appropriate column heading.

  The detectors are sorted in the direction indicated by the arrow that appears on the column heading. To sort in the opposite direction, click the heading again.

Filtering the Detector List

License: FireSIGHT

You can filter the detectors you display on the Detectors page by a single criterion, or a combination of multiple criteria. The filter you construct is shown at the top of the page. You can use several filter groups, separately or in combination, to filter the list of detectors.

Name

Finds detectors with names or descriptions containing the string you type. Strings can contain any alphanumeric or special character.

Custom Filter

Finds detectors matching a custom application filter created on the object management page. For more information, see Working with Application Filters on page 192.

Author

Finds detectors according to who created the detector. You can filter detectors by:

- any individual user who has created or imported a detector
- **Sourcefire**, which represents all Sourcefire-provided detectors *except* individually imported add-on detectors; you are the author for any detector that you import
- **Any User**, which represents all detectors not provided by Sourcefire

State

Finds detectors according to their state, that is, **Active** or **Inactive**. For more information, see Activating and Deactivating Detectors on page 1750.

Type

Finds detectors according to the detector type: **Application Protocol**, **Web Application**, **Client**, or **Internal Detector**.

Application protocol detectors have three subtypes you can use to further filter detectors:

- **Port** application protocol detectors include the Sourcefire-provided well-known port detectors, as well as any port-based user-defined application detectors.
- **Pattern** application protocol detectors include pattern-based or port-and-pattern-based user-defined application detectors.
- **FireSIGHT** application protocol detectors are application protocol fingerprint detectors provided by Sourcefire that can be activated and deactivated.

For more information on detector types, see Working with Application Detectors on page 1735.

Protocol

Finds detectors according to which traffic protocol the detector inspects. Detectors can inspect TCP, UDP, or TCP and UDP traffic.

Category

Finds detectors according to the categories assigned to the application they detect.

Tag

Finds detectors according to the tags assigned to the application they detect.

Risk

Finds detectors according to the risks assigned to the application they detect: **Very High**, **High**, **Medium**, **Low**, and **Very Low**.

Business Relevance

Finds detectors according to the business relevance assigned to the application they detect: **Very High**, **High**, **Medium**, **Low**, and **Very Low**.

To apply a filter:

Access: Admin/Discovery Admin

1. On the Detectors page, expand the filter group you want to use to filter the detectors.
2. Type the name or select the specific filter you want to use. To select all filters in a group, right-click the group name and select **Check All**.
3. Optionally, if the filter you are using has subfilters, select the subfilter to further filter the detectors.

To remove a filter:

Access: Admin/Discovery Admin

- Click the remove icon (✖) in the name of the filter in the **Filters** field or disable the filter in the filter list. To remove all filters in a group, right-click the group name and select **Uncheck All**.

  The filter is removed and the results update.

To remove all filters:

Access: Admin/Discovery Admin

- Click **Clear all** next to the list of filters applied to the detectors.

Navigating to Other Detector Pages

LICENSE: FireSIGHT

The Detectors page displays 25 detectors at a time. The following table explains how to view additional pages of detectors using the navigation links at the bottom of the page.

ACCESS: Admin/Discovery Admin

Navigating Detector Pages

TO...	YOU CAN...
view the next page	click the right arrow icon ( ).
view the previous page	click the left arrow icon ( ).
view a different page	type the page number and press Enter.
jump to the last page	click the right end arrow icon ( ).
jump to the first page	click the left end arrow icon ( ).

Activating and Deactivating Detectors

LICENSE: FireSIGHT

You must activate a detector before you can use it to analyze network traffic. By default, all Sourcefire-provided detectors are activated.

You can activate multiple application detectors for each port to supplement the system's detection capability.

When you include an application in an access control rule in a policy and that policy is applied, if there is no active detector for that application, one or more detectors automatically activate. Similarly, while an application is in use in an applied policy, you cannot deactivate a detector if deactivating leaves no active detectors for that application.

WARNING! When you activate or deactivate an existing detector, a short pause in traffic flow and processing may occur on your managed devices, which may also cause a few packets to pass uninspected.

TIP! For improved performance, deactivate any application protocol, client, or web application detectors you are not interested in.

To activate or deactivate a detector:

Access: Admin/Discovery Admin

1. Select **Policies > Application Detectors**.

   The Detectors page appears.

2. Locate the detector you want to activate or deactivate.

   If the detector you want to activate or deactivate is not on the first page, you can find it by paging through the detector list or applying one or more filters. For more information, see Managing Detectors on page 1745.

3. You have the following options:

   - To **activate** a detector, so that the system will use it when analyzing network traffic, click the deactivated slider () next to the detector.
   - To **deactivate** a detector so that the system will not use it when analyzing network traffic, click the activated slider () next to the detector.

   Note that some application detectors are required by other detectors. If you deactivate one of these detectors, a warning appears to indicate that the detectors that depend on it are also disabled.

Modifying Application Detectors

License: FireSIGHT

Use the following procedure to modify user-defined application detectors.

To modify an application detector:

Access: Admin/Discovery Admin

1. Select **Policies > Applications**.

   The Detectors page appears.

2. Locate the detector you want to modify.

   If the detector you want to modify is not on the first page, you can find it by paging through the detector list or applying one or more filters. For more information, see Managing Detectors on page 1745.

3. To modify a user-defined detector, click **Edit** next to the detector you want to modify.

   The Edit Application Detector page appears.

4. Make changes to the detector.

   See Creating a User-Defined Application Protocol Detector on page 1738 for information on the various configurations you can change.

5. You have the following options:
   - If you are modifying an inactive user-defined detector, either click **Save** to save your changes, or click **Save as New** to save the detector as a new, inactive user-defined detector.
   - If you are modifying an active user-defined detector, either click **Save and Reactivate** to save your changes and immediately start using the modified detector, or click **Save as New** to save the detector as a new, inactive user-defined detector.

IMPORTANT! The system only uses applications with active detectors to analyze application traffic. For more information, see Activating and Deactivating Detectors on page 1750.

Deleting Detectors

License: FireSIGHT

Use the following procedure to delete a detector. You can delete user-defined detectors as well as individually imported add-on detectors provided by Sourcefire Professional Services. You cannot delete any of the other Sourcefire-provided detectors, though you can deactivate many of them.

IMPORTANT! While a detector is in use in an applied policy, you cannot deactivate or delete the detector.

To delete a detector:

Access: Admin/Discovery Admin

1. Select **Policies > Application Detectors**.

   The Detectors page appears.

2. Select the check box next to the detector you want to delete and click **Delete**.

   If the detector you want to delete is not on the first page, you can find it by paging through the detector list or applying one or more filters. For more information, see Managing Detectors on page 1745.

3. Click **OK** to confirm that you want to delete the detector.

   The detector is deleted.

Importing Host Input Data

License: FireSIGHT

If your organization has the capability to write scripts or create command line import files to import network map data from third parties, you can import data to augment the information in the network map. You can also use the host input

feature by modifying operating system or application identities or deleting application protocols, protocols, host attributes, or clients using the web interface.

The system may reconcile data from multiple sources to determine the current identity of an operating system or application. For more information on how the system does this, see Understanding Current Identities on page 1718.

Note that all data except third-party vulnerabilities is discarded when the affected host is removed from the network map. For more information on setting up scripts or import files, see the *Sourcefire 3D System Host Input API Guide*.

To include imported data in impact correlations, you must map the data to the operating system and application definitions in the database. For more information, see the following sections:

- Enabling the Use of Third-Party Data on page 1753
- Managing Third-Party Product Mappings on page 1754
- Mapping Third-Party Vulnerabilities on page 1759
- Managing Custom Product Mappings on page 1760

Enabling the Use of Third-Party Data

LICENSE: FireSIGHT

You can import network map data from third-party systems on your network. However, to enable features where intrusion and discovery data are used together, such as FireSIGHT recommendations, adaptive profiles, or impact assessment, you should map as many elements of it as possible to corresponding definitions. Consider the following requirements for using third-party data:

- If you have a third-party system that has specific data on your network assets, you can import that data using the host input feature. However, because third parties may name the products differently, you must map the third-party vendor, product, and versions to the corresponding Sourcefire product definition. After you map the products, you must enable vulnerability mappings for impact assessment in the system policy to allow impact correlation. For versionless or vendorless application protocols, you need to map vulnerabilities for the application protocols in the system policy. For more information, see Mapping Third-Party Products on page 1754.
- If you import patch information from a third party and you want to mark all vulnerabilities fixed by that patch as invalid, you must map the third-party fix name to a fix definition in the database. All vulnerabilities addressed by the fix will then be removed from hosts where you add that fix. For more information, see Mapping Third-Party Product Fixes on page 1757.

- If you import operating system and application protocol vulnerabilities from a third party and you want to use them for impact correlation, you must map the third-party vulnerability identification string to vulnerabilities in the database. Note that although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot import and map third-party client vulnerabilities. After the vulnerabilities are mapped, you must enable third-party vulnerability mappings for impact assessment in the system policy. For more information, see Mapping Third-Party Vulnerabilities on page 1759. To cause application protocols without vendor or version information to map to vulnerabilities, an administrative user must also map vulnerabilities for the applications in the system policy. For more information, see Mapping Vulnerabilities for Servers on page 2075.
- If you import application data and you want to use that data for impact correlation, you must map the vendor string for each application protocol to the corresponding Sourcefire application protocol definition. For more information, see Managing Custom Product Mappings on page 1760.

Managing Third-Party Product Mappings

License: FireSIGHT

When you add data from third parties to the network map through the user input feature, you must map the vendor, product, and version names used by the third party to the Sourcefire product definitions. Mapping the products to Sourcefire definitions assigns vulnerabilities based on those definitions.

Similarly, if you are importing patch information from a third party, such as a patch management product, you must map the name for the fix to the appropriate vendor and product and the corresponding fix in the database.

For more information, see the following sections:

- Mapping Third-Party Products on page 1754
- Mapping Third-Party Product Fixes on page 1757

Mapping Third-Party Products

License: FireSIGHT

If you import data from a third party, you must map the Sourcefire product to the third-party name to assign vulnerabilities and perform impact correlation using that data. Mapping the product associates Sourcefire vulnerability information with the third-party product name, which allows the system to perform impact correlation using that data.

If you import data using the host input import feature, you can also use the AddScanResult function to map third-party products to operating system and application vulnerabilities during the import.

As an example, if you import data from a third party that lists Apache Tomcat as an application and you know it is version 6 of that product, you could add a third-party map where **Vendor Name** is set to `Apache`, **Product Name** is set to

`Tomcat`, **Apache** is selected from the **Vendor** drop-down list, **Tomcat** is selected from the **Product** drop-down list, and **6** is selected from the **Version** drop-down list. That mapping would cause any vulnerabilities for Apache Tomcat 6 to be assigned to hosts with an application listing for Apache Tomcat.

Note that for versionless or vendorless applications, you must map vulnerabilities for the application types in the system policy. For more information, see Mapping Vulnerabilities for Servers on page 2075. Note that although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot import and map third-party client vulnerabilities.

TIP! If you have already created a third-party mapping on another Defense Center, you can export it and then import it onto this Defense Center. You can then edit the imported mapping to suit your needs. For more information, see Importing and Exporting Configurations on page 2308.

To map a third-party product to a Sourcefire product definition:

Access: Admin

1. Select **Policies > Application Detectors**, then click **User Third-Party Mappings**.

   The User Third-Party Mappings page appears.

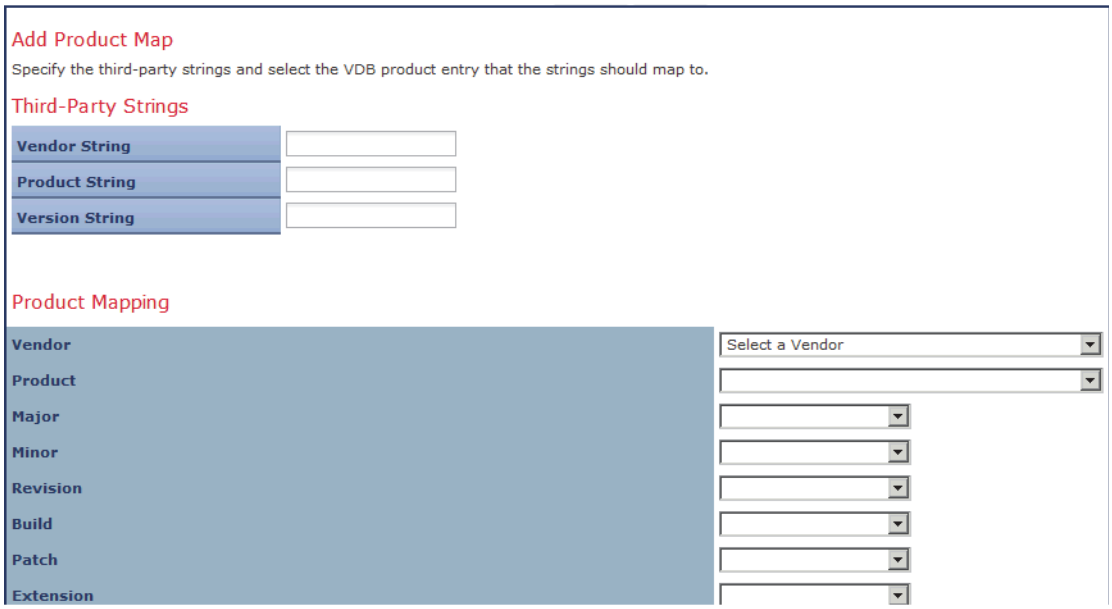
2. You have two choices:
   - To edit an existing map set, click **Edit** next to the map set.
   - To create a new map set, click **Create Product Map Set**.

   The Edit Third-Party Product Mappings page appears.

3. Type a name for the mapping set in the **Mapping Set Name** field.
4. Type a description in the **Description** field.

5. You have two choices:
   - To map a third-party product, click **Add Product Map.**
   - To edit an existing third-party product map, click **Edit** next to the map set.

   The Add Product Map page appears.



6. Type the vendor string used by the third-party product in the **Vendor String** field.
7. Type the product string used by the third-party product in the **Product String** field.
8. Type the version string used by the third-party product in the **Version String** field.
9. In the Product Mappings section, select the operating system, product, and versions you want to use for vulnerability mapping from the following lists (if applicable):
   - **Vendor**
   - **Product**
   - **Major Version**
   - **Minor Version**
   - **Revision Version**
   - **Build**

- **Patch**
- **Extension**

For example, if you want a host running a product whose name consists of third-party strings to use the vulnerabilities from Red Hat Linux 9, select **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

10. Click **Save**.

Mapping Third-Party Product Fixes

License: FireSIGHT

If you map a fix name to a particular set of fixes in the database, you can then import data from a third-party patch management application and apply the fix to a set of hosts. When the fix name is imported to a host, the system marks all vulnerabilities addressed by the fix as invalid for that host.

To map third-party fixes to Sourcefire fix definitions:

Access: Admin

1. Select **Policies > Application Detectors**, then click **User Third-Party Mappings**.

   The User Third-Party Mappings page appears.

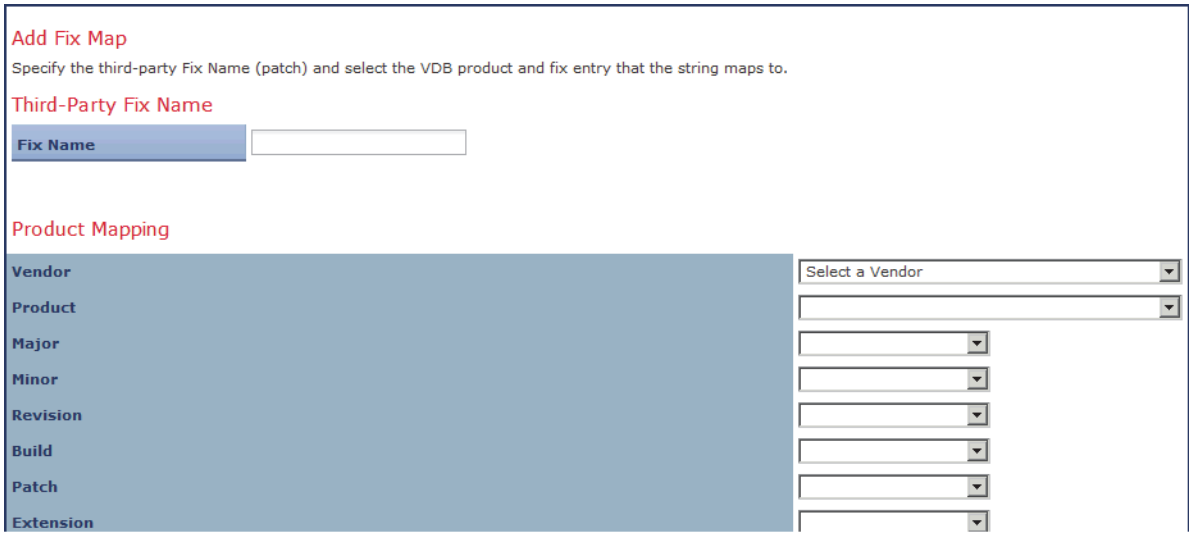
2. You have two choices:
   - To edit an existing map set, click **Edit** next to the map set.
   - To create a new map set, click **Create Product Map Set**.

   The Edit Third-Party Product Mappings page appears.

3. Type a name for the mapping set in the **Mapping Set Name** field.
4. Type a description in the **Description** field.

5. You have two choices:
   - To map a third-party product, click **Add Fix Map.**
   - To edit an existing third-party product map, click **Edit** next to it.

   The Add Fix Map page appears.



6. Type the name of the fix you want to map in the **Third-Party Fix Name** field.
7. In the Product Mappings section, select the operating system, product, and versions you want to use for fix mapping from the following lists (if applicable):
   - **Vendor**
   - **Product**
   - **Major Version**
   - **Minor Version**
   - **Revision Version**
   - **Build**
   - **Patch**
   - **Extension**

   For example, if you want your mapping to assign the selected fixes from Red Hat Linux 9 to hosts where the patch is applied, select **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.
8. Click **Save** to save the fix map.

Mapping Third-Party Vulnerabilities

License: FireSIGHT

To add vulnerability information from a third party to the VDB, you must map the third-party identification string for each imported vulnerability to any existing Sourcefire, Bugtraq, or Snort ID. After you create a mapping for the vulnerability, the mapping works for all vulnerabilities imported to hosts in your network map and allows impact correlation for those vulnerabilities.

Note that you must also enable impact correlation for third-party vulnerabilities to allow correlation to occur. For more information, see Enabling Vulnerability Impact Assessment Mappings on page 1349. For versionless or vendorless applications, you must also map vulnerabilities for the application types in the system policy. For more information, see Mapping Vulnerabilities for Servers on page 2075.

Also, although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot use third-party client vulnerabilities for impact assessment.

TIP! If you have already created a third-party mapping on another Defense Center, you can export it and then import it onto this Defense Center. You can then edit the imported mapping to suit your needs. For more information, see Importing and Exporting Configurations on page 2308.

To map a third-party vulnerability to an existing vulnerability:

Access: Admin

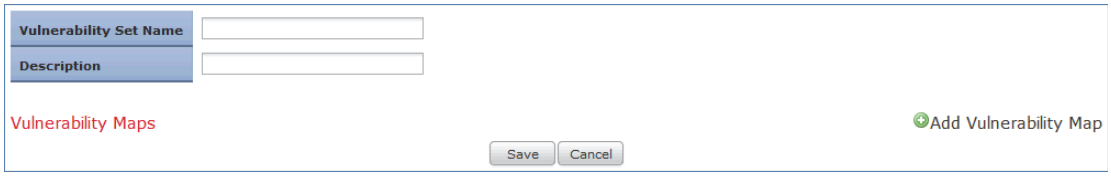
1. Select **Policies > Application Detectors**, then click **User Third-Party Mappings**.

   The User Third-Party Mappings page appears.

2. You have two choices:

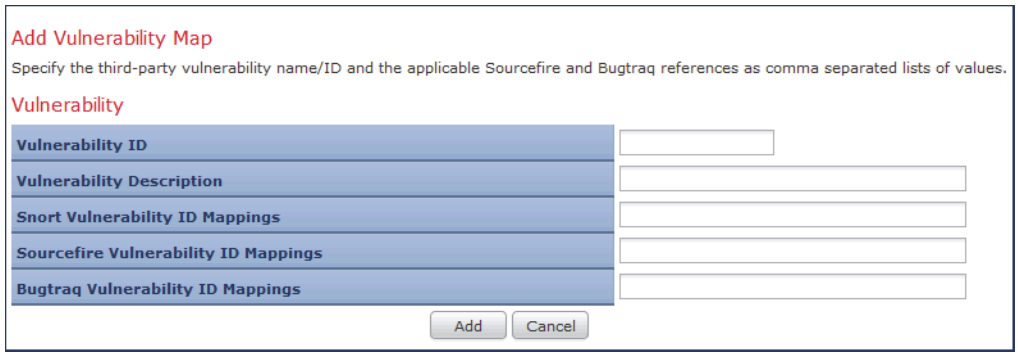
   - To edit an existing vulnerability set, click **Edit** next to the vulnerability set.
   - To create a new vulnerability set, click **Create Vulnerability Map Set**.

   The Edit Third-Party Vulnerability Mappings page appears.



3. Click **Add Vulnerability Map**.

   The Add Vulnerability Map pop-up window appears.



4. Type the third-party identification for the vulnerability in the **Vulnerability ID** field.
5. Type a description in the **Vulnerability Description** field.
6. Optionally, enter a Signature ID in the **Snort Vulnerability ID Mappings** field.
7. Optionally, enter an Sourcefire vulnerability ID in the **Sourcefire Vulnerability ID Mappings** field.
8. Optionally, enter a Bugtraq identification number in the **Bugtraq Vulnerability ID Mappings** field.
9. Click **Add**.

Managing Custom Product Mappings

LICENSE: FireSIGHT

You can use product mappings to ensure that servers input by a third party are associated with the appropriate Sourcefire definitions. After you define and activate the product mapping, all servers or clients on hosts in your network map that have the mapped vendor strings use the custom product mappings. For this reason, you may want to map vulnerabilities for all servers in the network map with a particular vendor string instead of explicitly setting the vendor, product, and version for the server.

For more information, see the following:

- Creating Custom Product Mappings on page 1761
- Editing Custom Product Mapping Lists on page 1762
- Managing Custom Product Mapping Activation State on page 1763

Creating Custom Product Mappings

LICENSE: FireSIGHT

If the system cannot map a server in the network map to a vendor and product in the VDB, you can manually create the mapping for the system to use when identifying servers. When you activate a custom product mapping, the system maps vulnerabilities for the selected vendor and product to all servers in the network map where that vendor string occurs.

IMPORTANT! Custom product mappings apply to all occurrences of an application protocol, regardless of the source of the application data (such as Nmap, the host input feature, or the Sourcefire 3D System itself). However, if third-party vulnerability mappings for data imported using the host input feature conflicts with the mappings you set through a custom product mapping, the third-party vulnerability mapping overrides the custom product mapping and uses the third-party vulnerability mapping settings when the input occurs. For more information, see Mapping Third-Party Vulnerabilities on page 1759.

You create lists of product mappings and then enable or disable use of several mappings at once by activating or deactivating each list. When you select a vendor to map to, the system updates the list of products to include only those made by that vendor.

After you create a custom product mapping, you must activate the custom product mapping list. After you activate a list of custom product mappings, the system updates all servers with occurrences of the specified vendor strings. For data imported through the host input feature, vulnerabilities update unless you have already explicitly set the product mappings for this server.

If, for example, your company modifies the banner for your Apache Tomcat web servers to read `Internal Web Server`, you can map the vendor string `Internal Web Server` to the vendor **Apache** and the product **Tomcat**, then activate the list containing that mapping, all hosts where a server labelled `Internal Web Server` occurs have the vulnerabilities for Apache Tomcat in the database.

TIP! You can use this feature to map vulnerabilities to local intrusion rules by mapping the SID for the rule to another vulnerability.

To create a custom product mapping:

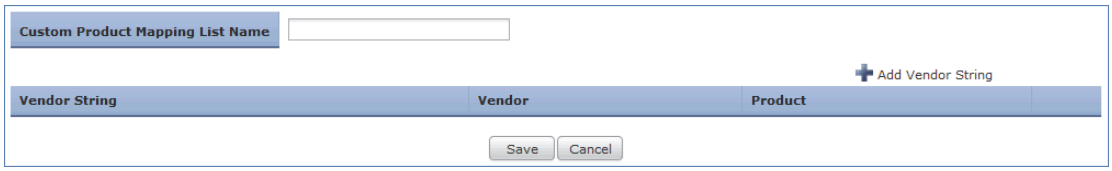
ACCESS: Admin

1. Select **Policies > Application Detectors**, and click **Custom Product Mappings**.

   The Custom Product Mappings page appears.

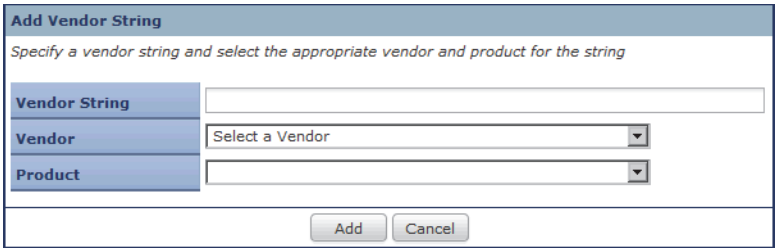
2. Click **Create Custom Product Mapping List**.

   The Edit Custom Product Mappings List page appears.



3. Type a name in the **Custom Product Mapping List Name** field.
4. Click **Add Vendor String**.

   The Add Vendor String pop-up window appears.



5. In the **Vendor String** field, type the vendor string that identifies the applications that should map to the selected vendor and product values.
6. Select the vendor you want to map to from the **Vendor** drop-down list.
7. Select the product you want to map to from the **Product** drop-down list.
8. Click **Add** to add the mapped vendor string to the list.
9. Optionally, repeat steps 4 to 8 as needed to add additional vendor string mappings to the list.
10. When you finish, click **Save**.

    The Custom Product Mappings page appears again, with the list you added.

Editing Custom Product Mapping Lists

License: FireSIGHT

You can modify existing custom product mapping lists by adding or removing vendor strings or changing the list name.

To edit a custom product mapping:

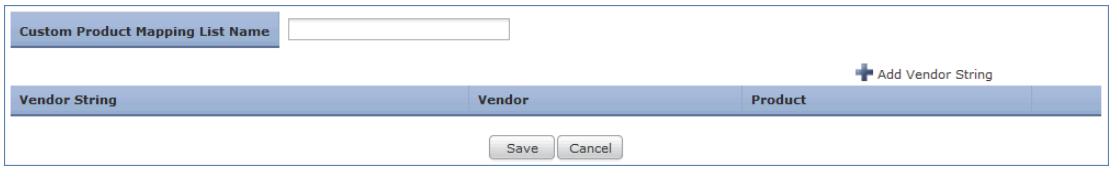
Access: Admin

1. Select **Policies > Application Detectors**, then click **Custom Product Mappings**.

   The Custom Product Mappings page appears.

2. Click the edit icon ( ) next to the product mapping list to edit.

   The Edit Custom Product Mappings List page appears.



3. Make changes to the list as needed. For more information, see Creating Custom Product Mappings on page 1761.
4. When you finish, click **Save**.

   The Custom Product Mappings page appears, with the list you updated.

Managing Custom Product Mapping Activation State

LICENSE: FireSIGHT

You can enable or disable use of an entire list of custom product mappings at once. After you activate a custom product mapping list, each mapping on that list applies to all applications on hosts in the network map with the specified vendor string, whether detected by managed devices or imported through the host input feature.

To activate or deactivate a custom product mapping list:

ACCESS: Admin

1. Select **Policies > Application Detectors**, then click **Custom Product Mappings**.

   The Custom Product Mappings page appears.
2. Modify the state of custom product mapping lists:
   - To enable use of a custom product mapping list, click **Activate**.
   - To disable use of a custom product mapping list, click **Deactivate**.

Chapter 41
Configuring Active Scanning

The Sourcefire 3D System builds a network map through passive analysis of traffic on your network. However, you may sometimes need to actively scan a host to determine information about that host. For example, if a host has a server running on an open port but the server has not received or sent traffic during the time that the system has been monitoring your network, the system does not add information about that server to the network map. If you directly scan that host using an active scanner, however, you can detect the presence of the server.

When you actively scan a host, you send packets in an attempt to obtain information about the host. The Sourcefire 3D System integrates with Nmap™ 6.01, an open source active scanner for network exploration and security auditing that can be used to detect operating systems and servers running on a host. With an Nmap scan, you can check for detailed information about the operating system and servers running on the host and refine the system's vulnerability reporting based on those results.

IMPORTANT! Some scanning options (such as portscans) may place a significant load on networks with low bandwidths. You should always schedule scans like these to run during periods of low network use.

For more information, see the following sections:

- Understanding Nmap Scans on page 1765
- Setting up Nmap Scans on page 1774
- Managing Nmap Scanning on page 1782

- Managing Scan Targets on page 1786
- Working with Active Scan Results on page 1788

Understanding Nmap Scans

LICENSE: FireSIGHT

Nmap allows you to actively scan ports on hosts on your network to determine operating system and server data for the hosts, which allows you to enhance your network map and fine-tune the accuracy of the vulnerabilities mapped to scanned hosts. Note that a host must exist in the network map before Nmap can append its results to the host profile. You can also view scan results in a results file.

When you scan a host using Nmap, servers on previously undetected open ports are added to the Servers list in the host profile for that host. The host profile lists any servers detected on filtered or closed TCP ports or on UDP ports in the Scan Results section. By default, Nmap scans more than 1660 TCP ports.

Nmap compares the results of the scan to over 1500 known operating system fingerprints to determine the operating system and assigns scores to each. The operating system assigned to the host is the operating system fingerprint with the highest score.

If the system recognizes a server identified in an Nmap scan and has a corresponding server definition, the system maps vulnerabilities for that server to the host. The system maps the names Nmap uses for servers to the corresponding Sourcefire server definitions, and then uses the vulnerabilities mapped to each server in the system. Similarly, the system maps Nmap operating system names to Sourcefire operating system definitions. When Nmap detects an operating system for a host, the system assigns vulnerabilities from the corresponding Sourcefire operating system definition to the host.

For more information the underlying Nmap technology used to scan, refer to the Nmap documentation at http://insecure.org.

For more information on Nmap on your Sourcefire appliance, see the following topics:

- Understanding Nmap Remediations on page 1765
- Creating an Nmap Scanning Strategy on page 1769
- Sample Nmap Scanning Profiles on page 1771

Understanding Nmap Remediations

LICENSE: FireSIGHT

You can define the settings for an Nmap scan by creating an Nmap remediation. An Nmap remediation can be used as a response in a correlation policy, run on demand, or scheduled to run at a specific time. In order for the results of an Nmap scan to appear in the network map, the scanned host must already exist in the network map.

Note that Nmap-supplied server and operating system data remain static until you run another Nmap scan. If you plan to scan a host for operating system and server data using Nmap, you may want to set up regularly scheduled scans to keep any Nmap-supplied operating system and server data up-to-date. For more information, see Automating Nmap Scans on page 2013. Also note that if the host is deleted from the network map, any Nmap scan results for that host are discarded.

For more information about Nmap functionality, refer to the Nmap documentation at http://insecure.org. The following table explains the options configurable in Nmap remediations on a Sourcefire 3D System.

Nmap Remediation Options

Option	Description	Corresponding Nmap Option
Scan Which Address(es) From Event?	When you use an Nmap scan as a response to a correlation rule, select an option to control which address in the event is scanned, that of the source host, the destination host, or both.	N/A
Scan Types	Select how Nmap scans ports: • The **TCP Syn** scan connects quickly to thousand of ports without using a complete TCP handshake. This options allows you to scan quickly in stealth mode on hosts where the `admin` account has raw packet access or where IPv6 is not running, by initiating TCP connections but not completing them. If a host acknowledges the Syn packet sent in a TCP Syn scan, Nmap resets the connection. • The **TCP Connect** scan uses the `connect()` system call to open connections through the operating system on the host. You can use the TCP Connect scan if the `admin` user on your Defense Center or managed device does not have raw packet privileges on a host or you are scanning IPv6 networks. In other words, use this option in situations where the TCP Syn scan cannot be used. • The **TCP ACK** scan sends an ACK packet to check whether ports are filtered or unfiltered. • The **TCP Window** scan works in the same way as a TCP ACK scan but can also determine whether a port is open or closed. • The **TCP Maimon** scan identifies BSD-derived systems using a FIN/ACK probe.	**TCP Syn**: `-sS` **TCP Connect**: `-sT` **TCP ACK**: `-sA` **TCP Window**: `-sW` **TCP Maimon**: `-sM`
Scan for UDP ports	Enable to scan UDP ports in addition to TCP ports. Note that scanning UDP ports may be time-consuming, so avoid using this option if you want to scan quickly.	`-sU`

Nmap Remediation Options (Continued)

Option	Description	Corresponding Nmap Option
Use Port From Event	If you plan to use the remediation as a response in a correlation policy, enable to cause the remediation to scan only the port specified in the event that triggers the correlation response. **TIP!** You can also control whether Nmap collects information about operating system and server information. Enable the **Use Port From Event** option to scan the port associated with the new server.	N/A
Scan from reporting detection engine	Enable to scan a host from the appliance where the detection engine that reported the host resides.	N/A
Fast Port Scan	Enable to scan only the TCP ports listed in the `nmap-services` file located in the `/var/sf/nmap/share/nmap/nmap-services` directory on the device that does the scanning, ignoring other port settings. Note that you cannot use this option with the **Port Ranges and Scan Order** option.	`-F`
Port Ranges and Scan Order	Set the specific ports you want to scan, using Nmap port specification syntax, and the order you want to scan them. Note that you cannot use this option with the **Fast Port Scan** option.	`-p`
Probe open ports for vendor and version information	Enable to detect server vendor and version information. If you probe open ports for server vendor and version information, Nmap obtains server data that it uses to identify servers. It then replaces the Sourcefire server data for that server.	`-sv`
Service Version Intensity	Select the intensity of Nmap probes for service versions. Higher service intensity numbers cause more probes to be used and result in higher accuracy, while lower intensity probes are faster but obtain less information.	`--version-intensity <intensity>`
Detect Operating System	Enable to detect operating system information for the host. If you configure detection of the operating system for a host, Nmap scans the host and uses the results to create a rating for each operating system that reflects the likelihood that the operating system is running on the host. For more information on when and how Nmap-identified identity data appears in the network map, see Understanding Current Identities on page 1718.	`-o`

Nmap Remediation Options (Continued)

Option	Description	Corresponding Nmap Option
Treat All Hosts As Online	Enable to skip the host discovery process and run a port scan on every host in the target range. Note that when you enable this option, Nmap ignores settings for **Host Discovery Method** and **Host Discovery Port List**.	`-PN`
Host Discovery Method	Select to perform host discovery for all hosts in the target range, over the ports listed in the **Host Discovery Port List**, or if no ports are listed, over the default ports for that host discovery method. Note that if you also enabled **Treat All Hosts As Online**, however, the **Host Discovery Method** option has no effect and host discovery is not performed. Select the method to be used when Nmap tests to see if a host is present and available: • The **TCP SYN** option sends an empty TCP packet with the SYN flag set and recognizes the host as available if a response is received. TCP SYN scans port 80 by default. Note that TCP SYN scans are less likely to be blocked by a firewall with stateful firewall rules. • The **TCP ACK** option sends an empty TCP packet with the ACK flag set and recognizes the host as available if a response is received. TCP ACK also scans port 80 by default. Note that TCP ACK scans are less likely to be blocked by a firewall with stateless firewall rules. • The **UDP** option sends a UDP packet and assumes host availability if a port unreachable response comes back from a closed port. UDP scans port 40125 by default.	**TCP SYN**: `-PS` **TCP ACK**: `-PA` **UDP**: `-PU`
Host Discovery Port List	Specify a customized list of ports, separated by commas, that you want to scan when doing host discovery.	port list for host discovery method
Default NSE Scripts	Enable to run the default set of Nmap scripts for host discovery and server and operating system and vulnerability detection. See http://nmap.org/nsedoc/categories/default.html for the list of default scripts.	`-sC`
Timing Template	Select the timing of the scan process; the higher the number you select, the faster and less comprehensive the scan.	**0**: `T0` (paranoid) **1**: `T1` (sneaky) **2**: `T2` (polite) **3**: `T3` (normal) **4**: `T4` (aggressive) **5**: `T5` (insane)

Creating an Nmap Scanning Strategy

License: FireSIGHT

While active scanning can obtain valuable information, overuse of a tool such as Nmap may overload your network resources or even crash important hosts. When using any active scanner, you should create a scanning strategy to make sure that you are scanning only the hosts and ports that you need to scan.

For more information, see the following sections:

- Selecting Appropriate Scan Targets on page 1769
- Selecting Appropriate Ports to Scan on page 1770
- Setting Host Discovery Options on page 1770

Selecting Appropriate Scan Targets

License: FireSIGHT

When you configure Nmap, you can create scan targets that identify which hosts you want to scan. A scan target includes a single IP address, a CIDR block or octet range of IP addresses, an IP address range, or a list of IP addresses or ranges to scan, as well as the ports on the host or hosts.

You can specify targets in the following ways:

- For IPv6 hosts:
  - an exact IP address (for example, 192.168.1.101)
- For IPv4 hosts:
  - an exact IP address (for example, 192.168.1.101) or a list of IP addresses separated by commas or spaces
  - an IP address block using CIDR notation (for example, 192.168.1.0/24 scans the 254 hosts between 192.168.1.1 and 192.168.1.254, inclusive)

    For information on using CIDR notation in the Sourcefire 3D System, see IP Address Conventions on page 63.
  - an IP address range using octet range addressing (for example, `192.168.0-255.1-254` scans all addresses in the `192.168.x.x` range, except those that end in .0 and or .255)
  - an IP address range using hyphenation (for example, 192.168.1.1 - 192.168.1.5 scans the six hosts between 192.168.1.1 and 192.168.1.5, inclusive)
  - a list of addresses or ranges separated by commas or spaces (for example, for example, `192.168.1.0/24, 194.168.1.0/24` scans the 254 hosts between 192.168.1.1 and 192.168.1.254, inclusive and the 254 hosts between 194.168.1.1 and 194.168.1.254, inclusive)

Ideal scan targets for Nmap scans include hosts with operating systems that the system is unable to identify, hosts with unidentified servers, or hosts recently

detected on your network. Remember that Nmap results cannot be added to the network map for hosts that do not exist in the network map.

WARNING! Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, you may want to set up regularly scheduled scans to keep any Nmap-supplied operating system and server data up to date. For more information, see Automating Nmap Scans on page 2013. Also note that if the host is deleted from the network map, any Nmap scan results are discarded. In addition, make sure you have permission to scan your targets. Using Nmap to scan hosts that do not belong to you or your company may be illegal.

Selecting Appropriate Ports to Scan

LICENSE: FireSIGHT

For each scan target you configure, you can select the ports you want to scan. You can designate individual port numbers, port ranges, or a series of port numbers and port ranges to identify the exact set of ports that should be scanned on each target.

By default, Nmap scans TCP ports 1 through 1024. If you plan to use the remediation as a response in a correlation policy, you can cause the remediation to scan only the port specified in the event that triggers the correlation response. If you run the remediation on demand or as a scheduled task, or if you do not use the port from the event, you can use other port options to determine which ports are scanned. You can choose to scan only the TCP ports listed in the `nmap-services` file, ignoring other port settings. You can also scan UDP ports in addition to TCP ports. Note that scanning for UDP ports may be time-consuming, so avoid using that option if you want to scan quickly. To select the specific ports or range of ports to scan, use Nmap port specification syntax to identify ports.

Setting Host Discovery Options

LICENSE: FireSIGHT

You can decide whether to perform host discovery before starting a port scan for a host, or you can assume that all the hosts you plan to scan are online. If you choose not to treat all hosts as online, you can choose what method of host discovery to use and, if needed, customize the list of ports scanned during host discovery. Host discovery does not probe the ports listed for operating system or server information; it uses the response over a particular port only to determine whether a host is active and available. If you perform host discovery and a host is not available, Nmap does not scan ports on that host.

Sample Nmap Scanning Profiles

License: FireSIGHT

The following scenarios provide examples of how Nmap might be used on your network:

- Example: Resolving Unknown Operating Systems on page 1771
- Example: Responding to New Hosts on page 1772

Example: Resolving Unknown Operating Systems

License: FireSIGHT

If the system cannot determine the operating system on a host on your network, you can use Nmap to actively scan the host. Nmap uses the information it obtains from the scan to rate the possible operating systems. It then uses the operating system that has the highest rating as the host operating system identification.

Using Nmap to challenge new hosts for operating system and server information deactivates the system's monitoring of that data for scanned hosts. If you use Nmap to discover host and server operating system for hosts the system marks as having unknown operating systems, you may be able to identify groups of hosts that are similar. You can then create a custom fingerprint based on one of them to cause the system to associate the fingerprint with the operating system you know is running on the host based on the Nmap scan. Whenever possible, create a custom fingerprint rather than inputting static data through a third-party source like Nmap because the custom fingerprint allows the system to continue to monitor the host operating system and update it as needed.

To discover operating systems with Nmap:

Access: Admin/Discovery Admin

1. Configure a scan instance for an Nmap module.

   For more information, see Creating an Nmap Scan Instance on page 1774.

2. Create an Nmap remediation using the following settings:
   - Enable **Use Port From Event** to scan the port associated with the new server.
   - Enable **Detect Operating System** to detect operating system information for the host.
   - Enable **Probe open ports for vendor and version information** to detect server vendor and version information.
   - Enable **Treat All Hosts as Online**, because you know the host exists.

   For information on creating Nmap remediations, see Creating an Nmap Remediation on page 1777.

3. Create a correlation rule that triggers when the system detects a host with an unknown operating system.

   The rule should trigger when **an discovery event occurs** and **the OS information for a host has changed** and it meets the following conditions: **OS Name is unknown**.

   For information on creating correlation rules, see Creating Rules for Correlation Policies on page 1530.

4. Create a correlation policy that contains the correlation rule.

   For more information on creating correlation policies, see Creating Correlation Policies on page 1584.

5. In the correlation policy, add the Nmap remediation you created in step 2 as a response to the rule you created in step 3.

6. Activate the correlation policy.

7. Purge the hosts on your network map to force network discovery to restart and rebuild the network map.

8. After a day or two, search for events generated by the correlation policy. Analyze the Nmap results for the operating systems detected on the hosts to see if there is a particular host configuration on your network that the system does not recognize.

   For more information on analyzing Nmap results, see Analyzing Scan Results on page 1791.

9. If you find hosts with unknown operating systems whose Nmap results are identical, create a custom fingerprint for one of those hosts and use it to identify similar hosts in the future.

   For more information, see Fingerprinting Clients on page 1722.

Example: Responding to New Hosts

License: FireSIGHT

When the system detects a new host in a subnet where intrusions may be likely, you may want to scan that host to make sure you have accurate vulnerability information for it.

You can accomplish this by creating and activating a correlation policy that detects when a new host appears in this subnet, and that launches a remediation that performs an Nmap scan on the host.

After you activate the policy, you can periodically check the remediation status view (**Policy & Response > Responses > Remediations > Status**) to see when the remediation launched. The remediation's dynamic scan target should include the IP addresses of the hosts it scanned as a result of the server detection. Check the host profile for those hosts to see if there are vulnerabilities that need to be

addressed for the host, based on the operating system and servers detected by Nmap.

WARNING! If you have a large or dynamic network, detection of a new host may be too frequent an occurrence to respond to using a scan. To prevent resource overload, avoid using Nmap scans as a response to events that occur frequently. In addition, note that using Nmap to challenge new hosts for operating system and server information deactivates Sourcefire monitoring of that data for scanned hosts.

To scan in response to the appearance of a new host:

Access: Admin/Discovery Admin

1. Configure a scan instance for an Nmap module.

   For more information, see Creating an Nmap Scan Instance on page 1774.

2. Create an Nmap remediation using the following settings:
   - Enable **Use Port From Event** to scan the port associated with the new server.
   - Enable **Detect Operating System** to detect operating system information for the host.
   - Enable **Probe open ports for vendor and version information** to detect server vendor and version information.
   - Enable **Treat All Hosts as Online**, because you know the host exists.

   For information on creating Nmap remediations, see Creating an Nmap Remediation on page 1777.

3. Create a correlation rule that triggers when the system detects a new host on a specific subnet.

   The rule should trigger when **a discovery event occurs** and **a new host is detected**.

   For information on creating correlation rules, see Creating Rules for Correlation Policies on page 1530.

4. Create a correlation policy that contains the correlation rule.

   For more information on creating correlation policies, see Creating Correlation Policies on page 1584.

5. In the correlation policy, add the Nmap remediation you created in step as a response to the rule you created in step 3.

6. Activate the correlation policy.

7. When you are notified of a new host, check the host profile to see the results of the Nmap scan and address any vulnerabilities that apply to the host.

Setting up Nmap Scans

License: FireSIGHT

To scan using Nmap, you must first configure a scan instance and a scan remediation. If you plan to schedule Nmap scans, you must also define a scan target.

For more information, see the following sections:

- Creating an Nmap Scan Instance on page 1774
- Creating an Nmap Scan Target on page 1776
- Creating an Nmap Remediation on page 1777

Creating an Nmap Scan Instance

License: FireSIGHT

You can set up a separate scan instance for each Nmap module that you want to use to scan your network for vulnerabilities. You can set up scan instances for the local Nmap module on your Defense Center and for any devices you want to use to run scans remotely. The results of each scan are always stored on the Defense Center where you configure the scan, even if you run the scan from a remote device. To prevent accidental or malicious scanning of mission-critical hosts, you can create a blacklist for the instance to indicate the hosts that should never be scanned with the instance.

Note that you cannot add a scan instance with the same name as any existing scan instance.

To create a scan instance:

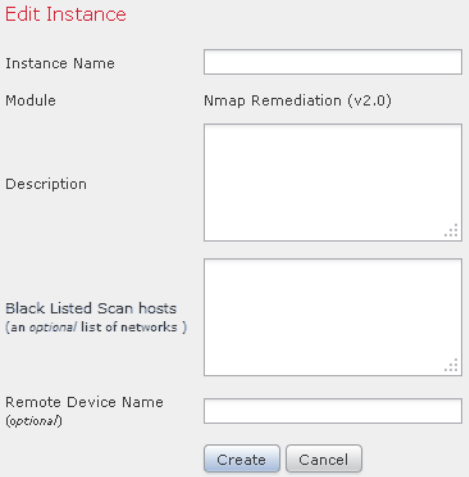
Access: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.

   The Scanners page appears.

2. Click **Add Nmap Instance**.

   The Instance Detail page appears.



3. In the **Instance Name** field, enter a name that includes 1 to 63 alphanumeric characters, with no spaces and no special characters other than underscore (_) and dash (-).
4. In the **Description** field, specify a description with 0 to 255 alphanumeric characters, which can include spaces and special characters.
5. Optionally, in the **Black Listed Scan hosts** field, specify any hosts or networks that should *never* be scanned with this scan instance, using the following syntax:
   - For IPv6 hosts, an exact IP address (for example, `2001:DB8::fedd:eeff`)
   - For IPv4 hosts, an exact IP address (for example, `192.168.1.101`) or an IP address block using CIDR notation (for example, `192.168.1.0/24` scans the 254 hosts between `192.168.1.1` and `192.168.1.254`, inclusive)
   - Note that you cannot use an exclamation mark (!) to negate an address value.

   If you specifically target a scan to a host that is in a blacklisted network, that scan will not run.
6. Optionally, to run the scan from a remote device instead of the Defense Center, specify the IP address or name of the device as it appears in the Information page for the device in the Defense Center web interface, in the **Remote Device Name** field.
7. Click **Create**.

   The scan instance is created.

Creating an Nmap Scan Target

LICENSE: FireSIGHT

You can create and save scan targets that identify specific hosts and ports. Then, when you perform an on-demand scan or schedule a scan, you can use one of the saved scan targets.

For scans of targets with IPv4 addresses, you can use an IP address, a list of IP addresses, CIDR notation, or Nmap scan octets to select the hosts to scan. You can also specify a range of addresses using a hyphen. Separate addresses and ranges in a list with commas or spaces.

For scans of IPv6 addresses, use an IP address. Ranges are not supported.

Note that Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, you may want to set up regularly scheduled scans to keep any Nmap-supplied operating system and server data up to date. For more information, see Automating Nmap Scans on page 2013. Also note that if the host is deleted from the network map, any Nmap scan results for that host are discarded.

To create a scan target:

ACCESS: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.

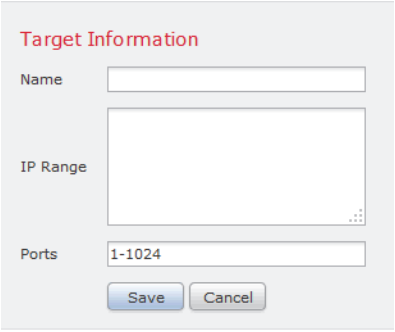
   The Scanners page appears.

2. On the toolbar, click **Targets**.

   The Scan Target List page appears.

3. Click **Create Scan Target**.

   The Scan Target page appears.



4. In the **Name** field, type the name you want to use for this scan target.

5. In the **IP Range** text box, specify the host or hosts you want to scan, using the following syntax:
   - for IPv6 hosts, an exact IP address (for example, `2001:DB8::fedd:eeff`)
   - for IPv4 hosts, an exact IP address (for example, `192.168.1.101`) or comma-separated list of IP addresses
   - for IPv4 hosts, an IP address block using CIDR notation (for example, `192.168.1.0/24` scans the 254 hosts between 192.168.1.1 and 192.168.1.254, inclusive)

     For information on using CIDR notation in the Sourcefire 3D System, see IP Address Conventions on page 63.
   - for IPv4 hosts, an IP address range using octet range addressing (for example, `192.168.0-255.1-254` scans all addresses in the `192.168.x.x` range, except those that end in .0 and or .255)
   - for IPv4 hosts, an IP address range using hyphenation (for example, `192.168.1.1 - 192.168.1.5` scans the 6 hosts between 192.168.1.1 and 192.168.1.5, inclusive)
   - for IPv4 hosts, a list of addresses or ranges separated by commas or spaces (for example, for example, `192.168.1.0/24, 194.168.1.0/24` scans the 254 hosts between 192.168.1.1 and 192.168.1.254, inclusive and the 254 hosts between 194.168.1.1 and 194.168.1.254, inclusive)

IMPORTANT! The **IP Range** text box accepts up to 255 characters. In addition, note that if you use a comma in a list of IP addresses or ranges in a scan target, the comma converts to a space when you save the target.

6. In the **Ports** field, specify the ports you want to scan.

   You can enter any of the following, using values from 1 to 65535:
   - a port number
   - a list of ports separated by commas
   - a range of port numbers separated by a dash
   - ranges of port numbers separated by dashes, separated by commas
7. Click **Save**.

   The scan target is created.

Creating an Nmap Remediation

License: FireSIGHT

You can define the settings for an Nmap scan by creating an Nmap remediation. An Nmap remediation can be used as a response in a correlation policy, run on demand, or scheduled to run at a specific time. In order for the results of an

Nmap scan to appear in the network map, the scanned host must already exist in the network map.

For more information on the specific settings in an Nmap remediation, see Understanding Nmap Remediations on page 1765.

Note that Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host for operating system and server data using Nmap, you may want to set up regularly scheduled scans to keep any Nmap-supplied operating system and server data up-to-date. For more information, see Automating Nmap Scans on page 2013. Also note that if the host is deleted from the network map, any Nmap scan results for that host are discarded.

For general information about Nmap functionality, refer to the Nmap documentation at http://insecure.org.

To create an Nmap remediation:

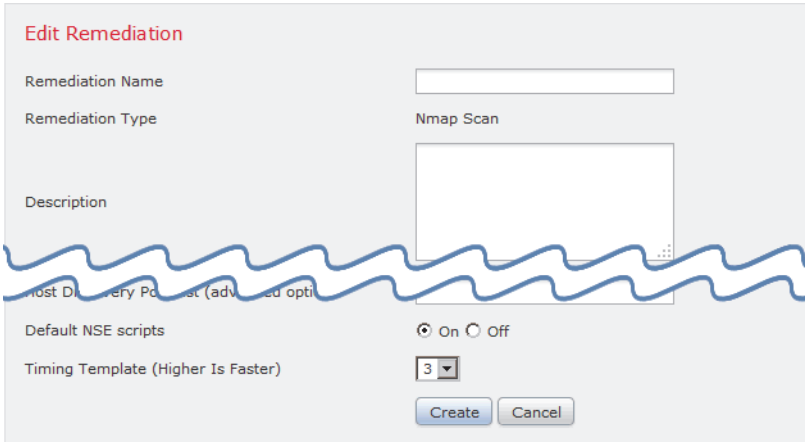
Access: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.

   The Scanners page appears.

2. Click **Add Remediation** next to the scan instance where you want to add a remediation.

   The Edit Remediation page appears.



3. In the **Remediation Name** field, type a name for the remediation that includes 1 to 63 alphanumeric characters, with no spaces and no special characters other than underscore (_) and dash (-).

4. In the **Description** field, type a description for the remediation that includes 0 to 255 alphanumeric characters, including spaces and special characters.
5. If you plan to use this remediation in response to a correlation rule that triggers on an intrusion event, a connection event, or a user event, configure the **Scan Which Address(es) From Event?** option:
   - Select **Scan Source and Destination Addresses** to scan the hosts represented by the source IP address and the destination IP address in the event.
   - Select **Scan Source Address Only** to scan the host represented by the event's source IP address.
   - Select **Scan Destination Address Only** to scan the host represented by the event's destination IP address.

   If you plan to use this remediation in response to a correlation rule that triggers on a discovery event or a host input event, by default the remediation scans the IP address of the host involved in the event; you do not need to configure this option.

   IMPORTANT! Do **not** assign an Nmap remediation as a response to a correlation rule that triggers on a traffic profile change.

6. Configure the **Scan Type** option:
   - To scan quickly in stealth mode on hosts where the `admin` account has raw packet access or where IPv6 is not running, by initiating TCP connections but not completing them, select **TCP Syn Scan**.
   - To scan by using a system `connect()` call, which can be used on hosts where the `admin` account on your Defense Center does not have raw packet access or where IPv6 is running, select **TCP Connect Scan**.
   - To send an ACK packet to check whether ports are filtered or unfiltered, select **TCP ACK Scan**.
   - To send an ACK packet to check whether ports are filtered or unfiltered but also to determine whether a port is open or closed, select **TCP Window Scan**.
   - To identify BSD-derived systems using a FIN/ACK probe, select **TCP Maimon Scan**.
7. Optionally, to scan UDP ports in addition to TCP ports, select **On** for the **Scan for UDP ports** option.

   TIP! A UDP portscan takes more time than a TCP portscan. To speed up your scans, leave this option disabled.

8. If you plan to use this remediation in response to correlation policy violations, configure the **Use Port From Event** option:
   - Select **On** to scan the port in the correlation event, rather than the ports you specify in step 11.

     If you scan the port in the correlation event, note that the remediation scans the port on the IP addresses that you specified in step 5. These ports are also added to the remediation's dynamic scan target.
   - Select **Off** to scan only the ports you will specify in step 11.
9. If you plan to use this remediation in response to correlation policy violations and want to run the scan using the appliance running the detection engine that detected the event, configure the **Scan from reporting detection engine** option:
   - To scan from the appliance running the reporting detection engine, select **On**.
   - To scan from the appliance configured in the remediation, select **Off**.
10. Configure the **Fast Port Scan** option:
    - To scan only the ports listed in the `nmap-services` file located in the `/var/sf/nmap/share/nmap/nmap-services` directory on the device that does the scanning, ignoring other port settings, select **On**.
    - To scan all TCP ports, select **Off**.
11. In the **Port Ranges and Scan Order** field, type the ports you want to scan by default, using Nmap syntax, in the order you want to scan those ports.

    Specify values from 1 to 65535. Separate ports using commas or spaces. You can also use a hyphen to indicate a port range. When scanning for both TCP and UDP ports, preface the list of TCP ports you want to scan with a T and the list of UDP ports with a U. For example, to scan ports 53 and 111 for UDP traffic, then scan ports 21-25 for TCP traffic, enter `U:53,111,T:21-25`.

    Note that the **Use Port From Event** option overrides this setting when the remediation is launched in response to a correlation policy violation, as described in step 8.
12. To probe open ports for server vendor and version information, configure **Probe open ports for vendor and version information:**
    - Select **On** to scan open ports on the host for server information to identify server vendors and versions.
    - Select **Off** to continue using Sourcefire server information for the host.
13. If you choose to probe open ports, set the number of probes used by selecting a number from the **Service Version Intensity** drop-down list:
    - To use more probes for higher accuracy with a longer scan, select a higher number.
    - To use fewer probes for less accuracy with a faster scan, select a lower number.

14. To scan for operating system information, configure **Detect Operating System** settings:
    - Select **On** to scan the host for information to identify the operating system.
    - Select **Off** to continue using Sourcefire operating system information for the host.
15. To determine whether host discovery occurs and whether port scans are only run against available hosts, configure **Treat All Hosts As Online**:
    - To skip the host discovery process and run a port scan on every host in the target range, select **On**.
    - To perform host discovery using the settings for **Host Discovery Method** and **Host Discovery Port List** and skip the port scan on any host that is not available, select **Off**.
16. Select the method you want Nmap to use when it tests for host availability:
    - To send an empty TCP packet with the SYN flag set and elicit an RST response on a closed port or a SYN/ACK response on an open port on available hosts, select **TCP SYN**.

      Note that this option scans port 80 by default and that TCP SYN scans are less likely to be blocked by a firewall with stateful firewall rules.
    - To send an empty TCP packet with the ACK flag set and elicit an RST response on available hosts, select **TCP ACK.**

      Note that this option scans port 80 by default and that TCP ACK scans are less likely to be blocked by a firewall with stateless firewall rules.
    - To send a UDP packet to elicit port unreachable responses from closed ports on available hosts, select **UDP**. This option scans port 40125 by default.
17. If you want to scan a custom list of ports during host discovery, type a list of ports appropriate for the host discovery method you selected, separated by commas, in the **Host Discovery Port List** field.
18. Configure the **Default NSE Scripts** option to control whether to use the default set of Nmap scripts for host discovery and server, operating system, and vulnerability discovery:
    - To run the default set of Nmap scripts, select **On**.
    - To skip the default set of Nmap scripts, select **Off**.

    See http://nmap.org/nsedoc/categories/default.html for the list of default scripts.
19. To set the timing of the scan process, select a timing template number; select a higher number for a faster, less comprehensive scan and a lower number for a slower, more comprehensive scan.

20. Click **Save**, then click **Done**.

    The remediation is created.

Managing Nmap Scanning

LICENSE: FireSIGHT

You can modify or delete Nmap scan instances and remediations as needed. You can also run an on-demand Nmap scan. You can also view or download Nmap results for previous scans. For more information, see the following sections:

- Managing Nmap Scan Instances on page 1782
- Managing Nmap Remediations on page 1784
- Running an On-Demand Nmap Scan on page 1785

Managing Nmap Scan Instances

LICENSE: FireSIGHT

You can edit or delete Nmap scan instances. For more information, see the following sections:

- Editing an Nmap Scan Instance on page 1782
- Deleting an Nmap Scan Instance on page 1783

Editing an Nmap Scan Instance

LICENSE: FireSIGHT

Use the following procedure to modify scan instances. Note that you can view, add, and delete remediations associated with the instance when you modify it.

To edit a scan instance:

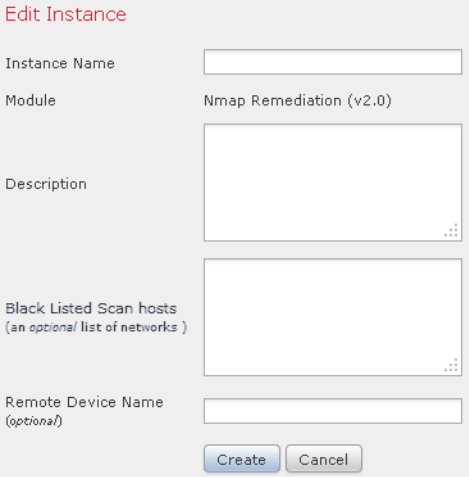
ACCESS: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.

   The Scanners page appears.

2. Click **View** next to the instance you want to edit.

   The Instance Detail page appears.



3. Optionally, click **View** next to the remediation you want to view or edit.

   For more information on editing remediations, see Editing an Nmap Remediation on page 1784.

4. Optionally, click **Delete** next to the remediation you want to delete.

   For more information on deleting remediations, see Deleting an Nmap Remediation on page 1784.

5. Optionally, click **Add** to add a new remediation to this scan instance.

   For more information on creating new remediations, see Managing Nmap Remediations on page 1784.

6. Optionally, make changes to the scan instance settings, then click **Save**.

7. Click **Done**.

   The scan instance is modified.

Deleting an Nmap Scan Instance

License: FireSIGHT

Delete an Nmap scan instance when you no longer want to use the Nmap module profiled in the instance. Note that when you delete the scan instance, you also delete any remediations that use that instance.

To delete a scan instance:

Access: Admin/Discovery Admin

1. Click **Policies > Actions > Scanners**.

   The Scanners page appears.

2. Click **Delete** next to the scan instance you want to delete.

   The instance is deleted.

Managing Nmap Remediations

License: FireSIGHT

You can edit or delete Nmap remediations. For more information, see the following sections:

- Editing an Nmap Remediation on page 1784
- Deleting an Nmap Remediation on page 1784

Editing an Nmap Remediation

License: FireSIGHT

Modifications you make to Nmap remediations do not affect scans in progress. The new settings take effect when the next scan starts.

To edit an Nmap remediation:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.

   The Scanners page appears.

2. Next to the remediation you want to edit, click **View**.

   The Remediation Edit page appears.

3. Make modifications as necessary.

   For information on the settings you can change, see Creating an Nmap Remediation on page 1777.

4. Click **Save**, then click **Done**.

   The remediation is modified.

Deleting an Nmap Remediation

License: FireSIGHT

Delete an Nmap remediation if you no longer need it.

To delete an Nmap remediation:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.

   The Scanners page appears.

2. Next to the remediation you want to delete, click **Delete**.

3. Confirm that you want to delete the remediation.

   The remediation is deleted.

Running an On-Demand Nmap Scan

LICENSE: FireSIGHT

You can launch on-demand Nmap scans whenever needed. You can specify the target for an on-demand scan by entering the IP addresses and ports you want to scan or by selecting an existing scan target.

Note that Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, you may want to set up regularly scheduled scans to keep any Nmap-supplied operating system and server data up to date. For more information, see Automating Nmap Scans on page 2013. In addition, note that if the host is deleted from the network map, any Nmap scan results are discarded.

To run an on-demand Nmap scan:

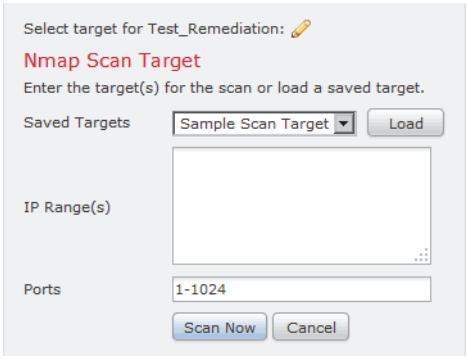
ACCESS: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.

   The Scanners page appears.

2. Next to the Nmap remediation you want to use to perform the scan, click **Scan**.

   The Nmap Scan Target dialog box appears.



3. Optionally, to scan using a saved scan target, select a target from the **Saved Targets** drop-down list and click **Load**.

   The IP addresses and ports associated with the scan target populate the **IP Range(s)** and **Ports** fields.

   TIP! To create a scan target, click **Edit/Add Targets**. For more information, see Creating an Nmap Scan Target on page 1776.

4. In the **IP Range(s)** field, specify the IP address for hosts you want to scan or modify the loaded list, up to 255 characters.

   For hosts with IPv4 addresses, you can specify multiple IP addresses separated by commas or use CIDR notation. You can also negate IP addresses by preceding them with an exclamation point (!). For information on using CIDR notation in the Sourcefire 3D System, see IP Address Conventions on page 63.

   For hosts with IPv6 addresses, use an exact IP address. Ranges are not supported.

5. In the **Ports** field, specify the ports you want to scan or modify the loaded list.

   You can enter a port number, a list of ports separated by commas, or a range of port numbers separated by a dash. For details on entering ports, see Specifying Ports in Searches on page 1849.

6. Click **Scan Now**.

   The Nmap server performs the scan.

   Note that Nmap validates IP address ranges and displays an error message if the range is invalid. If this occurs, correct the contents of the **IP Range(s)** field to indicate a valid IP address range.

Managing Scan Targets

License: FireSIGHT

When you configure an Nmap module, you can create and save scan targets that identify the hosts and ports you want to target when you perform an on-demand or a scheduled scan, so that you do not have to construct a new scan target every time. A scan target includes a single IP address or a block of IP addresses to scan, as well as the ports on the host or hosts. For Nmap targets, you can also use Nmap octet range addressing or IP address ranges. For more information on Nmap octet range addressing, refer to the Nmap documentation at http://insecure.org.

Note that scans for scan targets containing a large number of hosts can take an extended period of time. As a workaround, scan fewer hosts at a time.

After you create a scan target, you can modify or delete it.

For more information, see the following sections:

- Creating an Nmap Scan Target on page 1776
- Editing a Scan Target on page 1787
- Deleting a Scan Target on page 1788

Editing a Scan Target

LICENSE: FireSIGHT

You can modify scan targets you created.

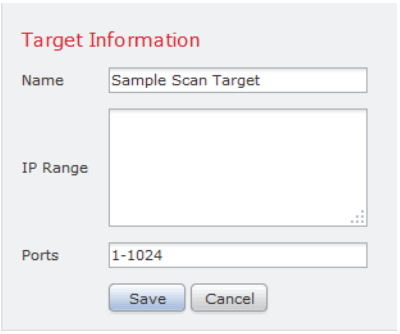
TIP! You might want to edit a remediation's dynamic scan target if you do not want to use the remediation to scan a specific IP address, but the IP address was added to the target because the host was involved in a correlation policy violation that launched the remediation.

To edit an existing scan target:

ACCESS: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.
   The Scanners page appears.
2. On the toolbar, click **Targets**.
   The Scan Target List page appears.

3. Click **Edit** next to the scan target you want to edit.
   The Scan Target page appears.



4. Make modifications as necessary and click **Save**.
   The scan target is updated.

Deleting a Scan Target

License: FireSIGHT

Delete a scan target if you no longer want to scan the hosts listed in it.

To delete a scan target:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.
   The Scanners page appears.
2. On the toolbar, click **Targets**.
   The Scan Target List page appears.

3. Next to the scan target you want to delete, click **Delete**.
   The scan target is deleted.

Working with Active Scan Results

License: FireSIGHT

For information on how to monitor Nmap scans in progress, import results from scans previously performed through the Sourcefire 3D System or results preformed outside the Sourcefire 3D System, and view and analyze scan results, see the following sections:

- Viewing Scan Results on page 1788
- Understanding the Scan Results Table on page 1790
- Analyzing Scan Results on page 1791
- Monitoring Scans on page 1791
- Importing Scan Results on page 1792
- Searching for Scan Results on page 1793

Viewing Scan Results

License: FireSIGHT

You can view a table of scan results, and then manipulate the event view depending on the information you are looking for.

The page you see when you access scan results differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of scan results.

You can also create a custom workflow that displays only the information that matches your specific needs. For information on creating a custom workflow, see

Creating Custom Workflows on page 1916.

The Scan Results Table Functions table below describes some of the specific actions you can perform on a scan results workflow page.

Scan Results Table Functions

To...	You can...
learn more about the contents of the columns in the table	find more information in Understanding the Scan Results Table on page 1790.
modify the time and date range for the scan result	click the time range link. For more information, see Setting Event Time Constraints on page 1896.
sort scan results	click the column title. Click the column title again to reverse the sort order.
constrain the columns that appear	click the close icon (✖) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**. **TIP!** To hide or show other columns, select or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, Click the expand arrow ( ) to expand the search constraints, then click the column name under **Disabled Columns**.
drill down to the next page in the workflow, constraining on a specific value	use one of the following methods: • on a drill-down page that you created in a custom workflow, click a value within a row. Note that clicking a value within a row in a table view constrains the table view and does **not** drill down to the next page. • To drill down to the next workflow page constraining on some users, select the check boxes next to the users you want to view on the next workflow page, then click **View**. • To drill down to the next workflow page keeping the current constraints, click **View All**. **TIP!** Table views always include "Table View" in the page name. For more information, see Constraining Events on page 1905.

Scan Results Table Functions (Continued)

To...	You can...
configure scan instances and remediations	Click **Scanners** in the toolbar. For more information, see Setting up Nmap Scans on page 1774.
navigate within and between workflow pages	find more information in Using Workflow Pages on page 1889.
navigate to other event views to view associated events	the name of the event view you want to see from the **Jump to** drop-down list. For more information, see Navigating Between Workflows on page 1911.
search for scan results	click **Search**. For more information, see Searching for Scan Results on page 1793.

To view scan results:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners.**
2. Click **Scan Results**.

   The first page of the default scan results workflow appears. To use a different workflow, including a custom workflow, click **(switch workflows)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

Understanding the Scan Results Table

License: FireSIGHT

When you run an Nmap scan, the Defense Center collects the scan results in a database. The fields in the scan results table are described in the Scan Results Fields table.

Scan Results Fields

Field	Description
Start Time	The date and time that the scan that produced the results started.
End Time	The date and time that the scan that produced the results ended.

Scan Results Fields (Continued)

Field	Description
Scan Target	The IP address (or host name, if DNS resolution is enabled) of the scan target for the scan that produced the results.
Scan Type	Either `Nmap` or the name of the third-party scanner to indicate the type of the scan that produced the results.
Scan Mode	The mode of the scan that produced the results: • `On Demand` — results from scans run on demand. • `Imported` — results from scans on a different system and imported onto the Defense Center. • `Scheduled` — results from scans run as a scheduled task.

Analyzing Scan Results

License: FireSIGHT

You can view scan results that you create using the local Nmap module as a rendered page in a pop-up window. You can also download the Nmap results file in raw XML format.

You can also view operating system and server information detected by Nmap in host profiles and in the network map. If a scan of a host produces server information for servers on filtered or closed ports, or if a scan collects information that cannot be included in the operating system information or the servers section, the host profile includes those results in an Nmap Scan Results section. For more information, see Viewing Host Profiles on page 1398.

Monitoring Scans

License: FireSIGHT

You can check the progress of an Nmap scan and cancel scan jobs currently in progress. Scan results provide the start time and end time of each scan. Also, after a scan is completed, you can also view the scan results as a rendered page in a pop-up window. Nmap results you can download and view using the Nmap Version 1.01 DTD, available at http://insecure.org. You can also clear scan results.

To monitor a scan:

Access: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners.**
2. Click **Scan Results**.

   The first page of the default scan results workflow appears. To use a different workflow, including a custom workflow, click **(switch workflows)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

   TIP! If you are using a custom workflow that does not include the table view of scan results, click **(switch workflows)** by the workflow title, then select **Scan Results**.

3. You can perform the following actions:
   - To view the scan results as a rendered page in a pop-up window, click **View** next to the scan job.
   - To save a copy of the scan results file so that you can view the raw XML code in any text editor, click **Download** next to the scan job.

Importing Scan Results

License: FireSIGHT

You can import XML results files created by an Nmap scan performed outside of the Sourcefire 3D System. You can also import XML results files that you previously downloaded from the Sourcefire 3D System. To import Nmap scan results, the results file must be in XML format and adhere to the Nmap Version 1.01 DTD. For more information on creating Nmap results and on the Nmap DTD, refer to the Nmap documentation at http://insecure.org. For information on downloading XML results from the Sourcefire 3D System, see Monitoring Scans on page 1791.

Note that a host must exist in the network map before Nmap can append its results to the host profile.

To import results:

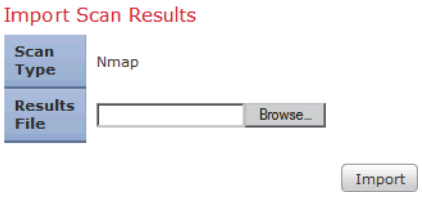
Access: Admin/Discovery Admin

1. Select **Policies > Actions > Scanners**.

   The Scan Instances page appears.

2. On the toolbar, click **Import Results**.

   The Import Results page appears.



3. Click **Browse** to navigate to the results file.
4. After you return to the Import Results page, click **Import** to import the results.

   The results file is imported.

Searching for Scan Results

LICENSE: FireSIGHT

You can search for Nmap or third-party scan results for any scans run on an appliance or managed appliance in your Sourcefire 3D System.

Scan Results Search Criteria

FIELD	SEARCH CRITERIA RULES
Start Time	Type the date and time that the scan that produced the results started. See Specifying Time Constraints in Searches on page 1847 for the syntax for entering time.
End Time	Type the date and time that the scan that produced the results ended. See Specifying Time Constraints in Searches on page 1847 for the syntax for entering time.
Scan Target	Type the IP address (or host name, if DNS resolution is enabled) of the scan target for the scan that produced the results. Use a specific IP address or CIDR notation to specify a range of IP addresses. See Specifying IP Addresses in Searches on page 1848 for a full description of the syntax allowed for IP addresses.
Scan Type	Type `Nmap` or a third-party scanner ID to indicate the type of the scan that produced the results.
Scan Mode	Type the mode of the scan that produced the results: • Type `On Demand` to retrieve results from scans run on demand. • Type `Imported` to retrieve results from scans on a different system and imported onto the Defense Center. • Type `Scheduled` to retrieve results from scans run as a scheduled task.

For more information on searching, including how to load and delete saved searches, see Searching for Events on page 1842.

To search for scan results:

Access: Admin/Discovery Admin

1. Select **Analysis > Search**, then select **Scan Results** from the **Table** drop-down list.

   The Scan Results search page appears.

   TIP! To search the database for a different kind of event, select it from the **Table** drop-down list.

2. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, the Defense Center automatically creates one when you save the search.

3. Enter your search criteria in the appropriate fields, as described in the Scan Results Search Criteria table. If you enter multiple criteria, the Defense Center returns only the records that match all the criteria.

4. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search so that only you can use it.

   TIP! If you want to save a search as a restriction for custom user roles with restricted privileges (or for converted Restricted Event Analysts from pre-4.10.1 versions), you **must** save it as a private search.

5. You have the following options:
   - Click **Search** to start the search.

     Your search results appear.
   - Click **Save** if you are modifying an existing search and want to save your changes.
6. Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

CHAPTER 42
WORKING WITH REPORTS

The Sourcefire 3D System provides a flexible reporting system that allows you to quickly and easily generate multi-section reports with the event views or dashboards that appear on your Defense Center. You can also design your own custom reports from scratch. Reporting is available only on Defense Centers.

A report is a document file formatted in PDF, HTML, or CSV with the content you want to communicate. A report template specifies the data searches and formats for the report and its sections. The Sourcefire 3D System includes a powerful report designer that automates the design of report templates. You can replicate the content of any event view table or dashboard graphic displayed in the web interface.

You can build as many report templates as you need. Each report template defines the individual sections in the report and specifies the database search that creates the report's content, as well as the presentation format (table, chart, detail view, and so on) and the time frame. Your template also specifies document attributes, such as the cover page and table of contents and whether the document pages have headers and footers (available only for reports in PDF format). You can export a report template in a single configuration package file and import it for reuse on another Defense Center.

You can include input parameters in a template to expand its usefulness. Input parameters allow you to produce tailored variations of the same report. When you generate a report with input parameters, the generation process prompts you to enter a value for each input parameter. The values you type constrain the report contents on a one-time basis. For example, you can place an input parameter in the destination IP field of the search that produces an intrusion event report; at report generation time, you can specify a department's network segment when

prompted for the destination IP address. The generated report then contains only information concerning that particular department.

See the following sections for more information on reports and report templates:

- Generating Reports on page 1797
- Using Report Templates on page 1808
- Managing Report Templates and Report Files on page 1838

Generating Reports

License: Any

The Sourcefire 3D System's reporting feature allows you to quickly capture the content of any event view, dashboard, or workflow from your Defense Center and present it in report format.

For more information, see the following sections:

- Creating a Report Template from an Event View on page 1797
- Creating a Report Template by Importing a Dashboard or Workflow on page 1799
- Generating Reports from a Report Template on page 1801
- Using Report Generation Options on page 1804

Creating a Report Template from an Event View

License: Any

Before you generate a report, the reporting system creates a report template that you can modify to meet your needs. You can add additional sections, modify automatically included sections, and delete sections.

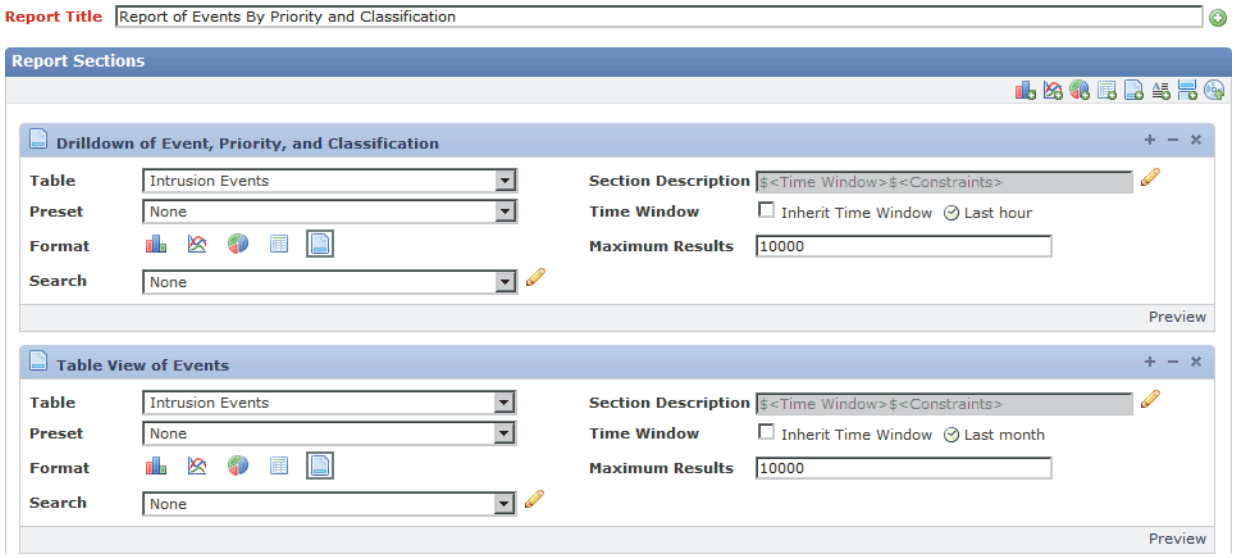
To create a report template from an event view:

Access: Admin/Any Security Analyst

1. Populate an event view with the events you want in the report. You can do this in various ways:
   - Use an event search to define the events you want to view. For details on using the event search, see Searching for Events on page 1842.
   - Drill down through a workflow until you have the appropriate events in your event view. For details on workflows and how to constrain events within a workflow, see Understanding and Using Workflows on page 1865.

2. From the event view page, click **Report Designer**.

   The Report Sections page appears with a section for each view in the captured workflow. The following graphic shows the first two sections of a report template built from an intrusion event workflow.



3. Optionally, type a new name in the **Report Title** field and click **Save**.

4. Optionally, delete any template sections that you want to exclude from the report by clicking the delete icon (✖) in the section's title bar, and confirm the deletion.

   The deleted sections disappear.

IMPORTANT! The last report section in some workflows contains detail views that show packets, host profiles, or vulnerabilities, depending on the workflow. Retrieving large numbers of events with these detail views when generating your report may affect performance of the Defense Center.

5. Optionally, adjust the settings of the fields in your report sections.

   For details on configuring the fields in a report section, see Editing the Sections of a Report Template on page 1815.

TIP! To view the current column layout or chart formatting for a section, click the section's **Preview** link.

6. Optionally, change the title of any section by clicking the section title in the title bar.

   The Set Section Title pop-up window appears. Type the section title and click **OK**.

7. Optionally, add page breaks. Click the add page break icon ( ).

   A new page break object appears at the bottom of the template. Drag it in front of the section that should start the new page. For information on using page breaks, see Editing the Sections of a Report Template on page 1815.

8. Optionally, add text sections. Click the add text section icon ( ).

   A new text section appears at the bottom of the template. Drag it to the place where it should appear in the report template. For information about editing a text section, see Editing the Sections of a Report Template on page 1815.

   TIP! Text sections, which support rich text (bold, italics, variable font size, and so on) as well as imported images, are useful for introductions to your report or your report sections.

9. Optionally, click **Advanced Settings** to add a cover page, table of contents, starting page number, or header and footer text. For more information, see Editing Document Attributes in a Report Template on page 1828.

10. When the report template is correct, click **Save**.

    The report template is saved and an entry for the report template appears on the Report Templates page.

Creating a Report Template by Importing a Dashboard or Workflow

LICENSE: Any

You can quickly create a new report by importing dashboards, workflows, and statistics summaries. The import creates a section for each widget graphic in your dashboard and each event view in your workflow. You can delete any unnecessary sections to focus on the most important information. The Data Source Options on Import Report Sections Window table describes the import options.

Data Source Options on Import Report Sections Window

SELECT THIS OPTION...	TO IMPORT...
Import Dashboard	any custom analysis widget on the selected dashboard.

Data Source Options on Import Report Sections Window (Continued)

SELECT THIS OPTION...	TO IMPORT...
Import Workflow	any predefined or custom workflow. **TIP!** Selections have the format: `Table - Workflow name` For example, `Connection Events - Traffic by Port` imports the views in the Traffic by Port workflow generated from the Connection Events table.
Import Summary Sections	any of the following generic summaries: • Intrusion Detailed Summary • Intrusion Short Summary • Discovery Detailed Summary • Discovery Short Summary

To create a report template from a dashboard, workflow, or statistics summary:

ACCESS: Admin/Any Security Analyst

1. Identify the dashboard, workflow, or summary you want to replicate in your report.
2. Select **Overview > Reporting**.
3. Click the **Report Templates** tab.

   The Report Templates page appears.
4. Click **Create Report Template**.

   The Report Sections page appears.
5. Type a name for your new report template in the **Report Title** field.
6. Click **Save** to save the report template under the new name.

   The report template is saved and an entry for the report template appears on the Report Templates page.
7. Click the import sections from dashboard, summaries and workflows icon ().

   The Import Report Sections pop-up window appears. You can choose any of the data sources described in the Data Source Options on Import Report Sections Window table.
8. Select a dashboard, workflow or summary from the drop-down menus.

9. For the data sources you want to add, click **Import**.

   The Report Sections page for your template reappears with a section for each element of the selected data source. For dashboards, each widget graphic will have its own section; for workflows, each event view will have its own section.

10. Make changes to the content of your sections as needed.

    For information on editing a report template, see Editing the Sections of a Report Template on page 1815.

    IMPORTANT! The last report section in some workflows contains detail views that show packets, host profiles, or vulnerabilities, depending on the workflow. Retrieving large numbers of events with these detail views when generating your report may affect performance of the Defense Center.

11. When the report template is correct, click **Save**.

    The report template is saved and an entry for the report template appears on the Report Templates page.

Generating Reports from a Report Template

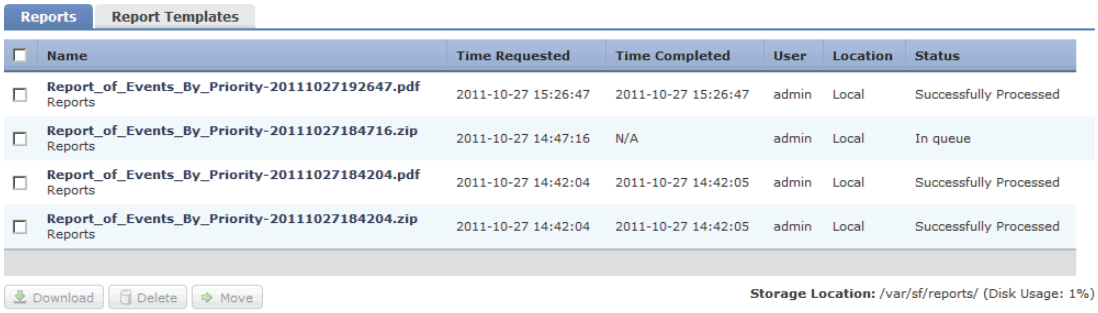
LICENSE: Any

After you define your report template, you are ready to generate the report itself. The generation process lets you select the report's format (HTML, PDF, or CSV). You can also adjust the report's global time window, which applies a consistent time frame to all sections except those you exempt. For information on setting the report time window, see Setting the Time Window for a Template and Its Sections on page 1819.

If the report template includes user input parameters in its search specification, the generation process prompts you to enter values, which tailor this run of the report to a subset of the data. For information on input parameters, see Using Input Parameters on page 1822.

The Reports tab lists all previously generated reports, with report name, date and time of generation, generating user, and whether the report is stored locally or remotely. A status column indicates whether the report is already generated, is in

the generation queue (for example, for scheduled tasks), or failed to generate (for example, due to lack of disk space).



The Reports tab page shows all locally stored reports. It shows remotely stored reports as well, if remote storage is currently configured. The location of your currently configured report storage appears at the bottom of the page, with disk usage for local, NFS, and SMB storage. If you access remote storage using SSH, disk usage data is not available. For information on setting up remote storage, see Using Remote Storage for Reports on page 1837.

IMPORTANT! If you store remotely and then switch back to local storage, the reports in remote storage do not appear on the Reports tab list. Similarly, if you switch from one remote storage location to another, the reports in the previous location do not appear in the list.

Note that reports only display the IP address if the system cannot resolve the IP address to a host name.

Use the following procedure to generate and view reports. Note that users with Administrator access can view all reports; other users can view only the reports they generated.

To generate a report from a report template:

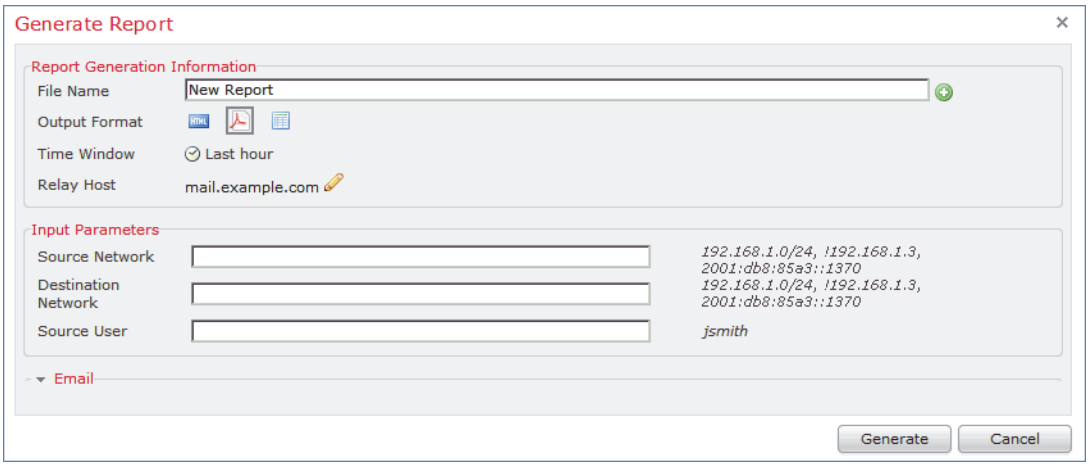
Access: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Click the **Report Templates** tab.

   The Report Templates page appears.

3. Click the generate report icon ( ) for the template you want to use.

   The Generate Report pop-up dialog appears.



4. Optionally, type a new name in the **File Name** field. This sets the name of the generated report file. You may also use the input parameter icon ( ) to add one or more input parameters to the file name. For information on input parameters, see Using Input Parameters on page 1822.

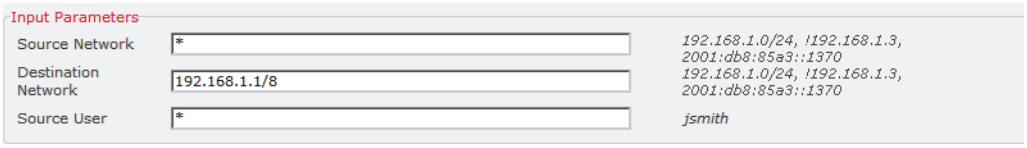
5. Select the output format for the report by clicking the corresponding icon: HTML, PDF, or CSV.

6. Optionally, change the global time window by clicking the time window icon ( ).

   The Events Time Window pop-up window appears. For information on setting the events time window, see Setting Event Time Constraints on page 1896.

IMPORTANT! Setting the global time window affects the content of individual report sections only if they are configured to inherit the global setting. For information on report section inheritance of the global time window, see Setting the Time Window for a Template and Its Sections on page 1819.

7. Type values for any fields that appear in the **Input Parameters** section.

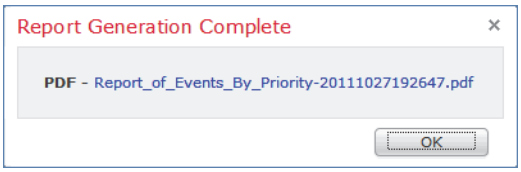


TIP! You can ignore user parameters by typing the * wildcard character in the field. This eliminates the user parameter's constraint on the search.

8. Optionally, if an email relay host is configured in your system policy, click **Email** to automate email delivery of the report when it generates. For details about email delivery features, see Distributing Reports by Email at Generation Time on page 1835.

9. Click **OK** and confirm when prompted.

   The Report Generation Complete pop-up window appears with a link to view your report.



10. Click either:
    - the report link, which opens a new window to display the report, or
    - **OK** to return to the Report Section page, where you can modify your report design.

You can review completed reports after initial generation, as well.

To view a generated report:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Click the **Reports** tab.

   The Reports page appears.
3. Click the name of the report.

   The default program on your local host opens the report in a new window.
4. When finished viewing the document, use your browser to return to the **Reports** tab.

Using Report Generation Options

LICENSE: Any

You have the following options when generating reports:

- schedule your reports to be automatically generated — see Generating Reports Using the Scheduler on page 1835
- automatically distribute new reports by email — see Distributing Reports by Email at Generation Time on page 1835
- store your report files on a remote host — see Using Remote Storage for Reports on page 1837

Managing Reports

LICENSE: Any

You have the following options for managing the report files you have generated:

- saving report files to your local computer — see Downloading Reports on page 1840
- deleting report files — see Deleting Reports on page 1841

Understanding Report Templates

LICENSE: Any

You use report templates to define the content and format of the data in each of the report's sections, as well as the document attributes of the report file (cover page, table of contents, and page headers and footers). After you generate a report, the template stays available for reuse until you delete it.

Your reports contain one or more information sections. You choose the format (text, table, or chart) for each section individually. The format you select for a section may constrain the data that can be included. For example, you cannot show time-based information in certain tables using a pie chart format. You can change the data criteria or format of a section at any time to obtain optimum presentation.

You can base a report's initial design on a predefined event view, or you can start your design by importing content from any defined dashboard, workflow, or summary. You can also start with an empty template shell, adding sections and defining their attributes one by one.

All sections in a report template have a title bar and various attribute fields that control the section's contents and appearance. For more information, see the following:

- the Report Section Title Bar Elements table on page 1806
- the Report Section Fields table on page 1806

The Report Section Title Bar Elements table describes the controls on the title bar for each template section.

Report Section Title Bar Elements

ATTRIBUTE	DEFINITION
title bar name	Contains the name of the section as it appears in the report. Change it by clicking it and typing a new name.
title bar icons	Click the duplicate icon (+) to add a duplicate of the section to the report template. Click the minimize icon (−) to minimize the section. Click the delete icon (×) to delete the section, after confirmation.

The Report Section Fields table defines the fields in each section of a report template.

Report Section Fields

FIELD NAME	DEFINITION
Table	Presents a drop-down menu that allows you to select the table from which the section data is extracted.
Preset	Presents a drop-down menu of predefined searches. You can select an appropriate preset to initialize the search criteria when you define a new search.

Report Section Fields (Continued)

Field Name	Definition
Format	Presents icons that allow you to select the format of the section data. Options include:  Bar chart: Compares quantities of the selected variables.  Line chart: Shows trends/changes over time of a selected variable. Available only for time-based tables.  Pie chart: Shows each selected variable as a percentage of the whole. Variables with quantities of zero are dropped from the chart. Very small quantities are clustered into a category labeled **Other**.  Table view: Shows values of attributes for each record. Not available for summary or statistical data.  Detail view: Shows complex object data associated with certain events, such as packets (for intrusion events) and host profiles (for host events). Format is available only for certain event types that involve such objects. Output may degrade performance if large numbers are requested.
Search or Filter	Presents a drop-down menu of searches or application filters. For most tables, you can constrain a report using a predefined or saved **Search**. You can also create a new search by clicking the edit icon (); see Working with Searches in Report Template Sections on page 1821. For the Application Statistics table, you use a user-defined application **Filter** to constrain a report; for information on creating filters, see Working with Application Filters on page 192.
X-Axis	Presents a drop-down menu of available data columns for the X-axis of the selected chart. Appears only when you select a chart format. For line charts, the X-axis value is always **Time**. For bar and pie charts, you cannot select **Time** as the X-axis value.
Y-Axis	Presents a drop-down menu of available data columns for the Y-axis of the selected chart.

Report Section Fields (Continued)

Field Name	Definition
Section Description	Defines the descriptive text that precedes the search data in the section. Enter a combination of text and input parameters. Default for a new section is the following set of two input parameters: $<Time Window> and $<Constraints>. For more information on input parameters, see Using Input Parameters on page 1822.
Time Window	Defines the time window for the data that appears in the section. If the section searches time-based tables, you can select the check box to inherit the report's global time window. Alternatively, you can set a specific time window for the section. For information about setting the time window, see Editing the Sections of a Report Template on page 1815.
Results	Select either **Top** or **Bottom** and enter the maximum number of records to be included in the section.
Color	Defines the colors for graphed data in the section. Select one or more colors, as applicable.

Using Report Templates

License: Any

You can build a new report template in any of the following ways:

- Creating a Report Template from an Event View on page 1797
- Creating a Report Template by Importing a Dashboard or Workflow on page 1799
- Creating Report Templates from Existing Templates on page 1809
- Creating New Report Templates on page 1812

After you have populated your template with sections, you can edit the document attributes and section attributes as necessary. For information, see:

- Editing Document Attributes in a Report Template on page 1828
- Editing the Sections of a Report Template on page 1815

The key to successful reports is defining the searches that populate the report's sections. For information on defining these searches, see Working with Searches in Report Template Sections on page 1821.

Creating Report Templates from Existing Templates

LICENSE: Any

You can build a new report template by copying any existing template. If you identify a good model among your existing templates, you can copy it and edit its attributes as necessary.

TIP! Sourcefire provides a set of predefined report templates. You can see their names in the list of templates on the **Report Templates** tab. For a description of their attributes, see Using Sourcefire Predefined Report Templates on page 1809.

To create a report template from an existing template:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Click the **Report Templates** tab.

   The Report Templates page appears. For information about Sourcefire-provided report templates, see Using Sourcefire Predefined Report Templates on page 1809.
3. Click the copy icon () next to the report template you want to copy as a model.

   The copied template appears as a new report template.
4. In the **Report Title** field, type a name for your new report template.
5. Click **Save**.

   The report template is saved and an entry for the new report template appears on the Report Templates page.
6. Make changes to the template as needed.

   For information on defining the sections of the template and the document attributes, see:

   - Editing the Sections of a Report Template on page 1815
   - Editing Document Attributes in a Report Template on page 1828

Using Sourcefire Predefined Report Templates

LICENSE: Any

The following Sourcefire-predefined report templates are included with the Sourcefire 3D System:

- Host Report: $<Host>
- User Report: $<User>
- Attack Report: Attack $<Attack SID>
- Malware Report

- Sourcefire FireSIGHT Report: $<Customer Name>
- Files Report

You can use these templates as is, edit them, or use them as the basis for your own templates.

Host Report: $<Host>

The Host Report: $<Host> report template provides information about a specific host on the network. This report template contains the following sections:

- Server Applications
- Client Applications
- Intrusion Events Originating from This Host
- Intrusion Events Destined to This Host
- Connections Originating from This Host
- Connections Destined to This Host
- Users of This Host
- White List Violations by This Host

User Report: $<User>

The User Report: $<User> report template provides information about a specific user on the network. This report template contains the following sections:

- Client Applications Used by This User
- Web Applications Used by This User
- Application Protocols Used by This User
- Comprehensive List of Applications Used by This User
- Intrusion Events Originated By This User's Machines
- Intrusion Events Destined to This User's Machines
- Connections Originating from This User's Machines
- Connections Destined to This User's Machines
- Hosts for This User

Attack Report: Attack $<Attack SID>

The Attack Report: Attack $<Attack SID> report template provides information about a specific attack on the network. This report template contains the following sections:

- General Information About This Attack
- Number of Attacks
- Number of Machines Initiating Attack
- Number of Machines Being Attacked

- Sources of This Attack
- Destinations of This Attack
- Traffic Patterns of This Attack

Malware Report

The Malware Report report template provides information about network and endpoint-based malware events. This report template contains the following sections:

- Malware Threats
- Threat Detections over Time
- Application Protocols Transferring Malware
- Hosts Receiving Malware
- Hosts Sending Malware
- Users Affected by Malware
- Malware Intrusions
- File Types Infected with Malware
- Applications Introducing Malware
- Table View of Malware Events

Note that neither Series 2 devices nor the DC500 Defense Center support network-based malware protection, which can affect the data detected and displayed. For example, a Series 3 Defense Center managing only Series 2 devices can display only endpoint-based malware events.

Sourcefire FireSIGHT Report: $<Customer Name>

The Sourcefire FireSIGHT Report: $<Customer Name> report template provides overall information about an organization's network. This report template contains the following sections:

- Summary of Application Traffic by Risk
- Risky Applications with Low Business Relevance
- Users of Risky Applications
- Anonymizers and Proxies
- Typically High Bandwidth Applications
- Applications by Total Bandwidth
- Hosts Accessing Sensitive Network
- Users Accessing Sensitive Network
- Applications on Sensitive Network
- Ports and Protocols Related to Sensitive Network
- Hosts Visiting Malicious URLs

- Users Visiting Malicious URLs
- Granular Application Usage
- Web Applications
- Client Applications
- Application Protocols
- Web Browser Versions
- Operating System Versions
- Overall User Activity
- Intrusion Events by Impact
- Intrusion Events by Impact (After Blocking)
- Intrusion Events by Application
- Top Intrusion Events
- Comprehensive Application List

Files Report

The Files Report report template provides information about files detected in network traffic by managed devices. This report template contains the following sections:

- File Transfers over Time
- Application Protocols Used by File Transfers
- File Dispositions
- File Actions
- Hosts Receiving Files
- Hosts Sending Files
- Users Transferring Files
- File Categories
- File Types
- File Names
- Table View of File Events

Creating New Report Templates

LICENSE: Any

If you do not want to copy an existing report template, you can create an entirely new template. First, you create a default template shell. Then, in the order you

prefer, you design the individual template sections and set attributes for the report document. For information on these steps, see the following sections:

- Creating a Template Shell on page 1813
- Configuring the Content of the Template Sections on page 1814
- Setting Attributes for PDF and HTML Report Documents on page 1814

Creating a Template Shell

LICENSE: Any

A report template is a framework of sections, each independently built from its own database query. The first step in creating a template is to generate the framework shell that allows you to add and format the sections.

To create a template shell:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Click the **Report Templates** tab.

   The Report Templates page appears.
3. Click **Create Report Template**.

   The Report Sections page appears with the default template name, `New Report`, in the **Report Title** field.
4. Optionally, type a name for your new template in the **Report Title** field and click **Save**. The report title can contain any combination of alphanumeric characters and spaces.

   An entry with the new template name appears on the Report Templates page list.
5. The report title can also contain input parameters. To add an input parameter, place your cursor at the spot in the title where the value of the parameter should appear, then click the insert input parameter icon ( ). For information on input parameters, see Using Input Parameters on page 1822.

   The added input parameters appear in the **Report Title** field.
6. Use the set of add icons under the Report Sections title bar to insert section shells as necessary. For information on section formatting, see the Report Section Fields table on page 1806.

   Each added section appears at the bottom of the template. Drag it to the correct location.
7. Click the section title on the section title bar and type a name for the section.
8. Click **Save** to save the template.

   Your template is saved.

Configuring the Content of the Template Sections

LICENSE: Any

Each template section consists of a dataset generated by a search or filter, and has a format specification (table, pie chart, and so on) that determines the mode of presentation. You further determine section content by selecting the fields in the data records you want to include in the output, as well as the time frame and number of records to show.

To configure report template sections:

ACCESS: Admin/Any Security Analyst

1. Edit the section attributes as described in Editing the Sections of a Report Template on page 1815.
2. Optionally, click **Preview** at the bottom of the section window to view the column layout or graphic format you selected.

IMPORTANT! Use the section preview utility to check the column selection and output characteristics such as pie chart colors. It is not a reliable indicator of the correctness of your configured search.

Setting Attributes for PDF and HTML Report Documents

LICENSE: Any

The report you generate from the template has several document attributes that span all sections and control features, such as the cover page, headers and footers, page numbering, and so on.

To set attributes for the report documents:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Click the **Report Templates** tab.

   The Report Templates page appears.
3. Click **Edit** for the report template you want to use to generate the report.

   The Report Sections page for your template appears.
4. Click **Advanced**.

   The Advanced Settings pop-up window appears.
5. For documents in PDF or HTML format, perform the tasks described in Editing Document Attributes in a Report Template on page 1828.

   If you selected CSV as your document format, you have no document attributes to set.

Editing the Sections of a Report Template

LICENSE: Any

You can modify a variety of report section attributes to adjust the content of the section and its data presentation. For information, see the following sections:

- Setting the Table and Data Format for a Template Section on page 1815
- Specifying the Search or Filter for a Template Section on page 1816
- Setting the Search Fields that Appear in Table Format Sections on page 1817
- Adding a Text Section to a Report Template on page 1817
- Adding a Page Break to a Report Template on page 1818
- Setting the Time Window for a Template and Its Sections on page 1819
- Renaming a Template Section on page 1820
- Previewing a Template Section on page 1820

IMPORTANT! Security Analysts can edit only report templates they created.

Setting the Table and Data Format for a Template Section

LICENSE: Any

Each section in a report template queries a database table to generate content for that section. Changing the section's data format uses the same data query, but modifies the fields that appear in the section according to the analytical purpose of the format type. For example, the table view of intrusion events populates the section with a large number of data fields per event record, while a pie chart section shows the portion of all matching records that each selected attribute represents, with no details about individual events. Bar chart sections compare the total counts of matching records that have specific attributes. Line charts summarize changes in the matching records over time with respect to a single attribute. Line charts are available only for data that is time-based, not for information about hosts, users, third-party vulnerabilities, and so on.

For information on the different available formats, see the Report Section Fields table on page 1806.

To select the table and output format for a template section:

ACCESS: Admin/Any Security Analyst

1. Use the **Table** drop-down menu to select the table to query in this section.

   Icons appear in the **Format** field for each of the output formats available for the selected table.

2. Select the applicable output format icon for the section. For information about these formats, see the Report Section Title Bar Elements table on page 1806.

   The fields included in the output appear.

3. To change the search constraints, click the edit icon ( ) next to the **Search** or **Filter** field.

   The Search Editor pop-up window appears with options for constraining the search. For information on using this window, see Working with Searches in Report Template Sections on page 1821.

4. For graphic output formats (pie chart, bar chart, and so on), adjust the **X-Axis** and **Y-Axis** parameters using the drop-down menus.

   When you select a value for the X-axis, only compatible values appear in the Y-axis drop-down menu, and vice versa.

5. For table output, select the columns, order of appearance, and sort order in your output. For detailed information, see Setting the Search Fields that Appear in Table Format Sections on page 1817.

6. Click **Save** to save the template.

   Your template is saved.

Specifying the Search or Filter for a Template Section

License: Any

The search or filter in a report section specifies the database query on which the section content is based. For most tables, you can constrain a report using a predefined or saved search, or you can create a new search on the fly:

- Sourcefire predefined searches serve as examples for searching certain event tables and can provide quick access to important information about your network that you may want to include in reports.
- Saved event searches include all public event searches that you or others have created, plus all your saved private event searches. For information on defining, naming, and using saved event searches, see Searching for Events on page 1842.
- Saved searches for the current report template are accessible only in the report template itself. The search names of saved report template searches end with the string "Custom Search." Users create these searches while designing reports.

For the Application Statistics table, you use a user-defined application filter to constrain a report; for information on creating filters, see Working with Application Filters on page 192.

To specify a search or filter for a template section:

Access: Admin/Any Security Analyst

1. Select the database table to query from the **Table** drop-down menu:
   - For most tables, the **Search** drop-down list appears.
   - For the Application Statistics table, the **Filter** drop-down list appears.

2. Select the search or filter you want to use to constrain the report.

   You can view the search criteria or create a new search by clicking the edit icon (). For more information, see Working with Searches in Report Template Sections on page 1821.

Setting the Search Fields that Appear in Table Format Sections

LICENSE: Any

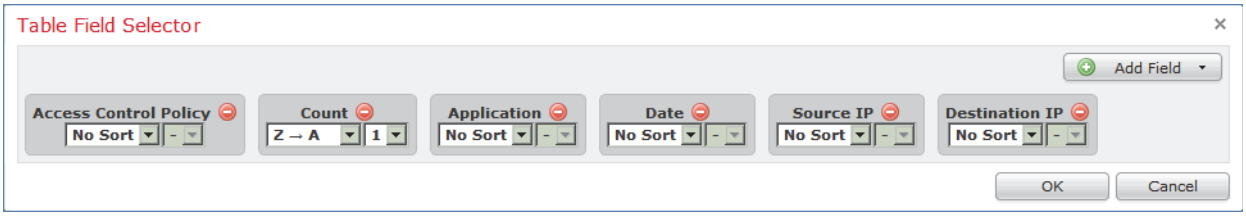
If you include table data in a section, you can choose which fields in the data record to show. All fields in the table are available for inclusion or exclusion. You select fields that accomplish the purpose of the report, then order and sort them accordingly.

To add and delete the fields in a table format section:

ACCESS: Admin/Any Security Analyst

1. For table format sections, click the edit icon () next to the **Fields** parameter.

   The Table Field Selector window appears.



2. Optionally, add and delete fields, and drag the field icons into the column order you want.
3. Optionally, change the sort order of any column. Use the drop-down lists on each field icon to set the sort order and priority.
4. When the fields are in the right order and have the necessary sort characteristics, click **OK**.

   The Report Sections page appears.

Adding a Text Section to a Report Template

LICENSE: Any

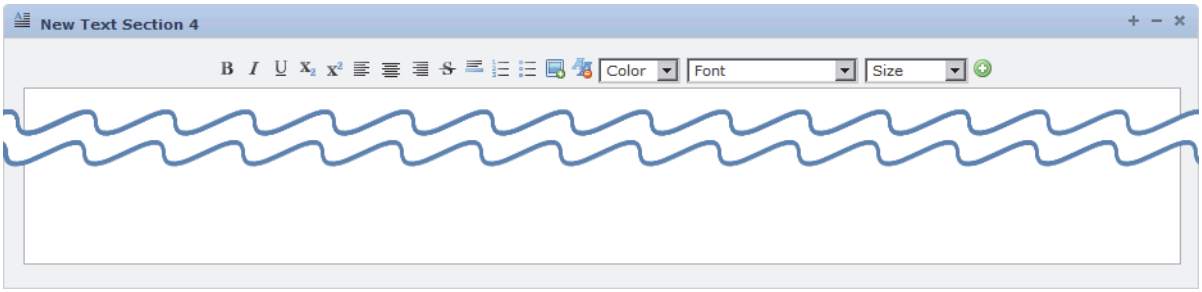
You can add text sections to your templates to provide custom text, such as an introduction, for the whole report or for individual sections. Text sections can have rich text with multiple font sizes and styles (bold, italic, and so on) as well as input parameters and imported images. For information on input parameters, see Using Input Parameters on page 1822.

To add a text section to a report template:

Access: Admin/Any Security Analyst

1. Click the add text section icon ( ).

   A text section appears at the bottom of the template.



2. Drag the new text section to its intended position in the report template.
3. Optionally, add page breaks before and after the text section. For information on page breaks, see Adding a Page Break to a Report Template on page 1818.
4. Optionally, click the text section's generic name in the title bar to type a new name.
5. Add formatted text and images to the body of the text section. You can include input parameters that dynamically update when you generate the report.
6. Click **Save** when finished.

   Your template is saved.

Adding a Page Break to a Report Template

License: Any

You can add page breaks before or after any section in the template. This feature is particularly helpful for multi-section reports with text pages that introduce the various sections.

To add a page break:

Access: Admin/Any Security Analyst

1. Click the add page break icon ( ).

   A page break appears at the bottom of the template.
2. Drag the page break to its intended location, before or after a section.
3. Repeat the process for all page breaks you add to the template.

Setting the Time Window for a Template and Its Sections

LICENSE: Any

A report template's time window defines the template's reporting period. Report templates with time-based data (such as intrusion or discovery events) have a global time window, which the time-based sections in the template inherit by default when created. Changing the global time window changes the local time window for the sections that are configured to inherit the global time window. You can disable time window inheritance for an individual section by clearing its **Inherit Time Window** check box. You can then edit the local time window.

IMPORTANT! Global time window inheritance applies only to report sections with data from time-based tables, such as intrusion events and discovery events. For sections that report on network assets (hosts and devices) and related information (such as vulnerabilities), you must set each time window individually.

To change a report template's global time window:

ACCESS: Admin/Any Security Analyst

1. On the Report Templates page, click the edit icon ( ) next to the report template you want to edit.

   The Report Sections page appears.

2. Click **Generate**.

   The Generate Report pop-up window appears.

3. To modify the global time window, click the time window icon ( ).

   The Events Time Window page appears in a new window. For information about using this page, see Setting Event Time Constraints on page 1896.

4. When you are finished, click **Apply** on the Events Time Window.

   The Generate Report pop-up window reappears with the new time window.

5. Click **Cancel** to return to the Report Sections page, or **OK** to generate the report.

Your report can have different time ranges per section. For example, your first section could be a summary for the month, and the remaining sections could drill down into details at the week level. In such cases, you set the section-level time windows individually.

To configure a section's local time window:

ACCESS: Admin/Any Security Analyst

1. On the Report Sections page of a template, clear the **Inherit Time Window** check box for the section if it is present.

   The local section time window icon appears.

2. To change the section's local time window, click the time window icon ( ).

   The Events Time Window page appears. For information about using this page, see Setting Event Time Constraints on page 1896.

   IMPORTANT! Sections with data from statistics tables can have only sliding time windows.

3. When you have set a new local time window, click **Apply** on the Events Time Window.
4. Click **Save**.

   The Report Sections page appears for further editing.

Renaming a Template Section

LICENSE: Any

When you create a new template, the sections you add receive generic section names and should be renamed to indicate their content.

To rename a template section:

ACCESS: Admin/Any Security Analyst

1. Click the current section name in the section header.

   The Set Section Title pop-up window appears.
2. Type a new name for the section and click **OK**.

   The name in the section title bar is changed.

Previewing a Template Section

LICENSE: Any

The preview function shows the field layout and sort order for table views and important legibility characteristics of graphics, such as pie chart colors.

To preview a template section:

ACCESS: Admin/Any Security Analyst

1. At any time while editing a section, click **Preview** for the section.

   The Preview pop-up window appears.
2. Close the preview by clicking **OK** at the bottom of the window.

   The Report Sections page appears.

Working with Searches in Report Template Sections

LICENSE: Any

The Sourcefire 3D System provides a search editor to view the searches available in your report templates and to define new custom searches.

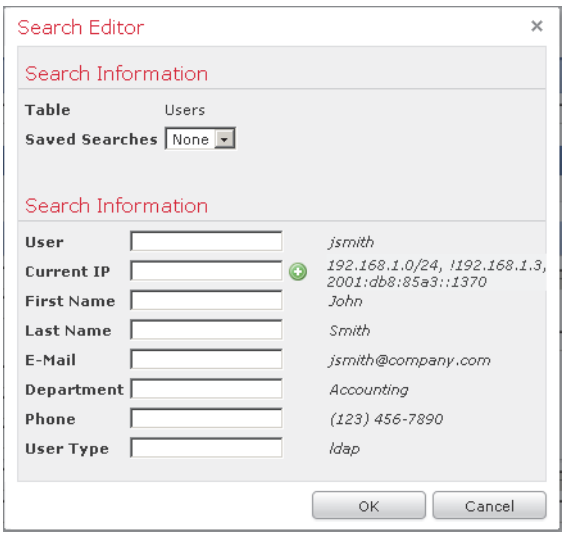
TIP! The custom searches you make in a report template are specific to the template where you create them. You can make searches that are reusable across all report templates in the event viewer. When you save a custom search in the event viewer, it appears in the **Search** drop-down menu of all report templates. For details on using the event viewer to create and save custom searches, see Searching for Events on page 1842.

To create a custom search:

ACCESS: Admin/Any Security Analyst

1. From the relevant section in the report template, click the edit icon ( ) next to the **Search** field.

   The Search Editor page appears with the table to be searched selected.



2. Optionally, from the **Saved Searches** drop-down menu, select a predefined search.

   The drop-down presents all available predefined searches for this table, including system-wide and report-specific predefined searches.

3. Edit the search criteria in the appropriate fields. For certain fields, your constraints can include the same operators (<, <>, and so on) as event searches. For the syntax of search criteria, see Searching for Events on page 1842.

   If you enter multiple criteria, the search returns only the records that match all the criteria.

4. Optionally, where the input parameter icon ( ) appears, you can insert an input parameter from the drop-down menu instead of typing a constraint value. For information on using input parameters in report designs, see Using Input Parameters on page 1822.

   For some search fields, the drop-down menu may contain user-defined managed objects instead of, or with, input parameters. Managed objects, which have distinctive icons depending on their type, are system configuration variables you can use as values in constraining searches. However, they do not produce the generation-time query for user input that occurs with input parameters. For information on managed objects, see Using Objects and Security Zones on page 174.

   IMPORTANT! When you edit the constraints of a reporting search, the system saves your edited search under the following name: *`section`* `custom search`, where *`section`* is the name in the section title bar followed by the string `custom search`. To have meaningful names for your saved custom searches, be sure you change the section name before you save the edited search. You cannot rename a saved reporting search.

5. When finished modifying the fields in the search editor, click **OK.**

   The Report Sections page reappears and a new predefined search appears in the section's **Search** drop-down menu.

Using Input Parameters

LICENSE: Any

You can use input parameters in a report template that the report can dynamically update at generation time. The input parameter icon ( ) indicates the fields that can process them. There are two kinds of input parameters:

- Predefined — see the Predefined Input Parameters on page 1823
- User-defined — see the User-Defined Input Parameter Types table on page 1825

Predefined Input Parameters

LICENSE: Any

Predefined input parameters are resolved by internal system functions or configuration information. For example, at report generation time, the system

replaces the `$<Time>` parameter with the current date and time. The Predefined Input Parameters table defines the parameters available for use. You might, for example, include `$<Month>` in the title of a monthly summary report that generates automatically under scheduler control. Your report title then automatically updates with the correct month.

Predefined Input Parameters

INSERT THIS PARAMETER...	...TO INCLUDE THIS INFORMATION IN YOUR TEMPLATE:
$<Logo>	The selected uploaded logo
$<Report Title>	The report title
$<Time>	The date and time of day the report ran, with one-second granularity
$<Month>	The current month
$<Year>	The current year
$<System Name>	The name of the Defense Center
$<Model Number>	The model number of the Defense Center
$<Time Window>	The time window currently applied to the report section
$<Constraints>	The search constraints currently applied to the report section

The Predefined Input Parameter Usage table lists the valid input parameters that can be used in different areas within the Report Templates page.

Predefined Input Parameter Usage

PARAMETER	REPORT TEMPLATE COVER PAGE	REPORT TEMPLATE REPORT TITLE	REPORT TEMPLATE SECTION DESCRIPTION	REPORT TEMPLATE TEXT SECTION	GENERATE REPORT FILE NAME	GENERATE REPORT EMAIL SUBJECT, BODY
$<Logo>	yes	no	no	no	no	no
$<Report Title>	yes	no	yes	yes	yes	yes
$<Time>	yes	yes	yes	yes	yes	yes

Predefined Input Parameter Usage (Continued)

Parameter	Report Template Cover Page	Report Template Report Title	Report Template Section Description	Report Template Text Section	Generate Report File Name	Generate Report Email Subject, Body
$<Month>	yes	yes	yes	yes	yes	yes
$<Year>	yes	yes	yes	yes	yes	yes
$<System Name>	yes	yes	yes	yes	yes	yes
$<Model Number>	yes	yes	yes	yes	yes	yes
$<Time Window>	no	no	yes	no	no	no
$<Constraints>	no	no	yes	no	no	no

User-Defined Input Parameters

License: Any

You can create your own input parameters to supply as constraints in section searches. Constraining a search with an input parameter instructs the system to collect a value at generation time from the person who requests the report. In this way, you can dynamically tailor a report at generation time to show a particular subset of data without changing the template. For example, you can provide an input parameter for the **Destination IP** field of a report section's search. Then, when you generate the report, you can type the IP network segment for a particular department to get data for that department only.

TIP! You can also type * in an input parameter field, with the effect of ignoring the constraint.

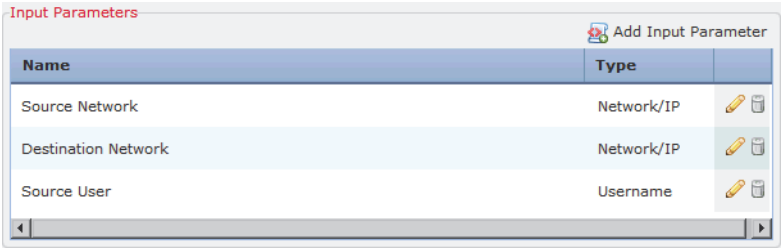
You can also define string-type input parameters to add dynamic text in certain fields of your report, such as in emails (subject or body), report file names, and text sections. You can personalize reports for different departments, with customized report file names, email addresses, and email messages, using the same template for all.

Each input parameter you define has a name and a type. The User-Defined Input Parameter Types table describes the parameter types.

User-Defined Input Parameter Types

USE THIS PARAMETER TYPE...	WITH FIELDS WITH THIS DATA...
Network/IP	any IP address or network segment in CIDR format
Application	name of an application protocol, client application, or web application
Event Message	any event view message
Device	3D appliance (Defense Center or Sourcefire managed device)
Username	user identification such as initiator user and responder user
Number (VLAN ID, Snort ID, Vuln ID)	any VLAN ID, Snort ID, or vulnerability ID
String	text fields such as application or OS version, notes, or descriptions

An input parameter's type determines the search fields where you can use it. You can use a given type only in appropriate fields, as described in the User-Defined Input Parameter Types table. For example, a user parameter you define as a string type is available for insertion in text fields but not in fields that take an IP address. In the graphic below, the input parameters **Source Network** and **Destination Network** are both of type **Network/IP** and therefore appear as options for search fields, such as **Source IP** and **Destination IP**, that take IP addresses.



To create user-defined input parameters for a report template:

Access: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears.
3. Click the edit icon ( ) for the template you want to edit.

   The Report Sections page appears.
4. Click **Advanced**.

   The Advanced Settings pop-up window appears.
5. Click the Add Input Parameter icon ( ).

   The Add Input Parameter pop-up window appears.
6. Type the parameter name in the **Name** field and use the **Type** drop-down menu to select the type, then click **OK**.

   The new parameter appears in the **Input Parameters** menu.
7. Repeat the steps above until you have defined all the parameters you need.
8. Click **OK**.

   Your new input parameters are saved for this template and the Report Sections page reappears.

If you reuse a report template, you can change the name and type for any input parameters to better reflect the purpose of the new report.

To edit user-defined input parameters for a report template:

Access: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears.
3. Click the edit icon ( ) for the template you want to edit.

   The Report Sections page appears.
4. Click **Advanced**.

   The Advanced Settings pop-up window appears. The **Input Parameters** section lists all available user-defined parameters for the report template.
5. Click the edit icon ( ).

   The Edit Input Parameter pop-up window appears.

6. Change the parameter name in the **Name** field and the parameter type using the **Type** drop-down menu, then click **OK**.

   The changed parameter appears in the **Input Parameters** section.

7. Repeat the steps above until you have defined all the parameters you need. Click **OK**.

   Your changes are saved and the Report Sections page reappears.

To delete user-defined input parameters for a report template:

Access: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears.

3. Click the edit icon ( ) for the template you want to edit.

   The Report Sections page appears.

4. Click **Advanced**.

   The Advanced Settings pop-up window appears. The **Input Parameters** section lists all available user-defined parameters for the report template.

5. Click the delete icon ( ) next to the input parameter and confirm.
6. Click **OK**.

   The input parameter is deleted and the Report Sections page reappears.

You use input parameters to expand the usefulness of your searches. The input parameter instructs the system to collect a value at generation time from the person who requests the report. In this way, you can dynamically constrain a report at generation time to show a particular subset of data without changing the search. For example, you can provide an input parameter for the **Destination IP** field of a report section that drills down on security events at a department level. When you generate the report, you can type the IP network segment for a particular department to get data for that department only.

To constrain the search in a report template with user-defined input parameters:

Access: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears.

3. Click the edit icon ( ) for the template you want to edit.

   The Report Sections page appears.

4. Click the edit icon ( ) next to the **Search** field within the section.
   The Search Editor pop-up window appears. Fields that can take an input parameter are marked with the input parameter icon ( ).

5. Click the input parameter icon ( ) next to the field, then select the input parameter from the drop-down menu. User-defined input parameters are marked with the icon ( ).
   The input parameter appears in the field.

   IMPORTANT! Input parameters you define are available only for search fields that match their parameter type. For example, a parameter of type **Network/IP** is available only for fields that accept IP addresses or network segments in CIDR format.

6. Click **OK** when you have added all necessary input parameters.
   The Report Sections page appears with your changes.

Editing Document Attributes in a Report Template

LICENSE: Any

Before you generate your report, you can set document attributes that affect the report's appearance. These attributes include the optional cover page and table of contents. Support for some attributes depends on the selected report format: PDF, HTML, or CSV. The Document Attribute Support table provides further details on attribute support by format.

Document Attribute Support

ATTRIBUTE	PDF SUPPORT?	HTML SUPPORT?	CSV SUPPORT?
Cover page	yes, with optional logo and custom appearance	yes, with optional logo and custom appearance	no
Table of contents	yes	yes	no
Page headers and footers	yes, with optional text or logo in any field	no	no

Document Attribute Support (Continued)

ATTRIBUTE	PDF SUPPORT?	HTML SUPPORT?	CSV SUPPORT?
Custom starting page number	yes	no	no
Option to suppress numbering of first page	yes	no	no

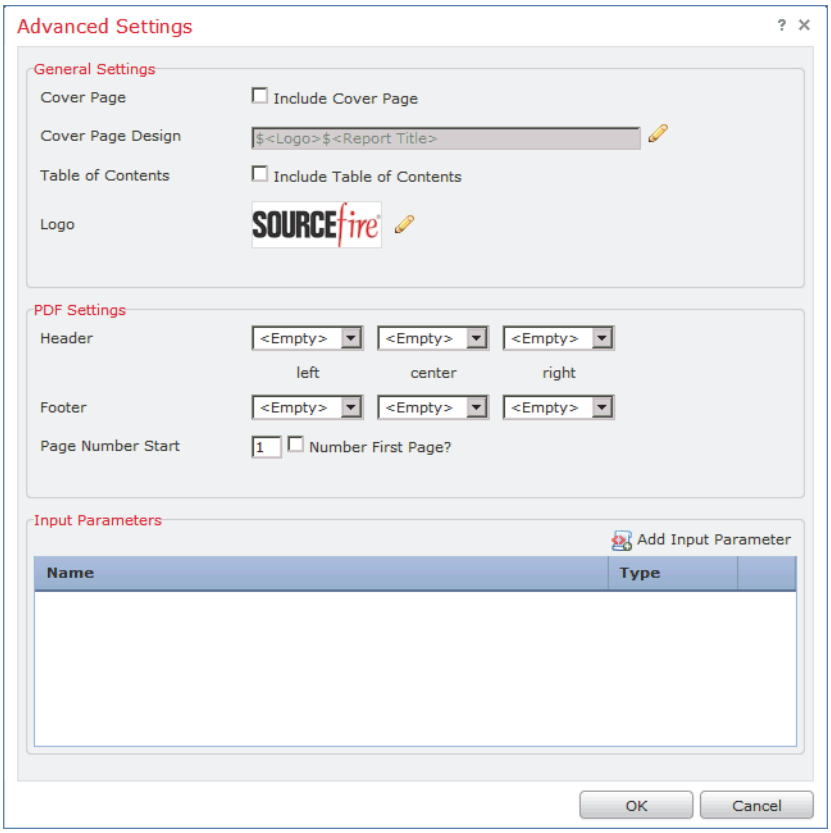
To set the document attributes for PDF and HTML reports:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.
   The Report Templates page appears.
3. Click the edit icon ( ) for the report template you want to edit.
   The Report Sections page appears.

4. Click **Advanced**.

   The Advanced Settings pop-up window appears.



5. Select **Include Cover Page** to add a cover page.

6. Click the edit icon ( ) next to the **Cover Page Design** field to edit the cover page design. For more information, see Customizing a Cover Page on page 1831.

7. Select **Include Table of Contents** to add a table of contents.

8. Configure the header and footer using the drop-downs of the three **Header** and **Footer** fields. You select header and footer content from the drop-down menus: logo, date, page number, and so on.

   If you select **Logo**, the default logo image appears in the selected field. To change the default logo image, see Managing Logos on page 1832.

9. In the **Page Number Start** field, select the page number of the report's first page.

   Select **Number First Page?** to show the page number on the first page following the cover page. If selected, the cover page is not numbered.

10. Click **OK**.

    The document attributes are saved and the Report Sections page reappears.

Customizing a Cover Page

LICENSE: Any

You can customize a report template's cover page. Cover pages can have rich text with multiple font sizes and styles (bold, italic, and so on) as well as input parameters and imported images. For information on input parameters, see Using Input Parameters on page 1822.

To customize a report template cover page:

ACCESS: Admin/Any Security Analyst

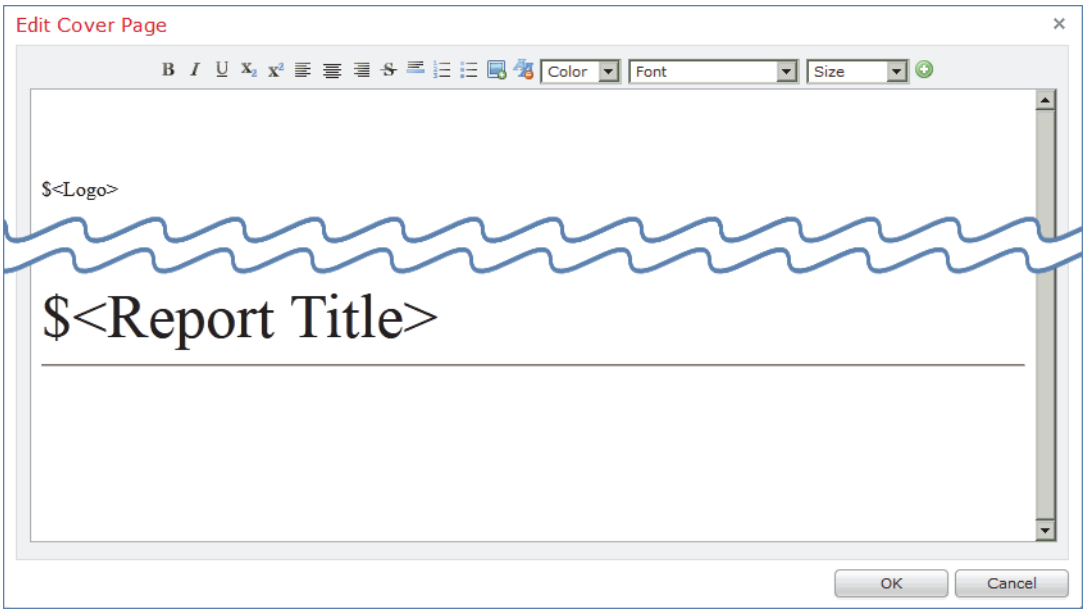
1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears and displays the list of templates.
3. Click the edit icon ( ) for a report template.

   The Report Sections page appears.
4. Click **Advanced**.

   The Advanced Settings pop-up window appears.
5. Click the edit icon ( ) next to **Cover Page Design**.

   The Edit Cover Page window appears, displaying the default cover page design.



6. Edit the cover page design within the rich text editor.
7. Click **OK**.

   The cover page design is saved and the Advanced Settings window reappears.

Managing Logos

LICENSE: Any

You can store multiple logos on the Defense Center and associate them with different report templates. You set the logo association when you design the template. If you export the template, the export package contains the logo.

For information on where you can insert a logo in reports, see Editing Document Attributes in a Report Template on page 1828.

See the following related procedures for more information:

- Adding a New Logo on page 1832
- Changing the Logo for a Report Template on page 1833
- Deleting a Logo on page 1834

Adding a New Logo

LICENSE: Any

Logos uploaded to your Defense Center are available for all report templates on that Defense Center. Logo images must be in JPG format.

To add a logo to a Defense Center:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears.
3. Click the edit icon () for the report template you want to edit.

   The Report Sections page appears.
4. Click **Advanced**.

   The Advanced Settings pop-up window appears. The logo currently associated with the template appears under **Logo** in **General Settings**.

5. Click the edit icon ( ) for the logo.

   The Select Logo pop-up window appears with images of currently uploaded logos.

6. Click **Upload Logo**.

   The Upload Logo pop-up window appears.

7. Select the logo file to upload by doing one of the following:
   - type the location of the logo file
   - click the **Browse** button and browse to the file's location

8. Click **Upload**.

   The image is uploaded to the Defense Center and appears in the Select Logo pop-up window.

9. Optionally, associate the new logo with the current template by selecting it and clicking **OK**.

   The Advanced Settings window reappears with the associated logo image.

Changing the Logo for a Report Template

License: Any

You can change the logo in a report to any JPG image uploaded to your Defense Center. For example, if you reuse a template, you can associate a logo for a different organization with the report.

To change the logo for a report template:

Access: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears.
3. Click the edit icon ( ) for the report template you want to edit.

   The Report Sections page appears.
4. Click **Advanced**.

   The Advanced Settings pop-up window appears. The logo currently associated with the template appears under **Logo** in **General Settings**.
5. Click the edit icon ( ) for the logo.

   The Select Logo pop-up window appears with images of currently uploaded logos.
6. Select the logo to associate with the report template.

   The selected logo is highlighted.
7. Click **OK**.

   The Advanced Settings window reappears with the associated logo image.

Deleting a Logo

License: Any

You can delete logos from your Defense Center. Deleting a logo removes it from all templates where it is used. The deletion cannot be undone.

Note that you cannot delete the predefined Sourcefire logo.

To delete a logo from a Defense Center:

Access: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears.
3. Click the edit icon ( ) for the report template you want to edit.

   The Report Sections page appears.
4. Click **Advanced**.

   The Advanced Settings pop-up window appears. The logo currently associated with the template appears under **Logo** in **General Settings**.

5. Click the edit icon ( ) for the logo.

   The Select Logo pop-up window appears with images of currently uploaded logos.

6. Select the logo you want to delete.

   The selected logo is highlighted.

7. Click **Delete Logo**.

   The deleted logo disappears from the Select Logo pop-up window.

8. Click **OK**.

   Your changes are saved and the Advanced Settings window reappears.

Using Report Generation Options

LICENSE: Any

You have several additional options when generating reports. You can automatically schedule report generation, send reports via email, and store generated reports remotely. For more information, see the following sections:

- Generating Reports Using the Scheduler on page 1835
- Distributing Reports by Email at Generation Time on page 1835
- Using Remote Storage for Reports on page 1837

Generating Reports Using the Scheduler

LICENSE: Any

You can use the Sourcefire 3D System scheduler to automate report generation. You can customize the schedule on a full range of time frames such as daily, weekly, monthly, and so on. For more information, see Automating Reports on page 2017.

Distributing Reports by Email at Generation Time

LICENSE: Any

When you generate a report from its template, you can choose to automatically send the report as an email attachment to a list of recipients.

IMPORTANT! You must have a properly configured mail relay host to deliver a report by email. If you have not previously set up a mail host, see Configuring a Mail Relay Host and Notification Address on page 2060.

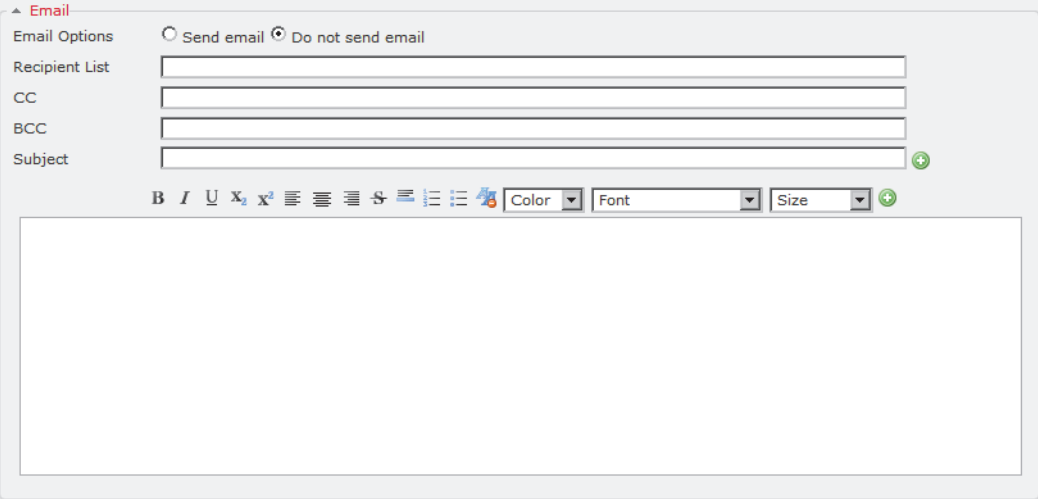
To email a report at generation time:

Access: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears.
3. Click the generate report icon ( ) for the template you want to generate from.

   The Generate Report pop-up window appears.
4. Expand the **Email** section of the window.



5. In the **Email Options** field, select **Send Email**.
6. In the **Recipient List, CC**, and **BCC** fields, type recipients' email addresses in comma-separated lists.
7. In the **Subject** field, type a subject for your email.

   TIP! You can provide input parameters in the **Subject** field and the message body to dynamically generate information in the email, such as a timestamp or the name of the Defense Center. For further information, see Using Input Parameters on page 1822.
8. Type a cover letter in the email body as necessary. The available rich text features include a wide range of fonts, numbered and bullet lists, and so on.

9. When all fields in the Generate Report window are correct, click **OK** and confirm.

   The system distributes the generated report by email. You can configure the email's From address under **Email Notification** in the system policy. For more information, see Managing System Policies on page 2038.

Using Remote Storage for Reports

LICENSE: Any

You can configure the reporting system to place newly generated report files in your configured remote storage location. You can also move any locally stored report to your remote storage location.

IMPORTANT! You cannot move reports in remote storage back to local storage.

To use remote storage, you must first configure a remote storage location. When configured, the remote storage location appears at the bottom of the report list. The location includes current disk usage for NFS and SMB mounted storage, but not for SSH. For configuration information, see Managing Remote Storage on page 2097.

To store reports remotely as they are generated:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Reports** tab.

   The Reports page appears.
3. Select the **Enable Remote Storage of Reports** check box at the bottom of the page.

   The Defense Center stores newly generated reports in the remote location indicated at the bottom of the page. The **Location** column data for these reports is `Remote`.

You can move your reports in local storage to a remote storage location in batch mode or singly.

To move generated reports from local to remote storage:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Reports** tab.

   The Reports page appears.

3. Select the check boxes next to the reports you want to move, then click **Move**.

TIP! Select the check box at the top left of the page to move all reports on the page. If you have multiple pages of reports, a second check box appears that you can select to move all reports on all pages.

4. Confirm that you want to move the reports.

   The reports are moved.

Managing Report Templates and Report Files

LICENSE: Any

In addition to creating and editing templates, you can perform the following template management tasks:

- Exporting and Importing Report Templates on page 1838
- Deleting Report Templates on page 1840

You can also perform the following management tasks for your generated report files:

- Downloading Reports on page 1840
- Deleting Reports on page 1841

Exporting and Importing Report Templates

LICENSE: Any

The file that you generate when you export a report template contains all necessary data to create the same report on another Defense Center. The export file, which is in a proprietary SFO format, includes:

- the report template, with all section design elements and document attributes
- all saved searches used in the report
- all images used in the report
- all custom tables used in the report

The only configuration that may be required after you import the template on another Defense Center is automatic report generation scheduling.

IMPORTANT! Importing and exporting report templates requires both Defense Centers to be at the same software version level.

To export a report template:

Access: Admin

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears.
3. For the template you want to export, click the export icon ( ).

   The system produces a Sourcefire configuration package file with `.sfo` extension and opens an Opening Object pop-up window that displays the package's file name.
4. Select **Save file** and **OK** to save the file to your local computer.
5. You can change the name of the `.sfo` package to a more descriptive one for your convenience. When you import the package, regardless of its name, the importing Defense Center will give the template the same name it had on the source Defense Center.

The SFO files exported from a Defense Center contain all elements necessary to add the report template to another Defense Center. The import process therefore requires only uploading the package to the second Defense Center and running the import process.

To import a report template:

Access: Admin

1. Select **System > Tools > Import/Export**.

   The Import/Export page appears, including a list of the report templates on the Defense Center.
2. Click **Upload Package**.

   The Package Name page appears.
3. You have two options:
   - Type the path to the package you want to upload.
   - Click **Browse** to locate the package.
4. Click **Upload**.

   The **Report Template** section of the configuration list appears, showing the template to be imported.

5. Select the check box next to the template and click **Import**.

   The template appears in the list of configurations on the destination Defense Center.

Deleting Report Templates

LICENSE: Any

Report templates remain listed on the Report Templates tab for reuse until you delete them. Note that you cannot delete Sourcefire-provided report templates.

IMPORTANT! Security Analysts can delete only report templates they created.

To delete a report template:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Report Templates** tab.

   The Report Templates page appears.
3. Next to the template you want to delete, click the delete icon ( ) and confirm.

   The template name disappears from the list.

Downloading Reports

LICENSE: Any

You can download any report file to your local computer. From there, you can email it or distribute it electronically by other available means. For information on distributing reports automatically by email at generation time, see Distributing Reports by Email at Generation Time on page 1835.

To download reports:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Reports** tab.

   The Reports page appears.

3. Select the check boxes next to the reports you want to download, then click **Download**.

> **TIP!** Select the check box at the top left of the page to download all reports on the page. If you have multiple pages of reports, a second check box appears that you can select to download all reports on all pages.

4. Follow your browser's prompts to download the reports.

   If you select multiple reports, they are downloaded in a single `.zip` file.

Deleting Reports

LICENSE: Any

You can delete your report files at any time. The procedure completely removes the files, and no recovery is possible. Although you still have the report template that generated the report, it may be difficult to regenerate a particular report file if the time window was expanding or sliding. For information on the time window, see Editing the Sections of a Report Template on page 1815. Regeneration may also be difficult if your template uses input parameters. For information on using input parameters, see Using Input Parameters on page 1822.

To delete reports:

ACCESS: Admin/Any Security Analyst

1. Select **Overview > Reporting**.
2. Select the **Reports** tab.

   The Reports page appears.
3. Select the check boxes next to the reports you want to delete, then click **Delete**.

> **TIP!** Select the check box at the top left of the page to delete all reports on the page. If you have multiple pages of reports, a second check box appears that you can select to delete all reports on all pages.

4. Confirm the deletion.

   The reports are deleted.

CHAPTER 43
SEARCHING FOR EVENTS

Sourcefire appliances generate information that is stored as events in database tables. Events contain multiple fields that describe the activity that caused the appliance to generate the event.

The Sourcefire 3D System provides predefined searches that serve as examples and can provide quick access to important information about your network. You can modify fields within the predefined searches for your network environment, then save the searches to reuse later. You can also use your own search criteria.

The search criteria you can use depends on the type of search, but the mechanics are the same. See the following sections for more information on how to perform a search and on the correct syntax to use in search fields:

Performing and Saving Searches

LICENSE: Any

You can create and save searches for any of the different event types. When you create a search you give it a name and specify whether the search will be available to you alone or to all users of the appliance. If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

For more information, see the following sections:

- Performing a Search on page 1843
- Loading a Saved Search on page 1846
- Deleting a Saved Search on page 1846

IMPORTANT! To search a custom table, follow a slightly different procedure; see Searching Custom Tables on page 1861.

Performing a Search

LICENSE: Any

For some event types, the Sourcefire 3D System provides predefined searches that serve as examples and can provide quick access to important information about your network. You can modify fields within the predefined searches for your network environment, then save the searches to reuse later. You can also use your own search criteria.

To perform a search:

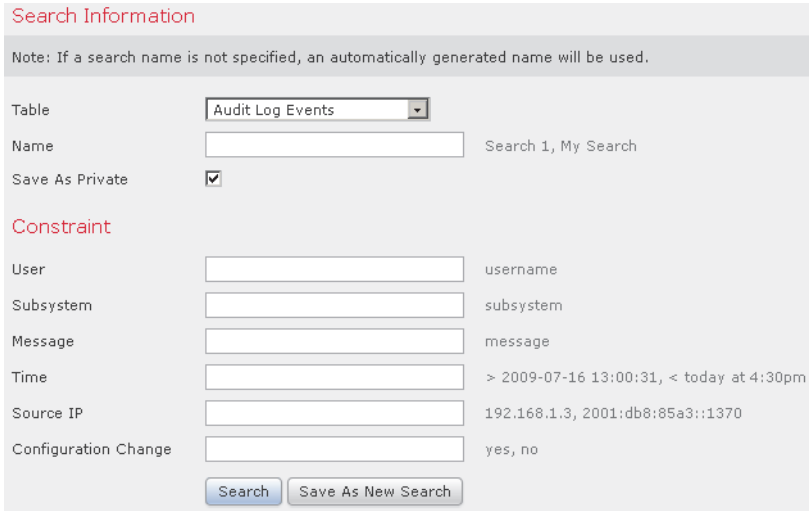
ACCESS: Admin/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select the type of event or data you want to search for

   The page reloads with the appropriate search constraints. The following graphic shows the search page for the audit log.



3. Optionally, if you want to save the search, enter a name for it in the **Name** field.

   If you do not enter a name, a name is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields.
   - All fields accept negation (`!`).
   - All fields accept comma-separated lists. If you enter multiple criteria, the search returns only the records that match all the criteria.
   - Many fields accept one or more asterisks (*) as wild cards.
   - Specify `n/a` in any field to identify events where information is not available for that field; use `!n/a` to identify the events where that field is populated.
   - Click the add object icon ( ) that appears next to a search field to use an object as a search criterion.

5. See the following sections for detailed information on the search criteria you can use:
   - Searching Audit Records on page 2279
   - Searching for Applications on page 1496
   - Searching for Application Details on page 1501
   - Searching for Captured Files on page 1291
   - Searching for Connection and Security Intelligence Data on page 622
   - Searching for Correlation Events on page 1597

- Searching for Discovery Events on page 1463
- Searching for File Events on page 1271
- Searching for Health Events on page 2266
- Searching for Host Attributes on page 1480
- Searching for Hosts on page 1472
- Searching for Intrusion Events on page 691
- Searching for Malware Events on page 1285
- Searching for Scan Results on page 1793
- Searching for Servers on page 1490
- Searching for Sourcefire Vulnerabilities on page 1508
- Searching the Rule Update Import Log on page 2171
- Searching for Remediation Status Events on page 1709
- Searching for Third-Party Vulnerabilities on page 1512
- Searching for Users on page 1520
- Searching for User Activity on page 1525
- Searching for Compliance White List Events on page 1647
- Searching for White List Violations on page 1653

6. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

TIP! If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

7. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in the default workflow for the table you are searching, constrained by time (if applicable). To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. Note that you **cannot** use a different workflow for scan results.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save As New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**) so that you can run it at a later time.

Loading a Saved Search

LICENSE: Any

If you previously saved a search, you can load it, make any necessary modifications, and then start the search.

To load a saved search:

ACCESS: Admin/Any Security Analyst

1. You have two options:
   - From any page on a workflow, click **Search**.
   - Select **Analysis > Search**, then select the type of events you want to search for.

   The Search page appears.
2. From the list of saved searches on the left of the page, select the search you want to load and click **Load**.

   Settings from the saved search populates the search constraints fields.
3. Optionally, change the search constraints.
4. Click **Search**.

   The events that match your search constraints appear.

Deleting a Saved Search

LICENSE: Any

If you have saved searches, you can delete them from the Search page.

To delete a saved search:

ACCESS: Admin/Any Security Analyst

1. You have two options:
   - From any page on a workflow, click **Search**.
   - Select **Analysis > Search**, then select the event type for the search that you want to delete.

   The Search page appears.
2. From the list of saved searches, select the search you want to delete and click **Delete**.

   The search is deleted.

Using Wildcards and Symbols in Searches

LICENSE: Any

Many text fields on search pages allow you to use an asterisk (*) to match characters in a string. For example, specifying `net*` matches `network`, `netware`, `netscape`, and so on.

If you want to search for non-alphanumeric characters (including the asterisk character), enclose the search string in quotation marks. For example, to search for the string:

```
Find an asterisk (*)
```

enter:

```
"Find an asterisk (*)"
```

Note that in text fields that allow a wildcard, you **must** use the wildcard if you want to match a partial string. For example, if you are searching the audit log for all audit records that involve page views (that is, the message is Page View), searching for `Page` returns no results. Instead, specify `Page*`.

Using Objects and Application Filters in Searches

LICENSE: Any

The Sourcefire 3D System allows you to create named objects, object groups, and application filters that can be used as part of your network configuration. You can use these objects, groups, and filters as search criteria when performing or saving searches.

When you perform a search, objects, object groups, and application filters appear in the format, `${object_name}`. For example, a network object with the object name `ten_ten_network` appears as `${ten_ten_network}` in a search.

You can click the add object icon () that appears next to a search field where you can use an object as a search criterion.

Specifying Time Constraints in Searches

LICENSE: Any

You can use a number of formats for specifying time search constraints. You can enter a time you want to match, and, optionally, a less than (<) or greater than (>) operator to match times before or after the time you enter.

The formats accepted by search criteria fields that take a time value are shown in the following table.

Time Specification in Search Fields

TIME FORMATS	EXAMPLE
today [at HH:MMam|pm]	`today` today at 12:45pm
YYYY-MM-DD HH:MM:SS	2006-03-22 14:22:59

You can precede a time value with one of the following operators/keyword.

Time Specification Operators

OPERATOR	EXAMPLE	EXPLANATION
<	`< 2006-03-22 14:22:59`	Returns events with a timestamp before 2:23 PM, March 22, 2006.
>	`> today at 2:45pm`	Returns events with a timestamp later than today at 2:45 PM.

Specifying IP Addresses in Searches

LICENSE: Any

When specifying IP addresses in searches, you can enter an individual IP address, a comma-separated list of addresses, an address block, or a range of IP addresses separated with a hyphen (-). You can also use negation.

For searches that support IPv6 (such as intrusion event, connection data, and correlation event searches) you can enter IPv4 and IPv6 addresses and CIDR/prefix length address blocks in any combination.

When you use CIDR or prefix length notation to specify a block of IP addresses, the Sourcefire 3D System uses **only** the portion of the network IP address specified by the mask or prefix length. For example, if you type `10.1.2.3/8`, the Sourcefire 3D System uses `10.0.0.0/8`.

The following table contains examples of valid ways to enter IP addresses. Because IP addresses can be represented by network objects, you can also click the add network object icon ( ) that appears next to an IP address search field

to use a network object as an IP address search criterion. For more information, see Using Objects and Application Filters in Searches on page 1847.

Acceptable IP Address Syntax

TO SPECIFY...	TYPE...	FOR EXAMPLE...
a single IP address	the IP address.	`192.168.1.1` `2001:db8::abcd`
multiple IP addresses using a list	a comma-separated list of IP addresses. Do **not** add a space before or after the commas.	`192.168.1.1,192.168.1.2` `2001:db8::b3ff, 2001:db8::0202`
a range of IP addresses that can be specified with a CIDR block or prefix length	the IP address block in IPv4 CIDR or IPv6 prefix length notation.	`192.168.1.0/24` This specifies any IP in the 192.168.1.0 network with a subnet mask of 255.255.255.0, that is, 192.168.1.0 through 192.168.1.255. For more information, see IP Address Conventions on page 63.
a range of IP addresses that cannot be specified with a CIDR block or prefix	the IP address range using a hyphen. Do **not** add a space before or after the hyphen.	`192.168.1.1-192.168.1.5` `2001:db8::0202-2001:db8::8329`

negation of any of the other ways to specify IP addresses or ranges of IP addresses	an exclamation point in front of the IP address, block, or range.	`192.168.0.0/32, !192.168.1.10`
		`!2001:db8::/32`
		`!192.168.1.10,!2001:db8::/32`

on a Defense Center, all IP addresses in the networks you are monitoring	`local`	`local`
on a Defense Center, all IP addresses that are **not** in the networks you are monitoring	`remote`	`remote`

Specifying Ports in Searches

LICENSE: Any

The Sourcefire 3D System accepts specific syntax for port numbers in searches. You can enter:

- a single port number
- a comma-separated list of port numbers

- two port numbers separated by a dash to represent a range of port numbers
- a port number followed by a protocol abbreviation, separated by a forward slash (only when searching for intrusion events)
- a port number or range of port numbers preceded by an exclamation mark to indicate a negation of the specified ports

IMPORTANT! Do **not** use spaces when specifying port numbers or ranges.

The Port Syntax Examples table contains examples of valid ways to enter ports as search constraints.

Port Syntax Examples

EXAMPLE	DESCRIPTION
21	Returns all events on port 21, including TCP and UDP events.
!23	Returns all events except those on port 23.
25/tcp	Returns all TCP-related intrusion events on port 25.
21/tcp,25/tcp	Returns all TCP-related intrusion events on ports 21 and 25
21-25	Returns all events on ports 21 through 25.

Stopping Long-Running Queries

LICENSE: Any
SUPPORTED DEVICES: Any Defense Center

System administrators can use a shell-based query management tool to locate and stop long-running queries.

IMPORTANT! Leaving the search page in the web interface does not stop a query. Queries that take a long time to return results impact overall system performance while the query is running.

The query management tool allows you to locate queries running longer than a specified number of minutes and stop those queries. The tool logs an event to the audit log and to syslog when you stop a query.

Note that the only locally-created user with shell access on Defense Centers is the `admin` user. If you use an external authentication object which grants shell access, users matching the shell access filter can also log into the shell.

Usage:

```
query_manager [-v] [-l [minutes]] [-k query_id [...]]
[--kill-all minutes]
```

Options:

`-h, --help`

Prints a brief help message.

`-l, --list [minutes]`

Lists all queries taking longer than passed in minutes. By default it will show all queries taking longer than 1 minute.

`-k, --kill query_id [...]`

Kills the query with the passed in id. The option can take multiple ids.

`--kill-all minutes`

Kills all queries taking longer than passed in minutes.

`-v, --verbose`

Verbose output including full SQL queries.

WARNING! Shell access should be limited to system administrators.

To stop a query on the Defense Center:

Access: `admin` or other user granted shell access

1. Connect to the Defense Center via `ssh`.
2. Run `query_manager` under `sudo` using the syntax described above.

CHAPTER 44
USING CUSTOM TABLES

As the Sourcefire 3D System collects information about your network, the Defense Center stores it in a series of database tables. When you use a workflow to view the resulting information, the Defense Center pulls the data from one of these tables. For example, the columns on each page of the Network Applications by Count workflow are taken from the fields in the Applications table.

If you determine that your analysis of the activity on your network would be enhanced by combining fields from different tables, you can create a custom table. For example, you could combine the host criticality information from the predefined Host Attributes table with the fields from the predefined Connection Data table and then examine connection data in a new context.

Note that you can create custom workflows for either predefined or custom tables. For more information on creating custom workflows, see Creating Custom Workflows on page 1916.

The following sections describe how to create and use your own custom tables:

Understanding Custom Tables

LICENSE: FireSIGHT

Custom tables contain fields from two or more predefined tables. The Sourcefire 3D System is delivered with a number of Sourcefire-defined custom tables, but you can create additional custom tables that contain only information that matches your specific needs.

For example, the Sourcefire 3D System is delivered with Sourcefire-defined custom tables that correlate intrusion event data with host data, so you can search for events that impact critical systems and view the results of that search in one workflow. The Sourcefire-defined Custom Tables table describes the custom tables provided with the system.

Sourcefire-defined Custom Tables

TABLE	DESCRIPTION
Hosts with Servers	Includes fields from the Hosts and Servers tables, providing you with information about the detected applications running on your network, as well as basic operating system information about the hosts running those applications.
Intrusion Events with Destination Criticality	Includes fields from the Intrusion Events table and the Hosts table, providing you with information on the intrusion events, as well as the host criticality of the destination host involved in each intrusion event. **TIP!** Use this table to search for intrusion events involving destination hosts with high host criticality.
Intrusion Events with Source Criticality	Includes fields from the Intrusion Events table and the Hosts table, providing you with information on the intrusion events and the host criticality of the source host involved in each intrusion event. **TIP!** Use this table to search for intrusion events involving source hosts with high host criticality.

Understanding Possible Table Combinations

LICENSE: FireSIGHT + Protection

When you create a custom table, you can combine fields from predefined tables that have related data. The Custom Table Combinations table lists the predefined tables you can combine to create a new custom table. Keep in mind that you can

create a custom table that combines fields from more than two predefined custom tables.

Custom Table Combinations

YOU CAN COMBINE FIELDS FROM...	WITH FIELDS FROM...
Applications	• Correlation Events • Intrusion Events • Connection Summary Data • Host Attributes • Application Details • Discovery Events • Connection Events • Hosts • Servers • White List Events
Correlation Events	• Applications • Host Attributes • Hosts
Intrusion Events	• Applications • Host Attributes • Hosts • Servers
Connection Summary Data	• Applications • Host Attributes • Hosts • Servers
Indications of Compromise	• Applications • Application Details • Captured Files • Connection Events • Connection Summary Data • Correlation Events • Discovery Events • Host Attributes • Hosts • Intrusion Events • Security Intelligence Events • Servers • White List Events

Custom Table Combinations (Continued)

YOU CAN COMBINE FIELDS FROM...	WITH FIELDS FROM...
Host Attributes	• Applications • Correlation Events • Intrusion Events • Connection Summary Data • Application Details • Discovery Events • Connection Events • Hosts • Servers • White List Events
Application Details	• Applications • Host Attributes • Hosts
Discovery Events	• Applications • Host Attributes • Hosts
Connection Events	• Applications • Host Attributes • Hosts • Servers
Security Intelligence Events	• Applications • Host Attributes • Hosts • Servers
Hosts	• Applications • Correlation Events • Intrusion Events • Connection Summary Data • Host Attributes • Application Details • Discovery Events • Connection Events • Servers • White List Events

Custom Table Combinations (Continued)

YOU CAN COMBINE FIELDS FROM...	WITH FIELDS FROM...
Servers	• Applications • Intrusion Events • Connection Summary Data • Host Attributes • Connection Events • Hosts
White List Events	• Applications • Host Attributes • Hosts

Sometimes a field in one table maps to more than one field in another table. For example, the predefined **Intrusion Events with Destination Criticality** custom table combines fields from the Intrusion Events table and the Hosts table. Each event in the Intrusion Events table has two IP addresses associated with it—a source IP address and a destination IP address. However, the "events" in the Hosts table each represent a single host IP address (hosts may have multiple IP addresses). Therefore, when you create a custom table based on the Intrusion Events table and the Hosts table, you must choose whether the data you display from the Hosts table applies to the host source IP address or the host destination IP address in the Intrusion Events table.

When you create a new custom table, a default workflow that displays all the columns in the table is automatically created. Also, just as with predefined tables, you can search custom tables for data that you want to use in your network analysis. You can also generate reports based on custom tables, as you can with predefined tables.

For more information on creating custom tables, see:

- Creating a Custom Table on page 1857
- Modifying a Custom Table on page 1859
- Deleting a Custom Table on page 1860
- Viewing a Workflow Based on a Custom Table on page 1860
- Searching Custom Tables on page 1861

Creating a Custom Table

LICENSE: FireSIGHT

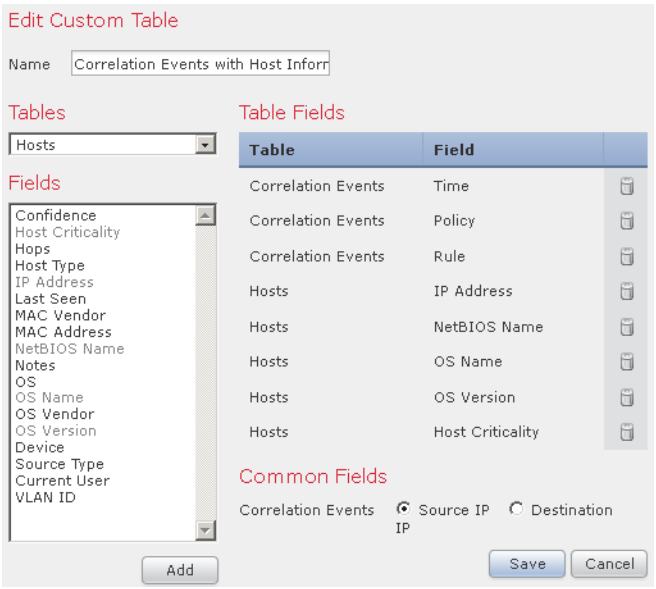
If you determine that your analysis of the activity on your network would be enhanced by combining fields from different tables, you can create a custom table.

TIP! Instead of creating a new custom table, you can export a custom table from another Defense Center, then import it onto your Defense Center. You can then edit the imported custom table to suit your needs. For more information, see Importing and Exporting Configurations on page 2308.

To create a custom table, decide which predefined tables delivered with the Sourcefire 3D System contain the fields you want to include in your custom table. You can then choose which fields you want to include and, if necessary, configure field mappings for any common fields.

TIP! Data involving the Hosts table allows you to view data associated with all IP addresses from one host, rather than one specific IP address.

For example, consider a custom table that combines fields from the Correlation Events table and the Hosts table. You can use this custom table to get detailed information about the hosts involved in violations of any of your correlation policies. Note that you must decide whether to display data from the Hosts table that matches the source IP address or the destination IP address in the Correlation Events table.



If you view the table view of events for this custom table, it displays correlation events, one per row. The following information is included:

- the date and time the event was generated
- the name of the correlation policy that was violated
- the name of the rule that triggered the violation
- the IP address associated with the source, or initiating, host involved in the correlation event
- the source host's NetBIOS name
- the operating system and version the source host is running
- the source host criticality

TIP! You could create a similar custom table that displays the same information for destination, or responding, hosts.

To build the custom table in the previous example:

Access: Admin

1. Select **Analysis > Custom > Custom Tables**.

   The Custom Tables page appears.

2. Click **Create Custom Table**.

   The Create Custom Table page appears.

3. In the **Name** field, type a name for the custom table, such as `Correlation Events with Host Information (Src IP)`.

4. From the **Tables** drop-down list, select **Correlation Events**.

   The fields in the Correlation Events table appear in the **Fields** list.

5. Under **Fields**, select **Time** and click **Add** to add the date and time when a correlation event was generated.

6. Repeat step 5 to add the **Policy** and **Rule** fields.

> **TIP!** You can use Ctrl or Shift while clicking to select multiple fields. You can also click and drag to select multiple adjacent values. However, if you want to specify the order the fields appear in the table view of events associated with the table, add the fields one at a time.

7. From the **Tables** drop-down list, select **Hosts**.

   The fields in the Hosts table appear in the **Fields** list. For more information on these fields, see Understanding the Hosts Table on page 1467.

8. Add the **IP Address**, **NetBIOS Name**, **OS Name**, **OS Version**, and **Host Criticality** fields to the custom table.

9. Under **Common Fields**, next to **Correlation Events**, select **Source IP**.

   Your custom table is configured to display the host information you chose in step 8 for the source, or initiating, hosts involved in correlation events.

> **TIP!** You could create a custom table that displays detailed host information for the destination, or responding, hosts involved in a correlation event by following this procedure but selecting **Destination IP** instead of **Source IP**.

10. Click **Save**.

    The custom table is saved.

Modifying a Custom Table

License: FireSIGHT

You can add or delete fields in a custom table as your needs change.

To modify a custom table:

Access: Any/Admin

1. Select **Analysis > Custom > Custom Tables**.

   The Custom Tables page appears.

2. Click the edit icon () next to the table you want to edit.

   The Edit Custom Table page appears. See Creating a Custom Table on page 1857 for information on the various configurations you can change.

3. Optionally, remove fields from the table by clicking the delete icon ( ) next to the fields you want to remove.

IMPORTANT! If you delete fields currently in use in reports, you will be prompted to confirm that you want to remove the sections using those fields from those reports.

4. Make other changes as needed and click **Save**.

   Your custom table is updated.

Deleting a Custom Table

License: FireSIGHT

You can delete a custom table that you no longer need. If you delete a custom table, saved searches that use the custom table are also deleted.

To delete a custom table:

Access: Any/Admin

1. Select **Analysis > Custom > Custom Tables**.

   The Custom Tables page appears.

2. Click the delete icon ( ) next to the custom table you want to delete.

   The table is deleted.

Viewing a Workflow Based on a Custom Table

License: FireSIGHT

When you create a custom table, the system automatically creates a default workflow for it. The first page of this workflow displays a table view of events. If you include intrusion events in your custom table, the second page of the workflow is the packet view. Otherwise, the second page of the workflow is a hosts page. You can also create your own custom workflows based on your custom table.

TIP! If you create a custom workflow based on a custom table, you can specify it as the default workflow for that table. For more information, see Configuring Event View Settings on page 2300.

You can use the same techniques to view events in your custom table that you use for event views based on predefined tables. See Using Workflow Pages on page 1889 for more information.

To view a workflow based on a custom table:

ACCESS: Any/Admin

1. Select **Analysis > Custom > Custom Tables**.

   The Custom Tables page appears.

2. Click the view icon ( ) next to the custom table on which the workflow you want to see is based.

   The first page of the default workflow for the custom table appears. To use a different workflow, click **(switch workflow)** by the workflow title. For information on how to specify a different default workflow, see Configuring Event View Settings on page 2300. If no events appear and the workflow can be constrained by time, you may need to adjust the time range; see Setting Event Time Constraints on page 1896.

Searching Custom Tables

LICENSE: FireSIGHT

You can create and save searches for a custom table. You may want to create searches customized for your network environment, then save them to reuse later. Note that if you delete a custom table, all searches you have saved for that custom table are also deleted.

The search criteria you can use are the same as the criteria for the predefined tables you used to build your custom table. See the sections listed in the following table for detailed information on the search criteria you can use.

Table Search Criteria

FOR SEARCH CRITERIA FOR...	SEE...
Audit Events	Searching Audit Records on page 2279
Application Details	Searching for Application Details on page 1501
Correlation Events	Searching for Correlation Events on page 1597
Connection Data	Searching for Connection and Security Intelligence Data on page 622
Hosts	Searching for Hosts on page 1472
Host Attributes	Searching for Host Attributes on page 1480
Hosts with Applications	Searching for Hosts on page 1472 and Searching for Servers on page 1490

Table Search Criteria

FOR SEARCH CRITERIA FOR...	SEE...
Intrusion Events	Searching for Intrusion Events on page 691
Intrusion Events with Destination Criticality	Searching for Intrusion Events on page 691 and Searching for Hosts on page 1472
Intrusion Events with Source Criticality	Searching for Intrusion Events on page 691 and Searching for Hosts on page 1472
Status Events	Searching for Remediation Status Events on page 1709
Discovery Events	Searching for Discovery Events on page 1463
User Events	Searching for User Activity on page 1525
Rule Update Import Log	Searching the Rule Update Import Log on page 2171
Applications	Searching for Applications on page 1496
Security Intelligence Events	Searching for Connection and Security Intelligence Data on page 622
Users	Searching for Users on page 1520
Vulnerabilities	Searching for Sourcefire Vulnerabilities on page 1508
White List Events	Searching for Compliance White List Events on page 1647
White List Violations	Searching for White List Violations on page 1653

To implement these criteria in a table search, see the following procedure.

To perform a search on a custom table:

ACCESS: Any/Admin

1. Select **Analysis > Custom > Custom Tables**.

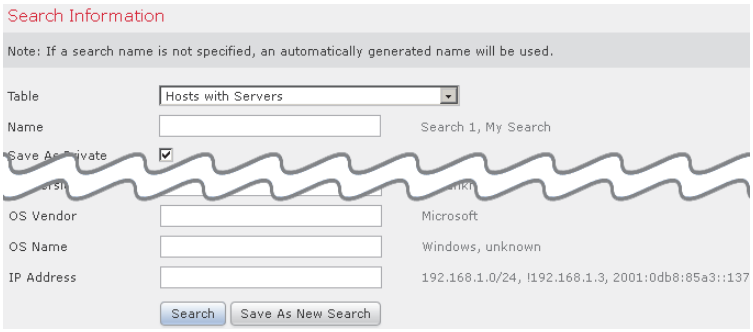
   The Custom Tables page appears.

2. Click the view icon ( ) next to the custom table you want to search.

   The first page of the default workflow for the custom table appears. To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. If no events appear and the workflow can be constrained by time, you may need to adjust the time range; see Setting Event Time Constraints on page 1896.

3. Click **Search**.

   The custom table's search page appears. The following graphic shows the search page for the Hosts with Servers predefined custom table.



TIP! To search the database for a different kind of event or data, select it from the **Table** drop-down list.

4. Optionally, if you want to save the search, enter a name for it in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

5. Enter your search criteria in the appropriate fields. For more information about choosing search criteria, see Table Search Criteria on page 1861.

   If you enter multiple criteria, the search returns only the records that match all criteria.

TIP! Click the object icon ( ) next to a search field to use an object as a search criterion. For more information on searches, including information on special search syntax, using objects in searches, and saving and loading searches, see Performing and Saving Searches on page 1843.

6. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

   TIP! If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

7. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in the default workflow for the custom table, constrained by the current time range (if applicable). To use a different workflow, including a custom workflow, click **(switch workflow)** by the workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

CHAPTER 45
UNDERSTANDING AND USING WORKFLOWS

A workflow is a tailored series of data pages on the Defense Center web interface that analysts can use to evaluate events generated by the system. The Defense Center provides three types of workflows:

- *Predefined workflows*, which are preset workflows installed on the system that you cannot modify or delete.
- *Saved custom workflows*, which are predefined custom workflows that you can modify or delete.
- *Custom workflows*, which are workflows that you create and customize for your specific needs.

For example, when you analyze intrusion events, you can choose from several predefined workflows specifically created for the task.

Note that the data displayed in a workflow often depends on such factors as how you license and deploy your managed devices, whether you configure features that provide the data and, in the case of Series 2 appliances, whether the appliance supports a feature that provides the data. For example, because neither the DC500 Defense Center nor Series 2 devices support URL filtering by category and reputation, the DC500 Defense Center does not display data for this feature and Series 2 devices do not detect this data.

See the following sections for more information about using predefined and custom workflows:

- Components of a Workflow on page 1866
- Using Workflows on page 1884
- Using Custom Workflows on page 1915

TIP! You can also use custom workflows as the basis for event reports. See Working with Reports on page 1796 for more information.

Components of a Workflow

LICENSE: Any

Workflows can include several types of pages, as described in the following sections.

Table Views

Table views include a column for each of the fields in the database on which your workflow is based.

For example, the table view of discovery events includes the Time, Event, IP Address, User, MAC Address, MAC Vendor, Port, Description, and Device columns.

By contrast, the table view of servers includes the Last Used, IP Address, Port, Protocol, Application Protocol, Vendor, Version, Web Application, Application Risk, Business Relevance, Hits, Source Type, Device, and Current User columns.

Drill-Down Pages

Drill-down pages contain a subset of columns that are available in the database.

For example, a drill-down page for discovery events might include only the IP Address, MAC Address, and Time columns. A drill-down page for intrusion events, on the other hand, might include the Priority, Impact Flag, Inline Result, and Message columns.

Generally, drill-down pages are intermediate pages that you use to narrow your investigation to a few events before moving to a table view page.

Graphs

Workflows based on connection data can include graph pages, also called *connection graphs*.

For example, a connection graph might display a line graph that shows the number of connections detected by the system over time. Generally, connection graphs are, like drill-down pages, intermediate pages that you use to narrow your

investigation. For more information, see Working with Connection Graphs on page 603.

Final Pages

The final page of a workflow depends on the type of event on which the workflow is based:

- The host view is the final page for workflows based on applications, application details, discovery events, hosts, indications of compromise (IOC), servers, or any type of vulnerabilities. Viewing host profiles from this page allows you to easily view data on all IP addresses associated with hosts that have multiple addresses. For more information, see Using Host Profiles on page 1394.
- The user detail view is the final page for workflows based on users and user activity. For more information, see Understanding User Details and Host History on page 1518.
- The vulnerability detail view is the final page for workflows based on Sourcefire vulnerabilities. For more information, see Viewing Vulnerability Details on page 1429.
- The packet view is the final page for workflows based on intrusion events. For more information, see Using the Packet View on page 669.

Workflows based on other kinds of events (for example, audit log events or malware events) do not have final pages.

See the following sections for more information on workflows:

- Comparing Predefined and Custom Workflows on page 1868
- Comparing Workflows for Predefined and Custom Tables on page 1868
- Predefined Intrusion Event Workflows on page 1869
- Predefined Malware Workflows on page 1871
- Predefined File Workflows on page 1872
- Predefined Captured File Workflows on page 1873
- Predefined Connection Data Workflows on page 1873
- Predefined Security Intelligence Workflows on page 1875
- Predefined Host Workflows on page 1876
- Predefined Indications of Compromise Workflows on page 1876
- Predefined Applications Workflows on page 1877
- Predefined Application Details Workflows on page 1878
- Predefined Servers Workflows on page 1878
- Predefined Host Attributes Workflows on page 1879
- Predefined Discovery Events Workflows on page 1879
- Predefined User Workflows on page 1880

Comparing Predefined and Custom Workflows

LICENSE: Any

The Sourcefire 3D System is delivered with a set of *predefined* workflows (described in the sections that follow) that you can use to analyze the events and other data it collects.

Custom workflows are workflows that you create to meet the unique needs of your organization. When you create a custom workflow, you choose the kind of event (or database table) on which the workflow is based. On the Defense Center, you can base a custom workflow on a custom table. You can also choose the pages a custom workflow contains; custom workflows can contain drill-down, table view, and host or packet view pages.

The Defense Center is delivered with several *saved custom workflows*, which are based on the saved custom tables that are also delivered with the Defense Center. The differences between workflows based on predefined and custom tables is described in the next section, Comparing Workflows for Predefined and Custom Tables.

Comparing Workflows for Predefined and Custom Tables

LICENSE: FireSIGHT

You can use the custom tables feature to create tables that use the data from two or more types of events. This is useful because you can, for example, create tables and workflows that correlate intrusion event data with discovery data to allow simple searches for events that affect critical systems. See Using Custom Tables on page 1852 for information about creating custom tables.

Each custom table has, by default, a workflow that you can use to view the events associated with the table. The features in the workflow differ depending on which type of table you use. For example, custom table workflows based on the intrusion event table always end with the packet view. However, custom table workflows based on discovery events end with the host view.

Unlike workflows based on the predefined event tables, workflows based on custom tables do not have links to other types of workflows.

Predefined Intrusion Event Workflows

LICENSE: Protection

The Predefined Intrusion Event Workflows table describes the predefined intrusion event workflows included with the Sourcefire 3D System. For information on accessing these workflows, see Viewing Intrusion Events on page 649 and Reviewing Intrusion Events on page 659.

Predefined Intrusion Event Workflows

WORKFLOW NAME	DESCRIPTION
Destination Port	Because destination ports are usually tied to an application, this workflow can help you detect applications that are experiencing an uncommonly high volume of alerts. The Destination Port column can also help you identify applications that should not be present on your network. This workflow begins with a page showing the destination ports associated with the intrusion events, followed by a page showing the event types that were generated. You can then see a tabular view of event information, called the table view of events, followed by a packet view that shows the decoded contents of the packets associated with each event.
Event-Specific	This workflow provides two useful features. Events that occur frequently may indicate: • false positives • a worm • a badly misconfigured network Events that occur infrequently are most likely evidence of a targeted attack and warrant special attention. This workflow begins with a page showing the event types that were generated. You can then view a page with two tables, one listing the source IP addresses associated with the events, the other showing the destination IP addresses associated with the events. The last pages in the workflow are the table view of events and the packet view.
Events by Priority and Classification	This workflow lists events and their type in order of event priority, along with a count showing how many times each event has occurred. This workflow begins with a drill-down page that contains the priority level, classification and count of each listed event. The last pages in the workflow are the table view of events and the packet view.
Events to Destinations	This workflow provides a high-level view of which host IP addresses are being attacked and the nature of the attack; where available, you can also see information about the countries involved in attacks. This workflow begins with a page of paired event types and destination IP addresses that you can use to investigate what types of events are directed towards specific IP addresses. The last pages in the workflow are the table view of events and the packet view.

Predefined Intrusion Event Workflows (Continued)

Workflow Name	Description
IP-Specific	This workflow shows which host IP addresses are generating the most alerts. Hosts with the greatest number of events are either public-facing and receiving worm-type traffic (indicating a good place to look for tuning) or require further investigation to determine the cause of the alerts. Hosts with the lowest counts also warrant investigation as they could be the subject of a targeted attack. Low counts may also indicate that a host may not belong on the network. This workflow begins with a page showing two tables, one each for the source and destination IP addresses that are associated with the events. The next page shows the event types that were generated. The last pages in the workflow are the table view of events and the packet view.
Impact and Priority	This workflow lets you find high-impact recurring events quickly. The reported impact level is shown with the number of times the event has occurred. Using this information, you can identify the high-impact events that recur most often, which might be an indicator of a widespread attack on your network. This workflow begins with a page showing the impact level, priority, and count associated with each event. Next, a drill-down page appears with the source and destination IP addresses for each event. Events on the second page are sorted by count. The last pages in the workflow are the table view of events and the packet view.
Impact and Source	This workflow can help you identify the source of an attack in progress. The reported impact level is shown with the associated source IP address for the event. If, for example, events with a level 1 impact are coming from the same source IP address repeatedly, they may indicate an attacker who has identified vulnerable systems and is targeting them. This workflow begins with a page showing the impact level, source IP address, priority, and count associated with each event. Within each event level, events are sorted by count, then priority. Next, a drill-down page appears with the source and destination IP addresses for each event. Events on the second page are sorted by count. The last pages in the workflow are the table view of events and the packet view.

Predefined Intrusion Event Workflows (Continued)

Workflow Name	Description
Impact to Destination	You can use this workflow to identify events repeatedly occurring on vulnerable computers, so you can address the vulnerabilities on those systems and stop any attacks in progress. This workflow begins with a page showing the impact level, inline result (whether the packet was or would have been dropped), destination IP address, priority, and count associated with each event. Within each event level, events are sorted by count, then priority. Next, a drill-down page appears with the source and destination IP addresses for each event. Events on the second page are sorted by count. The last pages in the workflow are the table view of events and the packet view.
Source Port	This workflow indicates which servers are generating the most alerts. You can use this information to identify areas that require tuning, and to decide which servers require attention. This workflow begins with a page showing the source ports associated with the intrusion events, followed by a page showing the types of events that were generated. The last pages in the workflow are the table view of events and the packet view.
Source and Destination	This workflow identifies host IP addresses sharing high levels of alerts. Pairs at the top of the list could be false positives, and may identify areas that require tuning. You can check pairs at the bottom of the list for targeted attacks, for users accessing resources they should not be accessing, or for hosts that do not belong on the network. This workflow begins with a page showing the source and destination IP addresses for each event, followed by a page showing the types of events that were generated. The last pages in the workflow are the table view of events and the packet view.

Predefined Malware Workflows

License: Any
Supported Devices: feature dependent
Supported Defense Centers: feature dependent

The Predefined Malware Workflows table describes the predefined malware workflows included on the Defense Center. All predefined malware workflows use the table view of malware events.

Note that because neither the DC500 Series 2 Defense Center nor Series 2 devices support network-based advanced malware protection, the DC500 Defense Center does not display data for this feature and Series 2 devices do not detect this data.

For information on accessing malware events, see Working with Malware Events on page 1274.

Predefined Malware Workflows

Workflow Name	Description
Malware Summary	This workflow provides a list of the malware detected in network traffic or by endpoint-based FireAMP Connectors, grouped by individual threat.
Malware Event Summary	This workflow provides a quick breakdown of the different malware event types and subtypes.
Hosts Receiving Malware	This workflow provides a list of host IP addresses that have received malware, grouped by the malware files' associated dispositions.
Hosts Sending Malware	This workflow provides a list of host IP addresses that have sent malware, grouped by the malware files' associated dispositions.
Applications Introducing Malware	This workflow provides a list of host IP addresses that have received files, grouped by the associated malware dispositions for those files.

Predefined File Workflows

License: Protection

The Predefined File Workflows table describes the predefined file event workflows included on the Defense Center. All the predefined file event workflows use the table view of file events. For information on accessing file events, see Working with File Events on page 1265.

Predefined File Workflows

Workflow Name	Description
File Summary	This workflow provides a quick breakdown of the different file event categories and types, along with any associated malware dispositions.
Hosts Receiving Files	This workflow provides a list of host IP addresses that have received files, grouped by the associated malware dispositions for those files.
Hosts Sending Files	This workflow provides a list of host IP addresses that have sent files, grouped by the associated malware dispositions for those files.

Predefined Captured File Workflows

LICENSE: Malware
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

The Predefined Captured File Workflows table describes the predefined captured file workflows included on the Defense Center. All predefined captured file workflows use the table view of captured files.

Note that because neither the DC500 Series 2 Defense Center nor Series 2 devices support network-based advanced malware protection, the DC500 Defense Center does not display data for this feature and Series 2 devices do not detect this data.

For information on accessing captured files, see Working with Captured Files on page 1288.

Predefined Captured File Workflows

WORKFLOW NAME	DESCRIPTION
Captured File Summary	This workflow provides a breakdown of captured files based on type, category, and threat score.
Dynamic Analysis Status	This workflow provides a count of captured files based on whether they have been submitted for dynamic analysis.

Predefined Connection Data Workflows

LICENSE: FireSIGHT

The Predefined Connection Data Workflows table describes the predefined connection data workflows included on the Defense Center. All the predefined connection data workflows use the table view of connection data. For information

on accessing connection data, see Viewing Connection and Security Intelligence Data on page 602.

Predefined Connection Data Workflows

Workflow Name	Description
Connection Events	This workflow provides a summary view of basic connection and detected application information, which you can then use to drill down to the table view of events.
Connections by Application	This workflow contains a graph of the 10 most active applications on the monitored network segment, based on the number of detected connections.
Connections by Initiator	This workflow contains a graph of the 10 most active host IP addresses on the monitored network segment, based on the number of connections where the host initiated the connection transaction.
Connections by Port	This workflow contains a graph of the 10 most active ports on the monitored network segment, based on the number of detected connections.
Connections by Responder	This workflow contains a graph of the 10 most active host IP addresses on the monitored network segment, based on the number of connections where the host IP was the responder in the connection transaction.
Connections over Time	This workflow contains a graph of the total number of connections on the monitored network segment over time.
Traffic by Application	This workflow contains a graph of the 10 most active applications on the monitored network segment, based on the number of kilobytes transmitted.
Traffic by Initiator	This workflow contains a graph of the 10 most active host IP addresses on the monitored network segment, based on the total number of kilobytes transmitted from each address.
Traffic by Port	This workflow contains a graph of the 10 most active ports on the monitored network segment, based on the number of kilobytes transmitted.
Traffic by Responder	This workflow contains a graph of the 10 most active host IP addresses on the monitored network segment, based on the total number of kilobytes received by each address.

Predefined Connection Data Workflows (Continued)

Workflow Name	Description
Traffic over Time	This workflow contains a graph of the total kilobytes transmitted on the monitored network segment over time.
Unique Initiators by Responder	This workflow contains a graph of the 10 most active responding host IP addresses on the monitored network segment, based on the number of unique initiators that contacted each address.
Unique Responders by Initiator	This workflow contains a graph of the 10 most active initiating host IP addresses on the monitored network segment, based on the number of unique responders that the addresses contacted.

Predefined Security Intelligence Workflows

License: Protection
Supported Devices: Series 3, virtual, X-Series
Supported Defense Centers: Any except DC500

The Predefined Security Intelligence Workflows table describes the predefined Security Intelligence workflows included on the Defense Center. All the predefined Security Intelligence workflows use the table view of Security Intelligence events. For more information on accessing Security Intelligence event data, see Viewing Connection and Security Intelligence Data on page 602.

Predefined Security Intelligence Workflows

Workflow Name	Description
Security Intelligence Events	This workflow provides a summary view of basic Security Intelligence and detected application information, which you can then use to drill down to the table view of events.
Security Intelligence Summary	This workflow is identical to the Security Intelligence Events workflow, but begins with the Security Intelligence Summary page, which lists security intelligence events by category and count only.

Predefined Host Workflows

LICENSE: FireSIGHT

The Predefined Host Workflows table describes the predefined workflows that you can use with host data.

Predefined Host Workflows

WORKFLOW NAME	DESCRIPTION
Hosts	This workflow contains a table view of hosts followed by the host view. Workflow views based on the Hosts table allow you to easily view data on all IP addresses associated with a host. See Viewing Hosts on page 1466 for more information.
Operating System Summary	You can use this workflow to analyze the operating systems in use on your network. This workflow provides a series of pages that start with a list of the operating systems and operating system vendors on your network, continuing with the number of hosts running each version of that operating system. The next page lists hosts by criticality, IP address, and NetBIOS name, with their associated operating systems and operating system vendors. The workflow finishes with a table view of hosts, followed by the host view. See Viewing Hosts on page 1466 for more information.

Predefined Indications of Compromise Workflows

LICENSE: FireSIGHT

The Predefined Indications of Compromise Workflows table describes the predefined workflows that you can use with IOC (Indications of Compromise) data.

Predefined Indications of Compromise Workflows

WORKFLOW NAME	DESCRIPTION
Indications of Compromise	This workflow begins with a summary view of IOC data grouped by count and category, followed by a detail view that further subdivides the summary data by event type. Next is a full table view of IOC data. The workflow concludes with the host view. For more information on viewing and interpreting IOC data, see Working with Indications of Compromise on page 1482.
Indications of Compromise by Host	You can use this workflow to gauge which hosts on your network are most likely to be compromised (based on IOC data). This workflow contains a view of host IP addresses by IOC data count, followed by a table view of IOC data and concluding with the host view. For more information on viewing and interpreting IOC data, see Working with Indications of Compromise on page 1482.

Predefined Applications Workflows

LICENSE: FireSIGHT

The Predefined Applications Workflows table describes the predefined workflows that you can use with application data.

Predefined Applications Workflows

WORKFLOW NAME	DESCRIPTION
Application Business Relevance	You can use this workflow to analyze running applications of each estimated business relevance level on your network, so you can monitor appropriate use of your network resources. This workflow begins with a count of hosts running applications of each relevance level, followed by a table of individual applications with their business relevance levels and host counts, a table view of applications, and the host view. See Viewing Applications on page 1493 for more information.
Application Category	You can use this workflow to analyze running applications of each category (such as email, search engine, or social networking) on your network, so you can monitor appropriate use of your network resources. This workflow begins with a count of hosts running applications of each category, followed by a count of hosts running individual applications, a table view of applications, and the host view. See Viewing Applications on page 1493 for more information.
Application Risk	You can use this workflow to analyze running applications of each estimated security risk level on your network, so you can estimate the potential risk of users' activity and take appropriate action. This workflow begins with a count of hosts running applications of each risk level, followed by a table of individual applications with their business relevance levels and host counts, a table view of applications, and the host view. See Viewing Applications on page 1493 for more information.
Application Summary	You can use this workflow to obtain detailed information about the applications and associated hosts on your network, so you can closely examine host application activity. This workflow begins with a list of individual host IP addresses running applications, followed by a table view of applications and the host view.
Applications	You can use this workflow to analyze running applications on your network, so you can gain an overview of how the network is being used. This workflow begins with a count of hosts running individual applications, followed by a table view of applications and the host view. See Viewing Applications on page 1493 for more information.

Predefined Application Details Workflows

LICENSE: FireSIGHT

The Predefined Application Details Workflows table describes the predefined workflows that you can use with application detail and client data.

Predefined Application Details Workflows

WORKFLOW NAME	DESCRIPTION
Application Details	You can use this workflow to analyze the client applications on your network in more detail. This workflow contains a series of pages that begin with a list of the client applications and application products on your network and a count of the number of hosts running each application. You can then view the number of hosts running each version of that application. The next page lets you identify which applications have been accessed most frequently on specific hosts. The workflow then provides a table view of client applications, followed by the host view. See Viewing Application Details on page 1498 for more information.
Clients	This workflow contains a table view of client applications, followed by the host view. See Viewing Application Details on page 1498 for more information.

Predefined Servers Workflows

LICENSE: FireSIGHT

The Predefined Servers Workflows table describes the predefined workflows that you can use with server data.

Predefined Servers Workflows

WORKFLOW NAME	DESCRIPTION
Network Applications by Count	You can use this workflow to analyze the most frequently used applications on your network. This workflow contains a series of pages that show applications with a count of hosts where each application occurs, then add the vendor and version of each application. The workflow then concludes with a table view listing the applications per host, followed by the host view. See Viewing Servers on page 1487 for more information.
Network Applications by Hit	You can use this workflow to analyze the most active applications on your network. This workflow contains a series of pages that show applications with a count of how often each application is accessed, then add the vendor and version information for each application. The workflow finishes with a page containing a table view listing the applications per host, followed by the host view. See Viewing Servers on page 1487 for more information.

Predefined Servers Workflows (Continued)

Workflow Name	Description
Server Details	You can use this workflow to analyze the vendors and versions of detected server application protocols in detail. The workflow contains a list of servers associated with their vendors, then a list of servers correlated with both vendor and version, finishing with a table view of servers and the host view.
Servers	This workflow contains a table view of applications followed by the host view. See Viewing Servers on page 1487 for more information.

Predefined Host Attributes Workflows

License: FireSIGHT

The Predefined Host Attributes Workflows table describes the predefined workflow that you can use with host attribute data.

Predefined Host Attributes Workflows

Workflow Name	Description
Attributes	You can use this workflow to monitor IP addresses of hosts on your network and the hosts' status. This workflow begins with a table view of host attributes that lists individual IP addresses with current user, host criticality, notes, and white list compliance. It finishes with the host view. For more information, see Viewing Host Attributes on page 1476.

Predefined Discovery Events Workflows

License: FireSIGHT

The Predefined Discovery Event Workflows table describes the predefined workflow that you can use with discovery event data.

Predefined Discovery Event Workflows

Workflow Name	Description
Discovery Events	This workflow provides a detailed list, in table view form, of discovery events, followed by the host view. For more information, see Understanding the Discovery Events Table on page 1461.

Predefined User Workflows

LICENSE: FireSIGHT

The Predefined User Workflows table describes the predefined user workflows included on the Defense Center.

Predefined User Workflows

WORKFLOW NAME	DESCRIPTION
Users	This workflow provides a list of user information collected from user events or from the LDAP server connection. For details about the user identity workflow, see Viewing Users on page 1516.

Predefined Vulnerabilities Workflows

LICENSE: FireSIGHT

The Predefined Vulnerabilities Workflows table describes the predefined vulnerabilities workflow included on the Defense Center.

Predefined Vulnerabilities Workflows

WORKFLOW NAME	DESCRIPTION
Vulnerabilities	You can use this workflow to review s a table view of vulnerabilities showing all the vulnerabilities in the database, followed by a table view of only those active vulnerabilities that apply to the detected hosts on your network.The workflow ends in a vulnerability detail view, which contains a detailed description for every vulnerability that meets your constraints. For more information, see Viewing Sourcefire Vulnerabilities on page 1503.

Predefined Third-Party Vulnerabilities Workflows

LICENSE: FireSIGHT

The Predefined Third-Party Vulnerabilities Workflows table describes the predefined third-party vulnerabilities workflows included on the Defense Center.

Predefined Third-Party Vulnerabilities Workflows

WORKFLOW NAME	DESCRIPTION
Vulnerabilities by IP Address	You can use this workflow to see quickly how many third-party vulnerabilities you have detected per host IP address on your monitored network. The workflow concludes with a table view of third-party vulnerabilities, followed by the host view. For more information, see Viewing Third-Party Vulnerabilities on page 1510.
Vulnerabilities by Source	You can use this workflow to see quickly how many third-party vulnerabilities you have detected per third-party vulnerability source, such as the QualysGuard Scanner. This workflow provides some details about those vulnerabilities on an intermediate drill-down page, then concludes with a table view of third-party vulnerabilities and the host view. For more information, see Viewing Third-Party Vulnerabilities on page 1510.

Predefined Correlation and White List Workflows

LICENSE: FireSIGHT

There is a predefined workflow for each type of correlation data, white list events, white list violations, and remediation status events.

Predefined Correlation Workflows

WORKFLOW NAME	DESCRIPTION
Correlation Events	This workflow contains a table view of correlation events. See Working with Correlation Events on page 1592 for more information.
White List Events	This workflow contains a table view of white list events. See Working with White List Events on page 1643 for more information.

Predefined Correlation Workflows (Continued)

Workflow Name	Description
Host Violation Count	This workflow provides a series of pages that list all the host IP addresses that violate at least one white list. The first page sorts the addresses based on the number of violations per address, with the IP addresses with the most number of violations at the top of the list. If a host IP address violates more than one white list, there is a separate row for each violated white list. The workflow also contains a table view of white list violations that lists all violations, with the most recently detected violation at the top of the list. Each row in the table contains a single detected violation. See Working with White List Violations on page 1650 for more information.
White List Violations	This workflow includes a table view of white list violations that lists all violations with the most recently detected violation at the top of the list. Each row in the table contains a single detected violation. See Working with White List Violations on page 1650 for more information.
Status	This workflow contains a table view of remediation status, which includes the name of the policy that was violated and the name and status of the remediation that was applied. See Working with Remediation Status Events on page 1704 for more information.

Predefined System Workflows

License: Any

The Sourcefire 3D System is delivered with some additional workflows, including system events such as audit events and health events, as well as workflows that list results from rule update imports and active scans.

Additional Predefined Workflows

Workflow Name	Description
Audit Log	This workflow contains a table view of the audit log that lists audit events. See Viewing Audit Records on page 2270 for more information.
Health Events	This workflow displays events triggered by the health monitoring policy. See Working with the Health Events Table View on page 2260 for more information.
Rule Update Import Log	This workflow contains a table view listing information about both successful and failed rule update imports. For more information, see Importing Rule Updates and Local Rule Files on page 2154.
Scan Results	This workflow contains a table view listing each completed scan. For more information, see Working with Active Scan Results on page 1788.

Saved Custom Workflows

LICENSE: Protection + FireSIGHT

In addition to predefined workflows, which cannot be modified, your Defense Center includes several saved custom workflows. Each of these workflows is based on a custom table and can be modified. For information on accessing these workflows, see Viewing a Workflow Based on a Custom Table on page 1860.

Saved Custom Workflows

WORKFLOW NAME	DESCRIPTION
Events by Impact, Priority, and Host Criticality	You can use this workflow to quickly pick out and focus in on hosts that are important to your network, currently vulnerable, and possibly currently under attack. By default, this workflow starts with a summary of events sorted by impact level, then by host criticality, and then by the number of occurrences of the event. You can use the second page of the workflow to drill down and view the source and destination addresses where specific events occur. The workflow concludes with a table view of Intrusion Events with Destination Criticality, then the packet view. This workflow is based on the Intrusion Events with Destination Criticality custom table. For more information, see Understanding Custom Tables on page 1853.
Events by Priority and Classification	This workflow lists events and their type in order of event priority, along with a count showing how many times each event has occurred. This workflow begins with a drill-down page that contains the priority level, classification and count of each listed event. The last pages in the workflow are the table view of events and the packet view. This workflow is based on the Intrusion Events custom table. For more information, see Understanding Custom Tables on page 1853.
Events with Destination, Impact, and Host Criticality	You can use this workflow to find the most recent attacks on hosts that are important to your network and currently vulnerable. By default, this workflow starts with a list of the most recent events, sorted by impact level. The next page of the workflow provides a table view of Intrusion Events with Destination Criticality, followed by the packet view. This workflow is based on the Intrusion Events with Destination Criticality custom table. For more information, see Understanding Custom Tables on page 1853.
Hosts with Servers Default Workflow	You can use this workflow to quickly view the basic information in the Hosts with Servers custom table. By default, this workflow begins with a table view of hosts with servers, followed by the host view. This workflow is based on the Hosts with Servers custom table. For more information, see Understanding Custom Tables on page 1853.

Saved Custom Workflows (Continued)

Workflow Name	Description
Intrusion Events with Destination Criticality Default Workflow	You can use this workflow to quickly view the basic information in the Intrusion Events with Destination Criticality custom table. By default, this workflow starts with a table view of Intrusion Events with Destination Criticality, followed by the packet view. This workflow is based on the Intrusion Events with Destination Criticality custom table. For more information, see Understanding Custom Tables on page 1853.
Intrusion Events with Source Criticality Default Workflow	You can use this workflow to quickly view the basic information in the Intrusion Events with Source Criticality custom table. By default, this workflow starts with a table view of Intrusion Events with Source Criticality, followed by the packet view. This workflow is based on the Intrusion Events with Source Criticality custom table. For more information, see Understanding Custom Tables on page 1853.
Server and Host Details	You can use this workflow to determine what servers are most frequently used on your network and which hosts are running those servers. By default, this workflow begins with a summary of servers with the frequency of access for each service. The next page lists servers by operating system vendor and version. The workflow concludes with a table view of hosts with servers, followed by the host view. This workflow is based on the Hosts with Servers custom table. For more information, see Understanding Custom Tables on page 1853.

Using Workflows

License: Any

The drill-down and table view pages in workflows allow you to quickly narrow your view of the data so you can zero in on events that are significant to your analysis. Although the data in each type of workflow is different, all workflows share a common set of features. The following sections describe these features and explain how to use them:

- Selecting Workflows on page 1885 describes the workflow selection page and how to select a workflow to use.
- Understanding the Workflow Toolbar on page 1888 describes the toolbar options available in workflows.
- Using Workflow Pages on page 1889 describes the features that appear on all workflow pages and explains how to use them.
- Setting Event Time Constraints on page 1896 describes how to set the time range for event-based workflows. The workflow includes events generated in the specified time range.

- Constraining Events on page 1905 describes features that are used in workflows to constrain, or narrow, the view of data in workflows and to advance through workflow pages.
- Using Compound Constraints on page 1908 explains how compound constraints can be used and provides examples.
- Sorting Drill-Down Workflow Pages on page 1910 describes features for sorting the data displayed in workflows, and for removing and restoring table columns to view.
- Selecting Rows on a Workflow Page on page 1910 describes how to select data rows in the displayed table that you want to analyze or on which you want to perform some other action.
- Navigating to Other Pages in the Workflow on page 1911 describes how to open other workflows using the constraints, including any selected events, from the current workflow.
- Navigating Between Workflows on page 1911 describes the **Jump to** drop-down list and explains how you can use it to apply the current constraints to a different workflow.
- Searching for Events on page 1842 provides information about the feature used to search event data.
- Using Bookmarks on page 1913 describes how to create, manage, and use bookmarks.

Selecting Workflows

LICENSE: Any

The Sourcefire 3D System provides predefined workflows for the types of data listed in the Features Using Workflows table.

Features Using Workflows

FEATURE	MENU PATH	OPTION
Intrusion events	Analysis > Intrusions	Events Reviewed Events Clipboard Incidents
Malware events	Analysis > Files	Malware Events
File events	Analysis > Files	File Events
Captured files	Analysis > Files	Captured Files

Features Using Workflows (Continued)

FEATURE	MENU PATH	OPTION
Connection events	Analysis > Connections	Events
Security Intelligence events	Analysis > Connections	Security Intelligence Events
Host events	Analysis > Hosts	Network Map Hosts Indications of Compromise Applications Application Details Servers Host Attributes Discovery Events
User events	Analysis > Users	User Activity Users
Vulnerability events	Analysis > Vulnerabilities	Vulnerabilities Third-Party Vulnerabilities
Correlation events	Analysis > Correlation	Correlation Events White List Events White List Violations Status
Audit events	System > Monitoring	Audit
Health events	Health > Health Events	n/a
Rule Update Import Log	System > Updates	n/a
Scan Results	Policies > Actions > Scanners	n/a

When you view any of the kinds of data described in the above table, events appear on the first page of the default workflow for that data.

Also note that workflow access depends on your user role (see Configuring User Roles on page 1981), as follows:

- Administrator users can access any workflow, and are the only users who can access the audit log, scan results, and the rule update import log.
- Maintenance Users can access health events.
- Security Analyst and Security Analyst (Read Only) users can access intrusion, malware, file, connection, discovery, vulnerability, correlation, and health workflows.

To view the data using a workflow other than the default:

Access: Admin/Any Security Analyst

1. Select the appropriate menu path and option as described in the Features Using Workflows table.

   The first page of the default workflow for that data type appears. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.

2. Optionally, use a different workflow. Click **(switch workflow)** next to the workflow title, then select the workflow you want to use.

   For example, the following graphic shows the workflows you can use to view intrusion events.

3. The first page of your selected workflow appears.

Understanding the Workflow Toolbar

LICENSE: Any

Each page in a workflow includes a toolbar that offers quick access to related features. The Workflow Toolbar Links table describes each of the links on the toolbar.

Workflow Toolbar Links

FEATURE	DESCRIPTION
Bookmark This Page	Bookmarks the current page so you can return to it later. Bookmarking captures the constraints in effect on the page you are viewing so you can return to the same data (assuming the data still exists) at a later time. See Using Bookmarks on page 1913 for information about creating bookmarks.
Report Designer	Opens the report designer with the currently constrained workflow as the selection criteria. See Creating a Report Template from an Event View on page 1797 for information about creating reports.
Dashboard	Opens a dashboard relevant to your current workflow. For example, Connection Events workflows link to the Connection Summary dashboard. See Using Dashboards on page 73 for information about using dashboards.
View Bookmarks	Displays a list of saved bookmarks from which you can select. See Using Bookmarks on page 1913 for information about creating and managing bookmarks.
Search	Displays a Search page where you can perform advanced searches on data in the workflow. You can also click the down arrow icon to select and use a saved search. See Searching for Events on page 1842 for information about searching workflows.

Using Workflow Pages

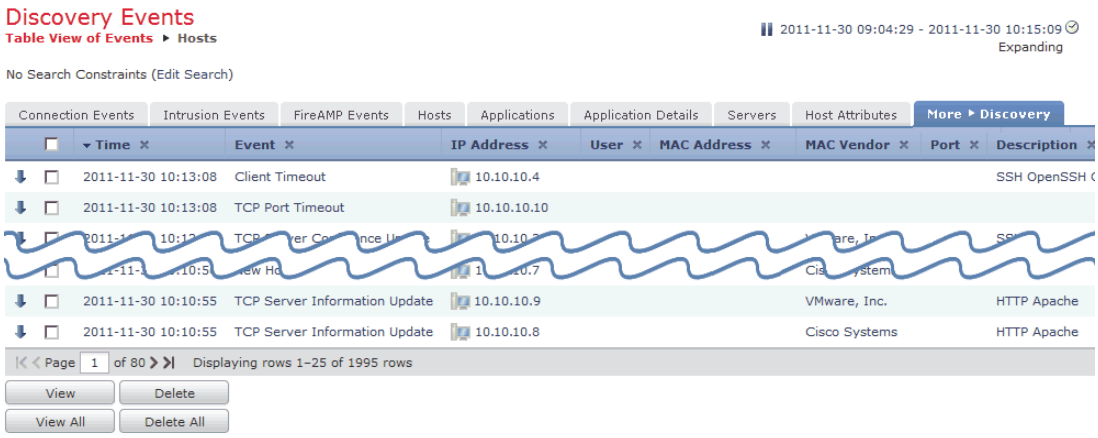
LICENSE: Any

The actions you can perform on a workflow page depend on the type of page. Table view pages and drill-down pages contain many features you can use to constrain the set of events you want to view or to navigate the workflow. For more information on the features available on each type of page, see the following sections:

Using Common Table View or Drill-Down Page Functionality

LICENSE: Any

Table view and drill-down workflow pages provide a set of icons and other features in the table header and table rows that you can use to perform actions on the displayed data.



The features are described in the Table View and Drill-Down Page Features table.

Table View and Drill-Down Page Features

Feature	Description
	Click the blue down-arrow icon to display the corresponding row in the next page of the workflow.
 (clean)  (malware)  (custom detection)  (unknown)  (unavailable)	Click the network file trajectory icon, which appears in file name and SHA-256 hash value columns, to view the file's trajectory map in a new window. For more information, see Analyzing Network File Trajectory on page 1296. Note that because neither the DC500 Defense Center nor Series 2 devices support network-based malware protection, you cannot view network file trajectory for network-based malware and file events on these appliances.
  (potentially compromised)  (blacklisted)  (blacklisted, set to monitor)	Click the host profile icon, which appears in IP address columns, to display the host profile associated with that IP address in a pop-up window. For more information, see Using Host Profiles on page 1394. Hosts that have been tagged as potentially compromised by triggered indications of compromise (IOC) rules appear with the compromised host icon instead of the usual icon. For more information on IOC, see Understanding Indications of Compromise on page 1329. If the host profile icon is grayed out, you cannot view the host profile because that host cannot be in the network map (for example, `0.0.0.0`). If you are performing traffic filtering based on Security Intelligence data, host icons next to blacklisted and monitored IP addresses in the connection event view look slightly different. This helps you identify which host in a connection was blacklisted. Note that neither the DC500 Defense Center nor Series 2 devices support Security Intelligence data.
 (Low threat score)  (Medium threat score)  (High threat score)  (Very High threat score)	Click the threat score icon, which appears in threat score columns, to view the Dynamic Analysis Summary report for the highest threat score associated with a file. Note that because neither the DC500 Defense Center nor Series 2 devices support network-based malware protection, you cannot view the Dynamic Analysis Summary report on these appliances.

Table View and Drill-Down Page Features (Continued)

FEATURE	DESCRIPTION
	Click the user icon, which appears in user identity columns, to view user profile information. For more information, see Understanding User Details and Host History on page 1518. If the user icon is grayed out, you cannot view the user profile because that user cannot be in the database (FireAMP Connector user).
	Click the vulnerability icon, which appears in third-party vulnerability ID columns, to view vulnerability details for third-party vulnerabilities. For more information, see Viewing Vulnerability Details on page 1429.
Check boxes	Select the check boxes by two or more rows on a page to indicate which rows you want to affect, then click one of the buttons at the bottom of the page (for example, the **View** button). You can also select the check box at the top of the row to select all the rows on the page.
Country flags and codes	In some workflow pages, such as those for connection events, intrusion events, file events, and malware events, routable IP addresses include information about the associated country. When this *geolocation* information is available, the country's flag and ISO code appear in the appropriate column (such as Source Country). Hover your pointer over the flag to view the country name. When viewing individual (rather than aggregated) data points, you can click the flag icon to view further geolocation details. See Using Geolocation on page 1892 for more information. Note that the DC500 Defense Center does not support geolocation data.
Search Constraints	Lists the values, if present, constraining the data view. Click the expand arrow (▶) to display the active constraints and disabled columns list or the collapse arrow (▼) to hide the list from view. By default, this list is collapsed, which is useful when the list of constraints is long and takes up too much of the screen. To remove a single constraint, click it. To remove a compound constraint, click **Compound Constraints**. Click **Edit Search** or **Save Search** to open a search page pre-populated with the current single constraints. See Constraining Events on page 1905 for more information. **IMPORTANT!** Compound constraints are constraints created based on rows with multiple non-count values. You cannot perform a search or save a search on a compound constraint.

Table View and Drill-Down Page Features (Continued)

Feature	Description
Time Range	The date range located in the upper right corner of the page sets a time range for events to include in the workflow. See Setting Event Time Constraints on page 1896 for more information. Note that events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.
Workflow Page Links	Workflow page links appear in the upper left corner of predefined workflow table view and drill-down pages, above events and below the workflow name. Click a workflow page link to display that page using any active constraints.
Workflow Name	The name of the workflow appears at the top of the page. Beside it, when applicable, is the **(switch workflows)** link, which you can use to select other workflows of the same type.

Using Geolocation

License: FireSIGHT
Supported Devices: feature dependent
Supported Defense Centers: Any except DC500

While monitoring your network, the *geolocation* feature provides you with additional data about the geographical sources of routable IP addresses (country, continent, and so on). You can use this data to determine if, for example, connections are originating from or terminating in countries unconnected with your organization.

Geolocation information is available for intrusion events, connection events, file events, malware events, host profiles, and user profiles. Geolocation information is also available in the Context Explorer and the dashboard.

You can use geolocation data (source and destination country/continent) as conditions for access control rules, as well as create custom geolocation objects for this purpose. For more information, see Working with Geolocation Objects on page 230 and Adding Geolocation Conditions on page 537.

By installing geolocation database (GeoDB) updates, you can view a Geolocation Details page with granular information available for an IP address, such as postal code, coordinates, time zone, Autonomous System Number (ASN), Internet service provider (ISP), use type (home or business), organization, domain name, connection type, and proxy information. You can also pinpoint the detected location with any of four third-party map tools. Without a GeoDB update, only the flag icon and country name appear; you cannot view the Geolocation Details page. For information on installing and updating the GeoDB, see Updating the Geolocation Database on page 2174. You can view the current version of your GeoDB update by clicking **Help > About**.

Depending on availability, a number of fields may appear on the Geolocation Details page; fields with no information are not displayed. The Geolocation Detail Fields table contains information on these fields.

Geolocation Detail Fields

Field	Contents
Country	Country associated with the host's IP address, accompanied by the country's flag. The continent is listed in parentheses. Examples: `United States (North America)`, `Equatorial Guinea (Africa)`
Region	State, province, or other subregion of the country where the host is located. Examples: `VA`, `35`
City	City where the host is located. Examples: `Seattle`, `Fukuoka`
Postal Code	Postal code of the region where the host is located. Examples: `361000`, `90210`
Latitude/Longitude	Exact coordinates of the host's location. Examples: `40.0375, -76.1053`; `53.4050, -0.5484`
Maps	Links to external mapping sites (Google Maps, Yahoo Maps, Bing Maps, and OpenStreetMap). Click any link to view a contextual map of the host's approximate location.
Timezone	Time zone of the host's location, with Daylight Savings Time noted where applicable. Examples: `GMT+8:00`, `GMT-4:00 (In DST)`
ASN	Autonomous System Number (ASN) associated with the host's IP address, and any additional information about that ASN. Examples: `14618 (Amazon.com Inc.)`; `4837 (Cncgroup China169 Backbone)`
ISP	Internet service provider (ISP) associated with the host's IP address. Examples: `Atlantic Broadband`; `China Unicom Ip Network`
Home/Business	Whether the host's connection is used for `Home` or `Business` purposes.
Organization	Organization associated with the host's IP address. Examples: `Amazon.com`, `Bank of America`
Domain Name	Domain name associated with the host's IP address. Examples: `amazonaws.com`, `xmcnc.net`
Connection Type	Connection type associated with the host's IP address. Examples: `Broadband`, `DSL`
Proxy Type	The type of proxy used. Examples: `Anonymous`, `Corporate`

To view geolocation details:

ACCESS: Any

- In an event view, host profile, or other geolocation-supporting page, click the small country flag icon or ISO country code that appears by an individual data point. (You cannot view geolocation details for aggregate geolocation information, such as on the Connection Summary dashboard, despite the presence of flag icons.)

TIP! In event views, hover your pointer over the flag icon to view a tooltip with the country's name.

The Geolocation Details page appears in a new window.

Using Table View Pages

LICENSE: Any

Table view*s* include a column for each of the fields in the database if the column is enabled by default. Note that when you disable a column on a table view, the Sourcefire 3D System adds the Count column to the event view if disabling the column would create two or more identical rows. When you click on a value in a table view page, you constrain by that value. When you create a custom workflow, you add a table view to it by clicking **Add Table View**.

Table view pages provide some additional features not available on drill-down, host view, packet view, or vulnerability detail pages. The Additional Table View Page Features table provides more information on those features.

Additional Table View Page Features

FEATURE	DESCRIPTION
✖	Click this icon in the column heading that you want to hide. In the pop-up window that appears, click **Apply**. **TIP!** To hide or show other columns, select or clear the appropriate check boxes before you click **Apply**.
Disabled Columns list	When you remove columns from a page, or columns are disabled by default, the column names appear in the Disabled Columns list, which is located above the table and hidden by default. To add a disabled column back to the event view, click the Search Constraints expand arrow (▶) to expand the search constraints, then click the column name under Disabled Columns. See Sorting Drill-Down Workflow Pages on page 1910 for more information.

Using Drill-Down Pages

LICENSE: Any

Drill-down pages contain a subset of columns that are available in the database. Note that drill-down pages for predefined workflows always have a Count column. Drill-down pages allow you to narrow the scope of events you are viewing and to move forward in the workflow. If you click on a value in a drill-down page, for example, you constrain by that value and move to the next page in the workflow, focusing more closely on events that match your selected values. Clicking a value in a drill-down page does not disable the column where the value is, even if the page you advance to is a table view. When you create a custom workflow, you add a drill-down page to it by clicking **Add Page**.

For more information on using features on drill-down pages to constrain the set of events as you go through a workflow, see Using Common Table View or Drill-Down Page Functionality on page 1889.

Using the Host View, Packet View, or Vulnerability Detail Pages

LICENSE: Any

The final page in a discovery event, host, host attributes, indications of compromise, servers, client applications, or connection data workflow is the host view. The final page in a vulnerability workflow is the vulnerability detail page. An intrusion event workflow always ends with the packet view. On the final page of a

workflow, you can expand detail sections to view specific information about each object in the set you focused on over the course of the workflow. Although the web interface does not list the constraints on the final page of a workflow, previously set constraints are retained and applied to the set of data.

Setting Event Time Constraints

LICENSE: Any

Each event has a time stamp that indicates when the event occurred. You can constrain the information that appears in some workflows by setting the time window, sometimes called the time range.

Workflows based on events that can be constrained by time include a time range line at the top of the page, as shown in the following graphic.

By default, workflows on Sourcefire appliances use an expanding time window set to the past hour. For example, if you log in at 11:30 AM, you will see events that occurred between 10:30 AM and 11:30 AM. As time moves forward, the time window expands. At 12:30 PM, you will see events that occurred between 10:30 AM and 12:30 PM.

You can change this behavior by setting your own default time window, which governs three properties:

- time window type (static, expanding, or sliding)
- time window length
- the number of time windows (either multiple time windows or a single global time window)

For general information on the default time window, see Default Time Windows on page 2302.

Regardless of the default time window setting, you can manually change the time window during your event analysis by clicking the time range at the top of the page, which displays the Date/Time pop-up window. Depending on the number of time windows you configured and the type of appliance you are using, you can also use the Date/Time window to change the default time window for the type of event you are viewing.

Finally, you can pause the time window, which allows you to examine the data provided by the workflow without the time window changing and removing or adding events that you are not interested in. Note that to avoid displaying the same events on different workflow pages, the time window automatically pauses when you click a link at the bottom of the page to display another page of events; you can unpause the time window when you are ready.

For more information, see the following sections:

- Changing the Time Window on page 1897
- Changing the Default Time Window for Your Event Type on page 1902
- Pausing the Time Window on page 1904

Changing the Time Window

LICENSE: Any

Regardless of the default time window, you can manually change the time window during your event analysis.

IMPORTANT! Manual time window settings are valid for only the current session. When you log out and then log back in, time windows are reset to the default.

Depending on the number of time windows you configured, changing the time window for one workflow may affect other workflows on the appliance. For example, if you have a single, global time window, changing the time window for one workflow changes it for all other workflows on the appliance. On the other hand, if you are using multiple time windows, changing the audit log or health event workflow time windows has no effect on any other time window, while changing the time window for other kinds of events affects all events that can be constrained by time (with the exception of audit events and health events).

Note that because not all workflows can be constrained by time, time window settings have no effect on workflows based on hosts, host attributes, applications, application details, vulnerabilities, users, or white list violations.

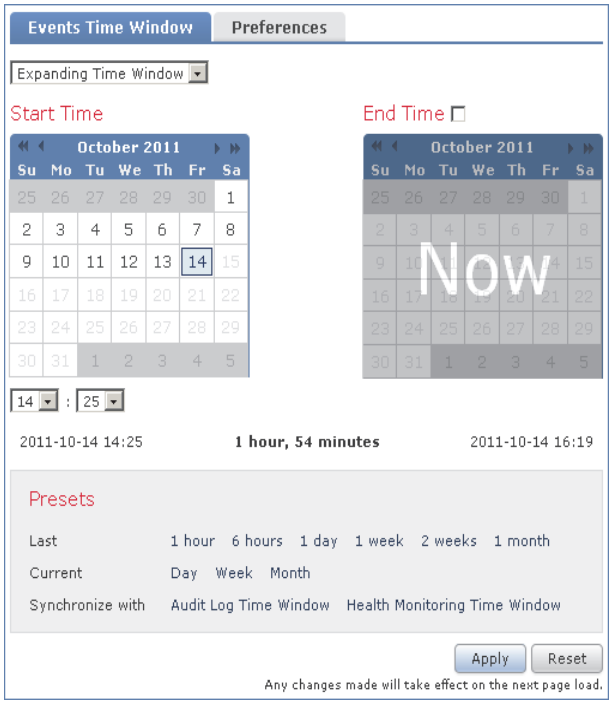
Use the Time Window tab on the Date/Time window to manually configure a time window. Depending on the number of time windows you configured in your default time window settings, the tab's title is one of the following:

- **Events Time Window**, if you configured multiple time windows and are setting the time window for a workflow other than the audit log or health events workflow
- **Health Monitoring Time Window**, if you configured multiple time windows and are setting the time window for the health events workflow
- **Audit Log Time Window**, if you configured multiple time windows and are setting the time window for the audit log
- **Global Time Window**, if you configured a single time window

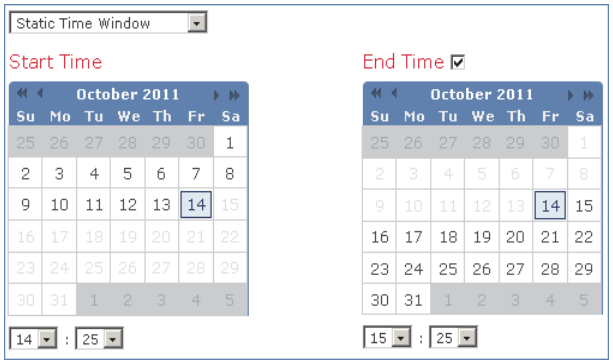
The first decision you must make when configuring a time window is the type of time window you want to use:

- A *static* time window displays all the events generated from a specific start time to a specific end time.
- An *expanding* time window displays all the events generated from a specific start time to the present; as time moves forward, the time window expands and new events are added to the event view.
- A *sliding* time window displays all the events generated from a specific start time (for example, one week ago) to the present; as time moves forward, the time window "slides" so that you see only the events for the range you configured (in this example, for the last week).

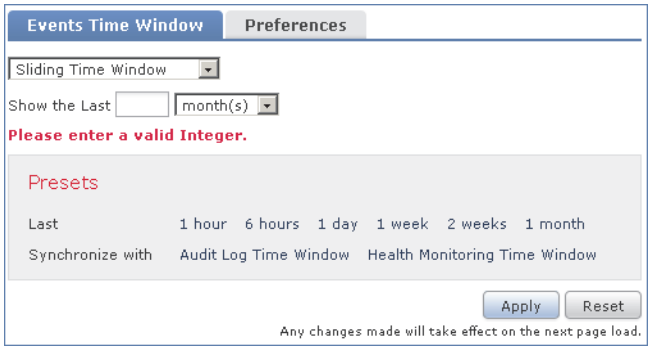
Depending on what type you select, the Date/Time window changes to give you different configuration options. The following graphic shows the Date/Time window, specifying that you want to use an expanding time window. With expanding time windows, the End Time calendar is grayed out and specifies that the end time is "Now."



If you use a static time window, you can set an end time.



If you choose to use a sliding time window, your options change further.



IMPORTANT! The Sourcefire 3D System uses a 24-hour clock based on the time you specified in your time zone preferences. See Setting Your Default Time Zone on page 2306 for information about configuring a time zone.

The Time Window Settings table explains the various settings you can configure on the Time Window tab.

Time Window Settings

SETTING	TIME WINDOW TYPE	DESCRIPTION
time window type drop-down list	n/a	Select the type of time window you want to use: static, expanding, or sliding. Note that events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.
Start Time calendar	static and expanding	Specify a start date and time for your time window. The maximum time range for all time windows is from midnight on January 1, 1970 (UTC) to 3:14:07 AM on January 19, 2038 (UTC). **TIP!** Instead of using the calendar, you can use the Presets options, described below.
End Time calendar	static	Specify an end date and time for your time window. The maximum time range for all time windows is from midnight on January 1, 1970 (UTC) to 3:14:07 AM on January 19, 2038 (UTC). Note that If you are using an expanding time window, the End Time calendar is grayed out and specifies that the end time is "Now." **TIP!** Instead of using the calendar, you can use the Presets options, described below.
Show the Last field and drop-down list	sliding	Configure the length of the sliding time window.

Time Window Settings (Continued)

Setting	Time Window Type	Description
Presets: Last	all	Click one of the time ranges in the list to change the time window, based on the local time of the appliance. For example, clicking **1 week** changes the time window to reflect the last week. Clicking a preset changes the calendars to reflect the preset you choose.
Presets: Current	static and expanding	Click one of the time ranges in the list to change the time window, based on the local time and date of the appliance. Clicking a preset changes the calendars to reflect the preset you choose. Note that: • the current day begins at midnight • the current week begins at midnight Sunday • the current month begins at midnight on the first of the month
Presets: Synchronize with	all (not available if you are using a global time window)	Click one of: • **Events Time Window** to synchronize the current time window with the events time window • **Health Monitoring Time Window** to synchronize the current time window with the health monitoring time window • **Audit Log Time Window** to synchronize the current time window with the audit log time window

To change the time window during event analysis:

Access: Admin/Maint/Any Security Analyst

1. On a workflow constrained by time, click the time range icon ( ).
   The Date/Time window appears.
2. On the **Time Window** tab, set the time window as described in the Time Window Settings table on page 1900.

   TIP! Click **Reset** to change the time window back to the default settings.

3. Click **Apply**.
   The window closes and the event view page displays events from the new time range.

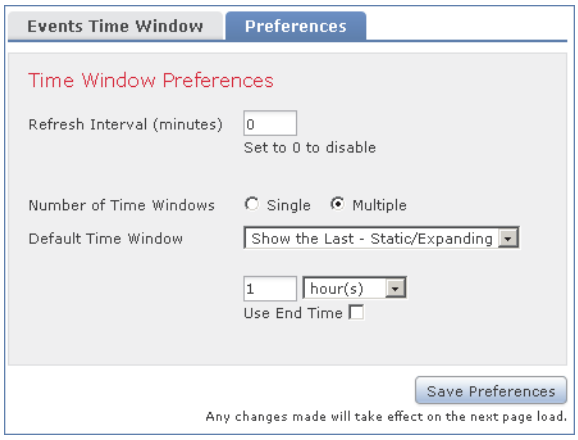
Changing the Default Time Window for Your Event Type

LICENSE: Any

During your event analysis, you can use the Preferences tab on the Date/Time window to change the default time window for the type of event you are viewing without having to use the event view settings (see Default Time Windows on page 2302).

Keep in mind that changing the default time window in this way changes the default time window for only the type of event you are viewing. For example, if you configured multiple time windows, changing the default time window on the Preferences tab changes the settings for either the events, health monitoring, or audit log window, in other words, whichever time window is indicated by the first tab. If you configured a single time window, changing the default time window on the Preferences tab changes the default time window for all types of events.

The following graphic shows the Defense Center version of the Preferences tab, on an appliance that has multiple time windows configured.



The Time Window Preferences table explains the various settings you can configure on the Preferences tab.

Time Window Preferences

PREFERENCE	DESCRIPTION
Refresh Interval	Sets the refresh interval for event views, in minutes. Entering zero disables the refresh option.
Number of Time Windows	Specify how many time windows you want to use: • Select **Multiple** to configure separate default time windows for the audit log, for health events, and for workflows based on events that can be constrained by time. • Select **Single** to use a global time window that applies to all events,

Time Window Preferences (Continued)

PREFERENCE	DESCRIPTION
Default Time Window: Show the Last - Sliding	This setting allows you to configure a sliding default time window of the length you specify. The appliance displays all the events generated from a specific start time (for example, 1 hour ago) to the present. As you change event views, the time window "slides" so that you always see events from the last hour.
Default Time Window: Show the Last - Static/ Expanding	This setting allows you to configure either a static or expanding default time window of the length you specify. For **static** time windows (enable the **Use End Time** check box), the appliance displays all the events generated from a specific start time (for example, 1 hour ago), to the time when you first viewed the events. As you change event views, the time window stays fixed so that you see only the events that occurred during the static time window. For **expanding** time windows (disable the **Use End Time** check box), the appliance displays all the events generated from a specific start time (for example, 1 hour ago), to the present. As you change event views, the time window expands to the present time.
Default Time Window: Current Day - Static/ Expanding	This setting allows you to configure either a static or expanding default time window for the current day. The current day begins at midnight, based on the time zone setting for your current session. For **static** time windows (enable the **Use End Time** check box), the appliance displays all the events generated from midnight to the time when you first viewed the events. As you change event views, the time window stays fixed so that you see only the events that occurred during the static time window. For **expanding** time windows (disable the **Use End Time** check box), the appliance displays all the events generated from midnight to the present. As you change event views, the time window expands to the present time. Note that if your analysis continues for over 24 hours before you log out, this time window can be more than 24 hours.
Default Time Window: Current Week - Static/ Expanding	This setting allows you to configure either a static or expanding default time window for the current week. The current week begins at midnight on the previous Sunday, based on the time zone setting for your current session. For **static** time windows (enable the **Use End Time** check box), the appliance displays all the events generated from midnight to the time when you first viewed the events. As you change event views, the time window stays fixed so that you see only the events that occurred during the static time window. For **expanding** time windows (disable the **Use End Time** check box), the appliance displays all the events generated from midnight Sunday to the present. As you change event views, the time window expands to the present time. Note that if your analysis continues for over 1 week before you log out, this time window can be more than 1 week.

To change time window preferences during event analysis:

Access: Admin/Maint/Any Security Analyst

1. On a workflow constrained by time, click the time range icon ( ).

   The Date/Time window appears.

2. Select the **Preferences** tab and change your preferences, as described in the Time Window Preferences table on page 1902.

3. Click **Save Preferences**.

   Your preferences are saved.

4. You have two options:

   - To apply your new default time window settings to the event view you are using, click **Apply** to close the Date/Time window and refresh the event view.
   - To continue with your analysis without applying the default time window settings, close the Date/Time window without clicking **Apply**.

Pausing the Time Window

License: Any

You can pause the time window, which allows you to examine a snapshot of the data provided by the workflow. This is useful because when an unpaused workflow updates, it may remove events that you want to examine or add events that you are not interested in.

Note that you cannot pause a static time window. In addition, pausing an event time window has no effect on dashboards, nor does pausing a dashboard have any effect on pausing an event time window.

When you are finished with your analysis, you can unpause the time window. Unpausing the time window updates it according to your preferences, and also updates the event view to reflect the unpaused time window.

If the database contains more events than can be displayed on a single workflow page, you can click the links at the bottom of the page to display more events (see Navigating to Other Pages in the Workflow on page 1911). When you do this, the time window automatically pauses so that you do not see the same events twice. You can unpause the time window when you are ready.

To pause the time window:

Access: Admin/Maint/Any Security Analyst

▶ On the time range control, click the pause icon ( ).

The time window is paused until you unpause it.

To unpause the time window:

ACCESS: Admin/Maint/Any Security Analyst

- On the time range control, click the play icon (▶).

  The time window is unpaused and updates according to your preferences. The event view updates to reflect the current time window.

Constraining Events

LICENSE: Any

The information that you see on a workflow page is determined by the constraints that you impose. For example, when you initially open an event workflow, the information is constrained to events that were generated in the previous hour.

To advance to the next page in the workflow and constrain the data you are viewing by specific values, select the rows with those values on the page and click **View**. To advance to the next page in the workflow retaining the current constraints and carrying forward all events, select **View All.**

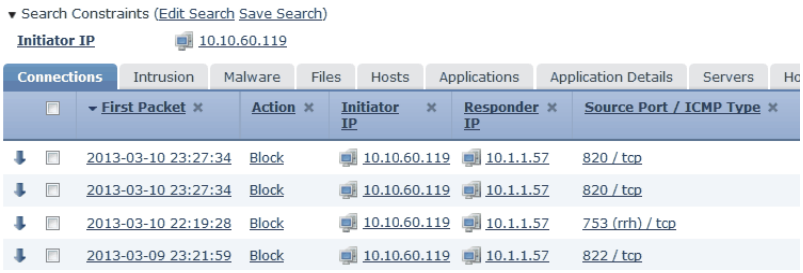
IMPORTANT! If you select a row with multiple non-count values and click **View**, you create a compound constraint. For more information on compound constraints, see Using Compound Constraints on page 1908.

There is a third method for constraining data in a workflow. To constrain the page to the rows with values that you selected and also add the selected value to the list of constraints at the top of the page, click a value within a row on the page.

For example, if you click **10.10.60.119** in the Initiator IP column on a page with the following events:

First Packet	Action	Initiator IP	Responder IP	Source Port / ICMP Type
2013-03-10 23:27:34	Block	10.10.60.119	10.1.1.57	820 / tcp
2013-03-10 23:27:34	Block	10.10.60.119	10.1.1.57	820 / tcp
2013-03-10 22:19:28	Block	10.10.60.119	10.1.1.57	753 (rrh) / tcp
2013-03-10 16:13:39	Block	10.10.32.124	10.10.60.165	856 / tcp

...then the constrained page includes only the events with that IP address:



TIP! The procedure for constraining connection events based on Monitor rule criteria is slightly different and you may need to take some extra steps. Additionally, you cannot constrain connection events by associated file or intrusion information. For more information, see Working with Connection and Security Intelligence Data Tables on page 617.

You can also use searches to constrain the information in a workflow. The search criteria you enter on the search page are listed as the constraints at the top of the page, with the resulting events constrained accordingly. On the Defense Center, the current constraints are also applied when navigating to other workflows, unless they are compound constraints (see Navigating Between Workflows on page 1911).

When searching, you must pay careful attention to whether your search constraints apply to the table you are searching. For example, client data is not available in connection summaries. If you search for connection events based on the detected client in the connection and then view the results in a connection summary event view, the Defense Center displays connection data as if you had not constrained it at all. Invalid constraints are labeled as not applicable (N/A) and are marked with a strikethrough, as shown in the following graphic.

The Search Constraint Functions table describes each of the actions you can perform when applying a constraint.

Search Constraint Functions

To...	Click...
constrain the view to events that match a single value	the value in the table. For example, if you are viewing a list of logged connections and want to constrain the list to only those you allowed using access control, click **Allow** in the **Action** column. As another example, if you are viewing intrusion events and want to constrain the list to only events where the destination port is 80, click **80 (http)/tcp** in the **DST Port/ICMP Code** column.
constrain the view to events that match multiple values	the check box for events with those values and click **View**. Note that a compound constraint is added if the row contains multiple non-count values. For more information on compound constraints, see Using Compound Constraints on page 1908.
remove a constraint	the name of the constraint in the Search Constraints box.
edit constraints using the search page	**Edit Search** in the Search Constraints box. Use this feature when you want to constrain against multiple values in a single column. For example, if you want to view the events related to two IP addresses, click **Edit Search**, then modify the appropriate IP address field on the Search page to include both addresses, and then click **Search**.
save constraints as a saved search	**Save Search** in the Search Constraints box and give the query a name. Note that you cannot save queries containing compound constraints. For more information on compound constraints, see Using Compound Constraints on page 1908.

Search Constraint Functions (Continued)

To...	Click...
use the same constraints with another event view	**Jump to** and select the event view. See Navigating Between Workflows on page 1911 for more information. Note that you do not retain compound constraints when you switch to another workflow. For more information on compound constraints, see Using Compound Constraints on page 1908.
toggle the display of constraints	the expand arrow (▶). This is useful when the list of constraints is large and takes up most of the screen.

Using Compound Constraints

License: Any

Compound constraints are based on all non-count values for a specific event. When you select a row with multiple non-count values, you set a compound constraint that only retrieves events matching all the non-count values in that row on that page. For example, if you select a row that has a source IP address of `10.10.31.17` and a destination IP address of `10.10.31.15` and a row that has a source IP address of `172.10.10.17` and a destination IP address of `172.10.10.15`, you retrieve all of the following:

- Events that have a source IP address of 10.10.31.17 AND a destination IP address of 10.10.31.15

  OR

- Events that have a source IP address of 172.10.31.17 AND a destination IP address of 172.10.31.15

When you combine compound constraints with simple constraints, the simple constraints are distributed across each set of compound constraints. If, for example, you added a simple constraint for a protocol value of `tcp` to the compound constraints listed above, you retrieve all of the following:

- Events that have a source IP address of 10.10.31.17 AND a destination IP address of 10.10.31.15 AND a protocol of tcp

  OR

- Events that have a source IP address of 172.10.31.17 AND a destination IP address of 172.10.31.15 AND a protocol of tcp

You cannot perform a search or save a search on a compound constraint. You also cannot retain compound constraints when you use the event view links or click **(switch workflow)** to switch to another workflow. If you bookmark an event view with compound constraints applied, the constraints are not saved with the bookmark.

To clear all compound constraints, click **Compound Constraints**.

Sorting Table View Pages and Changing Their Layout

LICENSE: Any

When viewing data in a workflow, you can sort the data based on any available column and remove and restore columns to view. You can sort data in ascending or descending order by column.

TIP! If you create a custom workflow, you can fully customize the arrangement of columns on the pages and predefine the page sort order. See Creating Custom Workflows on page 1916 for more information.

Sorting and Layout Functions

TO...	CLICK...
sort a column	the column title. Click the column title again to reverse the sort order. **TIP!** The direction icon (▼) indicates which column the data is sorted by, and whether the sort is ascending (upward-pointing icon) or descending (downward-pointing icon).
remove a column from a table view	the close icon (✖) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**. When you disable a column, it is disabled for the duration of your session (unless you add it back later). Note that when you disable the first column, the Count column is added. You cannot disable the Count column. **TIP!** To hide or show other columns, select or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, click the expand arrow (▶) to expand the search constraints, then click the column name under Disabled Columns.
add a disabled column back to the view	the column name under Disabled Columns. When you enable a column that is disabled by default, it is enabled for the duration of your session (unless you disable it later). Note that the Count column is removed if enabling results in no identical rows.

Sorting Drill-Down Workflow Pages

LICENSE: Any

When viewing data in a workflow or event view, you can sort the data based on any available column and remove and restore columns to view. You can sort data in ascending or descending order by column. The direction icon (▼) indicates which column the data is sorted by, and whether the sort is ascending (upward-pointing icon) or descending (downward-pointing icon).

TIP! If you create a custom workflow, you can fully customize the arrangement of columns on the pages and predefine the page sort order. See Creating Custom Workflows on page 1916 for more information.

To sort a column:

ACCESS: Admin/Maint/Any Security Analyst

▶ Click the column title.

To reverse the sort order:

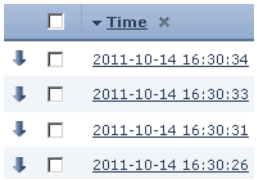
ACCESS: Admin/Maint/Any Security Analyst

▶ Click the column title again.

Selecting Rows on a Workflow Page

LICENSE: Any

There are several different ways to select and then act on the rows on workflow pages:



- To select all rows on the page, select the check box at the top of the page.

  You can then click any of the buttons at the bottom of the page (**View**, **Delete**, and so on) to perform that action on all of the events on that page.

- To select a single row, select the check box next to the individual row.

  You can then click any of the buttons at the bottom of the page to perform that action on only the events associated with that row.
- To select a single row and view its associated events on the next page of the workflow, click the arrow icon ( ).

IMPORTANT! You cannot select rows from multiple pages at once.

Navigating to Other Pages in the Workflow

LICENSE: Any

If the database contains more events than can be displayed on a single workflow page, you can click the links at the bottom of the page to display more events.

When you click one of these links, the time window automatically pauses so that you do not see the same events twice; you can unpause the time window when you are ready. For more information, see Setting Event Time Constraints on page 1896.

The Navigating Pages table describes how to use the navigation links.

Navigating Pages

TO...	CLICK...
view a different page	the page number, enter the page you wish to view, then press Enter
view the next page	>
view the previous page	<
jump to the last page	>|
jump to the first page	|<

Navigating Between Workflows

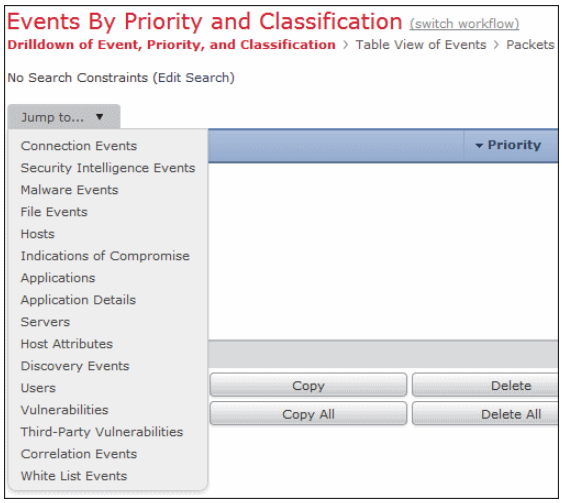
LICENSE: Any

You can navigate to other workflows using the links in the **Jump to...** drop-down list on a workflow page. Select the drop-down list to view and select additional workflows.

When you select a new workflow, properties shared by the rows you select and the constraints you set are used in the new workflow, if they are applicable. If configured constraints or event properties do not map to fields in the new workflow, they are dropped. In addition, compound constraints are not retained when you switch from one workflow to another. In addition, constraints from the captured files workflow only transfer to file and malware event workflows.

IMPORTANT! When you view event counts over a time range, the total number of events may not reflect the number of events for which more detailed data is available. This occurs because the system sometimes prunes older event details to manage disk space usage. To minimize the occurrence of event detail pruning, you can fine-tune event logging to log only those events most important to your deployment. For more information, see Logging Connection, File, and Malware Information on page 560.

Note that unless you have either paused the time window or have configured a static time window, the time window changes when you change workflows. For more information, see Setting Event Time Constraints on page 1896.



The Jump to drop-down list provides quick access to workflows for the following tables:

- connection events
- security intelligence events
- intrusion events
- malware events
- file events
- hosts
- indications of compromise

- applications
- application details
- servers
- host attributes
- discovery events
- users
- vulnerabilities
- third-party vulnerabilities
- correlation events
- white list events

This feature enhances your ability to investigate suspicious activity. For example, if you are viewing connection data and notice that an internal host is transmitting an abnormally large amount of data to an external site, you can select the responder IP address and the port as constraints and then jump to the **Applications** workflow. The applications workflow will use the responder IP address and port as IP Address and Port constraints and display additional information about the application, such as what kind of application it is. You can also click **Hosts** at the top of the page to view the host profile for the remote host.

After finding more information about the application, you can select **Correlation Events** to return to the connection data workflow, remove the Responder IP from the constraints, add the Initiator IP to constraints, and select **Application Details** to see what client the user on the initiating host used when transferring data to the remote host. Note that the Port constraint is not transferred to the Application Details page. While keeping the local host as a constraint, you can also use other navigation buttons to find additional information:

- To discover if any policies have been violated by the local host, keep the IP address as a constraint and select **Correlation Events** from the **Jump to** drop-down list.
- To find out if an intrusion rule triggered against the host, indicating a compromise, select **Intrusion Events** from the **Jump to** drop-down list.
- To view the host profile for the local host and determine if the host is susceptible to any vulnerabilities that may have been exploited, select **Hosts** from the **Jump to** drop-down list.

Using Bookmarks

LICENSE: Any

Create a bookmark if you want to return quickly to a specific location and time in an event analysis. Bookmarks retain information about:

- the workflow you are using
- the part of the workflow you are viewing

- the page number within the workflow
- any search constraints
- any disabled columns
- the time range you are using

The bookmarks you create are available to all user accounts with bookmark access. This means that if you uncover a set of events that require more in-depth analysis, you can easily create a bookmark and turn over the investigation to another user with the appropriate privileges.

IMPORTANT! If the events that appear in a bookmark are deleted (either directly by a user or by automatic database cleanup), the bookmark no longer displays the original set of events.

See these sections for more information about using bookmarks:

- Creating Bookmarks on page 1914 describes how to create a new bookmark.
- Viewing Bookmarks on page 1914 describes how to view and use existing bookmarks.
- Deleting Bookmarks on page 1915 describes how to delete bookmarks.

Creating Bookmarks

LICENSE: Any

Use the following procedure to create a new bookmark.

To create a bookmark:

ACCESS: Admin/Maint/Any Security Analyst

1. During an event analysis, with the events of interest displayed, click **Bookmark This Page**.

   The Create a Bookmark page appears.

2. In the **Bookmark Name** field, type a name (up to 80 alphanumeric characters and spaces) for the bookmark, then click **Save Bookmark**.

   The bookmark is saved and the event page you bookmarked appears again.

Viewing Bookmarks

LICENSE: Any

Use the following procedure to view and use existing bookmarks.

To view a bookmark:

ACCESS: Admin/Maint/Any Security Analyst

1. From any event view, click **View Bookmarks**.

   The Bookmarks page appears. The Defense Center version of the page is displayed below.

2. Next to the bookmark you want to use, click **View**.

   The page you bookmarked appears.

IMPORTANT! If the events that originally appeared in a bookmark are deleted (either directly by a user or by automatic database cleanup), the bookmark no longer displays the original set of events.

Deleting Bookmarks

LICENSE: Any

Use the following procedure to delete bookmarks. Note that deleting a bookmark does not affect the events retrieved by that bookmark.

To delete a bookmark:

ACCESS: Admin/Maint/Any Security Analyst

1. From any event view, click **View Bookmarks**.

   The Bookmarks page appears.

2. Click **Delete** next to the bookmark you want to remove.

   The bookmark is deleted.

Using Custom Workflows

LICENSE: Any

If the predefined and Sourcefire-provided custom workflows do not meet your needs, you can create custom workflows.

For more information, see:

- Creating Custom Workflows on page 1916 for a procedure to create custom workflows
- Creating Custom Connection Data Workflows on page 1918 for a procedure to create a custom workflow based on connection data

- Viewing Custom Workflows on page 1921 for procedures for viewing custom workflows based on event and custom tables
- Editing Custom Workflows on page 1922 for a procedure for editing custom workflows
- Deleting Custom Workflows on page 1922 for a procedure for deleting custom workflows

Creating Custom Workflows

LICENSE: Any

If the predefined and Sourcefire-provided custom workflows do not meet your needs, you can create custom workflows.

TIP! Instead of creating a new custom workflow, you can export a custom workflow from another appliance and then import it onto your appliance. You can then edit the imported workflow to suit your needs. For more information, see Importing and Exporting Configurations on page 2308.

When you create a custom workflow, you:

- select a table to be the source of the workflow
- provide a workflow name
- add drill-down pages and table view pages to the workflow

For each drill-down page in the workflow, you can:

- provide a name that appears at the top of the page in the web interface
- include up to five columns per page
- specify a default sort order, ascending or descending

You can add table view pages in any position in the sequence of workflow pages. They do not have any editable properties, such as a page name, sort order, or user-definable column positions.

The final page of a custom workflow depends on the table on which you base the workflow, as described in the Custom Workflow Final Pages table. These final pages are added by default when you create the workflow.

Custom Workflow Final Pages

WORKFLOWS BASED ON...	HAVE THIS FINAL PAGE...
discovery events	hosts
vulnerabilities	vulnerability detail
third-party vulnerabilities	hosts

Custom Workflow Final Pages (Continued)

WORKFLOWS BASED ON...	HAVE THIS FINAL PAGE...
users	users
indications of compromise	hosts
intrusion events	packets

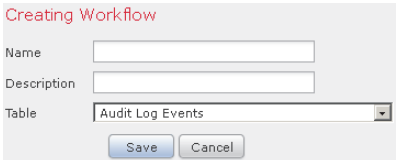
The appliance does not add a final page to custom workflows based on other kinds of events (for example, audit log or malware events).

IMPORTANT! The procedure for creating a custom workflow based on connection data is slightly different. For more information, see the next section, Creating Custom Connection Data Workflows.

To create a custom workflow:

ACCESS: Admin/Any Security Analyst

1. Select **Analysis > Custom > Custom Workflows**.
   The Custom Workflows page appears.
2. Click **Create Custom Workflow**.
   The Create Custom Workflow page appears.



3. Type a name for the workflow in the **Name** field.
   You can use up to 60 alphanumeric characters and spaces in the name.
4. Optionally, type a description for the workflow in the **Description** field.
   You can use up to 80 alphanumeric characters and spaces.
5. Select the table you want to include from the **Table** drop-down list.

6. Optionally, click **Add Page** to add one or more drill-down pages to the workflow.

   A drill-down page section appears.

   Begin by typing a name for the page in the **Page Name** field, using up to 80 alphanumeric characters, but no spaces.

   Under Column 1, select a sort priority and a table column. This column will appear in the leftmost column of the page. For example, to create a page showing the destination ports that are targeted, and to sort the page by count, select **2** from the **Sort Priority** drop-down list and **DST Port/ICMP Code** from the **Field** drop-down list.

   Continue selecting fields to include and setting their sort priority until all the fields to appear on the page have been specified. You can specify up to five fields per page.

   IMPORTANT! If you selected **Vulnerabilities** as the Table Type in step 5, then add **IP Address** as a table column, the IP Address column does not appear when you are viewing vulnerabilities using your custom workflow, unless you use the search feature to constrain the workflow to view a specific IP address or block of addresses. For more information on searching for vulnerabilities, see Searching for Sourcefire Vulnerabilities on page 1508.

7. Optionally, click **Add Table View** to add a table view page to the workflow.

   IMPORTANT! You must add at least one drill-down page or a table view of events to a custom workflow.

8. Click **Save**.

   The new workflow is saved and added to the list of custom workflows.

Creating Custom Connection Data Workflows

License: FireSIGHT

Custom workflows based on connection data are like other custom workflows, except you can include connection data graph pages as well as drill-down pages and table view pages. You can include as many of each type of page in the workflow as you want, in any order. Each connection data graph page contains a single graph, which can be a line graph, bar graph, or pie chart. On line and bar

graphs, you may include more than one dataset. For more information on connection data, including connection summaries, connection graphs, and datasets, see Understanding Connection Data on page 585.

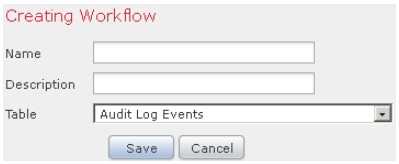
TIP! Instead of creating a new custom workflow, you can export a custom workflow from another appliance and then import it onto your appliance. You can then edit the imported workflow to suit your needs. For more information, see Importing and Exporting Configurations on page 2308.

To create a custom workflow based on connection data:

Access: Admin

1. Select **Analysis > Custom > Custom Workflow**.
2. Click **Create Custom Workflow**.

   The Create Custom Workflow page appears.



3. Type a name for the workflow in the **Name** field.

   You can use up to 60 alphanumeric characters and spaces.
4. Optionally, type a description for the workflow in the **Description** field.

   You can use up to 80 alphanumeric characters and spaces.
5. From the **Table** drop-down list, select **Connection Events**.

6. Optionally, add one or more drill-down pages to the workflow:
   - To add a drill-down page that contains data on individual connections, click **Add Page**.
   - To add a drill-down page that contains connection summary data, click **Add Summary Page**.

   In either case, a drill-down page section appears.

   Begin by typing a name for the page in the **Page Name** field using up to 80 alphanumeric characters, but no spaces.

   Under **Column 1**, select a sort priority and a table column. This column will appear in the leftmost column of the page.

   Continue selecting fields to include and setting their sort priority until all the fields to appear on the page have been specified. You can specify up to five fields per page.

   For example, to create a page showing the amount of traffic transmitted over your monitored network and to sort the page by the responders that transmitted the most traffic, select **1** from the **Sort Priority** drop-down list and **Responder Bytes** from the **Field** drop-down list.

7. Optionally, click **Add Graph** to add one or more graph pages to the workflow.

   A graph section appears.

   Begin by typing a name for the page in the **Graph Name** field using up to 80 alphanumeric characters, but no spaces.

   Then, select the type of graph you want to include on the page: line graph, bar graph, or pie chart.

   Then, specify what kind of data you want to graph by selecting the x- and y-axes of the graph. On a pie chart, the x-axis represents the independent variable and the y-axis represents the dependent variable.

   Finally, select the datasets you want to include on the graph. Note that pie charts can only include one data set.

8. Optionally, add a table view of connection data by clicking **Add Table View**.

9. Click **Save**.

   The new workflow is saved and added to the list of custom workflows.

Viewing Custom Workflows

LICENSE: Any

The method you use to view a workflow depends on whether the workflow is based on one of the predefined event tables or on a custom table.

If your custom workflow is based on a predefined event table, access it in the same way that you would access a workflow that ships with the appliance. For example, to access a custom workflow based on the Hosts table, select **Analysis Hosts**. If, on the other hand, your custom workflow is based on a custom table, you must access it from the Custom Tables page.

TIP! You can set a custom workflow as the default workflow for any event type; see Configuring Event View Settings on page 2300.

For more information, see:

- Viewing Custom Workflows for Predefined Tables on page 1921
- Viewing Custom Workflows for Custom Tables on page 1921

Viewing Custom Workflows for Predefined Tables

LICENSE: Any

Use the following procedure to view a custom workflow that is **not** based on a custom table. Keep in mind that workflow access depends on your platform and user role, as described in Selecting Workflows on page 1885.

To view a custom workflow based on a predefined table:

ACCESS: Admin/Any Security Analyst

▶ Select the appropriate menu path and option for the table on which you based your custom workflow, as described in the Features Using Workflows table.

The first page of the default workflow for that table appears. To use a different workflow, including a custom workflow, click **(switch workflow)** beside the current workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. If no events appear and the workflow can be constrained by time, you may need to adjust the time range; see Setting Event Time Constraints on page 1896.

Viewing Custom Workflows for Custom Tables

LICENSE: FireSIGHT

Use the following procedure to view a custom workflow that is based on a custom table.

To view a custom workflow based on a custom table:

ACCESS: Admin/Any Security Analyst

1. Select **Analysis > Custom > Custom Tables**.

   The Custom Tables page appears, listing the available custom tables.

2. Click the view icon next to the custom table you want to view, or click the name of the custom table.

   The first page of the default workflow for that table appears. To use a different workflow, including a custom workflow, click **(switch workflow)** beside the current workflow title. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. If no events appear and the workflow can be constrained by time, you may need to adjust the time range; see Setting Event Time Constraints on page 1896.

Editing Custom Workflows

LICENSE: Any

If your event evaluation process changes, you can edit custom workflows to meet your new needs. Note that you cannot edit any of the predefined workflows.

To edit a custom workflow:

ACCESS: Admin/Any Security Analyst

1. Select **Analysis > Custom > Custom Workflows**.

   The Custom Workflows page appears, listing the existing custom workflows.

2. Click the edit icon () next to the name of the workflow that you want to edit.

   The Edit Workflow page appears.

3. Make any changes that you want to the workflow and click **Save**.

   The changes you made to the workflow are saved.

Deleting Custom Workflows

LICENSE: Any

The following procedure explains how to delete a custom workflow that you no longer need.

To delete a custom workflow:

ACCESS: Admin/Any Security Analyst

1. Select **Analysis > Custom > Custom Workflows**.

   The Custom Workflows page appears, listing the available custom workflows.

2. Click the delete icon () next to the name of the workflow that you want to delete.

   The workflow is deleted.

CHAPTER 46
MANAGING USERS

If your user account has Administrator access, you can manage the user accounts that can access the web interface on your Defense Center or managed device. On the Defense Center, you can also set up user authentication via an external authentication server, rather than through the internal database.

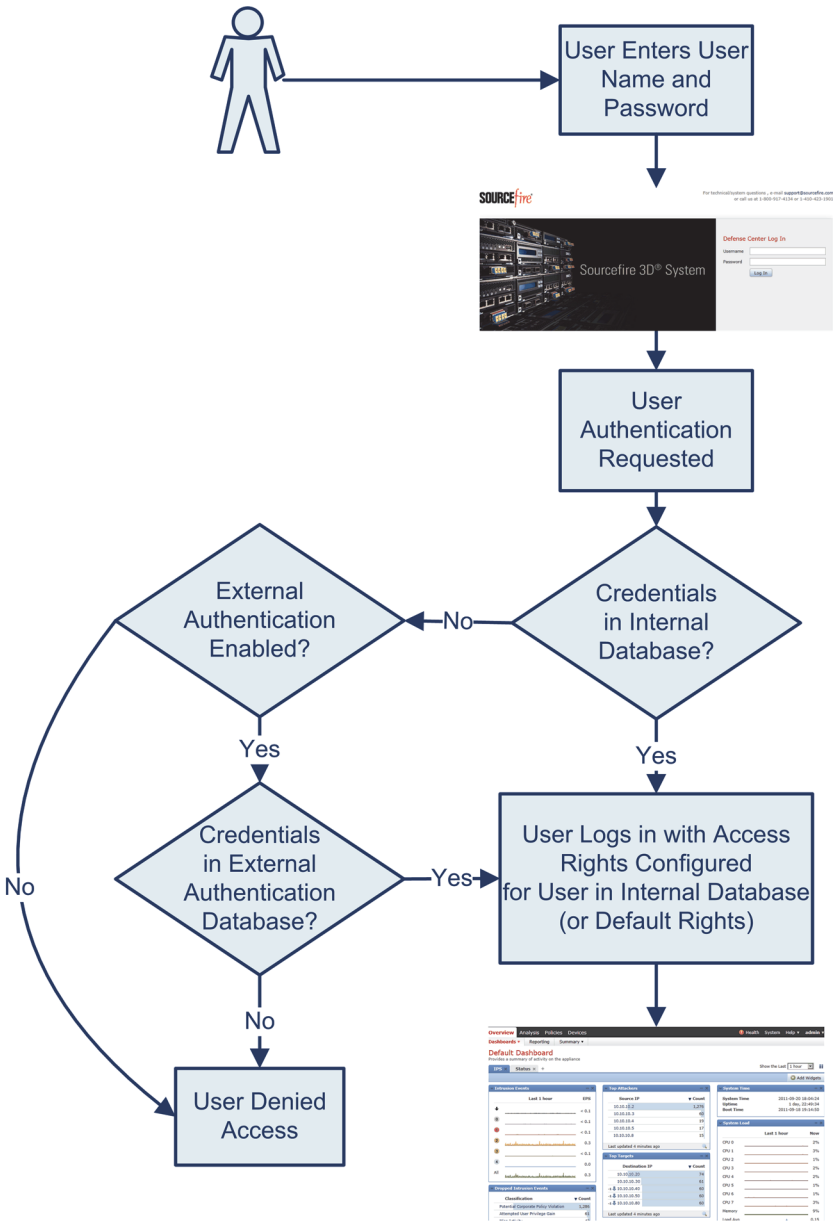
For more information, see the following sections:

Understanding Sourcefire User Authentication

LICENSE: Any

When a user logs into the web interface, the appliance looks for a match for the user name and password in the local list of users. This process is called *authentication*. There are two kinds of authentication: internal and external. If the user's account uses *internal authentication*, the authentication process checks the local database for this list. If the account uses *external authentication*, the process checks the local database to see if the user exists there and, if the user is not found locally, it queries an external server, such as a Lightweight Directory

Access Protocol (LDAP) directory server or a Remote Authentication Dial In User Service (RADIUS) authentication server, for a list of users.



For users with either internal or external authentication, you can control user permissions. Users with external authentication receive the permissions either for the group or access list they belong to, or based on the default user access role you set in the server authentication object or in a system policy on the managing Defense Center, unless you change the user permissions manually.

For more information, see the following sections:

- Understanding Internal Authentication on page 1925
- Understanding External Authentication on page 1925
- Understanding User Privileges on page 1926

Understanding Internal Authentication

LICENSE: Any

By default, the Sourcefire 3D System uses internal authentication to check user credentials when a user logs in. Internal authentication occurs when the user name and password are verified against records in the internal Sourcefire 3D System database. If you do not enable external authentication when you create a user, the user credentials are managed in the internal database.

Because you manually create each internally authenticated user, you set the access settings when you create the user and you do not need to set default settings.

IMPORTANT! Note that an internally authenticated user is converted to external authentication if you enable external authentication, the same user name exists for the user on the external server, and the user logs in using the password stored for that user on the external server. After an internally authenticated user converts to an externally authenticated user, you cannot revert to internal authentication for that user.

Understanding External Authentication

LICENSE: Any

External authentication occurs when the Defense Center or managed device retrieves user credentials from an external repository, such as an LDAP directory server or RADIUS authentication server. LDAP authentication and RADIUS authentication are types of external authentication. Note that you can only use one form of external authentication for an appliance.

If you want to use external authentication, you must configure an *authentication object* for each external authentication server where you want to request user information. The authentication object contains your settings for connecting to and retrieving user data from that server. You can then enable that object in a system policy on the managing Defense Center and apply the policy to an appliance to enable authentication. When any externally authenticated user logs in, the web interface checks each authentication server to see if that user is listed, in the order the servers are listed in the system policy.

When you create a user, you can specify whether that user is internally or externally authenticated.

IMPORTANT! Before enabling external authentication on Series 3 managed devices, remove any internally-authenticated shell users that have the same user name as externally-authenticated users included in your shell access filter.

You can push a system policy to a managed device to enable external authentication on that device, but you cannot control the authentication object from the device's web interface. The only configuration of external authentication on the device occurs when you select the type of authentication for a new user. If you want to disable external authentication on a managed device, disable it in the system policy on the managing Defense Center and reapply the policy to the device. If you apply a local system policy (created on the managed device) to the device itself, external authentication is also disabled.

TIP! You can use the Import/Export feature to export system policies. When you export a policy with external authentication enabled, the authentication objects are exported with the policy. You can then import the policy and object on another Defense Center. Do **not** import policies with authentication objects onto managed devices.

For more information on specific types of external authentication, see the following sections:

- Understanding LDAP Authentication on page 1928
- Understanding RADIUS Authentication on page 1959

Understanding User Privileges

LICENSE: Any

The Sourcefire 3D System lets you allocate user privileges based on the user's role. For example, an analyst typically needs access to event data to analyze the security of monitored networks, but might never require access to administrative functions for the Sourcefire 3D System itself. You can grant analysts predefined roles such as Security Analyst and Discovery Admin and reserve the Administrator role for the network administrator managing the Sourcefire 3D System. You can also create custom user roles with access privileges tailored to your organization's needs.

In the system policy on the Defense Center, you set a default access role for all users who are externally authenticated. After an externally authenticated user logs in for the first time, you can add or remove access rights for that user on the User Management page. If you do not modify the user's rights, the user has only the rights granted by default. Because you create internally authenticated users manually, you set the access rights when you create them.

If you configured management of access rights through LDAP groups, the access rights for users are based on their membership in LDAP groups. They receive the default access rights for the group that they belong to that has the highest level of access. If they do not belong to any groups and you have configured group access, they receive the default user access rights configured in the authentication object for the LDAP server. If you configure group access, those settings override the default access setting in the system policy.

Similarly, if you assign a user to specific user role lists in a RADIUS authentication object, the user receives all assigned roles, unless one or more of those roles are mutually incompatible. If a user is on the lists for two mutually incompatible roles, the user receives the role that has the highest level of access. If the user does not belong to any lists and you have configured a default access role in the authentication object, the user receives that role. If you configure default access in the authentication object, those settings override the default access setting in the system policy.

The Sourcefire 3D System supports the following predefined user roles, listed in order of precedence, depending on the features you have licensed:

- *Access Admins* can view and modify access control and file policies, but cannot apply their policy changes.
- *Administrators* can set up the appliance's network configuration, manage user accounts and FireAMP cloud connections, and configure system policies and system settings. Users with the Administrator role have all rights and privileges of all other roles (with the exception of lesser, restricted versions of those privileges).
- *Discovery Admins* can review, modify and delete network discovery policies, but cannot apply their policy changes.
- *External Database* users can query the Sourcefire 3D System database using an external application that supports JDBC SSL connections. On the web interface, they can access the online help and user preferences.
- *Intrusion Admins* can review, modify, and delete intrusion policies and intrusion rules.
- *Maintenance Users* can access monitoring functions (including health monitoring, host statistics, performance data, and system logs) and maintenance functions (including task scheduling and backing up the system).

  Note that maintenance users do not have access to the functions in the Policies menu and can only access the dashboard from the Analysis menu.
- *Network Admins* can review, modify, and apply device configurations as well as review and modify access control policies (but not file policies).
- *Security Approvers* can view and apply, but not create, configuration and policy changes.

- *Security Analysts* can review, analyze, and delete intrusion, discovery, user activity, connection, correlation, and network change events. They can review, analyze, and (when applicable) delete hosts, host attributes, services, vulnerabilities, and client applications. Security Analysts can also generate reports and view (but not delete or modify) health events.
- *Security Analysts (Read Only)* have all the same rights as Security Analysts, except that they cannot delete events.

In addition to the above predefined roles, you can also configure custom user roles with specialized access privileges. Any role can be the default access role for externally authenticated users.

You can grant user role escalation privileges to externally authenticated user accounts; you can also use an externally authenticated user's password as the escalation password. For more information, see Managing User Role Escalation on page 2002.

Managing Authentication Objects

LICENSE: Any

Authentication objects are server profiles for external authentication servers, containing connection settings and authentication filter settings for those servers. You can create, manage, and delete authentication objects on the Defense Center. See the following sections for details on these tasks:

Understanding LDAP Authentication

LICENSE: Any

LDAP, or the Lightweight Directory Access Protocol, allows you to set up a directory on your network that organizes objects, such as user credentials, in a centralized location. Multiple applications can then access those credentials and the information used to describe them. If you ever need to change a user's

credentials, you can change them in one place, rather than having to change them on each Sourcefire 3D System appliance.

You can create LDAP authentication objects on a Defense Center, but not on other Sourcefire 3D System appliances. However, you can use the external authentication object on any appliance by applying a system policy where the object is enabled to the appliance. When you apply the policy, the object is copied to the appliance.

IMPORTANT! Before enabling external authentication on Series 3 managed devices, remove any internally-authenticated shell users that have the same user name as externally-authenticated users included in your shell access filter.

Note that you can use LDAP naming standards for address specification and for filter and attribute syntax in your authentication object. For more information, see the RFCs listed in the Lightweight Directory Access Protocol (v3): Technical Specification, RFC 3377. Examples of syntax are provided throughout this procedure. Note that when you set up an authentication object to connect to a Microsoft Active Directory Server, you can use the address specification syntax documented in the Internet RFC 822 (Standard for the Format of ARPA Internet Text Messages) specification when referencing a user name that contains a domain. For example, to refer to a user object, you might type `JoeSmith@security.example.com` rather than the equivalent user distinguished name of `cn=JoeSmith,ou=security, dc=example,dc=com` when using Microsoft Active Directory Server.

IMPORTANT! Currently, Sourcefire supports LDAP external authentication on LDAP servers running Microsoft Active Directory on Windows Server 2003 and Windows Server 2008, Oracle Directory Server Enterprise Edition 7.0 on Windows Server 2003 and Windows Server 2008, or OpenLDAP on Linux. However, Sourcefire does not support external authentication for virtual devices or Sourcefire Software for X-Series.

For more information, see the following sections:

- Setting Defaults on page 1930
- Setting a Base DN on page 1930
- Setting a Base Filter on page 1930
- Selecting an Impersonation Account on page 1930
- Encrypting Your LDAP Connection on page 1931
- Setting the User Name Template on page 1931
- Setting a Connection Timeout on page 1931
- Using Attributes to Manage Access on page 1931
- Using Group Membership to Manage Access on page 1932

Setting Defaults

LICENSE: Any

You can populate several fields using default values based on the server type you plan to connect to. Default values propagate the User Name Template, UI Access Attribute, Shell Access Attribute, Group Member Attribute, and Group Member URL Attribute fields when you select a server type and set defaults.

Setting a Base DN

LICENSE: Any

When the local appliance searches the LDAP server to retrieve user information on the authentication server, it needs a starting point for that search. You can specify the tree that the local appliance should search by providing a base distinguished name, or *base DN*.

Typically, the base DN has a basic structure indicating the company domain and operational unit. For example, the Security organization of the Example company might have a base DN of `ou=security,dc=example,dc=com`.

After you identify a primary server, you can automatically retrieve a list of available base DNs from it and select the appropriate base DN.

Setting a Base Filter

LICENSE: Any

You can add a *base filter* that sets a specific value for a specific attribute. The base filter focuses your search by only retrieving objects in the base DN that have the attribute value set in the filter. Enclose the base filter in parentheses. For example, to filter for only users with a common name starting with F, use the filter `(cn=F*)`.

To test your base filter more specifically by entering a test user name and password, see Testing User Authentication on page 1953.

Selecting an Impersonation Account

LICENSE: Any

To allow the local appliance to access the user objects, you must supply user credentials for an impersonation account. The *impersonation account* is a user account with appropriate rights to browse the directory named by the base DN and retrieve the user objects you want to retrieve. Remember that the distinguished name for the user you specify must be unique to the tree for the server.

Encrypting Your LDAP Connection

License: Any

You can manage the encryption method for your LDAP connection. You can choose no encryption, Transport Layer Security (TLS), or Secure Sockets Layer (SSL) encryption.

Note that if you are using a certificate to authenticate when connecting via TLS or SSL, the name of the LDAP server in the certificate **must** match the name that you use in the Host Name/IP Address field. For example, if you enter `10.10.10.250` in the authentication profile and `computer1.example.com` in the certificate, the connection fails. Changing the name of the server in the authentication profile to `computer1.example.com` causes the connection to succeed.

Note that if you change the encryption method after specifying the port, the port resets to the default value for the selected server type.

Setting the User Name Template

License: Any

Selecting a user name template lets you indicate how user names entered on login should be formatted, by mapping the string conversion character (`%s`) to the value of the shell access attribute for the user. The user name template is the format for the distinguished name used for authentication. When a user enters a user name into the login page, the name is substituted for the string conversion character and the resulting distinguished name is used to search for the user credentials.

For example, to set a user name template for the Security organization of the Example company, you might enter `%s@security.example.com`.

Setting a Connection Timeout

License: Any

If you specify a backup authentication server, you can set a timeout for the connection attempt to the primary server. If the timeout period elapses without a response from the primary authentication server, the appliance then queries the backup server. For example, if the primary server has LDAP disabled, the appliance queries the backup server.

If LDAP is running on the port of the primary LDAP server and for some reason refuses to service the request (due to misconfiguration or other issues), however, the failover to the backup server does not occur.

Using Attributes to Manage Access

License: Any

Different types of LDAP servers use different attributes to store user data. If your LDAP server uses a UI access attribute of `uid`, the local appliance checks the `uid` attribute value for each object in the tree indicated by the base DN you set. If you

do not set a specific UI access attribute, the local appliance checks the distinguished name for each user record on the LDAP server to see if it matches the user name. If one of the objects has a matching user name and password, the user login request is authenticated.

You can substitute a different LDAP attribute to make the local appliance match a user name with that attribute rather than the value of the distinguished name. Selecting a server type and setting defaults fills in a UI access attribute appropriate for that type of server. If one of the objects has a matching user name and password as a value for the attribute you specify, the user login request is authenticated. You can use any attribute, if the value of the attribute is a valid user name for the Sourcefire 3D System web interface. Valid user names are unique, and can include underscores (_), periods (.), hyphens (-), and alphanumeric characters.

The shell access attribute of your LDAP server acts as a shell access attribute. If your LDAP server uses `uid`, the local appliance checks the user name entered on login against the attribute value of `uid`. You can also set a custom shell access attribute other than `uid`.

Note that selecting a server type and setting defaults prepopulates a shell access attribute typically appropriate for that type of server. You can use any attribute, if the value of the attribute is a valid user name for shell access. Valid user names are unique, and can include underscores (_), periods (.), hyphens (-), and alphanumeric characters.

Using Group Membership to Manage Access

LICENSE: Any

If you prefer to base default access settings on a user's membership in an LDAP group, you can specify distinguished names for existing groups on your LDAP server for each of the access roles used by your Sourcefire 3D System. When you do so, you can configure a default access setting for those users detected by LDAP that do not belong to any specified groups. When a user logs in, the Sourcefire 3D System dynamically checks the LDAP server and assigns default access rights according to the user's current group membership.

When a user authenticated by an LDAP server logs into a local Sourcefire 3D System appliance for the first time, the user receives the default access settings for groups the user belongs to, or if groups are not configured, the default access setting you selected in the system policy.

You can then modify those settings, unless the settings are granted through group membership.

Setting up Shell Access

LICENSE: Any

You can use the LDAP server to authenticate accounts for shell access on a managed device or Defense Center. Specify a search filter that retrieves entries for users to whom you want to grant shell access. Note that you can only

configure shell access for the first authentication object in your system policy. For more information on managing authentication object order, see Configuring Authentication Profiles on page 2052.

With the exception of the admin account, shell access is controlled entirely though the shell access attribute you set. Shell users are configured as local users on the appliance. The filter you set here determines which set of users on the LDAP server can log into the shell.

Note that a home directory for each shell user is created on login, and when an LDAP shell access user account is disabled (by disabling the LDAP connection), the directory remains, but the user shell is set to `/bin/false` in `/etc/password` to disable the shell. If the user then is re-enabled, the shell is reset, using the same home directory.

If all users qualified in the base DN are also qualified for shell access privileges, you can configure the shell access filter to search more efficiently by making the shell access filter the same as the base filter. Normally, the LDAP query to retrieve users combines the base filter with the shell access filter. If the shell access filter was the same as the base filter, the same query runs twice, which is unnecessarily time-consuming.

Shell users can log in using user names with lowercase, uppercase, or mixed case letters. Login authentication for the shell is case sensitive.

WARNING! On Series 3 Defense Centers, all shell users have `sudoers` privileges. Make sure that you restrict the list of users with shell access appropriately. On Series 3 and virtual devices, shell access granted to externally authenticated users defaults to the **Configuration** level of command line access, which also grants `sudoers` privileges.

Testing the Connection

LICENSE: Any

After you configure LDAP server and authentication settings, you can specify user credentials for a user who should be able to authenticate to test those settings.

For the user name, you can enter the value for the `uid` attribute for the user you want to test with. If you are connecting to a Microsoft Active Directory Server and supply a UI access attribute in place of `uid`, use the value for that attribute as the user name.

Preparing to Create an LDAP Authentication Object

LICENSE: Any

Before you configure a connection to your LDAP server, you should collect the information that you need to create the LDAP authentication object. For more information on specific aspects of configuration, see Understanding LDAP Authentication on page 1928.

You need the following for any authentication object:

- the server name or IP address for the server where you plan to connect
- the server type of the server where you plan to connect
- the user name and password for a user account with sufficient privileges to browse the LDAP tree
- if there is a firewall between the appliance and the LDAP server, an entry in the firewall to allow outgoing connections
- if possible, the base distinguished name for the server directory where the user names reside

Note that you can use a third-party LDAP client to browse the LDAP tree and see base DN and attribute descriptions. You can also use that client to confirm that your selected user can browse the base DN you select. Ask your LDAP administrator to recommend an approved LDAP client for your LDAP server.

Depending on how you plan to customize your LDAP authentication object configuration, you might also need the information in the following table.

Additional LDAP Configuration Information

TO...	YOU NEED...
connect over a port other than 389	the port number
connect via an encrypted connection	the certificate for the connection
filter the users who can access your appliance based on an attribute value	the attribute-value pair to filter by
use an attribute as a UI access attribute rather than checking the user distinguished name	the name of the attribute
use an attribute as a shell login attribute rather than checking the user distinguished name	the name of the attribute
filter the users who can access your appliance via the shell based on an attribute value	the attribute-value pair to filter by
associate groups with specific user roles	the distinguished name of each group, as well as the group member attribute if the groups are static groups or the group member URL attribute if the groups are dynamic groups

Quick Start to LDAP Authentication

LICENSE: Any

You can set up an LDAP authentication object where you customize many of the values. However, if you just want to authenticate all the users in a particular directory, you can create an authentication object with the base DN for that directory. If you set defaults to those for your server type and supply authentication credentials for the account used to retrieve user data from the server, you can quickly create an authentication object. Follow the procedure below to do so.

IMPORTANT! If you prefer to consider and possibly customize each authentication setting when creating the authentication object, use the procedure in Creating Advanced LDAP Authentication Objects on page 1940 to create the object. If you plan to encrypt your connection to the server, set user timeouts, customize the user name template, or assign Sourcefire 3D System user roles based on LDAP group membership, use the advanced procedure.

Before you configure a connection to your LDAP server, you should collect the information that you need to create the LDAP authentication object. For more information on specific aspects of configuration, see Understanding LDAP Authentication on page 1928.

You need the following:

- the server name or IP address for the server where you plan to connect
- the server type of the server where you plan to connect
- the user name and password for a user account with sufficient privileges to browse the LDAP tree

Optionally, if you want to constrain your user search further, you can add a base filter to set a specific value for a specific attribute. The base filter focuses your search by only retrieving objects in the base DN that have the attribute value set in the filter. Enclose the base filter in parentheses. For example, to filter for only users with a common name starting with F, use the filter `(cn=F*)`. When you save the authentication object, the local appliance queries using the base filter to test it and indicates whether or not the filter appears to be correct.

To create an LDAP authentication object:

ACCESS: Admin

1. Select **System > Local > User Management**.

   The User Management page appears

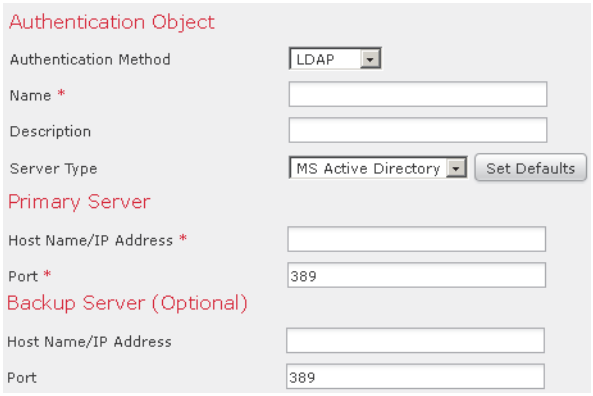
2. Click the **Login Authentication** tab.

   The Login Authentication page appears.

3. Click **Create Authentication Object**.

4. Select **LDAP** from the **Authentication Method** drop-down list.

   LDAP configuration options appear.



5. Type a name and description for the authentication server in the **Name** and **Description** fields.

6. Select your server type from the **Server Type** drop-down list, then click the **Set Defaults** button to configure default settings for that type. You have the following options:

   - If you are connecting to a Microsoft Active Directory Server, select **MS Active Directory**, then click **Set Defaults**.
   - If you are connecting to a Sun Java Systems Directory Server or Oracle Directory Server, select **Oracle Directory**, then click **Set Defaults**.
   - If you are connecting to an OpenLDAP server, select **OpenLDAP**, then click **Set Defaults**.
   - If you are connecting to a server other than those listed above and want to clear default settings, select **Other**, then click **Set Defaults**.

7. Type the IP address or host name for the primary server where you want to obtain authentication data in the **Primary Server Host Name/IP Address** field.

   IMPORTANT! If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

8. To fetch a list of all base DNs, click **Fetch DNs** and select the appropriate base DN from the drop-down list.

   For example, to authenticate names in the Security organization at the Example company, select `ou=security,dc=example,dc=com`.

9. Optionally, to set a filter that retrieves only specific objects within the directory you specified as the Base DN, type the attribute type, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses, in the **Base Filter** field.

   For example, if the user objects in a tree have a physicalDeliveryOfficeName attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, type `(physicalDeliveryOfficeName=NewYork)`.

10. In the **User Name** and **Password** fields, type the distinguished name and password for a user who has sufficient credentials to browse the LDAP server.

    For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute and the object for the administrator in the Security division at our example company has a `uid` value of `NetworkAdmin`, you might type `uid=NetworkAdmin,ou=security,dc=example,dc=com.`

    WARNING! If you are connecting to a Microsoft Active Directory Server, you cannot provide a server user name that ends with the `$` character.

11. Retype the password in the **Confirm Password** field.

12. Optionally, to retrieve users for shell access, type the attribute type you want to filter on in the **Shell Access Attribute** field.

    For example, on a Microsoft Active Directory Server, use the `sAMAccountName` shell access attribute to retrieve shell access users by typing `sAMAccountName` in the **Shell Access Attribute** field.

    IMPORTANT! IPv6 addresses are not supported for shell authentication.

13. In the **User Name** and **Password** fields, type the `uid` value or shell access attribute value and password for the user whose credentials should be used to validate access to the LDAP server. Note, again, that server user names associated with a Microsoft Active Directory Server cannot end with the character `$`.

    For example, to test to see if you can retrieve the `JSmith` user credentials at the Example company, type `JSmith.`

14. Click **Test** to test the connection.

    A message appears, either indicating success of the test or detailing what settings are missing or need to be corrected. If the test succeeds, the test output appears at the bottom of the page, including a list of the users retrieved by the connection. If the number of users that appear in the test output is limited by the number of user records your LDAP server returns, the test output indicates this limitation.

15. You have two options:
    - If the test succeeds, click **Save**.

      The Login Authentication page appears, with the new object listed.

      To enable LDAP authentication using the object on an appliance, you must apply a system policy with that object enabled to the appliance. For more information, see Configuring Authentication Profiles on page 2052 and Applying a System Policy on page 2042.
    - If the test fails, or if you want to refine the list of users retrieved, continue with the next section, Tuning Your LDAP Authentication Connection.

Tuning Your LDAP Authentication Connection

LICENSE: Any

If you create an LDAP authentication object and it either does not succeed in connecting to the server you select, or does not retrieve the list of users you want, you can tune the settings in the object.

If the connection fails when you test it, try the following suggestions to troubleshoot your configuration:

- Use the messages displayed at the top of the screen and in the test output to determine which areas of the object are causing the issue.
- Check that the user name and password you used for the object are valid:
  - Check that the user has the rights to browse to the directory indicated in your base distinguished name by connecting to the LDAP server using a third-party LDAP browser.
  - Check that the user name is unique to the directory information tree for the LDAP server.
  - Check that the user name contains only underscores, periods, hyphens, and alphanumeric characters.
  - If you see an LDAP bind error 49 in the test output, the user binding for the user failed. Try authenticating to the server through a third-party application to see if the binding fails through that connection as well.
- Check that you have correctly identified the server:
  - Check that the server IP address or host name is correct.
  - Check that you have TCP/IP access from your local appliance to the authentication server where you want to connect.
  - Check that access to the server is not blocked by a firewall and that the port you have configured in the object is open.
  - If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used for the server.

  - Check that you have not used an IPv6 address for the server connection if you are authenticating shell access.
  - If you used server type defaults, check that you have the correct server type and click **Set Defaults** again to reset the default values.

  For more information, see Identifying the LDAP Authentication Server on page 1942.
- If you typed in your base distinguished name, click **Fetch DNs** to retrieve all the available base distinguished names on the server, and select the name from the list.
- If you are using any filters, access attributes, or advanced settings, check that each is valid and typed correctly.
- If you are using any filters, access attributes, or advanced settings, try removing each setting and testing the object without it.
- If you are using a base filter or a shell access filter, make sure that the filter is enclosed in parentheses and that you are using a valid comparison operator. For more information, see Setting a Base Filter on page 1930 and Setting up Shell Access on page 1932.
- To test a more restricted base filter, try setting it to the base distinguished name for the user to retrieve just that user.
- If you are using an encrypted connection:
  - Check that the name of the LDAP server in the certificate matches the host name that you use to connect.
  - Check that you have not used an IPv6 address with an encrypted server connection.
- If you are using a test user, make sure that the user name and password are typed correctly.
- If you are using a test user, remove the user credentials and test the object.
- Test the query you are using by connecting to the LDAP server via the command line on the appliance you want to connect from using this syntax:

  ```
  ldapsearch -x -b 'base_distinguished_name'
  -h LDAPserver_ip_address -p port -v -D
  'user_distinguished_name' -W 'base_filter'
  ```

  For example, if you are trying to connect to the security domain on `myrtle.example.com` using the `domainadmin@myrtle.example.com` user and a base filter of `(cn=*)`, you could test the connection using this statement:

  ```
  ldapsearch -x -b 'CN=security,DC=myrtle,DC=example,DC=com'
  -h myrtle.example.com -p 389 -v -D
  'domainadmin@myrtle.example.com' -W '(cn=*)'
  ```

If you can test your connection successfully but authentication does not work after you apply a system policy, check that authentication and the object you want to use are both enabled in the system policy that is applied to the appliance.

If you connect successfully but want to adjust the list of users retrieved by your connection, you can add or change a base filter or shell access filter or use a more restrictive or less restrictive base DN. For more information, see the following topics:

- Setting a Base DN on page 1930
- Setting a Base Filter on page 1930
- Configuring LDAP-Specific Parameters on page 1944

Creating Advanced LDAP Authentication Objects

LICENSE: Any

You can create LDAP authentication objects to provide user authentication services for an appliance.

When you create an authentication object, you define settings that let you connect to an authentication server. You also select the directory context and search criteria you want to use to retrieve user data from the server. Optionally, you can configure shell access authentication.

Make sure you have TCP/IP access from your local appliance to the authentication server where you want to connect.

Although you can use the default settings for your server type to quickly set up a basic LDAP configuration, you can also customize advanced settings to control whether the appliance makes an encrypted connection to the LDAP server, the timeout for the connection, and which attributes the server checks for user information.

For the LDAP-specific parameters, you can use LDAP naming standards and filter and attribute syntax. For more information, see the RFCs listed in the Lightweight Directory Access Protocol (v3): Technical Specification, RFC 3377. Examples of syntax are provided throughout this procedure. Note that when you set up an authentication object to connect to a Microsoft Active Directory Server, you can use the address specification syntax documented in the Internet RFC 822 (Standard for the Format of ARPA Internet Text Messages) specification when referencing a user name that contains a domain. For example, to refer to a user object, you might type `JoeSmith@security.example.com` rather than the equivalent user distinguished name of `cn=JoeSmith,ou=security, dc=example,dc=com` when using Microsoft Active Directory Server.

To create an advanced authentication object:

Access: Admin

1. Select **System > Local > User Management**.

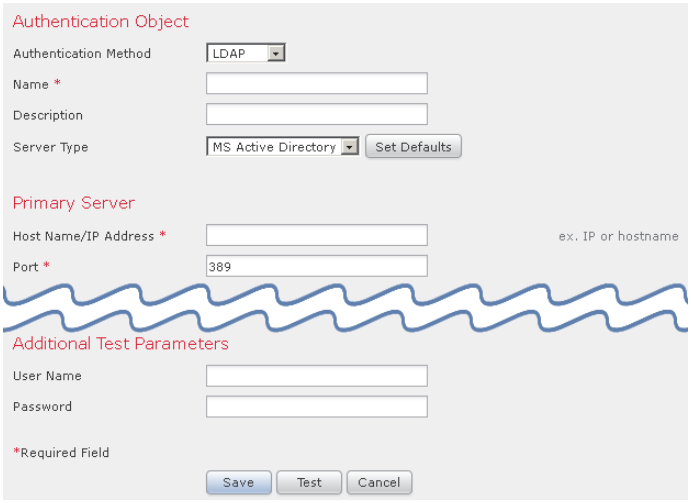
   The User Management page appears

2. Click the **Login Authentication** tab.

   The Login Authentication page appears.

3. Click **Create Authentication Object**.

   The Create Authentication Object page appears.



4. Identify the authentication server where you want to retrieve user data for external authentication. For more information, see Identifying the LDAP Authentication Server on page 1942.

5. Configure authentication settings to build a search request that retrieves the users you want to authenticate. Specify a user name template to format the user names that users enter on login. For more information, see Configuring LDAP-Specific Parameters on page 1944.

6. Optionally, configure LDAP groups to use as the basis for default access role assignments. For more information, see Configuring Access Settings by Group on page 1949.

7. Optionally, configure authentication settings for shell access. For more information, see Configuring Administrative Shell Access on page 1952.

8. Test your configuration by entering the name and password for a user who can successfully authenticate. For more information, see Testing User Authentication on page 1953.

   Your changes are saved. Remember that you have to apply a system policy with the object enabled to an appliance before the authentication changes take place on that appliance. For more information, see Configuring Authentication Profiles on page 2052 and Applying a System Policy on page 2042.

Identifying the LDAP Authentication Server

LICENSE: Any

When you create an authentication object, you first specify the primary and backup server and server port where you want the managed device or Defense Center to connect for authentication.

To identify an LDAP authentication server:

ACCESS: Admin

1. Select **System > Local > User Management**.

   The User Management page appears

2. Click the **Login Authentication** tab.

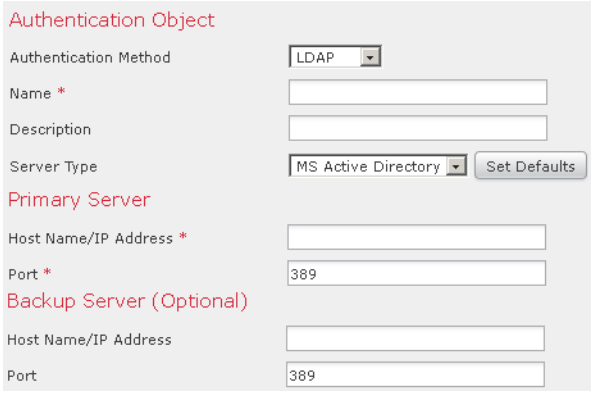
   The Login Authentication page appears.

3. Click **Create Authentication Object**.

   The Create Authentication Object page appears.

4. Select **LDAP** from the **Authentication Method** drop-down list.

   LDAP configuration options appear.



5. Type a name and description for the authentication server in the **Name** and **Description** fields.
6. Optionally, in the **Server Type** field, select the type of LDAP server you plan to connect to and click **Set Defaults** to populate the User Name Template, UI Access Attribute, Shell Access Attribute, Group Member Attribute, and Group Member URL Attribute fields with default values. You have the following options:
   - If you are connecting to a Microsoft Active Directory server, select **MS Active Directory** and click **Set Defaults**.
   - If you are connecting to a Sun Java Systems Directory Server or Oracle Directory Server, select **Oracle Directory** and click **Set Defaults**.
   - If you are connecting to an OpenLDAP server, select **OpenLDAP** and click **Set Defaults**.
   - If you are connecting to a LDAP server other than those listed above and want to clear default settings, select **Other** and click **Set Defaults**.
7. Type the IP address or host name for the primary server where you want to obtain authentication data in the **Primary Server Host Name/IP Address** field.

   IMPORTANT! If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

8. Optionally, modify the port used by the primary authentication server in the **Primary Server Port** field.
9. Optionally, type the IP address or host name for the backup server where you want to obtain authentication data in the **Backup Server Host Name/IP Address** field.
10. Optionally, modify the port used by the primary authentication server in the **Backup Server Port** field.

    Continue with Configuring LDAP-Specific Parameters.

Configuring LDAP-Specific Parameters

LICENSE: Any

The settings in the LDAP-specific parameters section determine the area of the LDAP directory where the appliance searches for user names, and control details of how the appliance connects to the LDAP server.

When configuring these settings, note that valid user names are unique, and can include underscores (_), periods (.), and hyphens (-), but otherwise only alphanumeric characters are supported.

In addition for most LDAP-specific settings, you can use LDAP naming standards and filter and attribute syntax. For more information, see the RFCs listed in the Lightweight Directory Access Protocol (v3): Technical Specification, RFC 3377. Examples of syntax are provided throughout this procedure. Note that when you set up an authentication object to connect to a Microsoft Active Directory Server, you can use the address specification syntax documented in the Internet RFC 822 (Standard for the Format of ARPA Internet Text Messages) specification when referencing a user name that contains a domain. For example, to refer to a user object, you might type `JoeSmith@security.example.com` rather than the equivalent user distinguished name of `cn=JoeSmith,ou=security, dc=example,dc=com` when using Microsoft Active Directory Server.

The following table describes each of the LDAP-specific parameters.

LDAP-Specific Parameters

SETTING	DESCRIPTION	EXAMPLE
Base DN	Supplies the base distinguished name of the directory where the appliance searches for user information on the LDAP server. Typically, the base DN has a basic structure indicating the company domain and operational unit. Note that after you identify a primary server, you can automatically retrieve a list of available base DNs from the server and select the appropriate base DN.	The Security organization of the Example company might have a base DN of `ou=security, dc=example,dc=com`
Base Filter	Focuses your search by only retrieving objects in the base DN that have the specific attribute-value pair set in the filter. Note that you must enclose the base filter in parentheses. To test your base filter more specifically by entering a test user name and password, see Testing User Authentication on page 1953.	To filter for only users with a common name starting with F, use the filter `(cn=F*)`.

LDAP-Specific Parameters (Continued)

Setting	Description	Example
User Name/ Password	Allow the local appliance to access the user objects. Supply user credentials for a user with appropriate rights to the authentication objects you want to retrieve. The distinguished name for the user you specify must be unique to the directory information tree for the LDAP server. Note that server user names associated with a Microsoft Active Directory Server cannot end with the `$` character.	The user name for the `admin` user in the Security organization of the Example company might have a user name of `cn=admin, ou=security, dc=example,dc=com`
Encryption	Determines whether and how the communications are encrypted. You can choose no encryption, Transport Layer Security (TLS), or Secure Sockets Layer (SSL) encryption. Note that if you are using a certificate to authenticate when connecting via TLS or SSL, the name of the LDAP server in the certificate **must** match the name that you use to connect. If you change the encryption method after specifying the port, the port resets to the default value for the selected server type.	If you enter `10.10.10.250` in the authentication profile and `computer1. example.com` in the certificate, the connection fails, even if `computer1. example.com` has an IP address of `10.10.10.250`. Changing the name of the server in the authentication profile to `computer1. example.com` causes the connection to succeed.
SSL Certificate Upload Path	Indicates the path on your local computer to the certificate to be used for encryption.	`c:/server.crt`
User Name Template	Indicates how user names entered on login should be formatted, by mapping the string conversion character (`%s`) to the value of the shell access attribute for the user. The user name template is the format for the distinguished name used for authentication. When a user enters a user name into the login page, the appliance substitutes the name for the string conversion character and uses the resulting distinguished name to search for the user credentials.	To set a user name template for the Security organization of the Example company, enter `%s@security. example.com`.

LDAP-Specific Parameters (Continued)

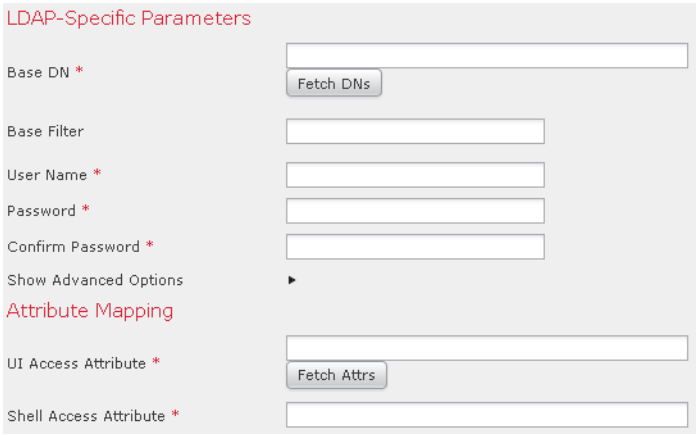
Setting	Description	Example
Timeout	Sets a timeout for the connection attempt to the primary server, so the connection rolls over to the backup server. If the number of seconds indicated in this field (or the timeout on the LDAP server) elapses without a response from the primary authentication server, the appliance then queries the backup server. However, if LDAP is running on the port of the primary LDAP server and for some reason refuses to service the request, the failover to the backup server does not occur.	If the primary server has LDAP disabled, the appliance queries the backup server.
UI Access Attribute	Tells the local appliance to match the value of a specific attribute rather than the value of the user distinguished name. You can use any attribute, if the value of the attribute is a valid user name for the Sourcefire 3D System web interface. If one of the objects has a matching user name and password, the user login request is authenticated. Selecting a server type and setting defaults prepopulates the **UI Access Attribute** with a value typically appropriate for that type of server. If you leave this field blank, the local appliance checks the user distinguished name value for each user record on the LDAP server to see if it matches the user name.	`sAMAccountName`
Shell Access Attribute	If you want to check a specific attribute for shell access credentials, you must explicitly set this field to match the attribute. You can use any attribute if the value of the attribute is a valid user name for shell access. If you leave this field blank, the user distinguished name is used for shell access authentication. Note that selecting a server type and setting defaults prepopulates this field with an attribute typically appropriate for that type of server.	`sAMAccountName`

To configure the LDAP-specific parameters for a server:

Access: Admin

1. In the LDAP-Specific Parameters section of the Create Authentication Object page, you have two options for setting the base DN:
   - To fetch a list of all available domains, click **Fetch DNs** and select the appropriate base domain name from the drop-down list.
   - Type the base distinguished name for the LDAP directory you want to access in the **Base DN** field.

   For example, to authenticate names in the Security organization at the Example company, type or select `ou=security,dc=example,dc=com`.



2. Optionally, to set a filter that retrieves only specific objects within the directory you specified as the Base DN, type the attribute type, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses, in the **Base Filter** field.

   For example, if the user objects in a directory tree have a physicalDeliveryOfficeName attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, type `(physicalDeliveryOfficeName=NewYork)`.

3. Type the distinguished name and password for the user whose credentials should be used to validate access to the LDAP directory in the **User Name** and **Password** fields.

   For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute and the object for the administrator in the Security division at our example company has a `uid` value of `NetworkAdmin`, you might type `uid=NetworkAdmin,ou=security,dc=example,dc=com.`

WARNING! If you are connecting to a Microsoft Active Directory Server, you cannot provide a server user name that ends with the `$` character.

4. Retype the password in the **Confirm Password** field.
5. After you configure the basic LDAP-specific parameters, you have several options:
   - To access advanced options, click the arrow next to **Show Advanced Options** and continue with the next step.
   - If you want to configure user default roles based on LDAP group membership, continue with Configuring Access Settings by Group on page 1949.
   - If you are not using LDAP groups for authentication, continue with Configuring Administrative Shell Access on page 1952.
6. Optionally, select one of the following encryption modes:
   - To connect using Secure Sockets Layer (SSL), select **SSL**.
   - To connect using Transport Layer Security (TLS), select **TLS**.
   - To connect without encryption, select **None**.

   IMPORTANT! Note that if you change the encryption method after specifying a port, you reset the port to the default value for that method. For none or TLS, the port uses the default value of 389. If you select SSL encryption, the port uses the default of 636.

7. If you selected TLS or SSL encryption and you want to use a certificate to authenticate, click **Browse** to browse to the location of a valid TLS or SSL certificate or, in the **SSL Certificate Upload Path** field, type the path to the certificate.

   A message appears, indicating a successful certificate upload.

   IMPORTANT! If you previously uploaded a certificate and want to replace it, upload the new certificate and reapply the system policy to your appliances to copy over the new certificate.

8. Optionally, in the **User Name Template** field, type the string conversion character (`%s`) used to determine the user name from the value found in the **UI Access Attribute**.

   For example, to authenticate all users who work in the Security organization of our example company by connecting to an OpenLDAP server where the shell access attribute is `uid`, you might type `uid=%s,ou=security,dc=example,dc=com` in the **User Name Template** field. For a Microsoft Active Directory server, you could type `%s@security.example.com`.
9. Optionally, in the **Timeout** field, type the number of seconds that should elapse before rolling over to the backup connection.

10. Optionally, to retrieve users based on an attribute instead of the Base DN and Base Filter, you have two options:
    - Click **Fetch Attrs** to retrieve a list of available attributes and select the appropriate attribute.
    - Type the attribute in the **UI Access Attribute** field.

    For example, on a Microsoft Active Directory Server, you may want to use the UI Access Attribute to retrieve users, because there may not be a `uid` attribute on Active Directory Server user objects. Instead, you can search the `userPrincipalName` attribute by typing `userPrincipalName` in the **UI Access Attribute** field.
11. Optionally, to retrieve users for shell access, type the attribute to filter by in the **Shell Access Attribute** field.

    For example, on a Microsoft Active Directory Server, use the `sAMAccountName` shell access attribute to retrieve shell access users by typing `sAMAccountName` in the **Shell Access Attribute** field.
12. For the next step, you have two choices:
    - If you want to configure user default roles based on LDAP group membership, continue with Configuring Access Settings by Group.
    - If you are not using LDAP groups for authentication, continue with Configuring Administrative Shell Access on page 1952.

Configuring Access Settings by Group

LICENSE: Any

If you prefer to base default access settings on a user's membership in an LDAP group, you can specify distinguished names for existing groups on your LDAP server for each of the access roles used by your Sourcefire 3D System. When you do so, you can configure a default access setting for those users detected by LDAP that do not belong to any specified groups. When a user logs in, the Sourcefire 3D System dynamically checks the LDAP server and assigns default access rights according to the user's current group membership.

Any group you reference must exist on the LDAP server. You can reference static LDAP groups or dynamic LDAP groups. Static LDAP groups are groups where membership is determined by group object attributes that point to specific users, and dynamic LDAP groups are groups where membership is determined by creating an LDAP search that retrieves group users based on user object attributes. Group access settings for a role only affect users who are members of the group.

The access rights granted when a user logs into the Sourcefire 3D System depend on the LDAP configuration:

- If no group access settings are configured for your LDAP server, when a new user logs in, the Sourcefire 3D System authenticates the user against the LDAP server and then grants user rights based on the default minimum access role set in the system policy.
- If you configure any group settings, new users belonging to specified groups inherit the minimum access setting for the groups where they are members.
- If a new user does not belong to any specified groups, the user is assigned the default minimum access role specified in the Group Controlled Access Roles section of the authentication object.
- If a user belongs to more than one configured group, the user receives the access role for the group with the highest access as a minimum access role.

You cannot use the Sourcefire 3D System user management page to remove the minimum access rights for users assigned an access role because of LDAP group membership. You can, however, assign additional rights. When you modify the access rights for an externally authenticated user, the Authentication Method column on the User Management page provides a status of **External - Locally Modified**.

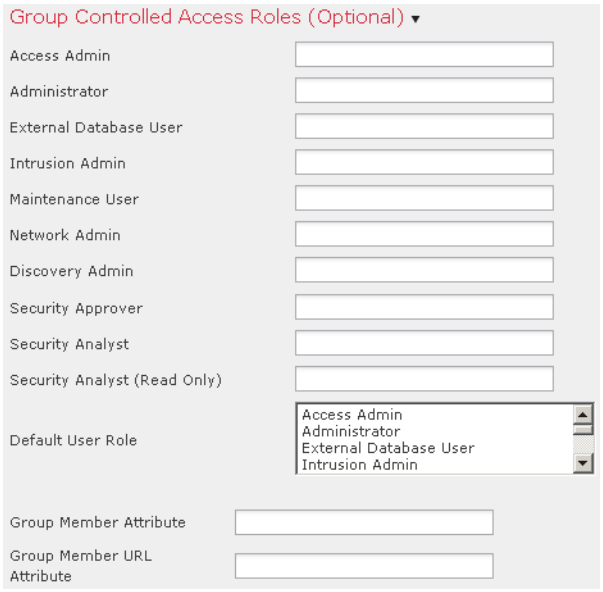
IMPORTANT! If you use a dynamic group, the LDAP query is used exactly as it is configured on the LDAP server. For this reason, the Sourcefire 3D System limits the number of recursions of a search to four to prevent search syntax errors from causing infinite loops. If a user's group membership is not established in those recursions, the default access role defined in the Group Controlled Access Roles section is granted to the user.

To configure default roles based on group membership:

Access: Admin

1. On the Create Authentication Object page, click the down arrow next to **Group Controlled Access Roles**.

   The section expands.



2. Optionally, configure access defaults by group membership.

   In the **DN** fields that correspond to Sourcefire 3D System user roles, type the distinguished name for the LDAP groups that contain users who should be assigned to those roles.

   For example, you might type the following in the **Administrator** field to authenticate names in the information technology organization at the Example company:

   ```
   cn=itgroup,ou=groups, dc=example,dc=com
   ```

   For more information on user access roles, see Adding New User Accounts on page 1974.

3. From the **Default User Role** list, select the default minimum access role for users that do not belong to any of the specified groups.

   TIP! Press the Ctrl key while clicking role names to select multiple roles.

4. If you used static groups, in the **Group Member Attribute** field, type the LDAP attribute that designates membership in a static group.

   For example, if the `member` attribute is used to indicate membership in the static group you reference for default Security Analyst access, type `member`.

5. If you used dynamic groups, in the **Group Member URL Attribute** field, type the LDAP attribute that contains the LDAP search string used to determine membership in a dynamic group.

   For example, if the `memberURL` attribute contains the LDAP search that retrieves members for the dynamic group you specified for default Admin access, type `memberURL`.

6. Continue with Configuring Administrative Shell Access.

Configuring Administrative Shell Access

LICENSE: Any

You can also use the LDAP server to authenticate accounts for shell access on your managed device or Defense Center. Specify a search filter that retrieves entries for users you want to grant shell access. Note that you can only configure shell access for the first authentication object in your system policy. For more information on managing authentication object order, see Configuring Authentication Profiles on page 2052.

IMPORTANT! Sourcefire does not support external authentication for virtual devices or Sourcefire Software for X-Series. In addition, IPv6 is not supported for shell access authentication.

With the exception of the admin account, shell access is controlled entirely though the shell access attribute you set. The shell access filter you set determines which set of users on the LDAP server can log into the shell.

Note that a home directory for each shell user is created on login, and when an LDAP shell access user account is disabled (by disabling the LDAP connection), the directory remains, but the user shell is set to `/bin/false` in `/etc/password` to disable the shell. If the user then is re-enabled, the shell is reset, using the same home directory.

The **Same as Base Filter** check box allows you to search more efficiently if all users qualified in the base DN are also qualified for shell access privileges. Normally, the LDAP query to retrieve users combines the base filter with the shell access filter. If the shell access filter was the same as the base filter, the same query runs twice, which is unnecessarily time-consuming. You can use the **Same as Base Filter** option to run the query only once for both purposes.

Shell users can log in using user names with lowercase, uppercase, or mixed case letters. Login authentication for the shell is case sensitive.

WARNING! On Series 3 Defense Centers, all shell users have `sudoers` privileges. Make sure that you restrict the list of users with shell access appropriately. On Series 3 and virtual devices, shell access granted to externally authenticated users defaults to the **Configuration** level of command line access, which also grants `sudoers` privileges.

To configure shell account authentication:

Access: Admin

1. Optionally, on the Create Authentication Object page, set a shell access account filter. You have multiple options:
   - To retrieve administrative user entries based on attribute value, type the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses, in the **Shell Access Filter** field.
   - To use the same filter you specified when configuring authentication settings, select **Same as Base Filter**.
   - To prevent LDAP authentication of shell access, leave the field blank. If you choose not to specify a shell access filter, a warning displays when you save the authentication object to confirm that you meant to leave the filter blank.

   For example, if all network administrators have a `manager` attribute which has an attribute value of `shell`, you can set a base filter of `(manager=shell)`.
2. Continue with Testing User Authentication.

Testing User Authentication

License: Any

After you configure LDAP server and authentication settings, you can specify user credentials for a user who should be able to authenticate to test those settings.

For the user name, you can enter the value for the `uid` attribute for the user you want to test with. If you are connecting to a Microsoft Active Directory Server and supplied a shell access attribute in place of `uid`, use the value for that attribute as the user name. You can also specify a fully qualified distinguished name for the user.

The test output lists valid and invalid user names. Valid user names are unique, and can include underscores (_), periods (.), and hyphens (-), but otherwise only

alphanumeric characters are supported. Invalid user names are user names containing other non-alphanumeric characters, such as spaces.

Note that testing the connection to servers with more than 1000 users only returns 1000 users because of web interface page size limitations.

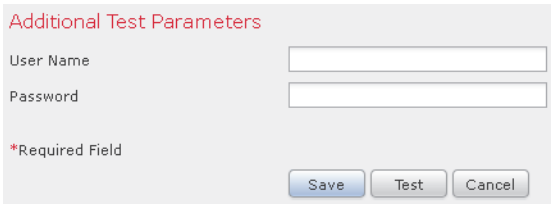
TIP! If you mistype the name or password of the test user, the test fails even if the server configuration is correct. Test the server configuration without the additional test parameters first. If that succeeds supply a user name and password to test with the specific user.

To test user authentication:

Access: Admin

1. In the **User Name** and **Password** fields, type the `uid` value or shell access attribute value and password for the user whose credentials should be used to validate access to the LDAP server.

   For example, to test to see if you can retrieve the `JSmith` user credentials at the Example company, type `JSmith`.



2. Click **Test**.

   A message appears, either indicating success of the test or detailing what settings are missing or need to be corrected. You have two options:

   - If the test succeeds, the test output appears at the bottom of the page. Click **Save**. The Login Authentication page appears, with the new object listed.

     To enable LDAP authentication using the object on an appliance, you must apply a system policy with that object enabled to the appliance. For more information, see Configuring Authentication Profiles on page 2052 and Applying a System Policy on page 2042.
   - If the test fails, see Tuning Your LDAP Authentication Connection on page 1938 for suggestions for troubleshooting the connection. Note that the error message that appears indicates what caused the connection to fail.

LDAP Authentication Object Examples

LICENSE: Any

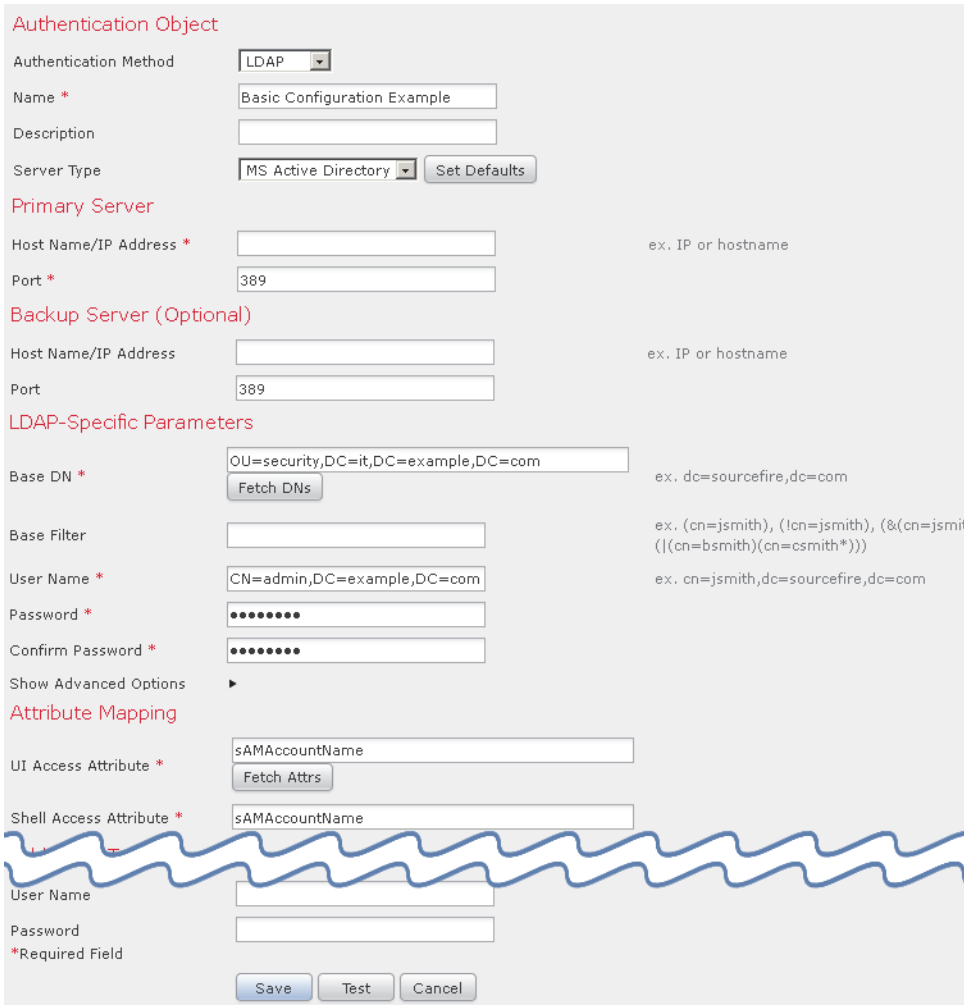
The following sections provide an example of LDAP configuration using basic settings and an example using more advanced configuration options:

- Example: Basic LDAP Configuration on page 1955
- Example: Advanced LDAP Configuration on page 1956

Example: Basic LDAP Configuration

LICENSE: Any

The following figure illustrates a basic configuration of an LDAP login authentication object for a Microsoft Active Directory Server. The LDAP server in this example has an IP address of 10.11.3.4. The connection uses port 389 for access.



This example shows a connection using a base distinguished name of `OU=security,DC=it,DC=example,DC=com` for the security organization in the information technology domain of the Example company.

However, because this server is a Microsoft Active Directory server, it uses the `sAMAccountName` attribute to store user names rather than the `uid` attribute. Selecting the MS Active Directory server type and clicking **Set Defaults** sets the **UI Access Attribute** to `sAMAccountName`. As a result, the Sourcefire 3D System checks the `sAMAccountName` attribute for each object for matching user names when a user attempts to log into the Sourcefire 3D System.

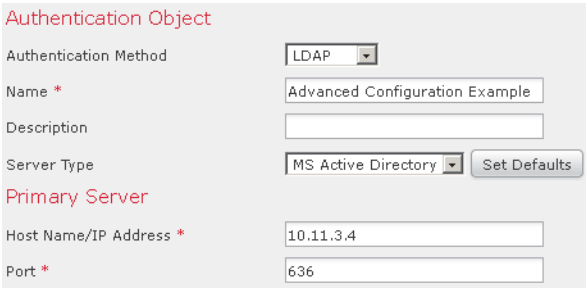
In addition, a **Shell Access Attribute** of `sAMAccountName` causes each `sAMAccountName` attribute to be checked for all objects in the directory for matches when a user logs into a shell account on the appliance.

Note that because no base filter is applied to this server, the Sourcefire 3D System checks attributes for all objects in the directory indicated by the base distinguished name. Connections to the server time out after the default time period (or the timeout period set on the LDAP server).

Example: Advanced LDAP Configuration

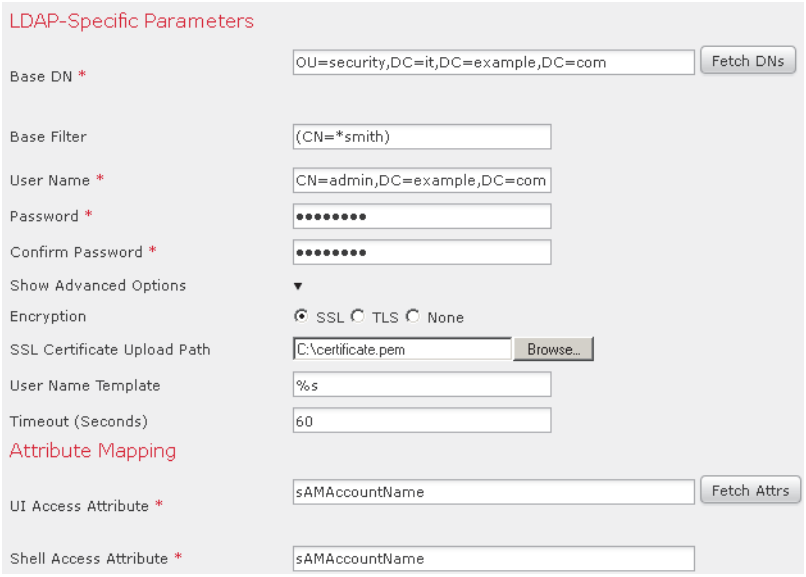
LICENSE: Any

This example illustrates an advanced configuration of an LDAP login authentication object for a Microsoft Active Directory Server. The LDAP server in this example has an IP address of 10.11.3.4. The connection uses port 636 for access.



This example shows a connection using a base distinguished name of `OU=security,DC=it,DC=example,DC=com` for the security organization in the information technology domain of the Example company. However, note that this

server has a base filter of `(cn=*smith)`. The filter restricts the users retrieved from the server to those with a common name ending in `smith`.

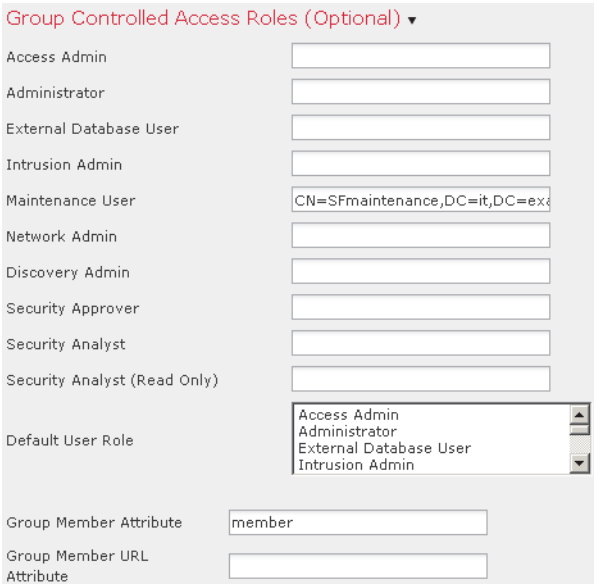


The connection to the server is encrypted using SSL and a certificate named `certificate.pem` is used for the connection. In addition, connections to the server time out after 60 seconds because of the **Timeout** setting.

Because this server is a Microsoft Active Directory server, it uses the `sAMAccountName` attribute to store user names rather than the `uid` attribute. Note that the configuration includes a **UI Access Attribute** of `sAMAccountName`. As a result, the Sourcefire 3D System checks the `sAMAccountName` attribute for each object for matching user names when a user attempts to log into the Sourcefire 3D System.

In addition, a **Shell Access Attribute** of `sAMAccountName` causes each `sAMAccountName` attribute to be checked for all objects in the directory for matches when a user logs into a shell account on the appliance.

This example also has group settings in place. The Maintenance User role is automatically assigned to all members of the group with a `member` group attribute and the base domain name of `CN=SFmaintenance,DC=it,DC=example,DC=com`.



The shell access filter is set to be the same as the base filter, so the same users can access the appliance through the shell as through the web interface.

Editing LDAP Authentication Objects

LICENSE: Any

You can edit an existing authentication object. Your changes do not take effect until you reapply the policy.

To edit an authentication object:

ACCESS: Admin

1. Select **System > Local > User Management**.

   The User Management page appears

2. Click the **Login Authentication** tab.

   The Login Authentication page appears.

3. Click the edit icon () next to the object you want to edit.

   The Create Authentication Object page appears.

4. Modify the object settings as needed.

   For more information, see the following topics:

   - Quick Start to LDAP Authentication on page 1935
   - Creating Advanced LDAP Authentication Objects on page 1940
   - Identifying the LDAP Authentication Server on page 1942
   - Configuring LDAP-Specific Parameters on page 1944
   - Configuring Access Settings by Group on page 1949
   - Configuring Administrative Shell Access on page 1952
   - Testing User Authentication on page 1953

5. Click **Test**.

   A message appears, either indicating success of the test or detailing what settings are missing or need to be corrected. If the test succeeds, the test output appears at the bottom of the page.

   If the test fails, see Tuning Your LDAP Authentication Connection on page 1938 for suggestions for troubleshooting the connection. Note that the error message that appears indicates what caused the connection to fail.

6. Click **Save**.

   Your changes are saved and the Login Authentication page appears. Remember that you have to apply a system policy with the object enabled to an appliance before the authentication changes take place on that appliance. For more information, see Configuring Authentication Profiles on page 2052 and Applying a System Policy on page 2042.

Understanding RADIUS Authentication

LICENSE: Any

The Remote Authentication Dial In User Service (RADIUS) is an authentication protocol used to authenticate, authorize, and account for user access to network resources. You can create an authentication object for any RADIUS server that conforms to RFC 2865.

IMPORTANT! Before enabling external authentication on Series 3 managed devices, remove any internally-authenticated shell users that have the same user name as externally-authenticated users included in your shell access filter.

When a user authenticated on a RADIUS server logs in for the first time, the user receives the roles specified for that user in the authentication object, or if the user is not listed for any of the user roles, the default access role you selected in the authentication object, or failing that, the system policy. You can modify a user's roles, if needed, unless the settings are granted through the user lists in the authentication object. Note that when a user authenticated on a RADIUS server using attribute matching attempts to log in for the first time, the login is rejected as the user account is created. The user must log in a second time.

The Sourcefire 3D System implementation of RADIUS supports the use of SecurID® tokens. When you configure authentication by a server using SecurID, users authenticated against that server append the SecurID token to the end of their SecurID pin and use that as their password when they log into a Sourcefire appliance. As long as SecurID is configured correctly to authenticate users outside the Sourcefire 3D System, those users can log into a Sourcefire 3D System appliance using their PIN plus the SecurID token without any additional configuration on the appliance.

Creating RADIUS Authentication Objects

LICENSE: Any

When you create a RADIUS authentication object, you define settings that let you connect to an authentication server. You also grant user roles to specific and default users. If your RADIUS server returns custom attributes for any users you plan to authenticate, you must define those custom attributes. Optionally, you can also configure shell access authentication.

Note that to create an authentication object, you need TCP/IP access from your local appliance to the authentication server where you want to connect.

To create an authentication object:

ACCESS: Admin

1. Select **System > Local > User Management**.

   The User Management page appears

2. Click the **Login Authentication** tab.

   The Login Authentication page appears.

3. Click **Create Authentication Object**.

   The Create Authentication Object page appears.

4. Identify the primary and backup authentication servers where you want to retrieve user data for external authentication and set timeout and retry values. For more information, see Configuring RADIUS Connection Settings on page 1961.

5. Set the default user role. Optionally, specify the users or user attribute values for users that you want to receive specific Sourcefire 3D System access roles. For more information, see Configuring RADIUS User Roles on page 1963.
6. Optionally, configure administrative shell access. For more information, see Configuring Administrative Shell Access on page 1966.
7. If the profiles for any of the users to authenticate return custom RADIUS attributes, define those attributes. For more information, see Defining Custom RADIUS Attributes on page 1967.
8. Test your configuration by entering the name and password for a user who should successfully authenticate. For more information, see Testing User Authentication on page 1968.

   Your changes are saved. Remember that you have to apply a system policy with the object enabled to an appliance before the authentication changes take place on that appliance. For more information, see Configuring Authentication Profiles on page 2052 and Applying a System Policy on page 2042.

Configuring RADIUS Connection Settings

LICENSE: Any

When you create a RADIUS authentication object, you first specify the primary and backup server and server port where you want the local appliance (managed device or Defense Center) to connect for authentication.

IMPORTANT! For RADIUS to function correctly, you must open its authentication and accounting ports (by default, 1812 and 1813) on your firewall.

If you specify a backup authentication server, you can set a timeout for the connection attempt to the primary server. If the number of seconds indicated in the **Timeout** field (or the timeout on the LDAP server) elapses without a response from the primary authentication server, the appliance then re-queries the primary server.

After the appliance re-queries the primary authentication server the number of times indicated by the **Retries** field and the number of seconds indicated in the **Timeout** field again elapses without a response from the primary authentication server, the appliance then rolls over to the backup server.

If, for example, the primary server has RADIUS disabled, the appliance queries the backup server. If RADIUS is running on the port of the primary RADIUS server and for some reason refuses to service the request (due to misconfiguration or other issues), however, the failover to the backup server does not occur.

To identify a RADIUS authentication server:

Access: Admin

1. Select **System > Local > User Management**.

   The User Management page appears

2. Click the **Login Authentication** tab.

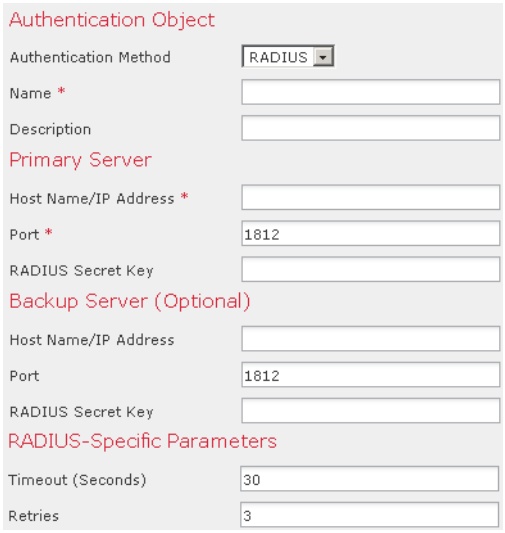
   The Login Authentication page appears.

3. Click **Create Authentication Object**.

   The Create Authentication Object page appears.

4. Select **RADIUS** from the **Authentication Method** drop-down list.

   RADIUS configuration options appear.



5. Type a name and description for the authentication server in the **Name** and **Description** fields.

6. Type the IP address or host name for the primary RADIUS server where you want to obtain authentication data in the **Primary Server Host Name/IP Address** field.

IMPORTANT! IPv6 addresses are not supported for shell authentication. To allow shell authentication when using an IPv6 address for your primary RADIUS server, set up an authentication object using an IPv4 address for the server and use that IPv4 object as the first authentication object in your system policy.

7. Optionally, modify the port used by the primary RADIUS authentication server in the **Primary Server Port** field.

   IMPORTANT! If your authentication port and accounting port numbers are not sequential, leave this field blank. The system then determines RADIUS port numbers from the `radius` and `radacct` data in your appliance's `/etc/services` file.

8. Type the secret key for the primary RADIUS authentication server in the **RADIUS Secret Key** field.
9. Type the IP address or host name for the backup RADIUS authentication server where you want to obtain authentication data in the **Backup Server Host Name/IP Address** field.
10. Optionally, modify the port used by the backup RADIUS authentication server in the **Backup Server Port** field.

    IMPORTANT! If your authentication port and accounting port numbers are not sequential, leave this field blank. The system then determines RADIUS port numbers from the `radius` and `radacct` data in your appliance's `/etc/services` file.

11. Type the secret key for the backup RADIUS authentication server in the **RADIUS Secret Key** field.
12. Type the number of seconds that should elapse before retrying the connection in the **Timeout** field.
13. Type the number of times the primary server connection should be tried before rolling over to the backup connection in the **Retries** field.
14. Continue with Configuring RADIUS User Roles.

Configuring RADIUS User Roles

LICENSE: Any

You can specify the access roles for existing users on your RADIUS server by listing the user names for each of the access roles used by your Sourcefire 3D System. When you do so, you can also configure a default access setting for those users detected by RADIUS that are not specified for a particular role.

When a user logs in, the Sourcefire 3D System checks the RADIUS server and grants access rights depending on the RADIUS configuration:

- If specific access settings are not configured for a user and a default access role is not selected, when a new user logs in, the Sourcefire 3D System authenticates the user against the RADIUS server and then grants user rights based on the default access role (or roles) set in the system policy.
- If a new user is not specified on any lists and default access roles are selected in the **Default User Role** list of the authentication object, the user is assigned those access roles.
- If you add a user to the list for one or more specific role, that user receives all assigned access roles.

You can also use attribute-value pairs, rather than user names, to identify users who should receive a particular user role. For example, if you know all users who should be Security Analysts have the value `Analyst` for their `User-Category` attribute, you can type `User-Category=Analyst` in the Security Analyst List field to grant that role to those users. Note that you need to define any custom attributes before you use them to set user role membership. For more information, see Defining Custom RADIUS Attributes on page 1967.

You can assign a default user role (or roles) to be assigned to any users that are authenticated externally but not listed for a specific role. You can select multiple roles on the **Default User Role** list.

For more information on the user roles supported by the Sourcefire 3D System, see Configuring User Roles on page 1981.

You cannot remove the minimum access rights for users assigned an access role because of RADIUS user list membership through the Sourcefire 3D System user management page. You can, however, assign additional rights.

WARNING! If you want to change the minimum access setting for a user, you must not only move the user from one list to another in the RADIUS Specific Parameters section or change the user's attribute on the RADIUS server, you must reapply the system policy, and you must remove the assigned user right on the user management page.

To base access on user lists:

Access: Admin

1. In the fields that correspond to Sourcefire 3D System user roles, type the name of each user or identifying attribute-value pair that should be assigned to those roles. Separate usernames and attribute-value pairs with commas.

   For example, to grant the Administrator role to the users `jsmith` and `jdoe`, type `jsmith, jdoe` in the **Administrator** field.

   As another example, to grant the Maintenance User role to all users with a `User-Category` value of `Maintenance`, type `User-Category=Maintenance` in the **Maintenance User** field.

   For more information on user access roles, see Configuring User Roles on page 1981.

2. Select the default minimum access role for users that do not belong to any of the specified groups from the **Default User Role** list.

   TIP! Press the Ctrl key while clicking role names to select multiple roles.

3. Continue with Configuring Administrative Shell Access.

Configuring Administrative Shell Access

LICENSE: Any

You can also use the RADIUS server to authenticate accounts for shell access on your local appliance (managed device or Defense Center). Specify user names for users you want to grant shell access. Note that you can only configure shell access for the first authentication object in your system policy. For more information on managing authentication object order, see Configuring Authentication Profiles on page 2052.

IMPORTANT! IPv6 addresses are not supported for shell authentication. If you configure a primary RADIUS server with an IPv6 address and also configure administrative shell access, the shell access settings are ignored. To allow shell authentication when using an IPv6 address for your primary RADIUS server, set up another authentication object using an IPv4 address for the server and use that object as the first authentication object in your system policy.

With the exception of the admin account, the shell access list you set on the RADIUS authentication object entirely controls shell access on the appliance. Shell users are configured as local users on the appliance when the system policy is applied. Note that when a user authenticated on a RADIUS server using attribute matching attempts to log in for the first time, the login is rejected as the user account is created. The user must log in a second time.

Note that a home directory for each shell user is created on login, and when an RADIUS shell access user account is disabled (by disabling the RADIUS connection), the directory remains, but the user shell is set to `/bin/false` in `/etc/password` to disable the shell. If the user then is re-enabled, the shell is reset, using the same home directory.

Shell users can log in using user names with lowercase, uppercase, or mixed case letters. Login authentication for the shell is case sensitive.

WARNING! On Series 3 Defense Centers, all shell users have `sudoers` privileges. Make sure that you restrict the list of users with shell access appropriately. On Series 3 and virtual devices, shell access granted to externally authenticated users defaults to the **Configuration** level of command line access, which also grants `sudoers` privileges.

To configure shell account authentication:

ACCESS: Admin

1. Type the user names, separated by commas, in the **Administrator Shell Access User List** field.

   IMPORTANT! If you choose not to specify a shell access filter, a warning displays when you save the authentication object to confirm that you meant to leave the filter blank.

2. Continue with Defining Custom RADIUS Attributes on page 1967.

Defining Custom RADIUS Attributes

LICENSE: Any

If your RADIUS server returns values for attributes not included in the `dictionary` file in `/etc/radiusclient/` and you plan to use those attributes to set user roles for users with those attributes, you need to define those attributes in the login authentication object.

You can locate the attributes returned for a user by looking at the user's profile on your RADIUS server.

When you define an attribute, you provide the name of the attribute, which consists of alphanumeric characters. Note that words in an attribute name should be separated by dashes rather than spaces. You also provide the attribute ID, which should be an integer and should not conflict with any existing attribute IDs in the `etc/radiusclient/dictionary` file. You also specify the type of attribute: string, IP address, integer, or date.

As an example, if a RADIUS server is used on a network with a Cisco router, you might want to use the `Ascend-Assign-IP-Pool` attribute to grant a specific role to all users logging in from a specific IP address pool. `Ascend-Assign-IP-Pool` is an integer attribute that defines the address pool where the user is allowed to log in, with the integer indicating the number of the assigned IP address pool. To declare that custom attribute, you create a custom attribute with an attribute name of `Ascend-IP-Pool-Definition`, an attribute ID of `218`, and an attribute type of `integer`. You could then type `Ascend-Assign-IP-Pool=2` in the **Security Analyst (Read Only)** field to grant read-only security analyst rights to all users with an `Ascend-IP-Pool-Definition` attribute value of `2.`

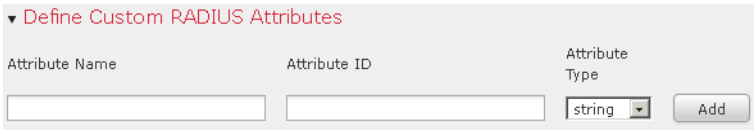
When you create a RADIUS authentication object, a new dictionary file for that object is created on the Sourcefire 3D System appliance in the `/var/sf/userauth` directory. Any custom attributes you add to the authentication object are added to the dictionary file.

To define a custom attribute:

ACCESS: Admin

1. Click the arrow to expand the Define Custom RADIUS Attributes section.

   The attribute fields appear.



2. Type an attribute name consisting of alphanumeric characters and dashes, with no spaces, in the **Attribute Name** field.
3. Type the attribute ID, in integer form, in the **Attribute ID** field.
4. Select the type of attribute from the **Attribute Type** drop-down list.
5. Click **Add** to add the custom attribute to the authentication object.

TIP! You can remove a custom attribute from an authentication object by clicking **Delete** next to the attribute.

6. Continue with Testing User Authentication on page 1968.

Testing User Authentication

LICENSE: Any

After you configure RADIUS connection, user role, and custom attribute settings, you can specify user credentials for a user who should be able to authenticate to test those settings.

For the user name, you can enter the user name for the user you want to test with.

Note that testing the connection to servers with more than 1000 users only returns 1000 users because of UI page size limitations.

TIP! If you mistype the name or password of the test user, the test fails even if the server configuration is correct. To verify that the server configuration is correct, click **Test** without entering user information in the **Additional Test Parameters** field first. If that succeeds, supply a user name and password to test with the specific user.

To test user authentication:

ACCESS: Admin

1. In the **User Name** and **Password** fields, type the user name and password for the user whose credentials should be used to validate access to the RADIUS server.

   For example, to test to see if you can retrieve the `jsmith` user credentials at our example company, type `jsmith.`

2. Select **Show Details** and click **Test**.

   A message appears, either indicating success of the test or detailing what settings are missing or need to be corrected.

3. If the test succeeds, click **Save**.

   The Login Authentication page appears, with the new object listed.

   To enable RADIUS authentication using the object on an appliance, you must apply a system policy with that object enabled to the appliance. For more information, see Configuring Authentication Profiles on page 2052 and Applying a System Policy on page 2042.

RADIUS Authentication Object Examples

LICENSE: Any

This section provides examples of RADIUS server authentication objects to show how Sourcefire 3D System RADIUS authentication features can be used. See the following sections for more information:

- Authenticating a User Using RADIUS on page 1969
- Authenticating a User with Custom Attributes on page 1970

Authenticating a User Using RADIUS

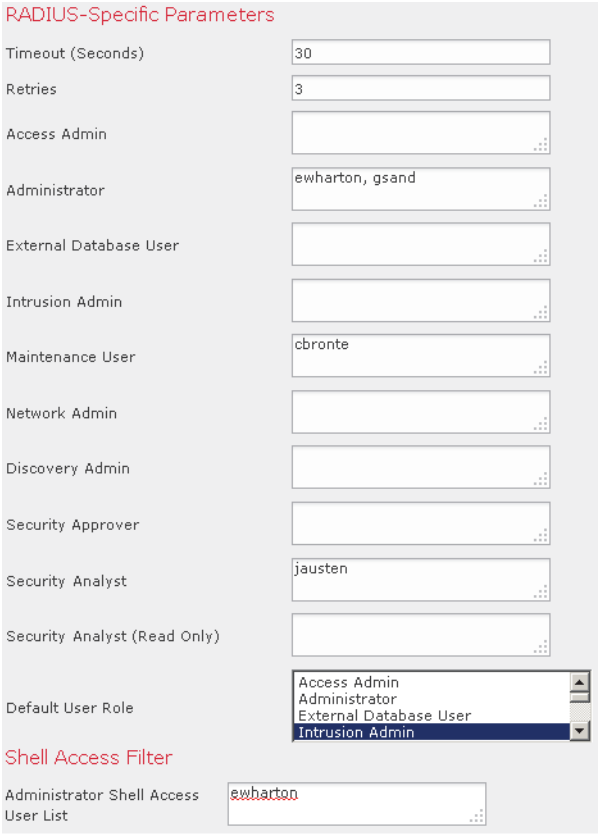
LICENSE: Any

The following figure illustrates a sample RADIUS login authentication object for a server running FreeRADIUS with an IP address of 10.10.10.98. Note that the connection uses port 1812 for access, and note that connections to the server time out after 30 seconds of disuse, then retry three times before attempting to connect to a backup authentication server.

This example illustrates important aspects of RADIUS user role configuration:

- Users **ewharton** and **gsand** are granted administrative access to Sourcefire 3D System appliances where this authentication object is enabled.
- The user **cbronte** is granted Maintenance User access to Sourcefire 3D System appliances where this authentication object is enabled.
- The user **jausten** is granted Security Analyst access to Sourcefire 3D System appliances where this authentication object is enabled.
- The user **ewharton** can log into the appliance using a shell account.

The following graphic depicts the role configuration for the example:



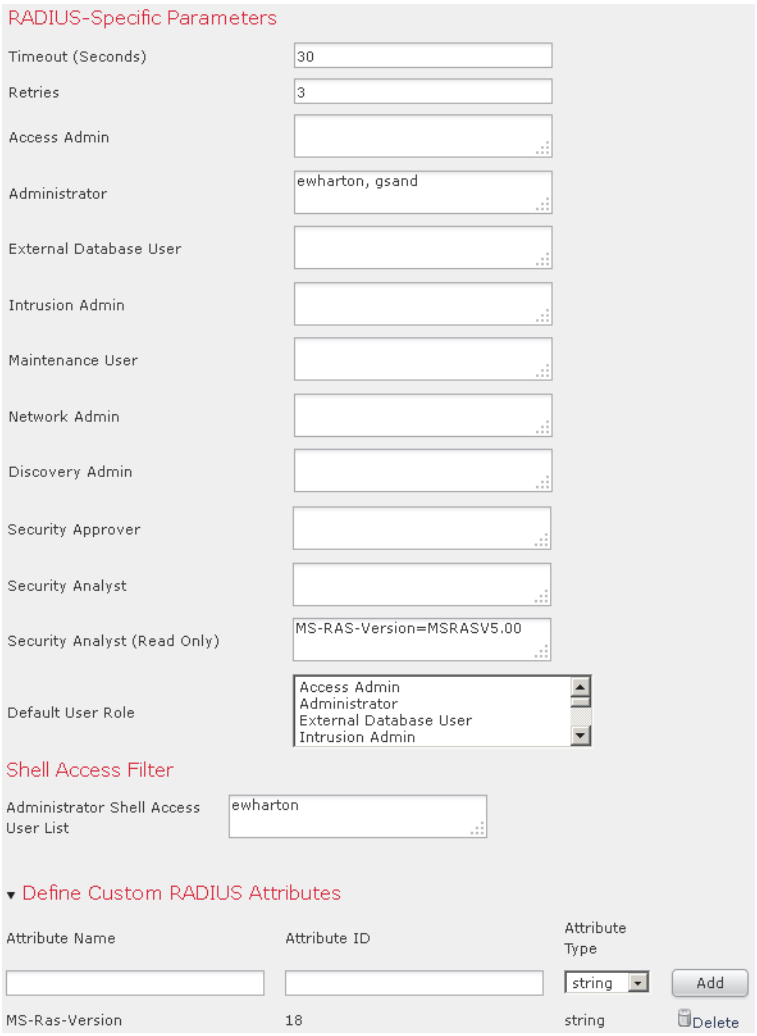
Authenticating a User with Custom Attributes

LICENSE: Any

You can use an attribute-value pair to identify users who should receive a particular user role. If the attribute you use is a custom attribute, you must define the custom attribute.

The following figure illustrates the role configuration and custom attribute definition in a sample RADIUS login authentication object for the same FreeRADIUS server as in the previous example.

In this example, however, the `MS-RAS-Version` custom attribute is returned for one or more of the users because a Microsoft remote access server is in use. Note the `MS-RAS-Version` custom attribute is a string. In this example, all users logging in to RADIUS through a Microsoft v. 5.00 remote access server should receive the Security Analyst (Read Only) role, so you type the attribute-value pair of `MS-RAS-Version=MSRASV5.00` in the **Security Analyst (Read Only)** field.



Editing RADIUS Authentication Objects

LICENSE: Any

You can edit an existing authentication object. If the object is in use in a system policy, the settings in place at the time the policy was applied stay in effect until you reapply the policy.

To edit an authentication object:

Access: Admin

1. Select **System > Local > User Management**.

   The User Management page appears

2. Click the **Login Authentication** tab.

   The Login Authentication page appears.

3. Click the edit icon ( ) next to the object you want to edit.

   The Create Authentication Object page appears.

4. Modify the object settings as needed.

   For more information, see the following topics:

   - Creating RADIUS Authentication Objects on page 1960
   - Configuring RADIUS Connection Settings on page 1961
   - Configuring RADIUS User Roles on page 1963
   - Configuring Administrative Shell Access on page 1966
   - Testing User Authentication on page 1968

5. Click **Save**.

   Your changes are saved and the Login Authentication page reappears. Remember that you have to apply a system policy with the object enabled to an appliance before the authentication changes take place on that appliance. For more information, see Configuring Authentication Profiles on page 2052 and Applying a System Policy on page 2042.

Deleting Authentication Objects

License: Any

You can delete an authentication object if it is not currently enabled in a system policy.

To delete an authentication object:

Access: Admin

1. Select **System > Local > User Management**.

   The User Management page appears

2. Click the **Login Authentication** tab.

   The Login Authentication page appears.

3. Click the delete icon ( ) next to the object you want to delete.

   The object is deleted and the Login Authentication page appears.

Managing User Accounts

LICENSE: Any

If you have Administrator access, you can use the web interface to view and manage user accounts on a Defense Center or a managed device, including adding, modifying, and deleting accounts. You can also create and modify custom user roles and configure user role escalation. User accounts without Administrator access are restricted from accessing management features. The navigation menu differs in appearance for each type of user.

See the following sections for more information about managing user accounts:

- Viewing User Accounts on page 1973 explains how to access the User Management page, where you can add, activate, deactivate, edit, and delete user accounts.
- Adding New User Accounts on page 1974 describes the different options you can use when you add a new user account.
- Managing Externally Authenticated User Accounts on page 1978 explains how externally authenticated users are added and what aspects of the user configuration you can manage within the Sourcefire 3D System.
- Modifying User Privileges and Options on page 1988 explains how to access and modify an existing user account.
- Understanding Restricted User Access Properties on page 1988 explains how to restrict the data available to a user account with restricted data access.
- Deleting User Accounts on page 1990 explains how to delete user accounts.
- User Account Privileges on page 1990 contains tables that list the menus and options each type of user account can access.

Viewing User Accounts

LICENSE: Any

From the User Management page, you can view, edit, and delete existing accounts. You can view the type of authentication for a user from the **Authentication Method** column. The **Password Lifetime** column indicates the days remaining on each user's password. The icons in the **Action** column allow you to edit users in more detail and set users active or inactive. Note that for externally authenticated users, if the authentication object for the server is disabled, the **Authentication Method** column displays **External (Disabled)**.

To access the User Management page:

ACCESS: Admin

▶ Select **System > Local > User Management**.

The User Management page appears, showing each user, with options to activate, deactivate, edit, or delete the user account.

See the following sections for information about the actions you can perform on the User Management page:

- Adding New User Accounts on page 1974
- Configuring User Roles on page 1981
- Modifying User Privileges and Options on page 1988
- Understanding Restricted User Access Properties on page 1988
- Modifying User Passwords on page 1989
- Deleting User Accounts on page 1990

Adding New User Accounts

LICENSE: Any
SUPPORTED DEVICES: feature dependent

When you set up a new user account, you can control which parts of the system the account can access. You can set password expiration and strength settings for the user account during creation. For a local account on a Series 3 device, you can also configure the level of command line access the user will have.

To add a new user:

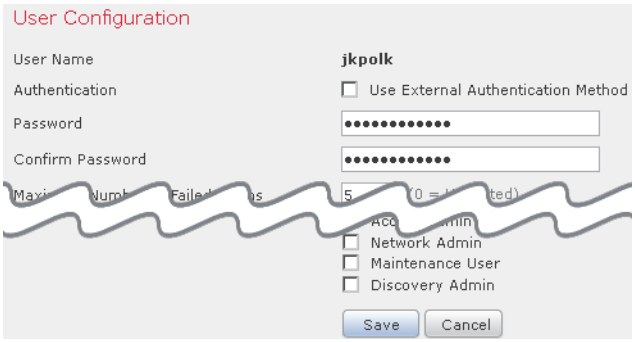
ACCESS: Admin

1. Select **System > Local > User Management**.

   The User Management page appears.

2. Click **Create User**.

   The Create User page appears.



3. In the **User Name** field, type a name for the new user.

   New user names must contain alphanumeric or hyphen characters with no spaces, and must be no more than 32 characters. User names are case sensitive.

4. If you want this user to authenticate to an external directory server on login, select **Use External Authentication Method**.

   If you enable this option, the password management options disappear. Skip to step 8 to continue with configuring an access role for the user.

   Note that for users to authenticate to an external directory server, you must use the Defense Center to create an authentication object for the server you want to use, then apply a system policy with authentication enabled. In addition, the external authentication server must be available in order for those users to log into Sourcefire 3D System appliances. For more information, see Managing Authentication Objects on page 1928 and Configuring Authentication Profiles on page 2052.

5. In the **Password** and **Confirm Password** fields, type a password (up to 32 alphanumeric characters).

   If you enable password strength checking, the password must be at least eight alphanumeric characters of mixed case and must include at least one numeric character and one special character. It cannot be a word that appears in a dictionary or include consecutive repeating characters.

   IMPORTANT! If you enable STIG compliance on an appliance, see the *Sourcefire 3D System STIG Release Notes* for Version 5.3 for more information on password settings for shell access users.

6. Configure the remaining user account login options.

   For more information, see the User Account Login Options table on page 1980.

7. If you are creating a local user through the web interface of a Series 3 device, you can assign the level of **Command-Line Interface Access** for the user:

   - Select **None** to disable access to the command line for the user.
   - Select **Basic** to allow the user to log into the shell and to access a specific subset of commands.
   - Select **Configuration** to allow the user to log into the shell and use any command line option, including expert mode if that is allowed on the appliance.

     For more information on command line access, see Managing Command Line Access on page 1976.

8. Select access roles to grant to the user.

IMPORTANT! For all physical managed devices, the Sourcefire-provided predefined user roles are limited to Administrator, Maintenance User, and Security Analyst.

For more information, see Configuring User Roles on page 1981.

9. Click **Save**.

The user is created and the User Management page appears again.

TIP! Click the slider next to the name of an internally authenticated user on the User Management page to reactivate a deactivated user, or to disable an active user account without deleting it.

Managing Command Line Access

LICENSE: Any
SUPPORTED DEVICES: Series 3, virtual

On a Series 3 or virtual device, you can assign command line interface access to local device users.

Note that you can also assign command line access for users on a virtual device, but you use commands from the command line interface. For more information, see Command Line Reference on page 2324.

The commands a user can run depend on the level of access you assign to the user. When you set **Command-Line Interface Access** to **None**, the user cannot log into the appliance on the command line. Any session the user starts will close when the user provides credentials. The access level defaults to **None** on user creation. When you set **Command-Line Interface Access** to **Basic**, a specific set of commands can be run by the user

Basic Command Line Commands

configure password	interfaces
end	lcd
exit	link-state
help	log-ips-connection
history	managers
logout	memory

Basic Command Line Commands (Continued)

?	model
??	mpls-depth
access-control-config	NAT
alarms	network
arp-tables	network-modules
audit-log	ntp
bypass	perfstats
clustering	portstats
cpu	power-supply-status
database	process-tree
device-settings	processes
disk	routing-table
disk-manager	serial-number
dns	stacking
expert	summary
fan-status	time
fastpath-rules	traffic-statistics
gui	version
hostname	virtual-routers
hyperthreading	virtual-switches
inline-sets	

When you set **Command-Line Interface Access** to **Configuration**, the user can access any of the command line options. Exercise caution in assigning this level of access to users.

WARNING! Shell access granted to externally authenticated users defaults to the **Configuration** level of command line access, granting rights to all command line utilities. For more information on shell access for externally authenticated users, see Setting up Shell Access on page 1932, Configuring Administrative Shell Access on page 1952, and Configuring Administrative Shell Access on page 1966.

Managing Externally Authenticated User Accounts

LICENSE: Any

When an externally authenticated user logs into an appliance that has external authentication enabled, the appliance grants the user the default access role you set by specifying group membership in the authentication object. If you did not configure access group settings, the appliance grants the default user role you set in the system policy. However, if you add users locally before they log into the appliance, the user privileges you configure on the User Management page override the default settings.

An internally authenticated user is converted to external authentication when all of the following conditions exist:

- You enable LDAP or RADIUS authentication.
- The same user name exists for the user on the LDAP or RADIUS server.
- The user logs in using the password stored for that user on the LDAP or RADIUS server.

For more information on selecting a default user role, see Configuring Authentication Profiles on page 2052 and Understanding User Privileges on page 1926. Note that you can set both predefined and custom user roles as the default user role for externally authenticated users. For more information, see Configuring User Roles on page 1981.

Note that you can only enable external authentication in a system policy on a Defense Center. You must use the Defense Center to apply the policy to managed devices if you want to use external authentication on them.

For more information on modifying user access, see Modifying User Privileges and Options on page 1988. Note that you cannot manage passwords for externally authenticated users or deactivate externally authenticated users through the Sourcefire 3D System interface. For externally authenticated users, you cannot remove the minimum access rights through the Sourcefire 3D System user management page for users assigned an access role because of LDAP group or RADIUS list membership or attribute values. On the Edit User page for an externally authenticated user, rights granted because of settings on an external authentication server are marked with a status of **Externally Modified**.

You can, however, assign additional rights. When you modify the access rights for an externally authenticated user, the Authentication Method column on the User Management page provides a status of **External - Locally Modified**.

Shell users can log in using user names with lowercase, uppercase, or mixed case letters. Login authentication for the shell is case sensitive.

WARNING! On Series 3 Defense Centers, all shell users have `sudoers` privileges. Make sure that you restrict the list of users with shell access appropriately. On Series 3 and virtual devices, shell access granted to externally authenticated users defaults to the **Configuration** level of command line access, which also grants `sudoers` privileges. For more information on setting up shell access, see Setting up Shell Access on page 1932, Configuring Administrative Shell Access on page 1952, and Configuring Administrative Shell Access on page 1966.

Managing User Login Settings

LICENSE: Any

You can control how and when the password for each user account is changed, as well as when user accounts are disabled. If you configured a timeout for web interface login sessions, you can exempt users from this timeout. The User Account Login Options table describes some of the options you can use to regulate passwords and account access.

Note that for locally authenticated users on Series 3 managed devices, changing a user's password for the web interface also changes that password for the command line interface.

If you enable the **Check Password Strength** option, the minimum password length is automatically set to 8 characters. If you also set a value for **Minimum Password Length** that exceeds 8 characters, the higher value applies.

IMPORTANT! After you enable **Use External Authentication Method**, login options no longer appear. Use the external authentication server to manage login settings.

User Account Login Options

Option	Description
Use External Authentication Method	Select this check box if you want this user's credentials to be externally authenticated. **IMPORTANT!** If you select this option for the user and the external authentication server is unavailable, that user can log into the web interface but cannot access any functionality.
Maximum Number of Failed Logins	Enter an integer, without spaces, that determines the maximum number of times each user can try to log in after a failed login attempt before the account is locked. The default setting is five tries; use 0 to allow an unlimited number of failed logins.
Minimum Password Length	Enter an integer, without spaces, that determines the minimum required length, in characters, of a user's password. The default setting is 8. A value of 0 indicates that no minimum length is required.
Days Until Password Expiration	Enter the number of days after which the user's password expires. The default setting is 0, which indicates that the password never expires.
Days Before Password Expiration Warning	Enter the number of warning days users have to change their password before their password actually expires. The default setting is 0 days. **WARNING!** The number of warning days must be **less than** the number of days before the password expires.
Force Password Reset on Login	Select this option to force users to change their passwords the first time they log in.

User Account Login Options (Continued)

Option	Description
Check Password Strength	Select this option to require strong passwords. A strong password must be at least eight alphanumeric characters of mixed case and must include at least one numeric character and one special character. It cannot be a word that appears in a dictionary or include consecutive repeating characters.
Exempt from Browser Session Timeout	Select this option if you do not want a user's login sessions to terminate due to inactivity. Users with the Administrator role cannot be made exempt. For more information on session timeouts, see Configuring User Interface Settings on page 2073.

Configuring User Roles

License: Any

Each Sourcefire 3D System user has an associated user access role or roles. For example, an analyst needs access to event data to analyze the security of your network, but might not require access to administrative functions for the Sourcefire 3D System itself. Using user roles, you can, for example, grant Security Analyst access to analysts while reserving the Administrator role for the user or users managing the Sourcefire 3D System. The Sourcefire 3D System includes ten predefined user roles designed for a variety of administrators and analysts. You can also create custom user roles with specialized access privileges.

The menus and other options in the web interface that users can access depend on their roles. Predefined user roles have a set of predetermined access privileges, while custom user roles have granular access privileges that their creator determines.

You configure user roles on the User Roles page.

To access the User Roles page:

Access: Admin

1. Select **System > Local > User Management**.

   The User Management page appears.

2. Click the **User Roles** tab.

   The User Roles page appears, showing all predefined and custom user roles, with options to activate, deactivate, edit, copy, delete, and export roles.

For more information on configuring the two types of user roles, see the following sections:

- Managing Predefined User Roles on page 1982
- Managing Custom User Roles on page 1984
- Creating a Custom Copy of a Predefined User Role on page 1987
- Deleting a Custom User Role on page 1987

Managing Predefined User Roles

LICENSE: Any

The Sourcefire 3D System includes ten predefined user roles that provide a range of access privilege sets to meet the needs of your organization. On the User Roles page, predefined user roles are labeled "Sourcefire Provided". Note that managed devices have access to only three of the ten predefined user roles: Administrator, Maintenance User, and Security Analyst.

Although you cannot edit predefined user roles, you can use their access privilege sets as the basis for custom user roles. For information on creating and editing custom user roles, see Managing Custom User Roles on page 1984. In addition, because you cannot edit predefined user roles, you cannot configure them to escalate to another user role. For more information, see Managing User Role Escalation on page 2002.

The Predefined User Roles table briefly describes the predefined roles available to you. For a list of the menus and options available to each role, see User Account Privileges on page 1990.

Predefined User Roles

USER ROLE	PRIVILEGES
Access Admin	Provides access to access control policy features. Note, however, that Access Admins cannot apply access control policies. Access Admins have access to access control-related options in the **Policies** menu.
Administrator	Provides access to analysis and reporting features, rule and policy configuration, system management, and all maintenance features. Administrators have access to all menu options; their sessions present a higher security risk if compromised, so you cannot make them exempt from login session timeouts. Note that you should limit use of the Administrator role for security reasons. This role is also available on managed devices.
Discovery Admin	Provides access to network discovery, correlation, and user activity features. Discovery Admins have access to relevant options in the **Policies** menu.

Predefined User Roles (Continued)

User Role	Privileges
External Database User	Provides read-only access to the Sourcefire 3D System database using an application that supports JDBC SSL connections. Note that for the third-party application to authenticate to the Sourcefire 3D System appliance, you must enable database access in the system settings as described in Enabling Access to the Database on page 2086. On the web interface, External Database Users have access only to online help-related options in the **Help** menu. Because this role's function does not involve the web interface, access is provided only for ease of support and password changes.
Intrusion Admin	Provides access to all intrusion policy and intrusion rule features. Intrusion Admins have access to intrusion-related options in the **Policies** menu. Note that Intrusion Admins cannot apply intrusion policies as part of access control policies.
Maintenance User	Provides access to monitoring and maintenance features. Maintenance Users have access to maintenance-related options in the **Health** and **System** menus. This role is also available on managed devices.
Network Admin	Provides access to access control and device configuration features. Network Admins have access to access control and device-related options in the **Policies** and **Devices** menus.
Security Approver	Provides limited access to access control policies. Security Approvers can view and apply intrusion and access control policies, but cannot make policy changes. They have access to applicable policy-related options in the **Policies** menu.
Security Analyst	Provides access to security event analysis features, including event views, reports, hosts, host attributes, services, vulnerabilities, client applications, and read-only access to health events. Security Analysts have access to analysis-related options in the **Overview**, **Analysis**, **Health**, and **System** menus. This role is also available on managed devices.
Security Analyst (Read Only)	Provides read-only access to security event analysis features, including event views, reports, hosts, host attributes, services, vulnerabilities, client applications, and health events. Security Analysts have access to analysis-related options in the **Overview**, **Analysis**, **Health**, and **System** menus.

Along with assigning an event analyst role to a user, you can restrict that user's deletion rights to only allow deletion of report profiles, searches, bookmarks, custom tables, and custom workflows created by that user. For more information, see Adding New User Accounts on page 1974.

Note that externally authenticated users, if assigned no other roles, have minimum access rights based on the settings in LDAP or RADIUS authentication objects and in the system policy. You can assign additional rights to these users,

but to remove or change minimum access rights, you must perform the following tasks:

- Move the user from one list to another in the authentication object or change the user's attribute value or group membership on the external authentication server.
- Reapply the system policy.
- Use the User Management page to remove the access from that user account.

You cannot delete predefined user roles, but you can deactivate them. Deactivating a role removes that role and all associated permissions from any user who is assigned that role.

WARNING! If a deactivated role is the only role assigned to a given user, that user can log in and access the User Preferences menu, but is otherwise unable to access the Sourcefire 3D System.

To activate or deactivate a user role:

Access: Admin

1. Select **System > Local > User Management**.

   The User Management page appears.

2. Click the **User Roles** tab.

   The User Roles page appears.

3. Click the slider next to the user role you want to activate or deactivate.

IMPORTANT! If you deactivate, then reactivate, a role with Lights-Out Management while a user with that role is logged in, or restore a user or user role from a backup during that user's login session, that user must log back into the web interface to regain access to IPMItool commands. For more information, see Using Lights-Out Management on page 2111.

Managing Custom User Roles

License: Any

In addition to the predefined user roles, you can also create custom user roles with specialized access privileges. Custom user roles can have any set of menu-based and system permissions, and may be completely original or based on a predefined user role. Like predefined user roles, custom roles can serve as the default role for externally authenticated users. Unlike predefined roles, you can modify and delete custom roles.

Selectable permissions are hierarchical, and are based on the Sourcefire 3D System menu layout. Permissions are expandable if they have sub-pages or if they have more fine-grained permissions available beyond simple page access. In that case, the parent permission grants page view access and the children granular access to related features of that page. For example, the Correlation Events permission grants access to the Correlation Events page, while the Modify Correlation Events check box allows the user to edit and delete the information available on that page. Permissions that contain the word "Manage" grant the ability to edit and delete information that other users create.

You can apply restricted searches to a custom user role. These constrain the data a user may see in the event viewer. You can configure a restricted search by first creating a private saved search and selecting it from the "Restricted Search" drop-down menu under the appropriate menu-based permission. For more information, see Performing a Search on page 1843.

When you configure a custom user role on a Defense Center, all menu-based permissions are available for you to grant. When you configure a custom user role on a managed device, only some permissions are available — those relevant to device functions. For more information on the menu-based permissions you can configure and their relationship with predefined user roles, see:

- Analysis Menu on page 1992
- Policies Menu on page 1996
- Devices Menu on page 1998
- Object Manager on page 1999
- Health Menu on page 1999
- System Menu on page 2000
- Help Menu on page 2002

The selectable options under System Permissions allow you to create a user role that can make queries to the external database or escalate to the permissions of a target user role. For more information, see Enabling Access to the Database on page 2086 and Managing User Role Escalation on page 2002.

Optionally, instead of creating a new custom user role, you can export a custom user role from another appliance, then import it onto your appliance. You can then edit the imported role to suit your needs before you apply it. For more information, see Exporting Configurations on page 2309 and Importing Configurations on page 2314.

To create a custom user role:

Access: Admin

1. Select **System > Local > User Management**.

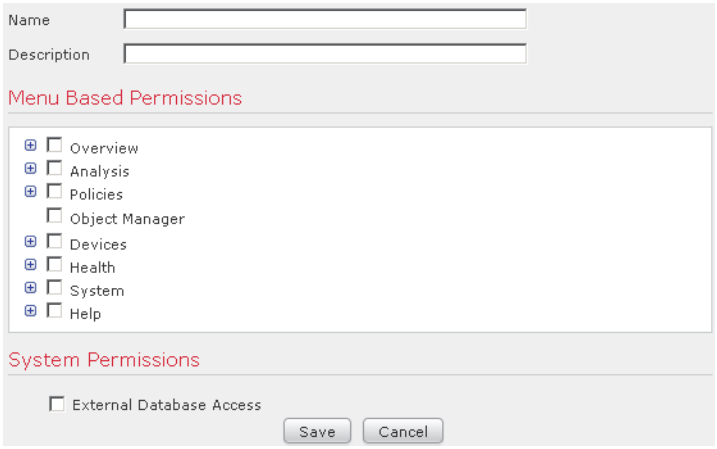
   The User Management page appears.

2. Click the **User Roles** tab.

   The User Roles page appears.

3. Click **Create User Role**.

   The User Role Editor page appears.



4. In the **Name** field, type a name for the new user role.

   You can use alphanumeric or hyphen characters, without spaces. Role names must be no more than 75 characters. User role names are case sensitive.

5. Optionally, add a description for the new role in the **Description** field.

   Role descriptions must be no more than 255 characters.

6. Select permissions for the new role.

   When you select an unselected permission, all of its children are selected, and the multi-value permissions choose the first value. If you deselect a high-level permission, all of its children are deselected also. Selected permissions without all children selected appear in italic text.

   Note that choosing to copy a predefined user role to use as the base for your custom role preselects the permissions associated with that predefined role. For more information on copying predefined user roles, see Creating a Custom Copy of a Predefined User Role on page 1987.

   The current escalation target role is listed beside the role escalation check box. If you select this check box, you can then choose to authenticate escalations either with the assigned user's password or with the password of another specified user role. For more information, see Managing User Role Escalation on page 2002.

7. Click **Save**.

   The custom user role is created and the User Roles page appears again.

Creating a Custom Copy of a Predefined User Role

License: Any

You can copy an existing role to use as the basis for a new custom role. This preselects the existing role's permissions in the User Role Editor so you can model one role on another.

To create a custom copy of a predefined user role:

Access: Admin

1. Select **System > Local > User Management**.

   The User Management page appears.

2. Click the **User Roles** tab.

   The User Roles page appears.

3. Click the copy icon ( ) next to the user role you want to copy.

   The User Role Editor page appears with the copied role's permissions preselected.

   Note that you can copy both custom and predefined user roles in this way.

Deleting a Custom User Role

License: Any

Unlike predefined user roles, you can delete custom roles that are no longer necessary. If you want to disable a custom role without removing it entirely, you can deactivate it instead; for more information, refer to the procedure in Managing Predefined User Roles on page 1982. Note that you cannot delete your own user role or a role that is set as a default user role in the system policy. For more information, see Configuring Authentication Profiles on page 2052.

To delete a custom user role:

Access: Admin

1. Select **System > Local > User Management**.

   The User Management page appears.

2. Click the **User Roles** tab.

   The User Roles page appears.

3. Click the delete icon ( ) next to the custom role you want to delete.

   The custom role is deleted.

   If a deleted role is the only role assigned to a given user, that user can log in and access the User Preferences menu, but is otherwise unable to access the Sourcefire 3D System.

Modifying User Privileges and Options

LICENSE: Any

After adding user accounts to the system, you can modify access privileges, account options, or passwords at any time. Note that password management options do not apply to users who authenticate to an external directory server. You manage those settings on the external server. However, you must configure access rights for all accounts, including those that are externally authenticated.

For externally authenticated users, you cannot remove the minimum access rights through the Sourcefire 3D System user management page for users assigned an access role because of LDAP group or RADIUS list membership or attribute values. You can, however, assign additional rights. When you modify the access rights for an externally authenticated user, the Authentication Method column on the User Management page provides a status of **External - Locally Modified**.

Note that if you change the authentication for a user from externally authenticated to internally authenticated, you must supply a new password for the user.

To modify user account privileges:

ACCESS: Admin

1. Select **System > Local > User Management**.

   The User Management page appears.

2. Click the edit icon ( ) next to the user you want to modify.

   The Edit User page appears.

3. Modify the account or accounts as needed:
   - See Managing Externally Authenticated User Accounts on page 1978 for a description of how users can be authenticated through external servers.
   - See Managing User Login Settings on page 1979 for information on changing password settings for internally authenticated users.
   - See Configuring User Roles on page 1981 for more information on configuring roles to grant access for Sourcefire 3D System functions.

Understanding Restricted User Access Properties

LICENSE: Any

You can restrict the data that a user role can view in the event viewer by applying a restricted search to that role. You can specify this information when creating or editing the role assigned to a user. To create a custom role with restricted access, you must choose the tables you want to restrict from the Menu Based Permissions list, then select private saved searches from the Restrictive Search drop-down lists. For more information, see Managing Custom User Roles on page 1984.

Modifying User Passwords

LICENSE: Any

You can modify user passwords from the User Management page for internally authenticated users. Note that you must manage externally authenticated user passwords on the LDAP or RADIUS server.

IMPORTANT! If you enable STIG compliance or Lights-Out Management (LOM) on an appliance, different password restrictions apply. For more information on password settings for shell access users on systems with STIG compliance enabled, see the FireSIGHT*Sourcefire 3D System STIG Release Notes* for Version 5.3. For more information on password settings for the system password for LOM users, see Enabling Lights-Out Management User Access on page 2108.

To change a user's password:

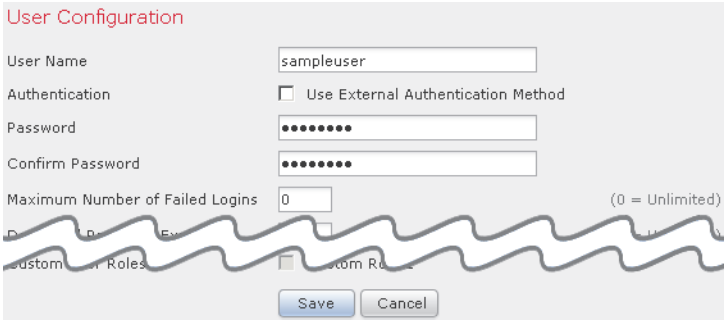
ACCESS: Admin

1. Select **System > Local > User Management**.

   The User Management page appears.

2. Next to the user name, click the edit icon ( ).

   The User Configuration page appears.



3. In the **Password** field, type the new password (up to 32 alphanumeric characters).
4. In the **Confirm Password** field, retype the new password.

   If password strength checking is enabled for the user account, the password must have at least eight alphanumeric characters of mixed case, with at least one number and one special character. It cannot be a word that appears in a dictionary or contain consecutive repeating characters.

5. Make any other changes you want to make to the user configuration:
   - For more information on password options, see Managing User Login Settings on page 1979.
   - For more information on user roles, see Configuring User Roles on page 1981.
6. Click **Save**.

   The password is changed and any other changes saved.

Deleting User Accounts

LICENSE: Any

You can delete user accounts from the system at any time, with the exception of the admin account, which cannot be deleted.

To delete a user account:

ACCESS: Admin

1. Select **System > Local > User Management**.

   The User Management page appears.
2. Next to the user whose account you want to delete, click the delete icon ( ). The account is deleted.

User Account Privileges

LICENSE: Any

The following sections provide a list of the configurable user permissions in the Sourcefire 3D System and the user roles that can access them. The permissions listed here follow the order of the Menu Based Permissions list that appears when you create a custom user role. Not all permissions are available on managed devices; permissions available only on the Defense Center are marked accordingly. For more information, see Managing Custom User Roles on page 1984.

Note that because the DC500 Defense Center and Series 2 devices support restricted features sets, not all permissions are applicable to these appliances. See the Supported Capabilities by Managed Device Model table on page 46 for a summary of Series 2 appliance features.

For more information on the access notations used in the tables that follow and throughout this documentation, see Access Conventions on page 62. The following sections refer to the user role privileges associated with each main menu in the web-based interface:

- Overview Menu on page 1991
- Analysis Menu on page 1992
- Policies Menu on page 1996

- Devices Menu on page 1998
- FireAMP on page 1999
- Devices Menu on page 1998
- Health Menu on page 1999
- System Menu on page 2000
- Help Menu on page 2002

Overview Menu

LICENSE: Any

The Overview Menu table lists, in order, the user role privileges required to access each option in the Overview menu and whether the user role has access to the sub-permissions within. The Security Approver, Discovery Admin, Intrusion Admin, Access Admin, Network Admin, and External Database User roles have no permissions in the Overview menu.

Help Menu

License: Any

The Help menu and its permissions are accessible to all user roles. You cannot restrict Help menu options.

Managing User Role Escalation

License: Any

You can give custom user roles the permission, with a password, to temporarily gain the privileges of another, targeted user role in addition to those of the base role. This allows you to easily substitute one user for another during an absence, or to more closely track the use of advanced user privileges.

For example, a user whose base role has very limited privileges may escalate to the Administrator role to perform administrative actions. You can configure this feature so that users can use their own passwords, or so they use the password of another user that you specify. The second option allows you to easily manage one escalation password for all applicable users. For more information, see Configuring a Custom User Role for Escalation on page 2003.

Note that only one user role at a time can be the escalation target role. You can use a custom or predefined user role. Each escalation lasts for the duration of a login session and is recorded in the audit log.

For more information on configuring and using this feature, please see the following sections:

- Configuring the Escalation Target Role on page 2003
- Configuring a Custom User Role for Escalation on page 2003
- Escalating Your User Role on page 2005

Configuring the Escalation Target Role

LICENSE: Any

You can assign any of your user roles, predefined or custom, to act as the system-wide escalation target role. This is the role to which any other role may escalate, if it has the ability.

To configure the escalation target role:

ACCESS: Admin

1. Select **System > Local > User Management**.

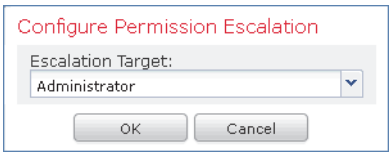
   The User Management page appears.

2. Click **User Roles**.

   The User Roles page appears.

3. Click **Configure Permission Escalation**.

   The Configure Permission Escalation dialog box appears.



4. Select a user role from the drop-down list.

5. Click **OK** to save your changes.

   Your changes are saved and the User Roles page appears.

IMPORTANT! Changing the escalation target role is effective immediately. Users in escalated sessions now have the permissions of the new escalation target.

Configuring a Custom User Role for Escalation

LICENSE: Any

To use the user role escalation feature, you must first configure a custom user role with the escalation permission, select its escalation password, and assign that role to a user. For more information, see Adding New User Accounts on page 1974 and Configuring User Roles on page 1981.

Consider the needs of your organization when you configure the escalation password for a custom role. If you want to easily manage many escalating users, you may want to select another user whose password serves as the escalation password. If you change that user's password or deactivate that user, all escalating users who require that password are affected. This allows you to manage user role escalation more efficiently, especially if you select an externally authenticated user that you can manage centrally.

To configure a custom user role for escalation:

Access: Admin

1. Select **System > Local > User Management**.

   The User Management page appears.

2. Click **User Roles**.

   The User Roles page appears.

3. Click **Create User Role** to create a new custom user role, or the edit icon ( ) next to an existing custom user role.

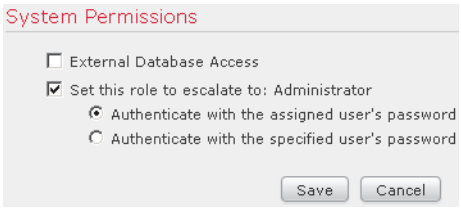
   The User Role Editor page appears.

4. Choose a name, description and menu-based permissions for the custom user role.

   For more information, see the procedure in Managing Custom User Roles on page 1984.

5. In System Permissions, select the **Set this role to escalate to:** check box.

   The escalation password options appear.



6. Select the password that this role uses to escalate. You have two options:
   - If you want users with this role to use their own passwords when they escalate, select **Authenticate with the assigned user's password**.
   - If you want users with this role to use the password of another user, select **Authenticate with the specified user's password** and type that username.

IMPORTANT! When authenticating with another user's password, you can enter any username, even that of a deactivated or nonexistent user. Deactivating the user whose password is used for escalation makes escalation impossible for users with the role that requires it. You can use this feature to quickly remove escalation powers if necessary.

7. Click **Save**.

   Your changes are saved and the User Roles page appears again. Users with this role can now escalate to the target user role. For more information on assigning roles to a user, see Adding New User Accounts on page 1974.

Escalating Your User Role

LICENSE: Any

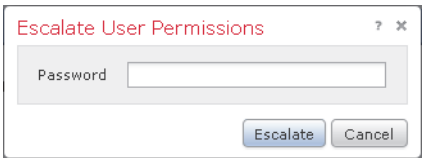
When a user has an assigned custom user role with permission to escalate, that user may escalate to the target role's permissions at any time. Note that escalation has no effect on user preferences. The **Escalate Permissions** option in the User menu does not appear if your assigned user role is not configured for user role escalation.

To escalate user permissions:

ACCESS: Any

1. Select **Local > User > Escalate Permissions**.

   The Escalate User Permissions dialog box appears.



2. Enter the authentication password.
3. Click **Escalate**.

   You now have all permissions of the escalation target role in addition to your current role.

   Note that escalation lasts for the remainder of your login session. To return to the privileges of your base role only, you must log out, then begin a new session.

CHAPTER 47
SCHEDULING TASKS

You can schedule many different types of administrative tasks to run at designated times, either once or on a recurring basis.

IMPORTANT! Some tasks (such as those involving automated software updates or that require pushing updates to managed devices) may place a significant load on networks with low bandwidths. You should schedule tasks like these to run during periods of low network use.

See the following sections for more information:

- Configuring a Recurring Task on page 2007 explains how to set up a scheduled task so that it runs at regular intervals.
- Automating Backup Jobs on page 2009 provides procedures for scheduling backup jobs.
- Automating Certificate Revocation List Downloads on page 2011 provides procedures for automatically refreshing the certificate revocation list (CRL) for an appliance.
- Automating Nmap Scans on page 2013 provides procedures for scheduling Nmap scans.
- Automating Applying an Intrusion Policy on page 2015 provides procedures for queueing an intrusion policy apply on managed devices.
- Automating Reports on page 2017 provides procedures for scheduling reports.

- Automating Geolocation Database Updates on page 2019 provides procedures for scheduling automatic updates of the geolocation database (GeoDB).
- Automating FireSIGHT Recommendations on page 2020 provides procedures for scheduling the automatic update of intrusion rule state recommendations.
- Automating Software Updates on page 2022 provides procedures for scheduling the download, push, and installation of software updates.
- Automating Vulnerability Database Updates on page 2028 provides procedures for scheduling the download and installation of VDB updates.
- Automating URL Filtering Updates on page 2032 provides procedures for automating updates of URL filtering data.
- Viewing Tasks on page 2034 describes how to view and manage tasks after they are scheduled.
- Editing Scheduled Tasks on page 2036 describes how to edit an existing task.
- Deleting Scheduled Tasks on page 2036 describes how to delete one-time tasks and all instances of recurring tasks.

Configuring a Recurring Task

LICENSE: Any

You set the frequency for a recurring task using the same process for all types of tasks.

Note that the time displayed on most pages on the web interface is the local time, which is determined by using the time zone you specify in your local configuration. Further, the Defense Center automatically adjusts its local time display for daylight saving time (DST), where appropriate. However, recurring tasks that span the transition dates from DST to standard time and back do not adjust for the transition. That is, if you create a task scheduled for 2:00 AM during standard time, it will run at 3:00 AM during DST. Similarly, if you create a task scheduled for 2:00 AM during DST, it will run at 1:00 AM during standard time.

To configure a recurring task:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

   The Scheduling page appears.

2. Click **Add Task**.

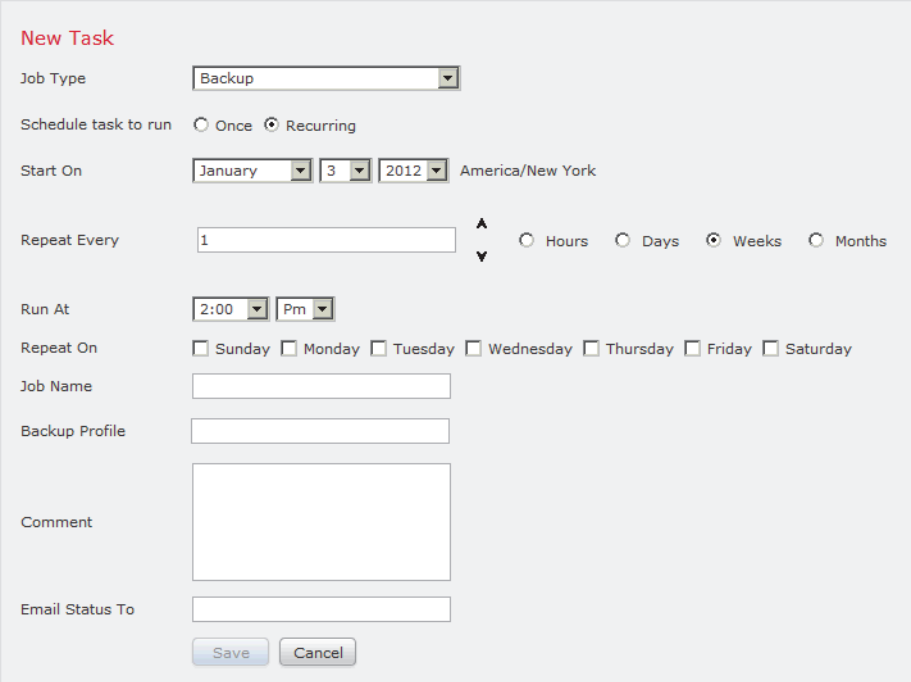
   The New Task page appears.

3. From the **Job Type** list, select the type of task that you want to schedule.

   Each of the types of tasks you can schedule is explained in its own section.

4. For the **Schedule task to run** option, select **Recurring**.

   The page reloads with the recurring task options.



5. In the **Start On** field, specify the date when you want to start your recurring task. You can use the drop-down list to select the month, day, and year.
6. In the **Repeat Every** field, specify how often you want the task to recur. You can specify a number of hours, days, weeks, or months.

   TIP! You can either type a number or click the up icon (▲) and the down (▼) icon to specify the interval. For example, type 2 and select Days to run the task every two days.

7. In the **Run At** field, specify the time when you want to start your recurring task.
8. If you selected `weeks` for **Repeat Every**, a **Repeat On** field appears. Select the check boxes next to the days of the week when you want to run the task.
9. If you selected `Months` for **Repeat Every**, a **Repeat On** field appears. Use the drop-down list to select the day of the month when you want to run the task.

   The remaining options on the New Task page are determined by the task you are creating. See the following sections for more information:

   - Automating Backup Jobs on page 2009
   - Automating Certificate Revocation List Downloads on page 2011

Automating Backup Jobs

LICENSE: Any

You can use the scheduler to automate system backups of a Defense Center or a managed device.

TIP! You must design a backup profile before you can configure it as a scheduled task. For information on backup profiles, see Creating Backup Profiles on page 2290.

To automate backup tasks:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

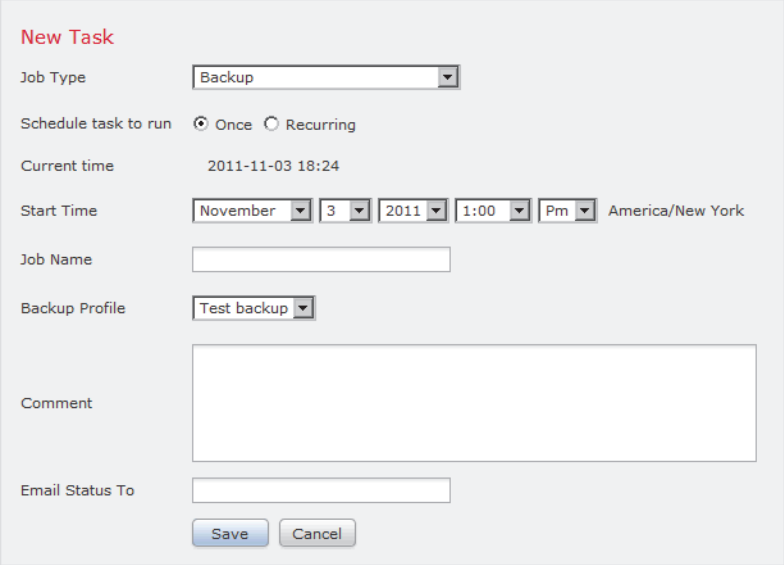
   The Scheduling page appears.

2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **Backup**.

   The page reloads to show the backup options. The Defense Center version of the page is shown below.



4. Specify how you want to schedule the backup, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the appliance.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.
5. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.
6. From the **Backup Profile** list, select the appropriate backup profile.

   For more information on creating new backup profiles, see Creating Backup Profiles on page 2290.
7. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

TIP! The comment field appears in the View Tasks section of the page, so you should try to keep it relatively short.

8. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured on the Defense Center to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.

9. Click **Save**.

   The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Automating Certificate Revocation List Downloads

LICENSE: Any

You can use the scheduler to automatically refresh the certificate revocation list (CRL) for the appliance web server on an appliance where you enable user certificates for the appliance. The Download CRL task is automatically created when you enable fetching of a CRL in the local appliance configuration, so this procedure explains how to open the scheduled task to set the frequency.

TIP! You must enable and configure user certificates and set a CRL download URL before scheduling this task. For information on configuring user certificates, see Configuring User Certificates on page 2085.

To automate download of certificate revocation lists:

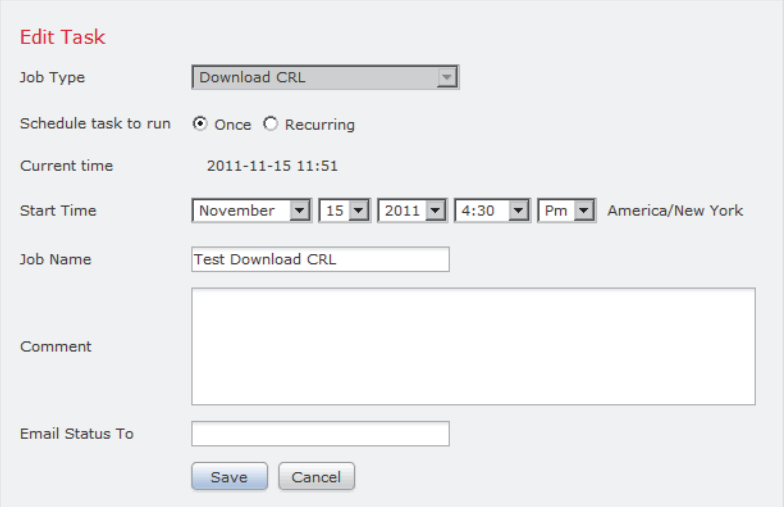
ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

   The Scheduling page appears.

2. Locate the **download CRL** task in the Task Details and click the edit icon ( ).

   The Edit Task page appears, showing the download options. The Defense Center version of the page is shown below.



3. Specify how you want to schedule the CRL download, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the appliance.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.
4. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

   TIP! The comment field appears in the View Tasks section of the page, so you should try to keep it relatively short.

5. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured on the Defense Center to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.
6. Click **Save**.

   The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Automating Nmap Scans

License: FireSIGHT

You can schedule regular Nmap scans of targets on your network. Automated scans allow you to refresh information previously supplied by an Nmap scan. Because the Sourcefire 3D System cannot update Nmap-supplied data, you need to rescan periodically to keep that data up to date. You can also schedule scans to automatically test for unidentified applications or servers on hosts in your network. See the following sections for more information:

- Preparing Your System for an Nmap Scan
- Scheduling an Nmap Scan

Note that a Discovery Administrator can also use an Nmap scan as a remediation. For example, when an operating system conflict occurs on a host, that conflict may trigger an Nmap scan. Running the scan obtains updated operating system information for the host, which resolves the conflict. For more information, see Nmap Scan Remediations on page 1696.

Preparing Your System for an Nmap Scan

License: FireSIGHT

If you have not used the Nmap scanning capability before, you must complete several Nmap configuration steps before defining a scheduled scan. See the following sections for more information:

- Creating an Nmap Scan Instance on page 1774 provides information on setting up an Nmap server connection profile.
- Creating an Nmap Scan Target on page 1776 provides information on setting up a scan target.
- Creating an Nmap Remediation on page 1777 provides information on setting up a remediation definition.

Scheduling an Nmap Scan

License: FireSIGHT

You can schedule a scan of a host or hosts on your network using the Nmap utility.

After Nmap replaces a host's operating system, applications, or servers detected by the system with the results from an Nmap scan, the system no longer updates the information replaced by Nmap for the host. Nmap-supplied service and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, you may want to set up regularly scheduled scans to keep Nmap-supplied operating systems, applications, or servers up to date. If the host is deleted from the network map and re-added, any Nmap scan results are discarded and the system resumes monitoring of all operating system and service data for the host.

To automate Nmap scanning:

Access: Admin/Maint

1. Select **System > Tools > Scheduling**.

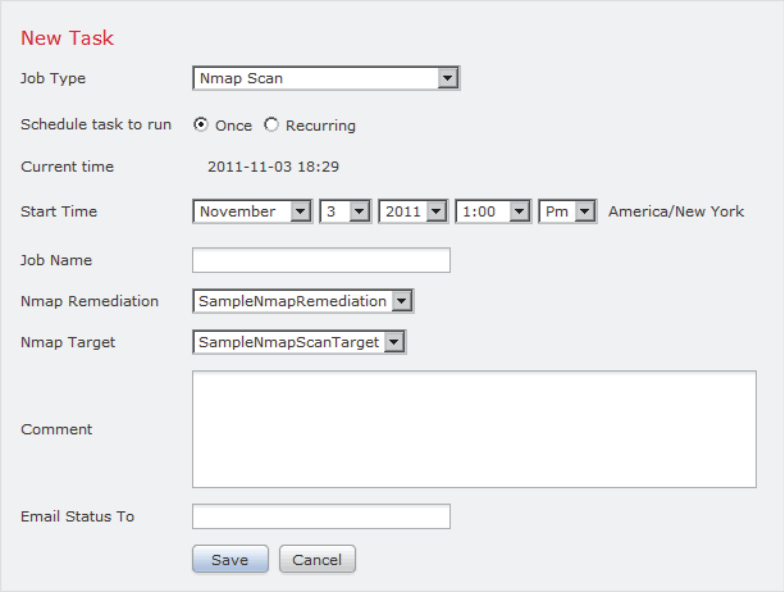
   The Scheduling page appears.

2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **Nmap Scan**.

   The page reloads to show the options for automating Nmap scans.



4. Specify how you want to schedule the task, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the appliance.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.

5. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.

6. In the **Nmap Remediation** field, select the Nmap remediation to use when running the scan.

7. In the **Nmap Target** field, select the scan target that defines the target hosts you want to scan.

8. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

   TIP! The comment field appears in the View Tasks section of the page, so you should try to keep it relatively short.

9. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.

10. Click **Save**.

    The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Automating Applying an Intrusion Policy

LICENSE: Protection

You can queue an intrusion policy apply to a managed device. This task only applies the intrusion policy if an access control policy that references the intrusion policy is applied to the selected device when the task runs. Otherwise, the task aborts before completion.

You must associate an intrusion policy with an access control policy and apply the access control policy to a device before scheduling this task. See the following sections for more information:

- Using Default Intrusion Policies on page 738
- Creating an Intrusion Policy on page 719
- Reapplying an Intrusion Policy on page 726
- Applying an Access Control Policy on page 506

To queue a policy apply to a managed device:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

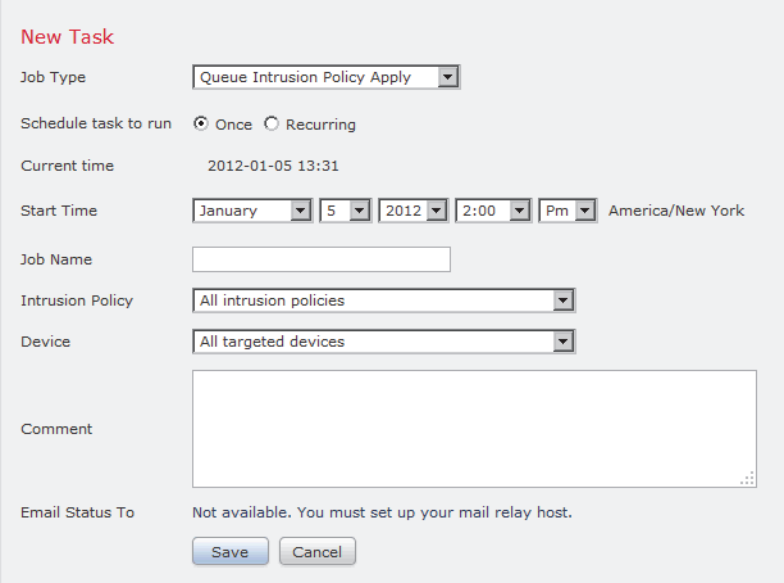
   The schedule calendar page for the current month appears.

2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **Queue Intrusion Policy Apply**.

   The page reloads to show the options for queueing a policy apply.



4. Specify how you want to schedule the task, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the Defense Center.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.
5. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.
6. In the **Intrusion Policy** field, you have the following options:
   - Select an intrusion policy to apply to the selected target device.
   - Select **All intrusion policies** to apply all intrusion policies already applied to the device selected in the **Device** field.
7. In the **Device** field, you have the following options:
   - Select a device to which you want to apply the intrusion policy selected in the **Intrusion Policy** field.
   - Select **All targeted devices** to apply the selected intrusion policy to all monitored devices which already have that intrusion policy applied.

TIP! This field only displays devices which have the intrusion policy selected in the **Intrusion Policy** field already applied.

8. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

   TIP! The comment field appears in the Tasks Details section at the bottom of the schedule calendar page, so you should limit the size of your comment.

9. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.

10. Click **Save**.

    The task is added. You can check the status of a running task in the Task Details section of the calendar page; see Viewing the Status of Long-Running Tasks on page 2321.

11. To edit your saved task, click the task anywhere it appears on the schedule calendar page.

    The Task Details section appears at the bottom of the page. To make any changes, click the edit icon ().

Automating Reports

LICENSE: Any

You can automate reports so that they run at regular intervals. However, you must design a template for your report before you can configure it as a scheduled task. See Understanding Report Templates on page 1805 for more information about using the report designer to create a report template.

IMPORTANT! You **cannot** run remote reports on Sourcefire Software for X-Series.

To automate report generation:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

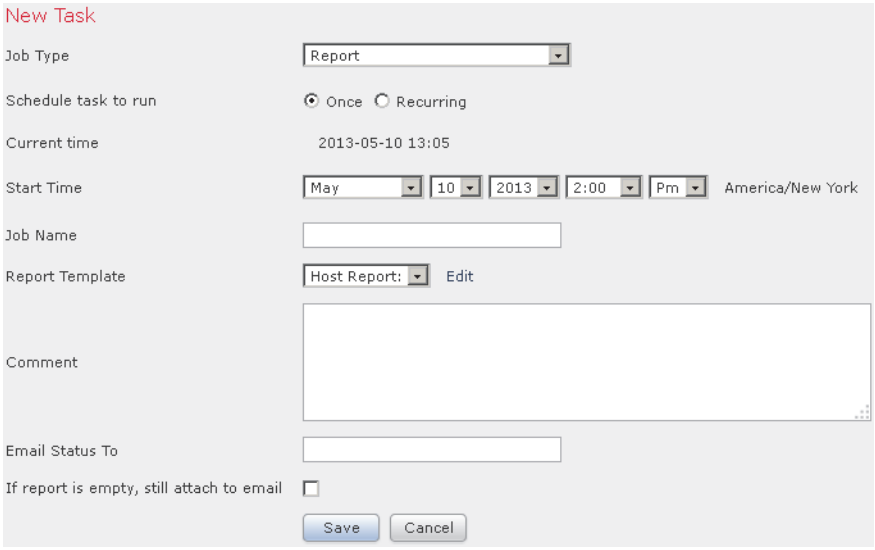
   The schedule calendar page for the current month appears.

2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **Report**.

   The page reloads to show the options for setting up a report to run automatically.



4. Specify how you want to schedule the task, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the Defense Center.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.
5. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.
6. In the **Report Template** field, select the report template that you want to use from the drop-down list.
7. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

   TIP! The comment field appears in the Tasks Details section at the bottom of the schedule calendar page, so you should limit the size of your comment.

8. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.

9. If you do not want to receive report email attachments when reports have no data (for example, when no events of a certain type occurred during the report period), select the **If report is empty, still attach to email** check box.
10. Click **Save**.

    The task is added. You can check the status of a running task in the Task Details section of the calendar page; see Viewing the Status of Long-Running Tasks on page 2321.
11. To edit your saved task, click the task anywhere it appears on the schedule calendar page.

    The Task Details section appears at the bottom of the page. To make any changes, click the edit icon ( ).

Automating Geolocation Database Updates

License: FireSIGHT
Supported Defense Centers: Any except DC500

You can use the scheduler to automate recurring geolocation database (GeoDB) updates. Recurring GeoDB updates run once every 7 days (weekly); you can configure the time the update recurs each week. For more information on GeoDB updates, see Updating the Geolocation Database on page 2174.

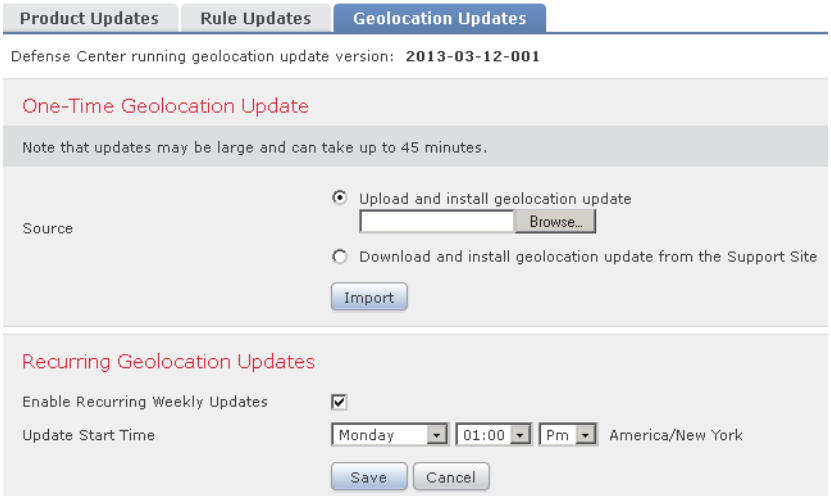
To automate geolocation database updates:

Access: Admin

1. Select **System > Updates**.

   The Product Updates page appears.
2. Click the **Geolocation Updates** tab.

   The Geolocation Updates page appears.



3. Under **Recurring Geolocation Updates**, select the **Enable Recurring Weekly Updates** check box.

   The Update Start Time field appears.

4. In the **Update Start Time** field, specify the time and day of the week when you want weekly GeoDB updates to occur.

5. Click **Save**.

   The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Automating FireSIGHT Recommendations

LICENSE: Protection

You can automatically generate rule state recommendations based on network discovery data for your network using the most recently saved configuration settings in your custom intrusion policy.

IMPORTANT! If the system automatically generates scheduled recommendations for an intrusion policy with unsaved changes, you must discard your changes in that policy and commit the policy if you want the policy to reflect the automatically generated recommendations. See Committing Intrusion Policy Changes on page 725 for more information.

When the task runs, the system automatically generates recommended rule states. Optionally, depending on the configuration of your policy, it also modifies the states of intrusion rules based on the criteria described in Managing FireSIGHT Rule State Recommendations on page 791. Modified rule states take effect the next time you apply your intrusion policy. See Using FireSIGHT Recommendations on page 795 for more information.

To automate rule state recommendation generation:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

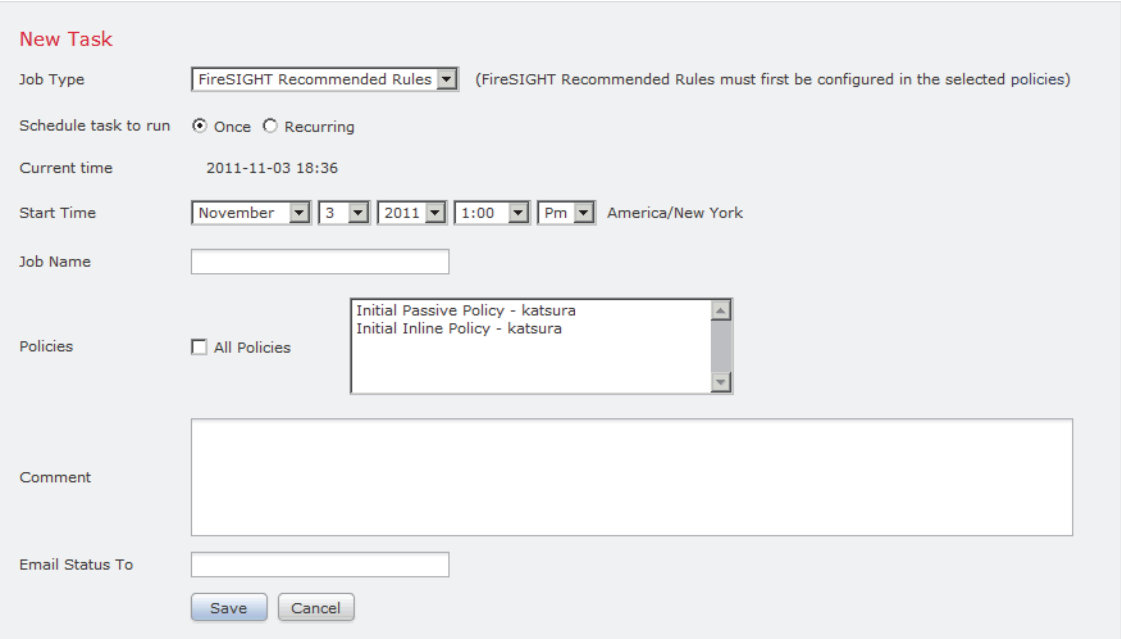
   The Scheduling page appears.

2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **FireSIGHT Recommended Rules**.

   The page reloads to show the options for generating FireSIGHT recommendations.



4. Optionally, click the **policies** link next to the **Job Type** field to display the Detection & Prevention page, where you can configure FireSIGHT Recommended Rules in a policy. See Managing FireSIGHT Rule State Recommendations on page 791 for more information.

5. Specify how you want to schedule the task, **Once** or **Recurring**:

   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the appliance.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.

6. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.

7. Next to **Policies**, select one or more policies where you want to generate recommendations. You have the following options:

   - In the **Policies** field, select one or more policies. Use the Shift and Ctrl keys to select multiple policies.
   - Click the **All Policies** check box to select all policies.

8. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

   TIP! The comment field appears in the View Tasks section of the page, so you should try to keep it relatively short.

9. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.

10. Click **Save**.

    The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Automating Software Updates

LICENSE: Any

You can automatically download and apply most patches and feature releases to the Sourcefire 3D System.

IMPORTANT! You must manually upload and install updates in two situations. First, you cannot schedule major updates to the Sourcefire 3D System. Second, you cannot schedule updates for or pushes from appliances that cannot access the Sourcefire Support Site. If your appliance is not directly connected to the Internet, you should set up a proxy as described in Configuring Network Settings on page 2088 to allow it to download updates from the Support Site. For information on manually updating the Sourcefire 3D System, see Updating System Software on page 2136.

The tasks you must schedule to install software updates vary depending on whether you are updating the Defense Center or are using a Defense Center to update managed devices. Sourcefire **strongly** recommends that you use your Defense Centers to update the devices they manage.

To update the Defense Center, schedule the software installation using the Install Latest Update task. To use a Defense Center to automate software updates for its managed devices, you must schedule two tasks:

1. Push (copy) the update to managed devices using the Push Latest Update task.
2. Install the update on managed devices using the Install Latest Update task.

When scheduling updates, schedule the push and install tasks to happen in succession. That is, to automate software updates on your managed devices, you must first push the update to the device before you can install it. (Note that during the manual update process you do not have to push an update to managed devices before you install it. For more information, see Updating Managed Devices on page 2146.)

IMPORTANT! You cannot create individual update tasks for managed devices in a clustered or stacked configuration.

Always allow enough time between tasks for the process to complete. Tasks should be scheduled at least 30 minutes apart. For example, if you schedule a task to install an update and the update has not finished copying from the Defense Center to the device, the installation task will not succeed. However, if the scheduled installation task repeats daily, it will install the pushed update when it runs the next day.

If you want to have more control over this process, you can use the **Once** option to download and install updates during off-peak hours after you learn that an update has been released.

See the following sections for more information:

- Automating Software Downloads on page 2023
- Automating Software Pushes on page 2025
- Automating Software Installs on page 2026

Automating Software Downloads

LICENSE: Any

You can create a scheduled task that automatically downloads the latest software updates from Sourcefire. You can use this task to schedule download of updates you plan to install manually.

To automate software update downloads:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

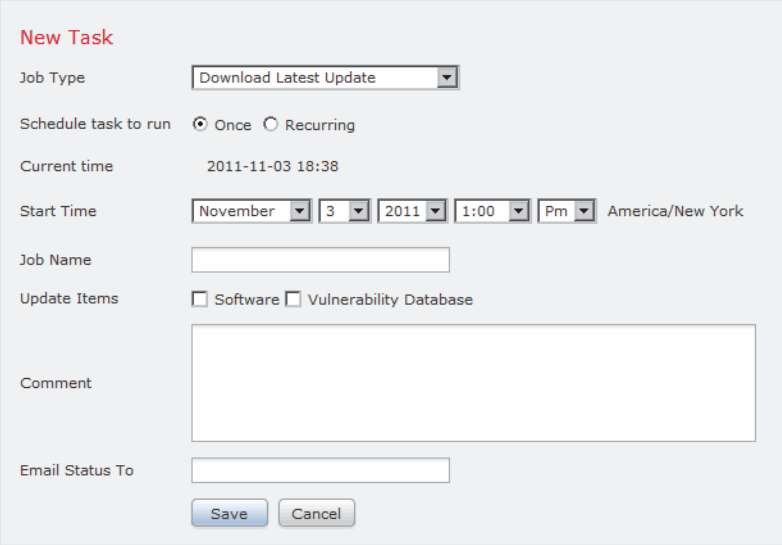
   The Scheduling page appears.

2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **Download Latest Update**.

   The New Task page reloads to show the update options.



4. Specify how you want to schedule the task, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the appliance.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.
5. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.
6. In the **Update Items** section, select **Software**.
7. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

   TIP! The comment field appears in the View Tasks section of the page, so you should try to keep it relatively short.

8. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.

9. Click **Save**.

   The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Automating Software Pushes

LICENSE: Any

If you want to automate the installation of software updates on managed devices, you must push the updates to the devices before installing.

When you push updates to managed devices, information about the push process status is reported on the Tasks page. See Viewing the Status of Long-Running Tasks on page 2321 for more information.

When you create the task to push software updates to managed devices, make sure you allow enough time between the push task and a scheduled install task for the updates to be copied to the device.

To push software updates to managed devices:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

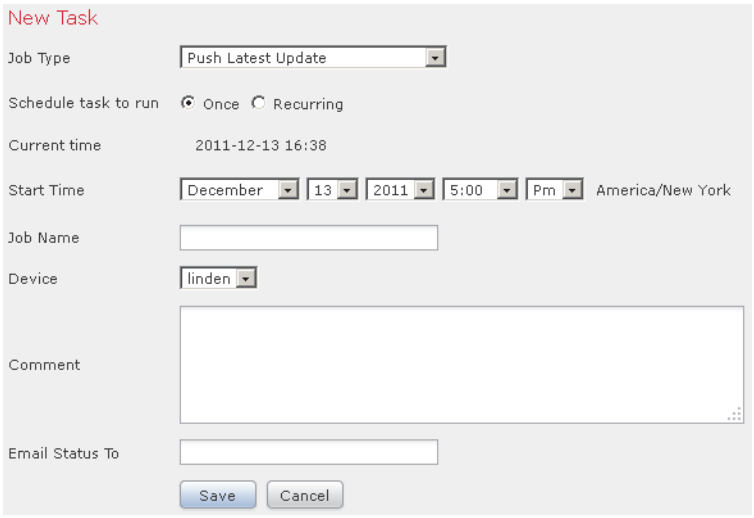
   The Scheduling page appears.

2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **Push Latest Update**.

   The page reloads to show the options for pushing updates.



4. Specify how you want to schedule the task, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the appliance.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.
5. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.
6. From the **Device** list, select the device that you want to receive updates.
7. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

   TIP! The comment field appears in the View Tasks section of the page, so you should try to keep it relatively short.

8. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.
9. Click **Save**.

   The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Automating Software Installs

License: Any

If you are using a Defense Center to create a task to install a software update on a managed device, make sure you allow enough time between the task that pushes the update to the device and the task that installs the update. See Automating Software Pushes on page 2025 for information about pushing updates to managed devices.

WARNING! Depending on the update being installed, the appliance may reboot after the software is installed.

To schedule a software installation task:

Access: Admin/Maint

1. Select **System > Tools > Scheduling**.

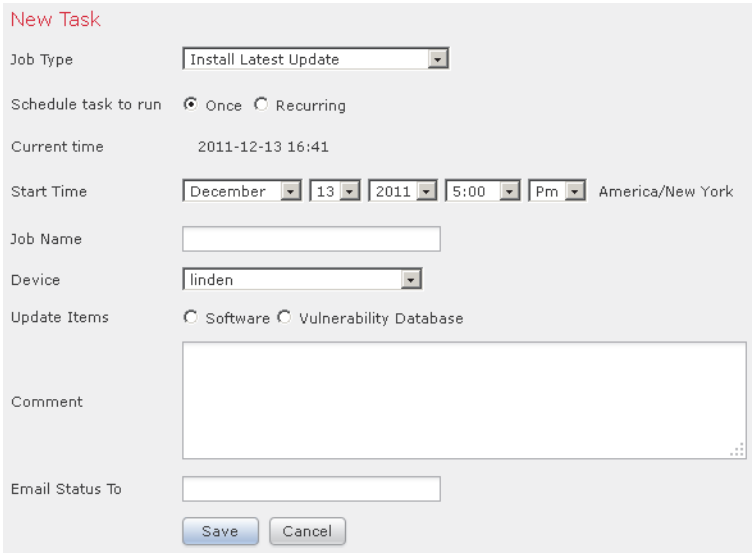
   The Scheduling page appears.

2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **Install Latest Update**.

   The page reloads to show the options for installing updates.



4. Specify how you want to schedule the task, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the appliance.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.
5. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.
6. From the **Device** list, you have the following options:
   - Select the device where you want to install the update.
   - Select the name of the Defense Center to install the update there.
7. In the **Update Items** section, select **Software**.
8. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

TIP! The comment field appears in the View Tasks section of the page, so you should try to keep it relatively short.

9. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.

10. Click **Save**.

    The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Automating Vulnerability Database Updates

LICENSE: FireSIGHT

Sourcefire uses vulnerability database (VDB) updates to expand the list of network assets, traffic, and vulnerabilities that the Sourcefire 3D System recognizes. You can use the scheduling feature to download and install the latest VDB update on your Defense Centers, thereby ensuring that you are using the most up-to-date information to evaluate the hosts on your network.

IMPORTANT! You cannot schedule updates for appliances that cannot access the Sourcefire Support Site. If your appliance is not directly connected to the Internet, you should set up a proxy as described in Configuring Network Settings on page 2088 to allow it to download updates from the Support Site. For information on manually updating the Sourcefire 3D System, see Updating System Software on page 2136.

When automating VDB updates, you must automate two separate steps:

1. Downloading the VDB update.
2. Installing the VDB update.

Always allow enough time between tasks for the process to complete. For example, if you schedule a task to install an update and the update has not fully downloaded, the installation task will not succeed. However, if the scheduled installation task repeats daily, it will install the downloaded VDB update when the task runs the next day.

If you want to have more control over this process, you can use the **Once** option to download and install VDB updates during off-peak hours after you learn that an update has been released.

IMPORTANT! Installing a VDB update causes a short pause in traffic flow and processing, and may also cause a few packets to pass uninspected.

See the following sections for more information:

- Automating VDB Update Downloads on page 2029
- Automating VDB Update Installs on page 2030

Automating VDB Update Downloads

LICENSE: FireSIGHT

You can create a scheduled task on the Defense Center that automatically downloads the latest VDB update from Sourcefire.

To automate VDB update downloads:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

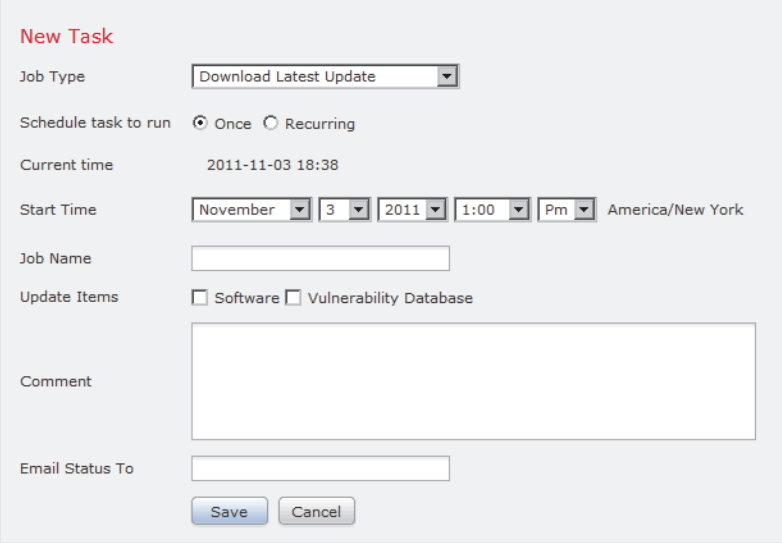
   The Scheduling page appears.

2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **Download Latest Update**.

   The New Task page reloads to show the update options.



4. Specify how you want to schedule the task, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the appliance.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.

5. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.
6. In the **Update Items** section, select **Vulnerability Database**.
7. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

   TIP! The comment field appears in the View Tasks section of the page, so you should try to keep it relatively short.

8. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.
9. Click **Save**.

   The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Automating VDB Update Installs

License: FireSIGHT

You should allow enough time between the task that downloads the VDB update and the task that installs the update; see Automating VDB Update Downloads on page 2029 for information.

IMPORTANT! Installing a VDB update causes a short pause in traffic flow and processing, and may also cause a few packets to pass uninspected.

To schedule a VDB update:

Access: Admin/Maint

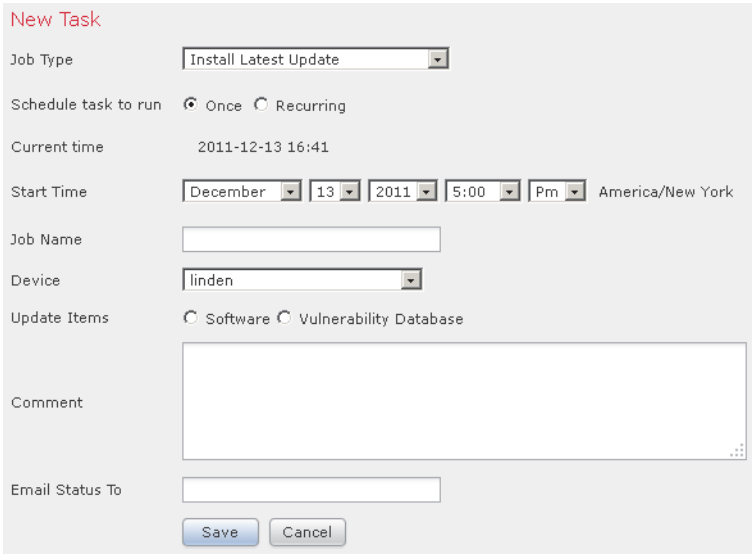
1. Select **System > Tools > Scheduling**.

   The Scheduling page appears.
2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **Install Latest Update**.

   The page reloads to show the options for installing updates.



4. Specify how you want to schedule the task, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the appliance.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.
5. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.
6. From the **Device** drop-down list, select the name of the Defense Center.
7. In the **Update Items** section, select **Vulnerability Database**.
8. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

   TIP! The comment field appears in the View Tasks section of the page, so you should try to keep it relatively short.

9. Optionally, in the **Email Status To:** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.

10. Click **Save**.

    The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Automating URL Filtering Updates

LICENSE: URL Filtering
SUPPORTED DEFENSE CENTERS: Any except DC500

You can use the scheduler to automate updates of URL filtering data from the Sourcefire cloud. For a URL filtering update task to succeed:

- The Defense Center must have access to the Internet or it cannot contact the cloud.
- You must enable URL filtering, as described in Enabling Sourcefire Cloud Communications on page 2113.

Note that when you enable URL filtering, you can also enable automatic updates. This forces the Defense Center to contact the cloud every 30 minutes for URL filtering data updates. If you have enabled automatic updates, you should **not** create a scheduled task to update URL filtering data.

Although daily updates tend to be small, if it has been more than five days since your last update, new URL filtering data may take up to 20 minutes to download, depending on your bandwidth. Then, it may take up to 30 minutes to perform the update itself.

To automate URL filtering data tasks:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

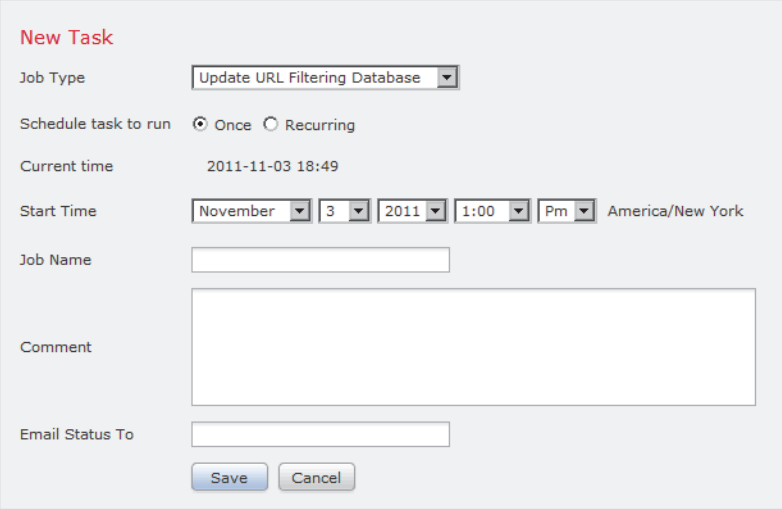
   The Scheduling page appears.

2. Click **Add Task**.

   The New Task page appears.

3. From the **Job Type** list, select **Update URL Filtering Database**.

   The page reloads to show the URL filtering update options.



4. Specify how you want to schedule the update, **Once** or **Recurring**:
   - For one-time tasks, use the drop-down lists to specify the start date and time. The **Current Time** field indicates the current time on the appliance.
   - For recurring tasks, you have several options for setting the interval between instances of the task. See Configuring a Recurring Task on page 2007 for details.
5. In the **Job Name** field, type a name using up to 255 alphanumeric characters, spaces, or dashes.
6. Optionally, in the **Comment** field, type a comment using up to 255 alphanumeric characters, spaces, or periods.

   TIP! The comment field appears in the View Tasks section of the page, so you should try to keep it relatively short.

7. Optionally, in the **Email Status To** field, type the email address (or multiple email addresses separated by commas) where you want status messages sent.

   You must have a valid email relay server configured to send status messages. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information about configuring a relay host.
8. Click **Save**.

   The task is added. You can check the status of a running task on the Task Status page; see Viewing the Status of Long-Running Tasks on page 2321.

Viewing Tasks

LICENSE: Any

After adding scheduled tasks, you can view them and evaluate their status. The View Options section of the page allows you to view scheduled tasks using a calendar and a list of scheduled tasks.

See the following sections for more information:

- Using the Calendar on page 2034
- Using the Task List on page 2035

Using the Calendar

LICENSE: Any

The Calendar view option allows you to view which scheduled tasks occur on which day.

To view scheduled tasks using the calendar:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

   The Scheduling page appears.

2. You can perform the following tasks using the calendar view:
   - Click the double left arrow icon (<<) to move back one year.
   - Click the single left arrow icon (<) to move back one month.
   - Click the single right arrow icon (>) to move forward one month.
   - Click the double right arrow icon (>>) to move forward one year.
   - Click **Today** to return to the current month and year.

- Click **Add Task** to schedule a new task.
- Click a date to view all scheduled tasks for the specific date in a task list table below the calendar.
- Click a specific task on a date to view the task in a task list table below the calendar.

IMPORTANT! For more information about using the task list, see Using the Task List.

Using the Task List

LICENSE: Any

The Task List shows a list of tasks along with their status. The task list appears below the calendar when you open the calendar. In addition, you can access it by selecting a date or task from the calendar. See Using the Calendar on page 2034 for more information.

Task List Columns

COLUMN	DESCRIPTION
Name	Displays the name of the scheduled task and the comment associated with it.
Type	Displays the type of scheduled task.
Start Time	Displays the scheduled start date and time.
Frequency	Displays how often the task is run.
Status	Describes the current status for a scheduled task: • A check mark icon ( ) indicates that the task ran successfully. • A question mark icon ( ) indicates that the task is in an unknown state. • An exclamation mark icon ( ) indicates that the task failed.
Creator	Displays the name of the user that created the scheduled task.
Edit	Edits the scheduled task.
Delete	Deletes the scheduled task.

Editing Scheduled Tasks

License: Any

You can edit a scheduled task that you previously created. This feature is especially useful if you want to test a scheduled task once to make sure that the parameters are correct. Later, after the task completes successfully, you can change it to a recurring task.

To edit an existing scheduled task:

Access: Admin/Maint

1. Select **System > Tools > Scheduling**.

   The Scheduling page appears.

2. Click either the task that you want to edit or the day on which the task appears.

   The Task Details table containing the selected task or tasks appears.

3. Locate the task you want to edit in the table and click the edit icon ( )

   The Edit Task page appears, showing the details of the task you selected.

4. Edit the task to meet your needs, including the start time, the job name, the comment, and how often the task runs, once or recurring. You cannot change the type of job.

   The remaining options are determined by the task you are editing. See the following sections for more information:

   - Automating Backup Jobs on page 2009
   - Automating Certificate Revocation List Downloads on page 2011
   - Automating Nmap Scans on page 2013
   - Automating Reports on page 2017
   - Automating FireSIGHT Recommendations on page 2020
   - Automating Software Updates on page 2022
   - Automating Vulnerability Database Updates on page 2028
   - Automating URL Filtering Updates on page 2032

5. Click **Save** to save your edits.

   Your change are saved and the Scheduling page appears again.

Deleting Scheduled Tasks

License: Any

There are two types of deletions you can perform from the Schedule View page. You can delete a specific one-time task that has not yet run or you can delete every instance of a recurring task. If you delete an instance of a recurring task, all

instances of the task are deleted. If you delete a task that is scheduled to run once, only that task is deleted.

The following sections describe how to delete tasks:

- To delete all instances of a task, see Deleting a Recurring Task on page 2037.
- To delete a single instance of a task, see Deleting a One-Time Task on page 2037.

Deleting a Recurring Task

LICENSE: Any

When you delete one instance of a recurring task, you automatically delete all instances of that task.

To delete a recurring task:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

   The Scheduling page appears.

2. On the calendar, select an instance of the recurring task you want to delete.

   The page reloads to display a table of tasks below the calendar.

3. Locate an instance of the recurring task you want to delete in the table and click the delete icon ( ).

   All instances of the recurring task are deleted.

Deleting a One-Time Task

LICENSE: Any

You can delete a one-time scheduled task or delete the record of a previously run scheduled task using the task list.

To delete a single task or, if it has already run, delete a task record:

ACCESS: Admin/Maint

1. Select **System > Tools > Scheduling**.

   The Scheduling page appears.

2. Click the task that you want to delete or the day on which the task appears.

   A table containing the selected task or tasks appears.

3. Locate the task you want to delete in the table and click the delete icon ( ).

   The instance of the task you selected is deleted.

CHAPTER 48
MANAGING SYSTEM POLICIES

A system policy allows you to manage the following on your Sourcefire 3D System appliances:

- access control preferences
- appliance access lists
- audit log settings
- authentication profiles
- dashboard settings
- database event limits
- DNS cache properties
- the mail relay host and notification address
- tracking intrusion policy changes
- specifying a different language
- custom login banners
- SNMP polling settings
- synchronizing time
- STIG compliance
- serving time from the Defense Center
- user interface and command line interface timeout settings
- mapping vulnerabilities for servers

You can use a system policy to control the aspects of your Defense Center that are likely to be similar for other appliances in your deployment. For example, your

organization's security policies may require that your appliances have a "No Unauthorized Use" message when a user logs in. With system policies, you can set the login banner once in a system policy on a Defense Center and then apply the policy to all the devices that it manages.

You can also benefit from having multiple system policies on a Defense Center. For example, if you have different mail relay hosts that you use under different circumstances or if you want to test different database limits, you can create several system policies and switch between them, rather than editing a single policy.

Contrast a system policy, which controls aspects of an appliance that are likely to be similar across a deployment, with system settings, which are likely to be specific to a single appliance. See Configuring Appliance Settings on page 2077 for more information.

IMPORTANT! You **cannot** apply a system policy to Sourcefire Software for X-Series.

See the following sections for more information:

- Creating a System Policy on page 2039
- Editing a System Policy on page 2041
- Applying a System Policy on page 2042
- Comparing System Policies on page 2043
- Deleting System Policies on page 2046
- Configuring a System Policy on page 2046

Creating a System Policy

LICENSE: Any

When you create a system policy, you assign it a name and a description. Next, you configure the various aspects of the policy, each of which is described in its own section.

Instead of creating a new policy, you can export a system policy from another appliance and then import it onto your appliance. You can then edit the imported policy to suit your needs before you apply it. For more information, see Importing and Exporting Configurations on page 2308.

To create a system policy:

Access: Admin

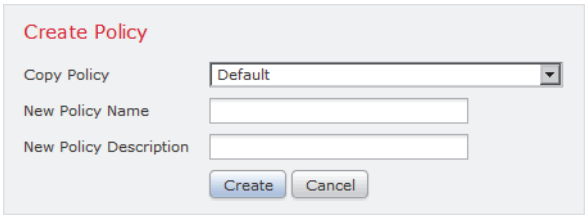
1. Select **System > Local > System Policy**.

   The System Policy page appears.

   The **Policy Name** column includes the system policy's description. The **Applied To** column indicates the number of appliances where the policy is applied and a count of **out-of-date** appliances where the previously applied policy has changed and should be reapplied.

2. Click **Create Policy**.

   The Create Policy page appears.



3. From the drop-down list, select an existing policy to use as a template for your new system policy.
4. Type a name for your new policy in the **New Policy Name** field.
5. Type a description for your new policy in the **New Policy Description** field.
6. Click **Create**.

   Your system policy is saved and the Edit System Policy page appears. For information about configuring each aspect of the system policy, see one of the following sections:

   - Configuring the Access List for Your Appliance on page 2048
   - Configuring Audit Log Settings on page 2050
   - Configuring Authentication Profiles on page 2052
   - Configuring Dashboard Settings on page 2055
   - Configuring Database Event Limits on page 2056
   - Configuring DNS Cache Properties on page 2058
   - Configuring a Mail Relay Host and Notification Address on page 2060
   - Configuring Access Control Policy Preferences on page 2047
   - Configuring Intrusion Policy Preferences on page 2062
   - Specifying a Different Language on page 2063

- Adding a Custom Login Banner on page 2064
- Configuring SNMP Polling on page 2065
- Enabling STIG Compliance on page 2068
- Synchronizing Time on page 2069
- Serving Time from the Defense Center on page 2072
- Configuring User Interface Settings on page 2073
- Mapping Vulnerabilities for Servers on page 2075

Editing a System Policy

License: Any

You can edit an existing system policy. If you edit a system policy that is currently applied to an appliance, reapply the policy after you have saved your changes. For more information, see Applying a System Policy on page 2042.

To edit an existing system policy:

Access: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears, including a list of the existing system policies.

2. Click the edit icon ( ) next to the system policy that you want to edit.

   The Edit Policy page appears. You can change the policy name and policy description. For information about configuring each aspect of the system policy, see one of the following sections:

   - Configuring Access Control Policy Preferences on page 2047
   - Configuring the Access List for Your Appliance on page 2048
   - Configuring Audit Log Settings on page 2050
   - Configuring Authentication Profiles on page 2052
   - Configuring Dashboard Settings on page 2055
   - Configuring Database Event Limits on page 2056
   - Configuring DNS Cache Properties on page 2058
   - Configuring a Mail Relay Host and Notification Address on page 2060
   - Configuring Intrusion Policy Preferences on page 2062
   - Specifying a Different Language on page 2063
   - Adding a Custom Login Banner on page 2064
   - Configuring SNMP Polling on page 2065
   - Synchronizing Time on page 2069
   - Serving Time from the Defense Center on page 2072

- Configuring User Interface Settings on page 2073
- Mapping Vulnerabilities for Servers on page 2075

IMPORTANT! If you are editing a system policy applied to an appliance, make sure you reapply the updated policy when you are finished. See Applying a System Policy on page 2042.

3. Click **Save Policy and Exit** to save your changes. The changes are saved, and the System Policy page appears.

Applying a System Policy

LICENSE: Any

You can apply a system policy to an appliance. If a system policy is already applied, any changes you make do not take effect until you reapply it.

IMPORTANT! You **cannot** apply a system policy to Sourcefire Software for X-Series.

To apply a system policy:

ACCESS: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

2. Click the apply icon ( ) next to the system policy that you want to apply.

   The Apply page appears.

3. Select the appliances to which you want to apply the system policy.

TIP! You can sort the appliances by group, model, health policy, or applied system policy. You can select either an individual appliance or an entire group.

4. Click **Apply**.

   The System Policy page appears. A message indicates the status of applying the system policy.

Comparing System Policies

LICENSE: Any

You can compare two system policies or two revisions of the same system policy, subject to the system policies you can access. This allows you to review policy changes for compliance with your organization's standards, or for optimization of system performance. To quickly compare your active system policy to another, you can select the **Running Configuration** option. Optionally, after you compare, you can generate a PDF report to record the differences between the system policies or system policy revisions.

There are two tools you can use to compare system policies or system policy revisions:

- The comparison view displays the differences between two system policies or system policy revisions in a side-by-side format. The name of each policy or policy revision appears in the title bar on the left and right sides of the comparison view.

  You can use this to view and navigate both policy revisions on the web interface, with their differences highlighted.
- The comparison report creates a record of the differences between two system policies or system policy revisions in a format similar to the system policy report, but in PDF format.

  You can use this to save, copy, print, and share your policy comparisons for further examination.

Using the System Policy Comparison View

LICENSE: Any

The comparison view displays both system policies or policy revisions in a side-by-side format, with each policy or policy revision identified by name in the title bar on the left and right sides of the comparison view. For all revisions, the system policy comparison view displays the time of last modification and the last user to the right of the policy name.

Differences between the two system policies or policy revisions are highlighted:

- Blue indicates that the highlighted setting is different in the two policies or policy revisions, and the difference is noted in red text.
- Green indicates that the highlighted setting appears in one policy or policy revision, but not the other.

You can perform any of the actions in the System Policy Comparison View Actions table.

System Policy Comparison View Actions

To...	You can...
navigate individually through changes	select **Previous** or **Next** above the title bar. The double-arrow icon () centered between the left and right sides moves, and the **Difference** number adjusts to identify which difference you are viewing.
generate a new system policy comparison view	select **New Comparison**. The **Select Comparison** window appears. See Using the System Policy Comparison Report for more information.
generate a system policy comparison report	select **Comparison Report**. The system policy comparison report is a PDF that contains information identical to the system policy comparison view.

Using the System Policy Comparison Report

License: Any

A system policy comparison report is a record of all differences between two system policies or two revisions of the same system policy identified by the system policy comparison view, presented in PDF format. You can use this report to further examine the differences between two system policy configurations and to save and disseminate your findings.

You can generate a system policy comparison report from the comparison view for any system policies to which you have access. Changes you make to a system policy do not appear in the system policy comparison report until you save the changes.

Depending on your configuration, a system policy comparison report can contain one or more sections. The following sample graphic displays the Policy Information, User Detection Settings, and Time Synchronization sections of a system policy comparison report, and lists the configuration for each rule for both system policy configurations. Each section uses the same format and provides

the same level of detail. Note that the Value A and Value B columns represent the policies or policy revisions you configured in the comparison view.

You use a similar procedure to compare other types of policies on the Sourcefire 3D System. For more information, see:

- Comparing Two Intrusion Policies on page 731
- Comparing Health Policies on page 2232

To compare two system policies or two revisions of the same policy:

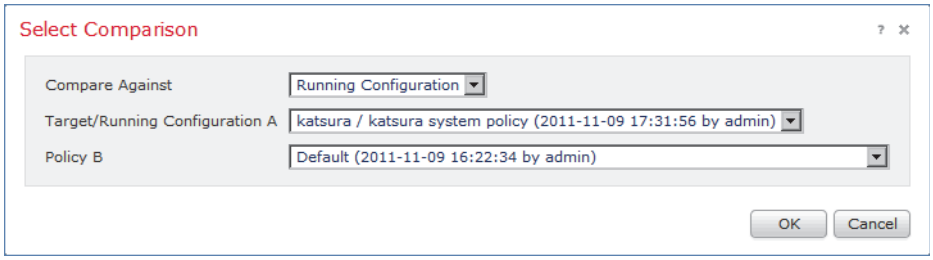
Access: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

2. Click **Compare Policies**.

   The Select Comparison pop-up window appears.



3. From the **Compare Against** drop-down list, select the type of comparison you want to make:
   - To compare two different policies, select **Other Policy**.
   - To compare two revisions of the same policy, select **Other Revision**.
   - To compare another policy to a currently active policy, select **Running Configuration.**

4. Depending on the comparison type you selected, you have the following choices:
   - If you are comparing two different policies, select the policies you want to compare from the **Policy A** and **Policy B** drop-down lists.
   - If you are comparing two revisions of the same policy, select the policy from the **Policy** drop-down list, then select the revisions you want to compare from the **Revision A** and **Revision B** drop-down lists.
   - If you are comparing a running configuration to another policy, select the running configuration from the **Target/Running Configuration A** drop-down list, and the other policy from the **Policy B** drop-down list.
5. Click **OK** to display the system policy comparison view.

   The comparison view appears.
6. Click **Comparison Report** to generate the system policy comparison report.

   The system policy comparison report appears. Depending on your browser settings, the report may appear in a pop-up window, or you may be prompted to save the report to your computer.

Deleting System Policies

LICENSE: Any

You can delete a system policy, even if it is in use. If the policy is still in use, it is used until a new policy is applied. Default system policies cannot be deleted.

To delete a system policy:

ACCESS: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.
2. Click the delete icon ( ) next to the system policy that you want to delete. To delete the policy, click **OK.**

   The System Policy page appears. A pop-up message appears, confirming the policy deletion.

Configuring a System Policy

LICENSE: Any

You can configure various system policy settings. For information about configuring each aspect of the system policy, see one of the following sections:

- Configuring Access Control Policy Preferences on page 2047
- Configuring the Access List for Your Appliance on page 2048

Configuring Access Control Policy Preferences

License: Protection

You can configure the system to prompt users for a comment when they add or modify a rule in an access control policy, prompting them to enter a rule comment. You can use this to track users' reasons for policy changes. If you enable comments on access control rule changes, you can make the rule comment optional or mandatory. The system prompts the user for a comment when each new change to a rule is saved.

The system adds the comment to the rule's comment history when the user saves the rule. For more information, see Adding Rule Comments on page 789.

To configure the access control policy rule comment settings:

Access: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

2. You have the following options:

   - To modify the access control policy settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the access control policy settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.

3. Click **Access Control Preferences**.

   The Access Control Preferences page appears.

4. You have the following options:
   - Select **Disabled** from the drop-down list to allow users to add or modify a rule in an access control policy without entering a comment.
   - Select **Optional** from the drop-down list to display the Description of Changes (Optional) window to users when they save changes to access control policy rules. This allows users the option to describe changes in a comment.
   - Select **Required** from the drop-down list to display the Description of Changes (Required) window to users when they save changes to access control policy rules. This requires users to describe changes in a comment before the changes are saved.

5. Click **Save Policy and Exit.**

   The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

Configuring the Access List for Your Appliance

LICENSE: Any

The Access List page allows you to control which computers can access your appliance on specific ports. By default, port 443 (Hypertext Transfer Protocol Secure, or HTTPS), which is used to access the web interface, and port 22 (Secure Shell, or SSH), which is used to access the command line, are enabled for any IP address. You can also add SNMP access over port 161. Note that you must add SNMP access for any computer you plan to use to poll for SNMP information.

WARNING! By default, access to the appliance is **not** restricted. To operate the appliance in a more secure environment, consider adding access to the appliance for specific IP addresses and then deleting the default **any** option.

The access list is part of the system policy. You can specify the access list either by creating a new system policy or by editing an existing system policy. In either case, the access list does not take effect until you apply the system policy.

Note that this access list does not also control external database access. For more information on the external database access list, see Enabling Access to the Database on page 2086.

To configure the access list:

Access: Admin

1. Select **System > Local > System Policy**.

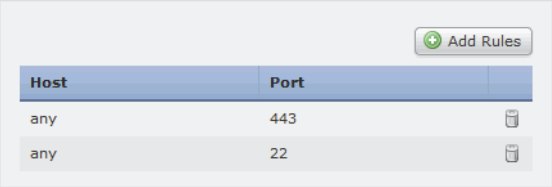
   The System Policy page appears.

2. You have the following options:

   - To modify the access list in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the access list as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.



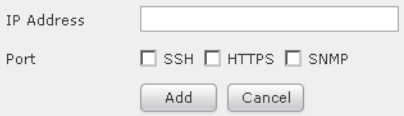
3. Optionally, to delete one of the current settings, click the delete icon ( ).

   The setting is removed.

WARNING! If you delete access for the IP address that you are currently using to connect to the appliance interface, and there is no entry for "`IP=any port=443`", you will lose access to the system when you apply the policy.

4. Optionally, to add access for one or more IP addresses, click **Add Rules**.

   The Add IP Address page appears.



5. In the **IP Address** field, you have the following options, depending on the IP addresses you want to add:

   - an exact IP address (for example, 192.168.1.101)
   - an IP address block using CIDR notation (for example, 192.168.1.1/24)

     For information on using CIDR in the Sourcefire 3D System, see IP Address Conventions on page 63.
   - `any`, to designate any IP address

6. Select **SSH**, **HTTPS**, **SNMP**, or a combination of these options to specify which ports you want to enable for these IP addresses.
7. Click **Add**.

   The Access List page appears again, reflecting the changes you made.
8. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

Configuring Audit Log Settings

LICENSE: Any

You can configure the system policy so that the appliance streams an audit log to an external host.

IMPORTANT! You must ensure that the external host is functional and accessible from the appliance sending the audit log.

The sending host name is part of the information sent. You can further identify the audit log stream with a facility, a severity, and an optional tag. The appliance does not send the audit log until you apply the system policy.

After you apply a policy with this feature enabled, and your destination host is configured to accept the audit log, the syslog messages are sent. The following is an example of the output structure:

```
Date Time Host [Tag] Sender: [User_Name]@[User_IP], [Subsystem],
[Action]
```

where the local date, time, and hostname precede the bracketed optional tag, and the sending device name precedes the audit log message.

For example:

```
Mar 01 14:45:24 localhost [TAG] Dev-DC3000: admin@10.1.1.2,
Operations > Monitoring, Page View
```

To configure the audit log settings:

ACCESS: Admin

1. Select **System > Local > System Policy**.

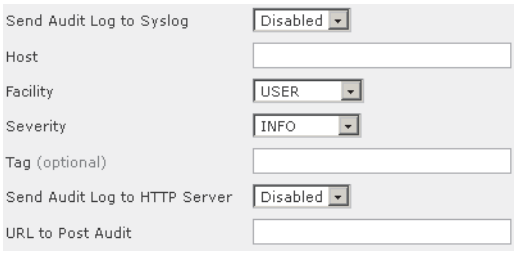
   The System Policy page appears.

2. You have the following options:
   - To modify the audit log settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the audit log settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.
3. Click **Audit Log Settings**.

   The Audit Log Settings page appears.



4. Select **Enabled** from the **Send Audit Log to Syslog** drop-down menu. (The default setting is **Disabled**.)
5. Designate the destination host for the audit information by using the IP address or the fully qualified name of the host in the **Host** field. The default port (514) is used.

   WARNING! If the computer you configure to receive an audit log is not set up to accept remote messages, the host will not accept the audit log.
6. Select a syslog facility from the **Facility** field.
7. Select a severity from the **Severity** field.
8. Optionally, insert a reference tag in the **Tag (optional)** field.
9. To send regular audit log updates to an external HTTP server, select **Enabled** from the **Send Audit Log to HTTP Server** drop-down list. The default setting is **Disabled**.
10. In the **URL to Post Audit** field, designate the URL where you want to send audit information. You must enter an URL that corresponds to a listener program that expects the HTTP POST variables as listed:
    - `subsystem`
    - `actor`
    - `event_type`
    - `message`
    - `action_source_ip`

- `action_destination_ip`
- `result`
- `time`
- `tag` (if defined, as above)

WARNING! To allow encrypted posts, you must use an HTTPS URL. Note that sending audit information to an external URL may affect system performance.

11. Click **Save Policy and Exit**.

    The system policy is updated. Your changes do not take effect until you apply the system policy to the Defense Center and its managed devices. See Applying a System Policy on page 2042 for more information.

Configuring Authentication Profiles

LICENSE: Any

Normally, when a user logs into an appliance, the appliance verifies user credentials by comparing the credentials to a user account stored in the appliance's local database. However, if you create an authentication object referencing an external authentication server, you can apply the system policy to let users logging into the Defense Center or managed device authenticate to that server, rather than using the local database.

When you apply a system policy with authentication enabled to an appliance, the appliance verifies the user credentials against users on an LDAP or RADIUS server. In addition, if a user has internal authentication enabled and the user credentials are not found in the internal database, the appliance then checks the external server for a set of matching credentials. If a user has the same username on multiple systems, all passwords across all servers work. Note, however, that if authentication fails on the available external authentication servers, the appliance does not revert to checking the local database.

When you enable authentication, you can set the default user role for any user whose account is externally authenticated. You can select multiple roles, as long as those roles can be combined. For example, if you set up an authentication profile that retrieves only users in the Network Security group in your company, you may set the default user role to include the Security Analyst role so users can access collected event data without any additional user configuration on your part. However, if your authentication profile retrieves records for other personnel in addition to the security group, you would probably want to leave the default role unselected. For more information on available user roles, see Understanding User Privileges on page 1926.

Note that when you create an LDAP authentication object on your Defense Center, you can set a filter search attribute to specify the set of users who can successfully authenticate against the LDAP server. See Configuring LDAP-

Specific Parameters on page 1944 for more information.

If no access role is selected, users can log in but cannot access any functionality. After a user attempts to log in, their account is listed on the User Management page, where you can edit the account settings to grant additional permissions. For more information on modifying a user account, see Modifying User Privileges and Options on page 1988. For a complete procedure for logging in initially as an externally authenticated user, see Logging into the Appliance to Set Up an Account on page 67.

If you configure the system policy to use one user role and apply the policy, then later modify the policy to use different default user roles and reapply, any user accounts created before the modification retain the first user role until you modify the accounts, or delete and recreate them.

You can enable authentication in a system policy on your Defense Center and then push that policy to managed devices. After you apply the policy to a device, eligible externally authenticated users can log into that device. To make changes to the authentication profile settings, you have to modify the system policy on the Defense Center, and then apply the policy to the device again. To disable authentication on a managed device, you can disable it in a system policy on the Defense Center and push that to the device.

Note that you can only enable external authentication on Defense Centers and managed devices. Enabling external authentication by applying a system policy is not supported on X-Series-based software devices.

If a user with internal authentication attempts to log in, the appliance first checks if that user is in the local user database. If the user exists, the appliance then checks the username and password against the local database. If a match is found, the user logs in successfully. If the login fails, however, and external authentication is enabled, the appliance checks the user against each external authentication server in the authentication order shown in the system policy. If the username and password match results from an external server, the appliance changes the user to an external user with the default privileges for that authentication object.

If an external user attempts to log in, the appliance checks the username and password against the external database. If a match is found, the user logs in successfully. If the login fails, the user login attempt is rejected. External users cannot authenticate against the user list in the local database. If the user is a new external user, an external user account is created in the local database with the default privileges for the external authentication object.

To enable authentication of users on external servers:

Access: Admin

1. Select **System > Local > System Policy**.

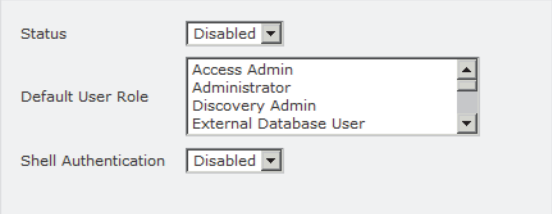
   The System Policy page appears.

2. You have the following options:
   - To modify the authentication profile settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the authentication profile settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.
3. Click **Authentication Profiles**.

   The Authentication Profiles page appears.



4. From the **Status** drop-down list, select **Enabled**.
5. From the **Default User Role** drop-down list, select user roles to define the default permissions you want to grant to externally authenticated users.

TIP! Press Ctrl before selecting roles to select multiple default user roles. Note that although you can select both a Security Analyst role and the corresponding Security Analyst (Read Only) role, only the Security Analyst role is applied.

6. If you want to use the external server to authenticate shell access accounts as well, select **Enabled** from the **Shell Authentication** drop-down list.
7. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy to the Defense Center and its managed devices. See Applying a System Policy on page 2042 for more information.
8. To enable use of a preconfigured authentication object, select the check box next to the object. You must select at least one authentication object to enable external authentication.

TIP! If you enabled shell authentication in step 6, you must select an authentication object configured to allow shell access. for more information, see Setting up Shell Access on page 1932.

9. Optionally, use the up and down arrows to change the order in which authentication servers are access when an authentication request occurs.

IMPORTANT! Remember that shell access used can only authenticate against the server whose authentication object is highest in the profile order.

Configuring Dashboard Settings

LICENSE: Any

You can configure the system policy so that Custom Analysis widgets are enabled on the dashboard. Dashboards provide you with at-a-glance views of current system status through the use of widgets: small, self-contained components that provide insight into different aspects of the Sourcefire 3D System.

The Custom Analysis widget allows you to create a visual representation of events based on a flexible, user-configurable query of the events in your appliance's database. See Understanding the Custom Analysis Widget on page 86 for more information on how to use custom widgets.

To enable Custom Analysis widgets:

ACCESS: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

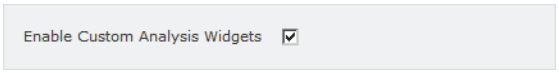
2. You have the following options:

   - To modify the dashboard settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the dashboard settings as part of a new system policy, click **Create Policy**. Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save.**

   In either case, the Access List page appears.

3. Click **Dashboard.**

   The Dashboard Settings page appears.



4. Select the **Enable Custom Analysis Widgets** check box to allow users to add Custom Analysis widgets to dashboards. Clear the check box to prohibit users from using those widgets.

5. Click **Save Policy and Exit.**

   The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

Configuring Database Event Limits

LICENSE: Any

Use the Database page to specify the maximum number of each type of event that the Defense Center can store. Note that the setting for audit records also applies to managed devices. To improve performance, you should tailor event limits to the number of events you regularly work with. For some event types, you can disable storage. The following table lists the minimum and maximum number of records you can store for each event type.

Database Event Limits

EVENT TYPE	UPPER EVENT LIMIT	LOWER EVENT LIMIT
intrusion events	2.5 million (DC500) 10 million (DC1000, virtual Defense Center) 20 million (DC750) 30 million (DC1500) 100 million (DC3000) 150 million (DC3500)	10,000
discovery events	10 million	zero (disables storage)
connection events/ Security Intelligence Events	10 million (DC500, DC1000, virtual Defense Center) 50 million (DC750) 100 million (DC1500, DC3000) 500 million (DC3500) Upper event limit is shared between connection events and Security Intelligence events; the sum of configured maximums for the two events cannot exceed the upper event limit.	zero (disables storage)
connection summaries (aggregated connection events)	10 million (DC500, DC1000, virtual Defense Center) 50 million (DC750) 100 million (DC1500, DC3000) 500 million (DC3500)	zero (disables storage)
correlation and compliance white list events	1 million	one
malware events	10 million	10,000
file events	10 million	zero (disables storage)
health events	1 million	zero (disables storage)
audit records	100,000	one

Database Event Limits (Continued)

Event Type	Upper Event Limit	Lower Event Limit
remediation status events	10 million	one
the white list violation history of the hosts on your network	a 30-day history of violations	one day's history
user activity (user events)	10 million	one
user logins (user history)	10 million	one
rule update import log records	1 million	one

If the number of events in the intrusion event database exceeds the maximum, the oldest events and packet files are pruned until the database is back within the event limits. See Configuring a Mail Relay Host and Notification Address on page 2060 for information about generating automated email notifications when events are automatically pruned.

For information on manually pruning the discovery and user databases, see Purging Discovery Data from the Database on page 2319.

In addition, you can configure an email address that will receive notifications when intrusion events and audit records are pruned from the database.

To configure the maximum number of records in the database:

Access: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

2. You have the following options:

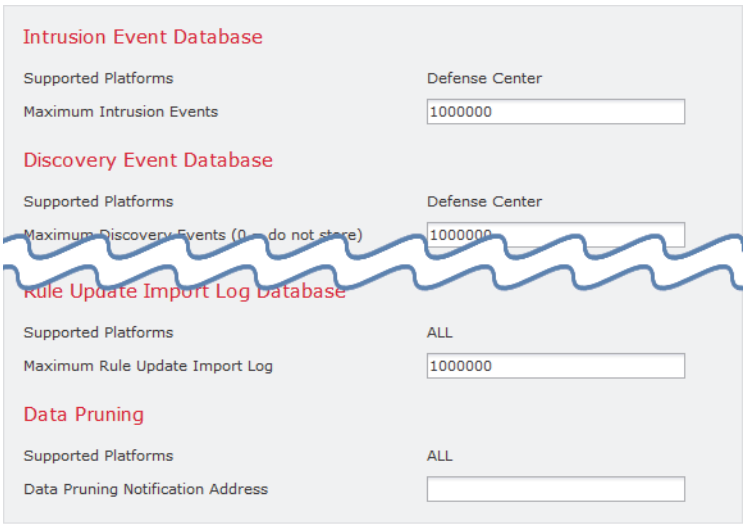
   - To modify the database settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the database settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access Control Preferences page appears.

3. Click **Database**.

   The Database page appears.



4. For each of the databases, enter the number of records you want to store.

   For information on how many records each database can maintain, see the Database Event Limits table on page 2056.

5. Optionally, in the **Data Pruning Notification Address** field, enter the email address you want to receive notifications when intrusion events, discovery events, audit records, security intelligence data, or URL filtering data are pruned from the appliance's database.

   Note that you must also configure an email server. See Configuring a Mail Relay Host and Notification Address on page 2060 for more information.

6. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

Configuring DNS Cache Properties

LICENSE: Any

If you have a DNS server configured on the Network page, you can configure the appliance to resolve IP addresses automatically on the event view pages. As a user assigned the Administrator role, you can also configure basic properties for DNS caching performed by the appliance. Configuring DNS caching allows you to identify IP addresses you previously resolved without performing additional lookups. This can reduce the amount of traffic on your network and speed the display of event pages when IP address resolution is enabled.

To configure the DNS cache properties:

Access: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

2. You have the following options:

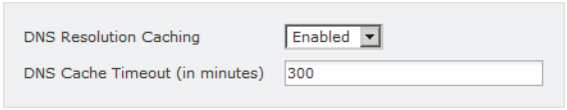
   - To modify the DNS cache settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the DNS cache settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.

3. Click **DNS Cache**.

   The DNS Cache page appears.



4. Select **Enabled** from the **DNS Resolution Caching** drop-down list to enable caching. Select **Disabled** to disable it.

IMPORTANT! DNS resolution caching is a system-wide setting that allows the caching of previously resolved DNS lookups. To configure IP address resolution on a per-user-account basis, users must also select **Event View Settings** from the **User Preferences** menu, enable **Resolve IP Addresses**, and then click **Save**. For information about configuring DNS servers, see Configuring Network Settings on page 2088. For information about configuring event view preferences, see Configuring Event View Settings on page 2300.

5. In the **DNS Cache Timeout (in minutes)** field, enter the number of minutes a DNS entry remains cached in memory before it is removed for inactivity.

   The default setting is 300 minutes (five hours).

6. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

WARNING! Although DNS caching is enabled for the appliance, IP address resolution is not enabled on a per-user basis unless it is configured on the Events page accessed from the User Preferences menu.

Configuring a Mail Relay Host and Notification Address

LICENSE: Any

You must configure a mail host if you plan to:

- email event-based reports
- email status reports for scheduled tasks
- email change reconciliation reports
- email data pruning notifications
- use email for discovery event, impact flag, and correlation event alerting
- use email for intrusion event alerting
- use email for health event alerting

You can select an encryption method for the communication between appliance and mail relay host, and can supply authentication credentials for the mail server if needed. After configuring settings, you can test the connection between the appliance and the mail server using the supplied settings.

To configure a mail relay host:

ACCESS: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

2. You have the following options:

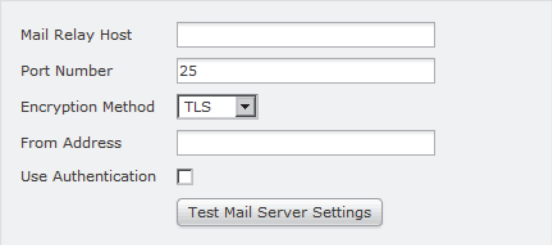
   - To modify the email settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the email settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.

3. Click **Email Notification**.

   The Configure Email Notification page appears.



4. In the **Mail Relay Host** field, type the hostname or IP address of the mail server you want to use.

   IMPORTANT! The mail host you enter must allow access from the appliance.

5. Enter the port number to use on the email server in the **Port Number** field. Typical ports include 25, when using no encryption, 465, when using SSLv3, and 587, when using TLS.

6. To select an encryption method, you have the following options:

   - To encrypt communications between the appliance and the mail server using Transport Layer Security, select **TLS** from the **Encryption Method** drop-down list.
   - To encrypt communications between the appliance and the mail server using Secure Socket Layers, select **SSLv3** from the **Encryption Method** drop-down list.
   - To allow unencrypted communication between the appliance and the mail server, select **None** from the **Encryption Method** drop-down list.

   Note that certificate validation is not required for encrypted communication between the appliance and mail server.

7. Enter a valid email address in the **From Address** field for use as the source email address for messages sent by the appliance.

8. Optionally, to supply a user name and password when connecting to the mail server, select **Use Authentication**. Enter a user name in the **Username** field. Enter a password in the **Password** field.

9. To send a test email using the configured mail server, click **Test Mail Server Settings**.

   A message appears next to the button indicating the success or failure of the test.

10. Click **Save Policy and Exit**.

    The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

Configuring Intrusion Policy Preferences

LICENSE: Protection

You can configure the system to prompt users for a comment when they modify an intrusion policy. You can use this to track users' reasons for policy changes. If you enable comments on intrusion policy changes, you can make the comments optional or mandatory. The change description is written to the audit log.

You can also have all intrusion policy changes written to the audit log. For more information on the audit log, see Managing Audit Records on page 2269.

To configure the intrusion policy comment settings:

ACCESS: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

2. You have the following options:

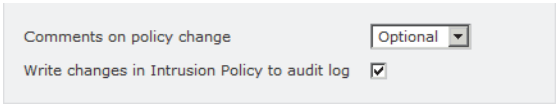
   - To modify the intrusion policy preferences in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the intrusion policy preferences as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.

3. Click **Intrusion Policy Preferences**.

   The Intrusion Policy Preferences page appears.



4. From the **Comments on policy change** drop-down list, you have the following options:
   - Select **Disabled** to allow users to modify an intrusion policy without entering a change description.
   - Select **Optional** to display the Description of Changes window to users when they save changes to an intrusion policy. This allows users the option to describe changes in a comment.
   - Select **Required** to display the Description of Changes window to users when they save changes to an intrusion policy. This requires users to describe changes in a comment before the changes are saved.
5. Optionally, if you want to write all intrusion policy changes to the audit log, select **Write changes in Intrusion Policy to audit log**.
6. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

Specifying a Different Language

LICENSE: Any

You can use the Language page to specify a different language for the web interface.

WARNING! The language you select here is used for the web interface for every user who logs into the appliance.

To select a different language for the user interface:

ACCESS: Admin

1. Select **System > Local > System Policy**.

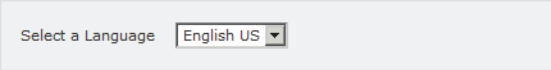
   The System Policy page appears.
2. You have the following options:
   - To modify the language settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the language settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.

3. Click **Language**.

   The Language page appears.



4. Select the language you want to use.
5. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

Adding a Custom Login Banner

LICENSE: Any

You can create a custom login banner that appears when users log into the appliance using SSH and on the login page of the web interface. Banners can contain any printable characters except the less-than symbol (<) and the greater-than symbol (>).

To add a custom banner:

ACCESS: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

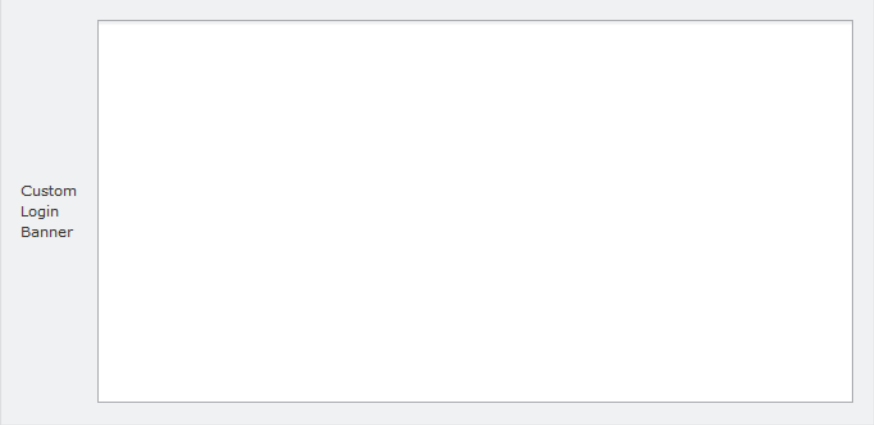
2. You have the following options:
   - To modify the login banner in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the login banner as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.

3. Click **Login Banner**.

   The Login Banner page appears.



4. In the **Custom Login Banner** field, enter the login banner you want to use with this system policy.
5. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

Configuring SNMP Polling

LICENSE: Any

You can enable Simple Network Management Protocol (SNMP) polling of an appliance using the system policy. The SNMP feature supports use of versions 1, 2, and 3 of the SNMP protocol.

This feature allows access to:

- the standard management information base (MIB) for the appliance, which includes system details such as contact, administrative, location, service information, IP addressing and routing information, and transmission protocol usage statistics
- additional MIBs for managed devices that include statistics on traffic passing through physical interfaces, logical interfaces, virtual interfaces, ARP, NDP, virtual bridges, and virtual routers

Note that enabling the system policy SNMP feature does not cause the appliance to send SNMP traps; it only makes the information in the MIBs available for polling by your network management system.

IMPORTANT! You must add SNMP access for any computer you plan to use to poll the appliance. For more information, see Configuring the Access List for Your Appliance on page 2048. Note that the SNMP MIB contains information that could be used to attack your appliance. Sourcefire recommends that you restrict your access list for SNMP access to the specific hosts that will be used to poll for the MIB. Sourcefire also recommends you use SNMPv3 and use strong passwords for network management access.

To configure SNMP polling:

Access: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

2. You have the following options:

   - To modify the SNMP polling settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the SNMP polling settings as part of a new system policy, click **Create Policy**.

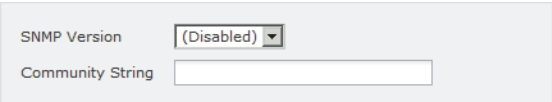
     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Create**.

   In either case, the Access List page appears.

3. If you have not already added SNMP access for each computer you plan to use to poll the appliance, do so now. For more information, see Configuring the Access List for Your Appliance on page 2048.

4. Click **SNMP**.

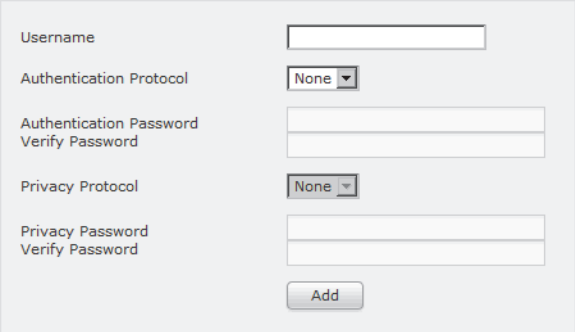
   The SNMP page appears.

5. From the **SNMP Version** drop-down list, select the SNMP version you want to use.

   The drop-down list displays the version you selected.

6. You have the following options:
   - If you selected **Version 1** or **Version 2**, type the SNMP community name in the **Community String** field. Go to step 15.
   - If you selected **Version 3**, click **Add User** to display the user definition page.



7. Enter a username in the **Username** field.
8. Select the protocol you want to use for authentication from the **Authentication Protocol** drop-down list.
9. Type the password required for authentication with the SNMP server in the **Authentication Password** field.
10. Retype the authentication password in the **Verify Password** field just below the **Authentication Password** field.
11. Select the privacy protocol you want to use from the **Privacy Protocol** list, or select **None** to not use a privacy protocol.
12. Type the SNMP privacy key required by the SNMP server in the **Privacy Password** field.
13. Retype the privacy password in the **Verify Password** field just below the **Privacy Password** field.
14. Click **Add**.

    The user is added. You can repeat steps 6 through 13 to add additional users. Click the delete icon ( ) to delete a user.
15. Click **Save Policy and Exit**.

    The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

Enabling STIG Compliance

LICENSE: Any

Organizations within the United States federal government sometimes need to comply with a series of security checklists set out in Security Technical Implementation Guides (STIGs). The STIG Compliance option enables settings intended to support compliance with specific requirements set out by the United States Department of Defense.

If you enable STIG compliance on any appliances in your deployment, you must enable it on all appliances. Non-compliant managed devices cannot be registered to STIG-compliant Defense Centers and STIG-compliant devices cannot be registered to non-compliant Defense Centers.

Enabling STIG compliance does not guarantee strict compliance to all applicable STIGs. For more information on Sourcefire 3D System STIG compliance when using this mode for this version of the product, contact Sourcefire Support to obtain a copy of the Sourcefire 3D System STIG Release Notes for Version 5.3.

When you enable STIG compliance, password complexity and retention rules for local shell access accounts change. For more information on these settings, see the Sourcefire 3D System STIG Release Notes for Version 5.3. In addition, you cannot use `ssh` remote storage when in STIG compliance mode.

Note that applying a system policy with STIG compliance enabled forces appliances to reboot. If you apply a system policy with STIG enabled to an appliance that already has STIG enabled, the appliance does not reboot. If you apply a system policy with STIG disabled to an appliance that has STIG enabled, STIG remains enabled and the appliance does not reboot.

For appliances upgraded from versions earlier than Version 5.2.0, applying a policy with compliance enabled also regenerates appliance certificates, so you will need to re-register already registered managed devices or peers.

WARNING! You cannot disable this setting without assistance from Sourcefire Support. In addition, this setting may substantially impact the performance of your system. Sourcefire does not recommend enabling STIG compliance except to comply with Department of Defense security requirements.

To enable STIG compliance:

ACCESS: Admin

1. Select **System > Local > System Policy**.

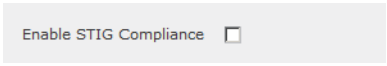
   The System Policy page appears.

2. You have the following options:
   - To modify the time settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the time settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.
3. Click **STIG Compliance**.

   The STIG Compliance page appears.

4. If you want to *permanently* enable STIG compliance on the appliance, select **Enable STIG Compliance**.

   WARNING! You cannot disable STIG compliance on an appliance after you apply a policy with STIG compliance enabled. If you need to disable compliance, contact Support.
5. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

   When you apply a system policy that enables STIG compliance to an appliance, note that the appliance reboots. Note that if you apply a system policy with STIG enabled to an appliance that already has STIG enabled, the appliance does not reboot.

   In addition, you need to re-register devices after enabling STIG compliance if the devices were upgraded from versions earlier than Version 5.2.0.

Synchronizing Time

LICENSE: Any

You can manage time synchronization on the appliance using the Time Synchronization page. You can choose to synchronize the time:

- manually
- using one or more NTP servers (one of which can be a Defense Center)

Time settings are part of the system policy. You can specify the time settings either by creating a new system policy or by editing an existing policy. In either case, the time setting is not used until you apply the system policy.

Note that time settings are displayed on most pages on the appliance in local time using the time zone you set on the Time Zone page (America/New York by default), but are stored on the appliance itself using UTC time. In addition, the current time appears in UTC at the top of the Time Synchronization page (local time is displayed in the Manual clock setting option, if enabled).

You must use native applications, such as command line interfaces or the operating system interface, to manage time settings for Sourcefire Software for X-Series. Synchronize time for Sourcefire Software for X-Series and its managing Defense Center from the same physical appliance or NTP server. For more information, see the *Sourcefire Software for X-Series Installation Guide*.

You can synchronize the appliance's time with an external time server. If you specify a remote NTP server, your appliance must have network access to it. Do not specify an untrusted NTP server. Connections to NTP servers do not use configured proxy settings. To use the Defense Center as an NTP server, see Serving Time from the Defense Center on page 2072.

Sourcefire recommends that you synchronize your virtual appliances to a physical NTP server. Do not synchronize your managed devices (virtual or physical) to a Virtual Defense Center.

IMPORTANT! Ensure that the time on your Defense Center and managed devices matches after time synchronization. Otherwise, unintended consequences may occur when the managed devices communicate with the Defense Center.

The procedure for synchronizing time differs slightly depending on whether you are using the web interface on a Defense Center or a managed device. Each procedure is explained separately below.

To synchronize time:

Access: Admin

1. Select **System > Local > System Policy**.

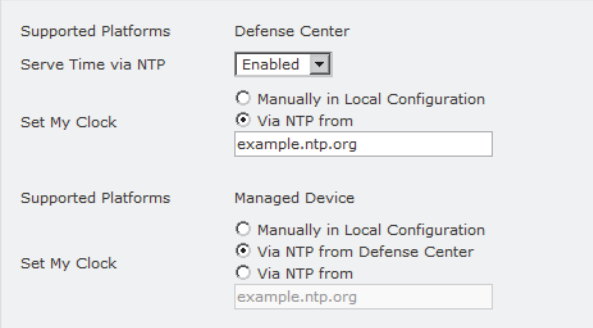
   The System Policy page appears.

2. You have the following options:
   - To modify the time settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the time settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.
3. Click **Time Synchronization**.

   The Time Synchronization page appears.



4. If you want to serve time from the Defense Center to your managed devices, in the **Serve time via NTP** drop-down list, select **Enabled**.
5. You have the following options for specifying how the time is synchronized on the Defense Center:
   - To set the time manually, select **Manually in Local Configuration**. See Setting the Time Manually on page 2095 for information about setting the time after you apply the system policy.
   - To receive time through NTP from a different server, select **Via NTP from** and, in the text box, type a comma-separated list of IP addresses for the NTP servers you want to use or, if DNS is enabled, type the fully qualified host and domain names.

WARNING! If the appliance is rebooted and your DHCP server sets an NTP server record different than the one you specify here, the DHCP-provided NTP server will be used instead. To avoid this situation, configure your DHCP server to set the same NTP server.

6. You have the following options for specifying how time is synchronized on any managed devices:
   - Select **Manually in Local Configuration** to set the time manually. See Setting the Time Manually on page 2095 for information about setting the time after you apply the system policy.
   - Select **Via NTP from Defense Center** to receive time through NTP from the Defense Center. See Serving Time from the Defense Center on page 2072 for more information.
   - Select **Via NTP from** to receive time through NTP from different servers. In the text box, type a comma-separated list of IP addresses of the NTP servers or, if DNS is enabled, type the fully qualified host and domain names.

   IMPORTANT! It may take a few minutes for the managed device to synchronize with the configured NTP servers. In addition, if you are synchronizing the managed device to a Defense Center that is configured as an NTP server, and the Defense Center itself is configured to use an NTP server, it may take some time for the time to synchronize. This is because the Defense Center must first synchronize with its configured NTP server before it can serve time to the managed device.

7. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy. See Applying a System Policy on page 2042 for more information.

Serving Time from the Defense Center

LICENSE: Any

You can configure the Defense Center as a time server using NTP and then use it to synchronize time between the Defense Center and managed devices.

Note that you cannot set the time manually after configuring the Defense Center to serve time using NTP. If you need to manually change the time, you should do so **before** configuring the Defense Center to serve time using NTP. If you need to change the time manually **after** configuring the Defense Center as an NTP server, disable the **Via NTP** option and click **Save**, change the time manually and click **Save**, and then enable **Via NTP** and click **Save**.

IMPORTANT! If you configure the Defense Center to serve time using NTP, and then later disable it, the NTP service on managed devices still attempts to synchronize time with the Defense Center. You must disable NTP from the managed devices' web interfaces to stop the synchronization attempts.

To configure the Defense Center as an NTP server:

ACCESS: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

2. You have the following options:

   - To modify the NTP server settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure the NTP server settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.

3. Click **Time Synchronization**.

   The Time Synchronization page appears.

4. From the **Serve Time via NTP** drop-down list, select **Enabled**.

5. In the **Set My Clock** option for the managed device, select **Via NTP from Defense Center**.

6. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy to the Defense Center and its managed devices. See Applying a System Policy on page 2042 for more information.

IMPORTANT! It may take a few minutes for the Defense Center to synchronize with its managed devices.

Configuring User Interface Settings

LICENSE: Any

Unattended login sessions of the Sourcefire 3D System web interface or command line interface may be security risks. You can configure, in minutes, the amount of idle time before a user's login session times out due to inactivity. You can also set a similar timeout for shell (command line) sessions.

Your deployment may have users who plan to passively, securely monitor the web interface for long periods of time. You can exempt users from the web interface session timeout with a user configuration option. (Users with the Administrator role, whose complete access to menu options poses an extra risk if compromised, cannot be made exempt from session timeouts.) For more information, see Managing User Login Settings on page 1979.

For cases in which you must restrict shell access to the system, a third option allows you to permanently disable the `expert` command in the command line. Disabling expert mode on an appliance prevents any user, even users with Configuration shell access, from going into expert mode in the shell. When a user goes into expert mode on the command line, the user can run any Linux command appropriate to the shell. When not in expert mode, command line users can only run the commands provided by the command line interface. Note that the command line interface is not supported for Series 2 appliances.

For more information on command line interface commands, see Command Line Reference on page 2324. For information on setting up users for command line access, see Managing Command Line Access on page 1976 and Command Line Reference on page 2324 (for virtual device CLI user management).

To configure user interface settings:

Access: Admin

1. Select **System > Local > System Policy**.

   The System Policy page appears.

2. You have the following options:

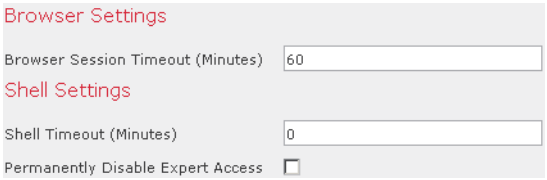
   - To modify user interface settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure user interface settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.

3. Click **User Interface**.

   The User Interface page appears.



4. You have the following options:

   - To configure session timeout for the web interface, type a number (of minutes) in the **Browser Session Timeout (Minutes)** field. The default value is 60; the maximum value is 1440 (24 hours).

     For information on how to exempt users from this session timeout, see Managing User Login Settings on page 1979.

- To configure session timeout for the command line interface, type a number (of minutes) in the **Shell Timeout (Minutes)** field. The default value is `0`; the maximum value is `1440` (24 hours).
- To permanently disable the `expert` command in the command line interface, select the **Permanently Disable Expert Access** check box.

WARNING! After you apply a system policy with expert mode disabled to an appliance, you cannot restore the ability to access expert mode through the web interface or the command line. You must contact Sourcefire Support to restore the expert mode capability.

5. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy to the Defense Center and its managed devices. Changes to session timeout intervals do not take effect until the next login session.

Mapping Vulnerabilities for Servers

LICENSE: Protection

The Sourcefire 3D System automatically maps vulnerabilities to a host IP address for any application protocol traffic received or sent from that address, when the server has an application ID in the discovery event database and the packet header for the traffic includes a vendor and version.

However, many servers do not include vendor and version information. For the server listed in the system policy, you can configure whether the system associates vulnerabilities with server traffic for vendor and versionless servers.

For example, a host serves SMTP traffic that does not have a vendor or version in the header. If you enable the SMTP server on the Vulnerability Mapping page of a system policy, then apply that policy to the Defense Center managing the device that detects the traffic, all vulnerabilities associated with SMTP servers are added to the host profile for the host.

Although detectors collect server information and add it to host profiles, the application protocol detectors will not be used for vulnerability mapping, because you cannot specify a vendor or version for a custom application protocol detector and cannot select the server for vulnerability mapping in the system policy.

To configure vulnerability mapping for servers:

ACCESS: Admin

1. Select **System > Local > System Policy**.

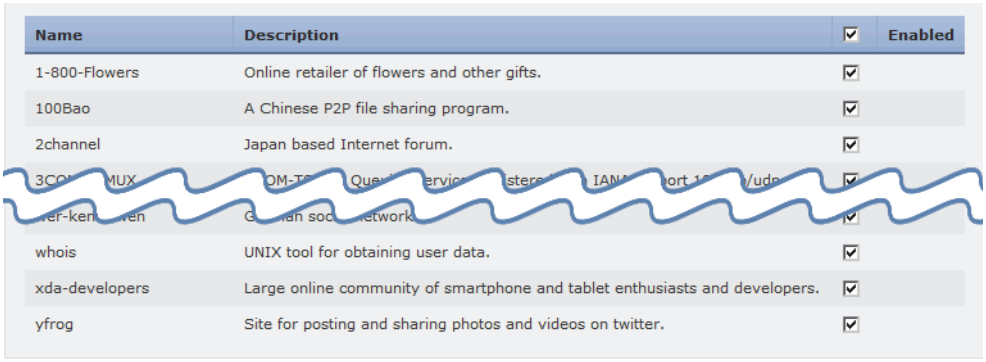
   The System Policy page appears.

2. You have the following options:
   - To modify vulnerability mapping settings in an existing system policy, click the edit icon ( ) next to the system policy.
   - To configure vulnerability mapping settings as part of a new system policy, click **Create Policy**.

     Provide a name and description for the system policy as described in Creating a System Policy on page 2039, and click **Save**.

   In either case, the Access List page appears.
3. Click **Vulnerability Mapping**.

   The Vulnerability Mapping page appears.



Name	Description		Enabled
1-800-Flowers	Online retailer of flowers and other gifts.	☑	
100Bao	A Chinese P2P file sharing program.	☑	
2channel	Japan based Internet forum.	☑	
3CO[illegible]MUX	[illegible]	☑	
[illegible]	[illegible]	☑	
whois	UNIX tool for obtaining user data.	☑	
xda-developers	Large online community of smartphone and tablet enthusiasts and developers.	☑	
yfrog	Site for posting and sharing photos and videos on twitter.	☑	

4. You have the following options:
   - To prevent vulnerabilities for a server from being mapped to hosts that receive application protocol traffic without vendor or version information, clear the check box for that server.
   - To cause vulnerabilities for a server to be mapped to hosts that receive application protocol traffic without vendor or version information, select the check box for that server.

   TIP! You can select or clear all check boxes at once using the check box next to **Enabled**.
5. Click **Save Policy and Exit**.

   The system policy is updated. Your changes do not take effect until you apply the system policy to the Defense Center and its managed devices. See Applying a System Policy on page 2042 for more information.

CHAPTER 49
CONFIGURING APPLIANCE SETTINGS

A Sourcefire 3D System appliance's *local configuration* (**System > Local > Configuration**) is a group of settings that is likely to be specific to a single appliance. Contrast the local configuration with the system policy (Managing System Policies on page 2038), which controls appliance settings that are likely to be similar across a deployment.

The following table summarizes an appliance's local configuration.

Local Configuration Options

OPTION	DESCRIPTION	FOR MORE INFORMATION, SEE...
Information	Allows you to view current information about the appliance. You can also change the appliance name.	Viewing and Modifying the Appliance Information on page 2078
HTTPS Certificate	Allows you to request an HTTPS server certificate, if needed, from a trusted authority and upload certificates to your appliance.	Using Custom HTTPS Certificates on page 2081
Database	Lets you enable external read-only access to the appliance database, and provides a client driver for you to download.	Enabling Access to the Database on page 2086
Network	Enables you to change options such as the IP address, hostname, and proxy settings of the appliance that were initially set up as part of the installation.	Configuring Network Settings on page 2088

Local Configuration Options (Continued)

Option	Description	For more information, see...
Management Interface	Allows you to view and modify the settings for the management interfaces on your appliance.	Editing Management Interface Configurations on page 2092
Process	Provides options that you can use to shut down or reboot the appliance, and restart Sourcefire 3D System-related processe.s	Shutting Down and Restarting the System on page 2094
Time	Displays the current time. If the time synchronization settings in the current system policy for the appliance is set to **Manually in Local Configuration**, then you can use this page to change the time.	Setting the Time Manually on page 2095
Remote Storage Device	On Defense Centers, allows you to configure remote storage for backups and reports.	Managing Remote Storage on page 2097
Change Reconciliation	Allows you to receive, via email, a detailed report of changes to your system over the last 24 hours.	Understanding Change Reconciliation on page 2104
Console Configuration	Allows you configure console access to Sourcefire appliances via VGA or serial port, or via Lights-Out Management (LOM), which allows you to perform limited monitoring and management tasks without being physically near the appliance.	Managing Remote Console Access on page 2105
Cloud Services	On Defense Centers, allows you to download URL filtering data from the Sourcefire cloud, perform lookups for uncategorized URLs, and send diagnostic information on detected files to Sourcefire.	Enabling Sourcefire Cloud Communications on page 2113

Viewing and Modifying the Appliance Information

License: Any

The Information page provides you with information about your appliances. The information includes read-only information, such as the product name and model number, the operating system and version, and the current appliance-level policies. The page also provides you with an option to change the name of the appliance.

The Appliance Information table describes each field.

Appliance Information

Field	Description
Name	A name you assign to the appliance. Note that this name is only used within the context of the Sourcefire 3D System. Although you can use the hostname as the name of the appliance, entering a different name in this field does not change the hostname.
Product Model	The model name for the appliance.
Software Version	The version of the software currently installed.
Serial Number	The chassis serial number of the appliance.
Store Events Only on Defense Center	Select this check box on the managed device to store event data on the Defense Center, but not the managed device. Clear this check box to store event data on both appliances.
Prohibit Packet Transfer to the Defense Center	Select this check box on the managed device to prevent the managed device from sending packet data with the events. Clear this check box to allow packet data to be stored on the Defense Center with events.
Operating System	The operating system currently running on the appliance.
Operating System Version	The version of the operating system currently running on the appliance.
IPv4Address	The IPv4 address of the appliance. If IPv4 management is disabled for the appliance, this field indicates that.
IPv6 Address	The IPv6 address of the appliance. If IPv6 management is disabled for the appliance, this field indicates that.
Current Policies	The appliance-level policies currently applied. If a policy has been updated since it was last applied, the name of the policy appears in italics.
Model Number	The model number for the appliance. This number may be important for troubleshooting.

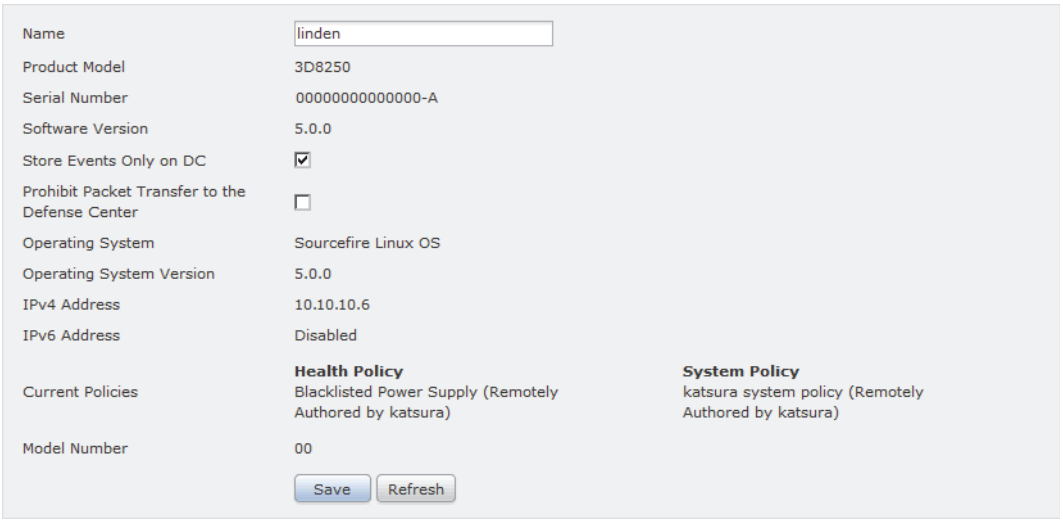
To modify the appliance information:

Access: Admin

1. Select **System > Local > Configuration**.

   The Information page appears. The Defense Center version of the page is shown below.

   For comparison, the managed device version of the page is shown below.



2. To change the appliance name, type a new name in the **Name** field.

   The name **must** be alphanumeric characters and cannot be composed of numeric characters only.

3. To save your changes, click **Save**.

   The page refreshes and your changes are saved.

Using Custom HTTPS Certificates

LICENSE: Any

Sourcefire Defense Centers and managed devices that support web-based user interfaces include default SSL (Secure Sockets Layer) certificates that you can use to initiate an encrypted communication channel between your web browser and the appliance. However, because the default certificate for an appliance is not generated by a certificate authority (CA) trusted by any globally known CA, you can replace it with a custom certificate signed by a globally known CA.

You can manage certificates through the local configuration for your appliance. For more information, see the following:

- Viewing the Current HTTPS Server Certificate on page 2081
- Generating a Server Certificate Request on page 2082
- Uploading Server Certificates on page 2083
- Configuring User Certificates on page 2085

Viewing the Current HTTPS Server Certificate

LICENSE: Any

You can view details from the server certificate currently in place for your appliance. The certificate provides the following information:

HTTPS Server Certificate Information

FIELD	DESCRIPTION
Subject	For the appliance where the certificate is installed, provides the commonName, countryName, organizationName, and organizationalUnitName.
Issuer	For the appliance that issued the certificate, provides the commonName, countryName, organizationName, and organizationalUnitName.
Validity	Indicates the timeframe during which the certificate is valid.
Version	Indicates the certificate version.
Serial Number	Indicates the certificate serial number.
Signature Algorithm	Indicates the algorithm used to sign the certificate.

To view the certificate details:

ACCESS: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **HTTPS Certificate**.

   The HTTPS Certificate page appears, with the details of the current certificate for the appliance.

Generating a Server Certificate Request

LICENSE: Any

You can generate a certificate request based on your appliance information and the identification information you supply. You can send the resulting request to a certificate authority to request a server certificate. You can also use it to self-sign a certificate if you have an internal certificate authority (CA) installed that is trusted by your browser. The generated key is in Base-64 encoded PEM format.

Note that when you generate a certificate request through the local configuration HTTPS Certificate page, you can only generate a certificate for a single server. You must type the fully qualified domain name of the server exactly as it should appear in the certificate in the **Common Name** field. If the common name and the DNS host name do not match, you receive a warning when connecting to the appliance. Similarly, if you install a certificate that is not signed by a globally known authority, you receive a security warning when you connect to the appliance.

To generate a certificate request:

ACCESS: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **HTTPS Certificate**.

   The Current HTTPS Certificate page appears.

3. Click **Generate New CSR**.

   The Generate Certificate Signing Request pop-up window appears.

4. Type the two-letter country code for your country into the **Country Name (two-letter code)** field.
5. Type the postal abbreviation for your state or province in the **State or Province** field.
6. Type the name of your **Locality or City**.
7. Type your **Organization** name.
8. Type an **Organizational Unit (Department)** name.
9. Type the fully qualified domain name of the server for which you want to request a certificate in the **Common Name** field, exactly as you want it to appear in the certificate.
10. Click **Generate**.

    The Certificate Signing Request pop-up window appears.

11. Open a text editor.
12. Copy the entire block of text in the certificate request, including the `BEGIN CERTIFICATE REQUEST` and `END CERTIFICATE REQUEST` lines, and paste it into a blank text file.
13. Save the file as *`servername`*`.csr`, where *`servername`* is the name of the server where you plan to use the certificate.
14. Upload the CSR file to the certificate authority where you want to request a certificate or use the CSR to create a self-signed certificate.

Uploading Server Certificates

LICENSE: Any

After you have a signed certificate from a certificate authority (CA), you can upload it. If the signing authority that generated the certificate requires you to

trust an intermediate CA, you must also supply a certificate chain, sometimes referred to as a certificate path. If you require user certificates, they must be generated by a certificate authority whose intermediate authority is included in the certificate chain.

To import a certificate:

Access: Admin

1. Select **System > Local > Configuration**.

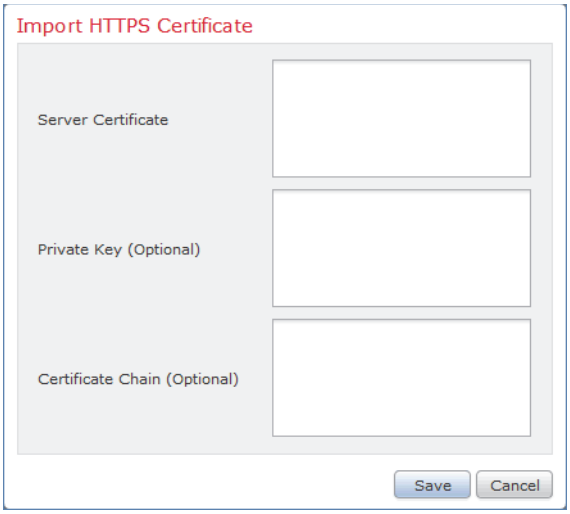
   The Information page appears.

2. Click **HTTPS Certificate**.

   The Current HTTPS Certificate page appears.

3. Click **Import HTTPS Certificate**.

   The Import HTTPS Certificate pop-up window appears.



4. Open the server certificate in a text editor, copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines, and paste it into the **Server Certificate** field.

5. Optionally, open the private key file, copy the entire block of text, including the `BEGIN RSA PRIVATE KEY` and `END RSA PRIVATE KEY` lines, and paste it into the **Private Key** field.

6. Open any intermediate certificates you need to provide, copy the entire block of text, for each, and paste it into the **Certificate Chain** field.

7. Click **Save** to import the certificate.

   The certificate imports and the Current Certificate View updates to reflect the new certificate.

Configuring User Certificates

LICENSE: Any

You can restrict access to the Sourcefire 3D System web server using client browser certificate checking. When you enable user certificates, the web server checks that a user's browser client has a valid user certificate selected. That user certificate must be generated by the same trusted certificate authority used for the server certificate. If the user selects a certificate in the browser that is not valid or not generated by a certificate authority in the certificate chain on the device, the browser cannot load the web interface.

You can also load a certificate revocation list (CRL) for the server. The CRL lists any certificates that have been revoked by the certificate authority, so the web server can verify that the client browser certificate has not been revoked. If the user selects a certificate that is listed in the CRL as a revoked certificate, the browser cannot load the web interface. The appliance supports upload of CRLs in Distinguished Encoding Rules (DER) format. You can only load one CRL for a server.

To ensure that the list of revoked certificates stays current, you can create a scheduled task to update the CRL. The most recent refresh of the CRL is listed in the interface.

Make sure you use the same certificate authority used for the server certificate and that you have uploaded the intermediate certificate for the certificates. For more information, see Uploading Server Certificates on page 2083.

To require valid user certificates:

ACCESS: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **HTTPS Certificate**.

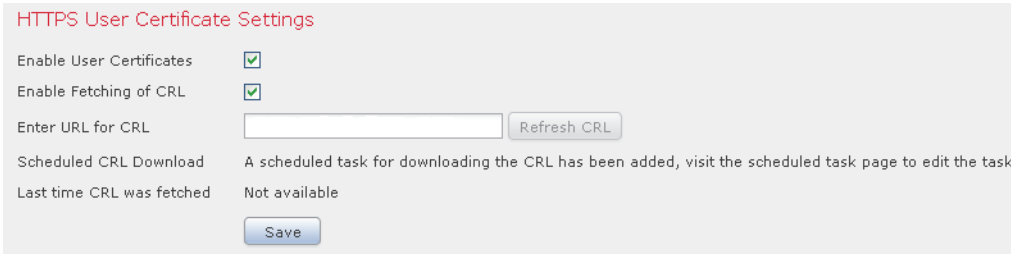
   The Current HTTPS Certificate page appears.

3. Select **Enable User Certificates**.

   The Enable Fetching of CRL option appears.

4. Optionally, select **Enable Fetching of CRL**.

   The remaining CRL configuration options appear.



5. Type a valid URL to an existing CRL file and click **Refresh CRL**.

   The current CRL at the supplied URL loads to the server.

   IMPORTANT! Enabling fetching of the CRL creates a scheduled task to update the CRL on a regular basis. Edit the task to set the frequency of the update. For more information, see Automating Certificate Revocation List Downloads on page 2011.

6. Verify that you have a valid user certificate generated by the same certificate authority that created the server certificate.

   WARNING! When you save a configuration with enabled user certificates, if you do not have a valid user certificate installed in your browser certificate store, you disable all web server access to the appliance. Make sure you have a valid certificate installed before saving settings.

7. To apply the user certificate configuration to the web server, click **Save**.

   Note that you can disable user certificate enforcement via the command line if you enable certificates and find that your user certificate does not enable access. For more information, see disable-http-user-cert on page 2363.

Enabling Access to the Database

LICENSE: Any

You can configure the Defense Center to allow read-only access to its database by a third-party client. This allows you to query the database using SQL using any of the following:

- industry-standard reporting tools such as Actuate BIRT, JasperSoft iReport, or Crystal Reports
- any other reporting application (including a custom application) that supports JDBC SSL connections
- the Sourcefire-provided command-line Java application called RunQuery, which you can either run interactively or use to obtain comma-separated results for a single query

From the Database Settings local configuration page, you can enable database access and create an access list that allows selected hosts to query the database. Note that this access list does not also control appliance access. For more information on appliance access lists, see Configuring the Access List for Your Appliance on page 2048.

You can also download a package that contains the following:

- RunQuery, the Sourcefire-provided database query tool
- InstallCert, a tool you can use to retrieve and accept the SSL certificate from the Defense Center you want to access
- the JDBC driver you must use to connect to the database

Note that when you connect to the database from an external client you must provide a username and password that match those for an Administrator or External Database user on the Defense Center. For more information, see Adding New User Accounts on page 1974.

For detailed information on configuring external access to the Sourcefire 3D System database, including information on the database schema and supported queries, see the *Sourcefire 3D System Database Access Guide*.

To enable database access:

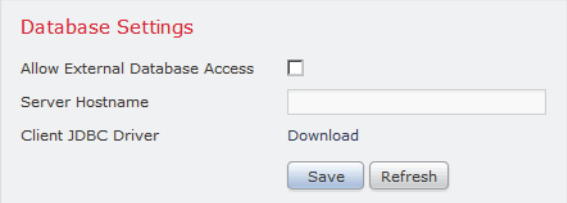
Access: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **Database**.

   The Database Settings page appears.



3. Select the **Allow External Database Access** check box.

   The **Access List** field appears. See step 6 for more information.

4. Type the fully qualified domain name (FQDN), IPv4 address, or IPv6 address of the Defense Center in the **Server Hostname** field, depending on your third-party application requirements.

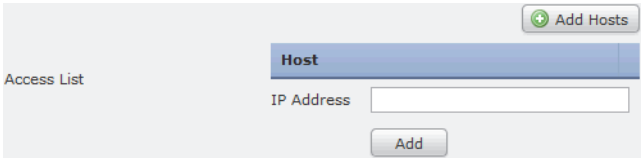
   If you type a FQDN, you must make sure that the client can resolve the FQDN of the Defense Center. If you type an IP address, you must make sure that the client can connect to the Defense Center using the IP address.

5. Next to **Client JDBC Driver**, click **Download** and follow your browser's prompts to download the `client.zip` package.

   See the *Sourcefire 3D System Database Access Guide* for information on using the tools in the package you downloaded to configure database access.

6. To add database access for one or more IP addresses, click **Add Hosts**.

   An **IP Address** field appears in the **Access List** field.



7. In the **IP Address** field, you have the following options, depending on the IP addresses you want to add:
   - an exact IP address (for example, 192.168.1.101)
   - an IP address block using CIDR notation (for example, 192.168.1.1/24)

     For information on using CIDR in the Sourcefire 3D System, see IP Address Conventions on page 63.
   - any, to designate any IP address
8. Click **Add**.

   The IP address is added to the database access list.
9. Optionally, to remove an entry in the database access list, click the delete icon ( ).
10. Click **Save**.

    Your database access settings are saved.

TIP! Click **Refresh** to revert to the last saved database settings.

Configuring Network Settings

LICENSE: Any

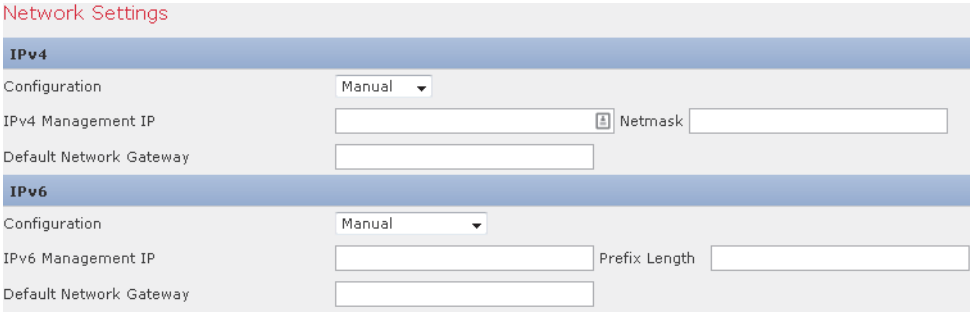
When you first set up an appliance, you configure its network settings so that it can communicate on your internal, protected management network. To change these settings and to configure additional network settings such as proxies, use the Network page (**System > Local > Configuration**, then click **Network**).

IMPORTANT! You must use command-line tools to modify network and proxy settings for virtual devices, and to modify network settings for Sourcefire Software for X-Series. Note that Sourcefire Software for X-Series does **not** support a proxy. For more information, see the *Sourcefire 3D System Virtual Installation Guide* and the *Sourcefire Software for X-Series Installation and Configuration Guide*.

You can customize the following network settings:

IPv4 and IPv6-Specific Management Interface Settings

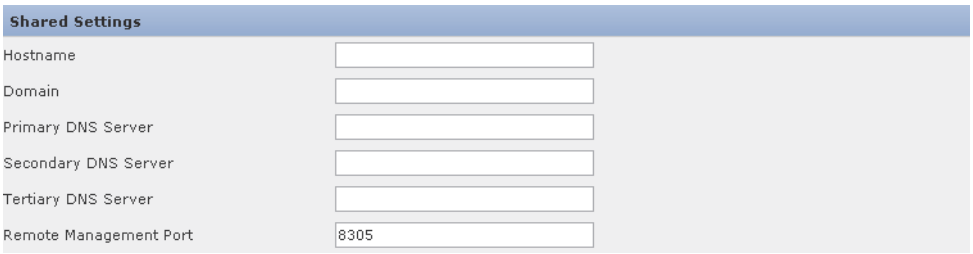
The Sourcefire 3D System provides a dual stack implementation for both IPv4 and IPv6 management environments. You can choose one or both protocols; disable the protocol (if any) you do not want to use.



For each enabled management protocol, you must specify the IP address of the management interface, a netmask or prefix length, and the default gateway. You can either set these manually or configure the appliance to retrieve them from a local DHCP server or IPv6 router.

Shared Management Settings

Regardless of your management environment, you can specify up to three DNS servers, as well as the host name and domain for the device.



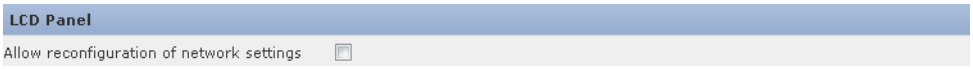
On Defense Centers, you can also change the maximum transmission unit (MTU) for the management interface, which designates the largest size packet, in bytes, that can pass through the interface. The default value is 1500 bytes.

Finally, you can change the management port. Sourcefire 3D System appliances communicate using a two-way, SSL-encrypted communication channel, which by default is on port 8305. Although Sourcefire **strongly** recommends that you keep the default setting, if the management port conflicts with other communications on your network, you can choose a different port.

WARNING! If you change the management port, you must change it for all appliances in your deployment that need to communicate with each other.

LCD Panel Settings (Series 3 devices)

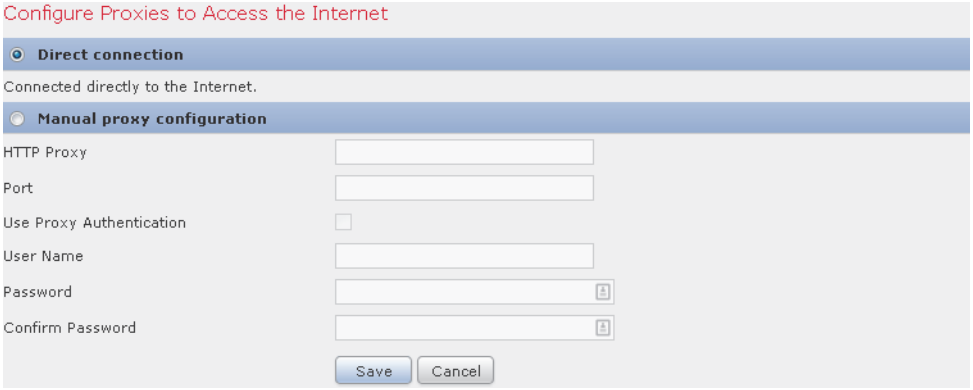
Series 3 devices allow you view device information using an LCD panel on the front of the device. On the Series 3 Network page, you can also allow people to change network settings using the LCD panel.



WARNING! Allowing reconfiguration using the LCD panel can present a security risk. You need only physical access, not authentication, to configure network settings using the LCD panel.

Proxy Settings

All Sourcefire appliances are configured to directly connect to the Internet on ports 443/tcp (HTTPS) and 80/tcp (HTTP); see Security, Internet Access, and Communication Ports on page 54. With the exception of Sourcefire Software for X-Series, Sourcefire appliances support use of a proxy server, to which you can authenticate via HTTP Digest.



To configure network settings for the local appliance:

Access: Admin

1. Select **System > Local > Configuration** to display the Information page, then click **Network**.

   The Network page appears.

2. Specify your management network protocol, as well as basic network settings for each protocol. Under IPv4 and IPv6, select one of:

   - **Disabled** - disables the protocol. Do **not** disable both IPv4 and IPv6.
   - **DHCP** (IPv4 and IPv6) - retrieves network settings from a DHCP server.
   - **Router assigned** (IPv6 only) - retrieves network settings from a local IPv6 router.
   - **Manual** - allows you to manually specify network settings. For IPv4, you must set the management IP address and netmask in dotted decimal form (for example: a netmask of 255.255.0.0). For IPv6, you must set the address in colon-separated hexadecimal form and the number of bits in the prefix (for example: a prefix length of 112).

3. Under Shared Settings, specify network settings that do not depend on the management network protocol.

   You can specify up to three DNS servers, as well as the host name and domain for the appliance. Note that if you selected **DHCP** in the previous step, you cannot manually specify these shared settings. You can also change the management interface MTU and the management port. For more information, see Shared Management Settings on page 2089.

4. Optionally, under Configure Proxies to Access the Internet, configure the appliance to access the Internet using a proxy. Select **Manual proxy configuration**, then:

   - Enter the IP address or fully qualified domain name of your proxy server in the **HTTP Proxy** field. Enter the port in the **Port** field.
   - Optionally, supply authentication credentials by selecting **Use Proxy Authentication** then providing a **User Name** and **Password**.

5. Optionally, on Series 3 devices, under LCD Panel, select the **Allow reconfiguration of network settings** check box to enable changing network settings using the device's LCD panel.

   WARNING! Allowing reconfiguration using the LCD panel can present a security risk. You need only physical access, not authentication, to configure network settings using the LCD panel. The web interface warns you that enabling this option is a potential security issue.

6. When you are finished configuring the appliance's network settings, click **Save**.

   The network settings are changed. If you changed the appliance's hostname, the new name is not reflected in the syslog until after you reboot the appliance.

Editing Management Interface Configurations

LICENSE: Any

You can use the Management Interface page to modify the default settings for each management interface on your Defense Center. Any changes you make to the Auto Negotiate value are ignored for Gigabit interfaces. Note that you can also configure management interfaces for a managed device from the managing device; see Configuring the Management Interface on page 305.

WARNING! Do not modify the settings for the management interface unless you have physical access to the appliance. It is possible to select a setting that makes it difficult to access the web interface.

To edit a management interface:

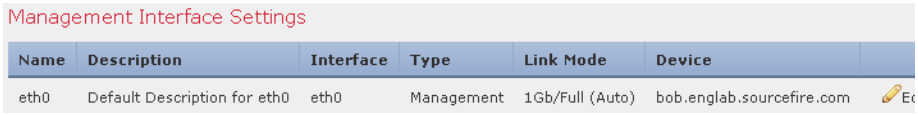
ACCESS: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **Management Interface**.

   The Management Interface page appears, listing the current settings for each interface on your Defense Center.



3. Click **Edit** next to the interface that you want to modify.

   The current settings for the interface appear.

   These settings include:

   - interface
   - device name
   - interface type: Management.
   - interface name
   - interface description
   - whether the interface is configured to auto-negotiate speed and duplex settings
   - the current link mode, including the bandwidth and duplex setting (Full or Half); N/A indicates that there is no link for the interface

   You can modify the interface name and description, MDI/MDIX settings, and the link mode as needed. However, keep the following in mind:

   - In the **Auto Negotiate** field, select **Off** only if you require a specific link mode setting. You cannot change the Auto Negotiate setting for 10Gb interfaces.
   - If **Auto Negotiate** is disabled and you need to specify a link mode, select it in the **Link Mode** field.
   - Any changes you make to the **Auto Negotiate** value are ignored for Gigabit interfaces.

4. Click **Save**.

   The Management Interface page appears again.

Shutting Down and Restarting the System

LICENSE: Any

You have several options for controlling the processes on your appliance. You can:

- shut down the appliance
- reboot the appliance
- restart communications, database, and HTTP server processes on the appliance (this is typically used during troubleshooting)
- restart the Snort process

WARNING! Do **not** shut off appliances using the power button; it may cause a loss of data. Shut down appliances completely via the Appliance Process page.

To shut down or restart your appliance:

ACCESS: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **Process**.

   The Appliance Process page appears. The Defense Center version of the page is shown below.

3. Specify the command you want to perform:

   On Defense Centers:

   - To shut down the appliance, click **Run Command** next to **Shutdown Defense Center**.
   - To reboot the appliance, click **Run Command** next to **Reboot Defense Center**. Note that this logs you out of the Defense Center.
   - To restart the appliance, click **Run Command** next to **Restart Defense Center Console**. Note that restarting the Defense Center may cause deleted hosts to reappear in the network map.

   IMPORTANT! When you reboot your Defense Center, the system runs a database check that can take up to an hour to complete.

   On managed devices:

   - To shut down the appliance, click **Run Command** next to **Shutdown Appliance**.
   - To reboot the appliance, click **Run Command** next to **Reboot Appliance**. Note that this logs you out of the device.
   - To restart the appliance, click **Run Command** next to **Restart Appliance Console**.
   - To restart the Snort process, click **Run Command** next to **Restart Snort**.

   IMPORTANT! When you reboot your managed device, the device runs a database check that can take up to an hour to complete.

Setting the Time Manually

LICENSE: Any

If the Time Synchronization setting in the currently applied system policy is set to **Manually in Local Configuration**, then you can manually set the time for the appliance using the Time page in the local configuration.

You must use native applications, such as command line interfaces or the operating system interface, to manage time settings for Sourcefire Software for X-Series. For more information, see the *Sourcefire Software for X-Series Installation Guide*.

If the appliance is synchronizing its time based on NTP, you cannot change the time manually. Instead, the NTP Status section on the Time page provides the following information:

NTP Status

Column	Description
NTP Server	The IP address and name of the configured NTP server.
Status	The status of the NTP server time synchronization. The following states may appear: • **Being Used** indicates that the appliance is synchronized with the NTP server. • **Available** indicates that the NTP server is available for use, but time is not yet synchronized. • **Not Available** indicates that the NTP server is in your configuration, but the NTP daemon is unable to use it. • **Pending** indicates that the NTP server is new or the NTP daemon was recently restarted. Over time, its value should change to **Being Used**, **Available**, or **Not Available**. • **Unknown** indicates that the status of the NTP server is unknown.
Offset	The number of milliseconds of difference between the time on the appliance and the configured NTP server. Negative values indicate that the appliance is behind the NTP server, and positive values indicate that it is ahead.
Last Update	The number of seconds that have elapsed since the time was last synchronized with the NTP server. The NTP daemon automatically adjusts the synchronization times based on a number of conditions. For example, if you see larger update times such as 300 seconds, that indicates that the time is relatively stable and the NTP daemon has determined that it does not need to use a lower update increment.

See Synchronizing Time on page 2069 for more information about the time settings in the system policy.

To manually configure the time:

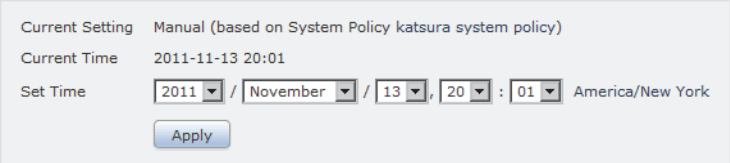
Access: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **Time**.

   The Time page appears.



3. Select the following from the **Set Time** drop-down lists:
   - year
   - month
   - day
   - hour
   - minute
4. Click **Apply**.

   The time is updated.
5. If you want to change the time zone, click the time zone link located next to the date and time. For more information, see Setting Your Default Time Zone on page 2306.

   A pop-up window appears.
6. From the left list, select the continent or area that contains the time zone you want to use.

   For example, if you want to use a time zone standard to North America, South America, or Canada, select **America**.
7. From the right list, select the zone (city name) that corresponds with the time zone you want to use.

   For example, if you want to use Eastern Standard Time, you would select **New York** after selecting **America** in the first time zone box.
8. Click **Save** and, after the time zone setting is saved, click **Done** to close the pop-up window.

   For more information about using the time zone page, see Setting Your Default Time Zone on page 2306.

Managing Remote Storage

LICENSE: Any

On Defense Centers, you can use local or remote storage for backups and reports. You can use Network File System (NFS), Secure Shell (SSH), or Server Message Block (SMB)/Common Internet File System (CIFS) for backup and report remote storage. You cannot send backups to one remote system and reports to

another, but you can choose to send either to a remote system and store the other on the local Defense Center. For information on backup and restore, see Using Backup and Restore on page 2286.

TIP! After configuring and selecting remote storage, you can switch back to local storage **only** if you **have not** increased the connection database limit.

You must ensure that your external remote storage system is functional and accessible from the Defense Center.

Select one of the backup and report storage options:

- To disable external remote storage and use the local Defense Center for backup and report storage, see Using Local Storage on page 2098.
- To use NFS for backup and report storage, see Using NFS for Remote Storage on page 2099.
- To use secure shell (SCP) via SSH for backup and report storage, see Using SSH for Remote Storage on page 2100.
- To use SMB for backup and report storage, see Using SMB for Remote Storage on page 2102.

IMPORTANT! You cannot use remote backup and restore to manage data on Sourcefire Software for X-Series.

Using Local Storage

LICENSE: Any

You can store backups and reports on the local Defense Center.

To store backups and reports locally:

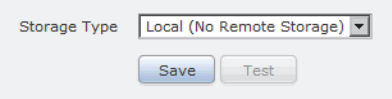
ACCESS: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **Remote Storage Device**.

   The Remote Storage Device page appears.



3. Select **Local (No Remote Storage)** from the **Storage Type** drop-down list.

4. Click **Save**.

   Your storage location choice is saved.

TIP! You do not use the **Test** button with local storage.

Using NFS for Remote Storage

LICENSE: Any

You can select Network File System (NFS) protocol to store your reports and backups. Optionally, select the **Use Advanced Options** check box to use one of the mount binary options as documented in an NFS mount man page.

To store backups and reports using NFS:

ACCESS: Admin

1. Select **System > Local > Configuration**.

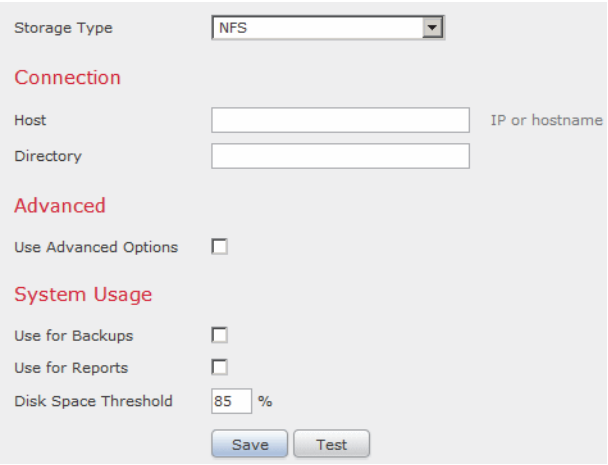
   The Information page appears.

2. Click **Remote Storage Device**.

   The Remote Storage Device page appears.

3. Select **NFS** from the **Storage Type** drop-down list.

   The page refreshes to display the NFS storage configuration options.



4. Add the connection information:
   - Enter the IPv4 address or hostname of the storage system in the **Host** field.
   - Enter the path to your storage area in the **Directory** field.

5. If there are any required command line options, select **Use Advanced Options**.

   A **Command Line Options** field appears where you can enter mount binary options.

6. Under **System Usage**, select either or both of the following:
   - Select **Use for Backups** to store backups on the designated host.
   - Select **Use for Reports** to store reports on the designated host.
   - Enter **Disk Space Threshold** for backup to remote storage. Default is 85%.

7. Optionally, click **Test**.

   The test ensures that the Defense Center can access the designated host and directory.

8. Click **Save**.

   Your remote storage configuration is saved.

Using SSH for Remote Storage

LICENSE: Any

You can select **SSH** to use secure copy (SCP) to store your reports and backups. Optionally, select the **Use Advanced Options** check box to use one of the mount binary options as documented in a SSH mount man page.

WARNING! If you enable STIG compliance on an appliance, you cannot use SSH for remote storage for that appliance. For more information, see Enabling STIG Compliance on page 2068.

To store backups and reports using SSH:

ACCESS: Admin

1. Select **System > Local > Configuration**.

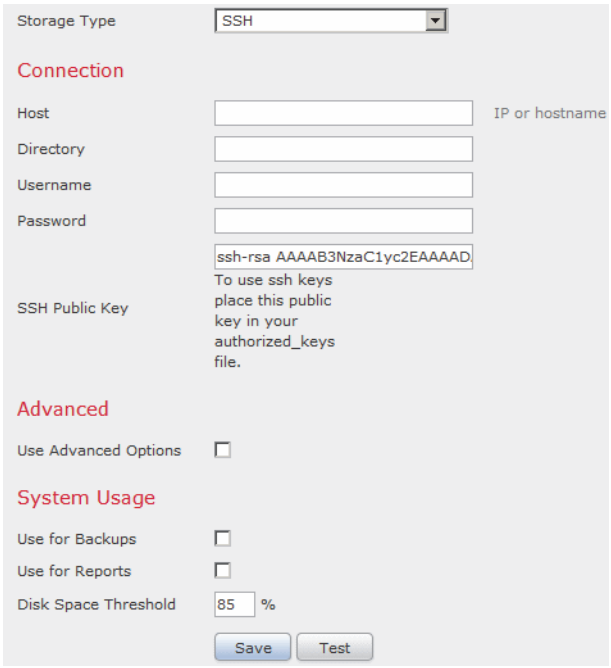
   The Information page appears.

2. Click **Remote Storage Device**.

   The Remote Storage Device page appears.

3. In **Storage Type**, select **SSH**.

   The page refreshes to display the SCP via SSH storage configuration options.



4. Add the connection information:
   - Enter the IP address or hostname of the storage system in the **Host** field.
   - Enter the path to your storage area in the **Directory** field.
   - Enter the storage system's user name in the **Username** field and the password for that user in the **Password** field. To specify a domain, precede the user name with the domain followed by a forward slash (/).
   - To use SSH keys, copy the content of the **SSH Public Key** field and place it in your authorized_keys file.
5. If there are any required command line options, select **Use Advanced Options**.

   A **Command Line Options** field appears where you can enter mount binary options.
6. Under System Usage, select either or both of the following:
   - Select **Use for Backups** to store backups on the designated host.
   - Select **Use for Reports** to store reports on the designated host.
7. Optionally, click **Test**.

   The test ensures that the Defense Center can access the designated host and directory.

8. Click **Save**.

   Your remote storage configuration is saved.

Using SMB for Remote Storage

LICENSE: Any

You can select Server Message Block (SMB) protocol to store your reports and backups. Optionally, select the **Use Advanced Options** check box to use one of the mount binary options, as documented in an SMB mount man page. For example, using SMB, you can enter the security mode in the **Command Line Options** field using the following format:

`sec=`*`mode`*

where *mode* is the security mode you want to use for remote storage. See the Security Mode Settings table for setting options.

Security Mode Settings

MODE	DESCRIPTION
[none]	Attempt to connect as null user (no name).
`krb5`	Use Kerberos version 5 authentication.
`krb5i`	Use Kerberos authentication and packet signing.
`ntlm`	Use NTLM password hashing. (Default)
`ntlmi`	Use NTLM password hashing with signing (may be Default if `/proc/fs/cifs/PacketSigningEnabled` is on or if server requires signing).
`ntlmv2`	Use NTLMv2 password hashing.
`ntlmv2i`	Use NTLMv2 password hashing with packet signing.

To store backups and reports using SMB:

ACCESS: Admin

1. Select **System > Local > Configuration**.

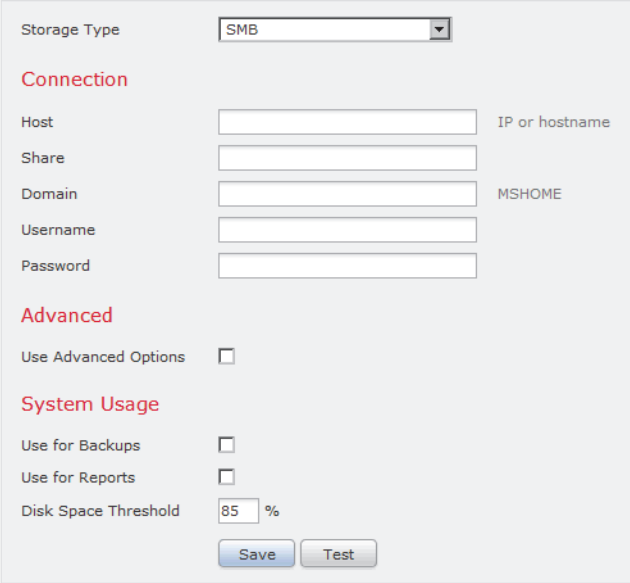
   The Information page appears.

2. Click **Remote Storage Device**.

   The Remote Storage Device page appears.

3. Under **Storage Type**, select **SMB**.

   The page refreshes to display the SMB storage configuration options.



4. Add the connection information:
   - Enter the IPv4 address or hostname of the storage system in the **Host** field.
   - Enter the share of your storage area in the **Share** field. Note that the system only recognizes top-level shares and not full file paths. To use the specified Share directory as a remote backup destination, it must be shared on the Windows system.
   - Optionally, enter the domain name for the remote storage system in the **Domain** field.
   - Enter the user name for the storage system in the **Username** field and the password for that user in the **Password** field.
5. If there are any required command line options, select **Use Advanced Options**.

   A **Command Line Options** field appears where you can enter the mount binary commands, such as security modes. See Security Mode Settings on page 2102 for more information.
6. Under System Usage, select either or both of the following:
   - Select **Use for Backups** to store backups on the designated host.
   - Select **Use for Reports** to store reports on the designated host.
7. Optionally, click **Test**.

   The test ensures that the Defense Center can access the designated host and directory.

8. Click **Save**.

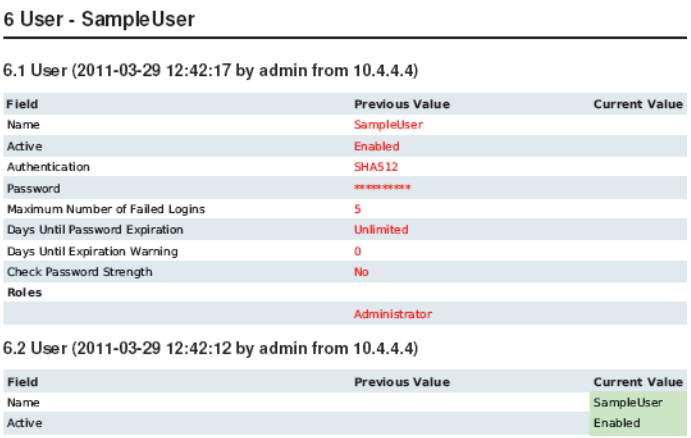
   Your remote storage configuration is saved.

Understanding Change Reconciliation

LICENSE: Any

To monitor the changes that users make and ensure that they follow your organization's preferred standard, you can configure your system to send, via email, a detailed report of changes made to your system over the past 24 hours. Whenever a user saves changes to the system configuration, a snapshot is taken of the changes. The change reconciliation report combines information from these snapshots to present a clear summary of recent system changes.

The following sample graphic displays a User section of an example change reconciliation report and lists both the previous value for each configuration and the value after changes. When users make multiple changes to the same configuration, the report lists summaries of each distinct change in chronological order, beginning with the most recent.



6 User - SampleUser

6.1 User (2011-03-29 12:42:17 by admin from 10.4.4.4)

Field	Previous Value	Current Value
Name	SampleUser	
Active	Enabled	
Authentication	SHA512	
Password	*********	
Maximum Number of Failed Logins	5	
Days Until Password Expiration	Unlimited	
Days Until Expiration Warning	0	
Check Password Strength	No	
Roles		
	Administrator	

6.2 User (2011-03-29 12:42:12 by admin from 10.4.4.4)

Field	Previous Value	Current Value
Name		SampleUser
Active		Enabled

You can view changes made during the previous 24 hours. However, to view prior changes, you must view the audit log. See Using the Audit Log to Examine Changes on page 2278 for more information.

To use the change reconciliation feature:

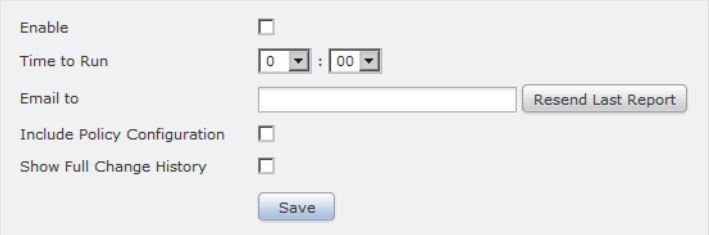
ACCESS: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **Change Reconciliation**.

   The Change Reconciliation page appears.



3. Select the **Enable** check box.
4. Select the time of day you want the system to send out the change reconciliation report from the **Time to Run** drop-down lists.
5. In the **Email to** field, enter the email addresses of report recipients. At any time, you can click **Resend Last Report** to send recipients another copy of the most recent change reconciliation report.

   IMPORTANT! To receive change reconciliation reports, you must first configure a mail relay host and notification address. For more information, see Configuring a Mail Relay Host and Notification Address on page 2060.

6. Optionally, select **Include Policy Configuration** to include records of policy changes in the change reconciliation report. This includes changes to access control, intrusion, system, health, and network discovery policies. If you do not select this option, the report will not show changes to any policies.

   IMPORTANT! This option is not available on managed devices.

7. Optionally, select **Show Full Change History** to include records of all changes over the past 24 hours in the change reconciliation report. If you do not select this option, the report includes only a consolidated view of changes for each category.
8. Click **Save**.

   Your changes are saved. The report runs daily at the time you selected.

Managing Remote Console Access

LICENSE: Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

You can use a Linux system console for remote access on any appliance via either the VGA port (which is the default) or the serial port on the physical appliance.

Choose the option most suitable to the physical layout of your organization's Sourcefire deployment.

You can use Lights-Out Management (LOM) on a Serial Over LAN (SOL) connection to remotely monitor or manage Series 3 appliances without logging into the management interface of the appliance. You can perform limited tasks, such as viewing the chassis serial number or monitoring such conditions as fan speed and temperature, using a command line interface on an out-of-band management connection. Series 2, virtual appliances, and Sourcefire Software for X-Series do not support LOM.

You must enable LOM for both the appliance and the user you want to manage the appliance. After you enable the appliance and the user, you use a third-party Intelligent Platform Management Interface (IPMI) utility to access and manage your appliance.

For more information, see the following topics:

- Configuring Remote Console Settings on the Appliance on page 2106
- Enabling Lights-Out Management User Access on page 2108
- Using a Serial Over LAN Connection on page 2109
- Using Lights-Out Management on page 2111

Configuring Remote Console Settings on the Appliance

LICENSE: Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

Use the web interface of the appliance you want to remotely manage to select and configure the remote console access option you want to use.

IMPORTANT! Before you can connect to a Series 3 device using LOM/SOL, you must disable Spanning Tree Protocol (STP) on any third-party switching equipment connected to the device's management interface.

To configure remote console settings:

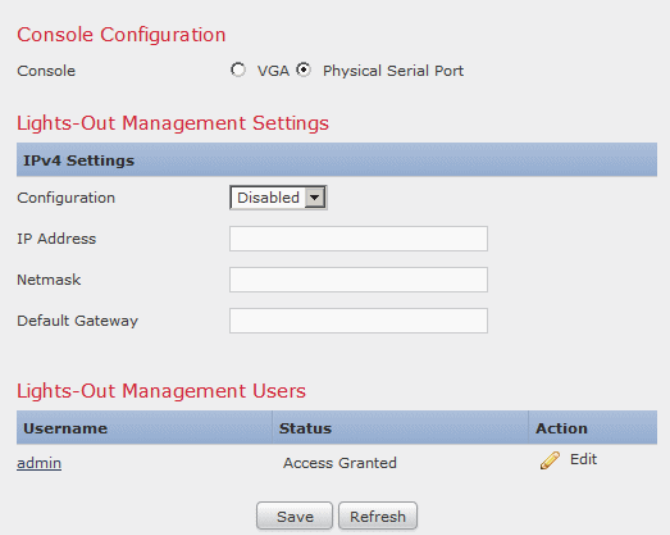
ACCESS: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Select **Console Configuration**.

   The Console Configuration page appears.



3. Select a remote console access option:

   - Select **VGA** to use the appliance's VGA port. This is the default option.
   - Select **Physical Serial Port** to use the appliance's serial port, or to use LOM/SOL on a Series 3 Defense Center or 8000 Series device.

     Note that 3D2100, 3D2500, 3D3500, and 3D4500 managed devices do not have serial ports.
   - Select **Lights-Out Management** to use LOM/SOL on a 7000 Series device. On these devices, you cannot use SOL and a regular serial connection at the same time.

   If you selected **Physical Serial Port** or **Lights-Out Management**, the LOM settings appear.

IMPORTANT! When you change your remote console from **Physical Serial Port** to **Lights-Out Management** or from **Lights-Out Management** to **Physical Serial Port** on the 70xx Family of devices, you may have to reboot the appliance twice to see the expected boot prompt.

4. To configure LOM via SOL, enter the appropriate settings:
   - DHCP **Configuration** for the appliance (**DHCP** or **Static**)
   - **IP Address** to be used for LOM

   IMPORTANT! The LOM IP address must be different from the management interface IP address of the appliance.

   - the **Netmask** for the appliance
   - the **Default Gateway** for the appliance
5. Click **Save**.

   Remote console configuration for the appliance is saved. If you configured Lights-Out Management, you must enable it for at least one user; see Enabling Lights-Out Management User Access on page 2108.

Enabling Lights-Out Management User Access

LICENSE: Any
SUPPORTED DEVICES: Series 3
SUPPORTED DEFENSE CENTERS: Series 3

You must explicitly grant Lights-Out Management permissions to users who will use the feature. You configure LOM and LOM users on a per-appliance basis using each appliance's local web interface. That is, you cannot use the Defense Center to configure LOM on a managed device. Similarly, because users are managed independently per appliance, enabling or creating a LOM-enabled user on the Defense Center does not transfer that capability to users on managed devices.

LOM users also have the following restrictions:

- You must assign the Administrator role to the user.
- The username may have up to 16 alphanumeric characters. Hyphens and longer user names are not supported for LOM users.
- The password may have up to 20 alphanumeric characters, except for 3D7100 Family devices. If LOM is enabled on a 3D7110, 3D7115, 3D7120 or 3D7125 device, the password may have up to 16 alphanumeric characters. Passwords longer than 20 or 16 characters, respectively, are not supported for LOM users. A user's LOM password is the same as that user's system password. Cisco recommends that you use a complex, non-dictionary-based password of the maximum supported length for your appliance and change it every three months.
- Series 3 Defense Centers and 8000 Series devices can have up to 13 LOM users. 7000 Series devices can have up to eight LOM users.

Note that if you deactivate, then reactivate, a role with LOM while a user with that role is logged in, or restore a user or user role from a backup during that

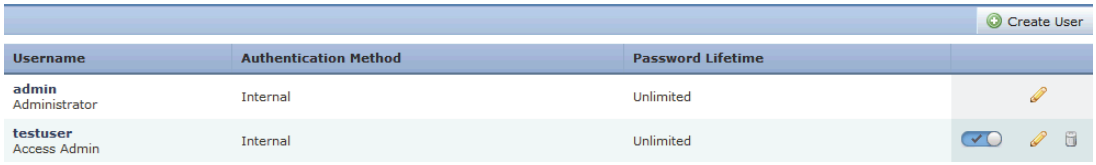
user's login session, that user must log back into the web interface to regain access to IPMItool commands. For more information, see Managing Predefined User Roles on page 1982.

To enable or view Lights-Out Management user access:

ACCESS: Admin

1. Select **System > Local > User Management.**

   The User Management page appears.



2. You have the following options:
   - To grant LOM user access to an existing user, click the edit icon ( ) next to a user name in the list.
   - To grant LOM user access to a new user, click **Create User**.
3. Under User Configuration, enable the Administrator role.

   Administrator Options appear.

4. Select the **Allow Lights-Out Management Access** check box.
5. Click **Save**.

   The user has LOM access for this appliance.

Using a Serial Over LAN Connection

LICENSE: Any
SUPPORTED DEVICES: Series 3
SUPPORTED DEFENSE CENTERS: Series 3

You use a third-party IPMI utility on your computer to create a Serial Over LAN connection to the appliance. If your computer uses a Linux-like or Mac environment, use IPMItool; for Windows environments, use IPMIutil.

IMPORTANT! Sourcefire recommends using IPMItool version 1.8.12 or greater.

Linux

IPMItool is standard with many distributions and is ready to use.

Mac

You must install IPMItool on a Mac. First, confirm that your Mac has Apple's XCode Developer tools installed, making sure that the optional components for command line development are installed (UNIX Development and System Tools in newer versions, or Command Line Support in older versions). Then you can install macports and the IPMItool. Use your favorite search engine for more information or try these sites:

`https://developer.apple.com/technologies/tools/`

`http://www.macports.org/`

Windows

You must compile IPMIutil on Windows. If you do not have access to a compiler, you can use IPMIutil itself to compile. Use your favorite search engine for more information or try this site:

`http://ipmiutil.sourceforge.net/`

Understanding IPMI Utility Commands

Commands used for IPMI utilities are composed of segments as in the following IPMItool example:

```
ipmitool -I lanplus -H IP_address -U user_name command
```

where:

- `ipmitool` invokes the utility
- `-I lanplus` enables encryption for the session
- `-H IP_address` indicates the IP address of the appliance you want to access
- `-U user_name` is the name of an authorized user
- `-command` is the name of the command you want to give

IMPORTANT! Sourcefire recommends using IPMItool version 1.8.12 or greater.

The same command for Windows looks like this:

```
ipmiutil command -V 4 -J 3 -N IP_address -U user_name
```

This command connects you to the command line on the appliance where you can log in as if you were physically present at the appliance. You may be prompted to enter a password.

To create a Serial Over LAN connection:

ACCESS: Admin with LOM access

▶ Enter the following command:

For IPMItool:

```
ipmitool -I lanplus -H IP_address -U user_name sol activate
```

IMPORTANT! Sourcefire recommends using IPMItool version 1.8.12 or greater.

For IPMIutil:

```
ipmiutil -J 3 -H IP_address -U username sol -a
```

The command line login for the appliance appears. You may be prompted to enter a password.

Using Lights-Out Management

LICENSE: Any
SUPPORTED DEVICES: Series 3
SUPPORTED DEFENSE CENTERS: Series 3

Lights-Out Management provides the ability to perform a limited set of actions over a SOL connection without the need to log into the appliance. You use the command to create a SOL connection followed by one of the commands listed in the Lights-Out Management Commands table. After the command is completed, the connection ends. Note that not all power control commands are valid on 70xx Family devices.

WARNING! In rare cases, if your computer is on a different subnet than the appliance's management interface and the appliance is configured for DHCP, attempting to access LOM features on a Series 3 appliance can fail. If this occurs, you can either disable and then re-enable LOM on the appliance, or use a computer on the same subnet as the appliance to ping its management interface. You should then be able to use LOM.

WARNING! Sourcefire is aware of a vulnerability inherent in the Intelligent Platform Management Interface (IPMI) standard (CVE-2013-4786). Enabling Lights-Out Management (LOM) on an appliance exposes this vulnerability. To mitigate the vulnerability, deploy your appliances on a secure management network accessible only to trusted users and use a complex, non-dictionary-based password of the maximum supported length for your appliance and change it every three months. To prevent exposure to this vulnerability, do not enable LOM.

If all attempts to access your appliance have failed, you can use LOM to restart your appliance remotely. Note that if a system is restarted while the SOL connection is active, the LOM session may disconnect or time out.

WARNING! Do **not** restart your appliance unless it does not respond to any other attempts to restart. Remotely restarting the appliance does not gracefully reboot the system and you may lose data.

Lights-Out Management Commands

IPMItool	IPMIutil	Description
(not applicable)	`-V 4`	Enables admin privileges for the IPMI session
`-I lanplus`	`-J 3`	Enables encryption for the IPMI session
`-H`	`-N`	Indicates the IP address of the remote appliance
`-U`	`-U`	Indicates the username of an authorized LOM account
`sol activate`	`sol -a`	Starts the SOL session
`sol deactivate`	`sol -d`	Ends the SOL session
`chassis power cycle`	`power -c`	Restarts the appliance (not valid on 70xx Family devices)
`chassis power on`	`power -u`	Powers up the appliance
`chassis power off`	`power -d`	Powers down the appliance (not valid on 70xx Family devices)
`sdr`	`sensor`	Displays appliance information, such as fan speeds and temperatures

For example, to display a list of appliance information, the IPMItool command is:

```
ipmitool -I lanplus -H IP_address -U user_name sdr
```

IMPORTANT! Sourcefire recommends using IPMItool version 1.8.12 or greater.

The same command with the IPMIutil utility is:

```
ipmiutil sensor -V 4 -J 3 -N IP_address -U user_name
```

To use Lights-Out Management:

ACCESS: Admin with LOM access

▶ Enter the following command:

For IPMItool:

```
ipmitool -I lanplus -H IP_address -U user_name command
```

IMPORTANT! Sourcefire recommends using IPMItool version 1.8.12 or greater.

For IPMIutil:

```
ipmiutil -J 3 -H IP_address -U username command
```

where *command* is one of the commands from the Lights-Out Management Commands table on page 2112.

The corresponding action as noted in the table is performed. You may be prompted to enter a password.

Enabling Sourcefire Cloud Communications

LICENSE: URL Filtering or Malware
SUPPORTED DEFENSE CENTERS: Any except DC500

The Sourcefire 3D System contacts the Sourcefire cloud to obtain various types of information:

- If your organization has a FireAMP subscription, you can receive endpoint-based malware events; see Working with Sourcefire Cloud Connections for FireAMP on page 1254.
- File policies associated with access control rules allow managed devices to detect files transmitted in network traffic. The Defense Center uses data from the Sourcefire cloud to determine if the files represent malware; see Understanding and Creating File Policies on page 1236.
- When you enable URL filtering, the Defense Center can retrieve category and reputation data for many commonly visited URLs, as well as perform lookups for uncategorized URLs. You can then quickly create URL conditions for access control rules; see Adding URL Conditions on page 551.

Use the Defense Center's local configuration to specify the following options:

Enable URL Filtering

You must enable this option to perform category and reputation-based URL filtering.

Query Cloud for Unknown URL

Allows the system to query the Sourcefire cloud when someone on your monitored network attempts to browse to a URL that is not in the local data set.

If the cloud does not know the category or reputation of a URL, or if the Defense Center cannot contact the cloud, the URL does **not** match access control rules with category or reputation-based URL conditions. You cannot assign categories or reputations to URLs manually.

Disable this option if you do not want your uncategorized URLs to be cataloged by the Sourcefire cloud, for example, for privacy reasons.

Enable Automatic Updates

Allows the system to contact the Sourcefire cloud on a regular basis to obtain updates to the URL data in your appliances' local data sets. Although the cloud typically updates its data once per day, enabling automatic updates forces the Defense Center to check every 30 minutes to make sure that you always have up-to-date information.

Although daily updates tend to be small, if it has been more than five days since your last update, new URL filtering data may take up to 20 minutes to download, depending on your bandwidth. Then, it may take up to 30 minutes to perform the update itself.

If you want to have strict control of when the system contacts the cloud, you can disable automatic updates and use the scheduler instead, as described in Automating URL Filtering Updates on page 2032.

IMPORTANT! Sourcefire recommends that you either enable automatic updates or use the scheduler to schedule updates. Although you can manually perform on-demand updates, allowing the system to automatically contact the cloud on a regular basis provides you with the most up-to-date, relevant URL data.

Share URI Information of malware events with Sourcefire

Optionally, Defense Centers can send information about the files detected in network traffic to the Sourcefire cloud. This information includes URI information associated with detected files and their SHA-256 hash values. Although sharing is opt-in, transmitting this information to Sourcefire will help with future efforts to identify and track malware.

Use legacy port 32137 for network AMP lookups

Selecting this check box allows your system to use port 32137/tcp (the previous default port) for network cloud lookups instead of port 443/tcp. If you updated your appliances from a previous version of the Sourcefire 3D System, this check box is selected by default.

Licensing

Performing category and reputation-based URL filtering and device-based malware detection require that you enable the appropriate licenses on your managed devices; see Licensing the Sourcefire 3D System on page 2118.

You **cannot** configure cloud connection options if you have no URL Filtering or Malware licenses on the Defense Center. If you have one license but not the other, the Cloud Services local configuration page displays only the options for which you are licensed. Defense Centers with expired licenses cannot contact the cloud.

Note that, in addition to causing the URL Filtering configuration options to appear, adding a URL Filtering license to your Defense Center automatically enables **Enable URL Filtering** and **Enable Automatic Updates**. You can manually disable the options if needed.

Note that receiving endpoint-based malware events using a FireAMP subscription does not require a license, nor does specifying individual URLs or groups of URLs to allow or block. For more information, see Understanding Malware Protection and File Control on page 1228 and Adding URL Conditions on page 551.

Internet Access and High Availability

The system uses ports 80/HTTP and 443/HTTPS to contact the Sourcefire cloud and also supports use of a proxy; see Configuring Network Settings on page 2088.

Although all URL filtering configurations and information are synchronized between Defense Centers in a high availability deployment, only the primary Defense Center downloads URL filtering data. If the primary Defense Center fails, you must make sure that the secondary Defense Center has direct access to the Internet and use the web interface on the secondary Defense Center to promote it to Active. For more information, see Monitoring and Changing High Availability Status on page 244.

On the other hand, although they share file policies and related configurations, Defense Centers in a high availability pair share neither cloud connections nor malware dispositions. To ensure continuity of operations, and to ensure that detected files' malware dispositions are the same on both Defense Centers, both primary and secondary Defense Centers must have access to the cloud.

Health Monitoring

The default health policy includes the following modules that track the state and stability of the Defense Center's cloud connections:

- URL Filtering Monitor, which also warns you if the Defense Center fails to push category and reputation updates to its managed devices
- Advanced Malware Protection

TIP! Another module, the FireAMP Status Monitor, tracks the Defense Center's connection to the Sourcefire cloud for FireAMP subscription holders. For more information on health monitoring, see Using the Health Monitor on page 2245.

The following procedures explain how to enable communications the Sourcefire cloud, and how to perform an on-demand update of URL data. Note that you cannot start an on-demand update if an update is already in progress.

To enable communications with the Sourcefire cloud:

Access: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **Cloud Services**.

   The Cloud Services page appears. If you have a URL Filtering license, the page displays the last time URL data was updated.

3. Configure cloud connection options as described above.

   You must **Enable URL Filtering** before you can **Enable Automatic Updates** or **Query Cloud for Unknown URLs**.

4. Click **Save**.

   Your settings are saved. If you enabled URL filtering, depending on how long it has been since URL filtering was last enabled, or if this is the first time you enabled URL filtering, the Defense Center retrieves URL filtering data from the cloud.

To perform an on-demand update of the system's URL data:

Access: Admin

1. Select **System > Local > Configuration**.

   The Information page appears.

2. Click **URL Filtering**.

   The URL Filtering page appears.

3. Click **Update Now**.

   The Defense Center contacts the cloud and updates its URL filtering data if an update is available.

CHAPTER 50
LICENSING THE SOURCEFIRE 3D SYSTEM

You can license a variety of features to create an optimal Sourcefire 3D System deployment for your organization. You use the Defense Center to manage licenses for itself and the devices it manages.

For more information, see:

- Understanding Licensing on page 2118
- Viewing Your Licenses on page 2130
- Adding a License to the Defense Center on page 2132
- Deleting a License on page 2134
- Changing a Device's Licensed Capabilities on page 2134

Understanding Licensing

LICENSE: Any

You can license a variety of features to create an optimal Sourcefire 3D System deployment for your organization. A FireSIGHT license is included with your Defense Center and is required to perform host, application, and user discovery.

Additional model-specific licenses allow your managed devices to perform a variety of functions including:

- intrusion detection and prevention
- Security Intelligence filtering
- file control and advanced malware protection
- application, user, and URL control

- switching and routing
- device clustering
- network address translation (NAT)
- virtual private network (VPN) deployments

There are a few ways you may lose access to licensed features in the Sourcefire 3D System. You can remove licenses from the Defense Center, which affects all of its managed devices. You can also disable licensed capabilities on specific managed devices. Finally, some licenses may expire. Though there are some exceptions, you cannot use the features associated with an expired or deleted license.

For more information, see:

- License Types and Restrictions on page 2119
- Licensing High Availability Pairs on page 2126
- Licensing Stacked and Clustered Devices on page 2127
- Licensing Series 2 Appliances on page 2127
- Understanding FireSIGHT Host and User License Limits on page 2127

License Types and Restrictions

LICENSE: Any

This section describes the types of licenses available in a Sourcefire 3D System deployment. The licenses you can enable on an appliance depend on its model, version, and (for managed devices) the other licenses enabled.

For virtual and Series 3 devices, licenses are model specific; you cannot enable a license on a managed device unless the license exactly matches the device's model. For example, you cannot use a 3D8250 Protection license to enable Protection capabilities on a 3D8140 device. As your organization and deployment grow, you can purchase additional licenses for additional managed devices.

Series 2 devices automatically have Protection capabilities (with the exception of Security Intelligence filtering). Although you do not need to explicitly enable Protection on Series 2 devices, you also cannot enable any other licenses.

Also note that although you can enable Control on a virtual device or Sourcefire Software for X-Series to perform user and application control, these devices do not support switching, routing, stacking, or clustering.

The following table summarizes Sourcefire 3D System licenses.

Sourcefire 3D System Licenses

License	Platforms	Granted Capabilities	Requires
FireSIGHT	Defense Centers	discovery	none
RNA Host and RUA User (legacy)	Defense Centers	discovery	none
Protection (licensed)	Series 3, virtual, X-Series	intrusion detection and prevention file control Security Intelligence filtering	none
Protection (automatic)	Series 2	intrusion detection and prevention file control	none
Control	virtual, X-Series	user and application control	Protection
Control	Series 3	user and application control switching and routing clustering	Protection
Malware	Series 3, virtual, X-Series	advanced malware protection (network-based malware detection and blocking)	Protection
URL Filtering	Series 3, virtual, X-Series	category and reputation-based URL filtering	Protection
VPN	Series 3	deploying virtual private networks	Control

Note that the DC500 Defense Center does not support the capabilities provided by a URL Filtering or Malware license; note also that on a Series 2 device, you can only enable Protection capabilities.

For more information, see:

- FireSIGHT on page 2121
- RNA Host and RUA User on page 2121
- Protection on page 2123
- Control on page 2123
- Malware on page 2125

- URL Filtering on page 2124
- VPN on page 2126

FireSIGHT

LICENSE: FireSIGHT

A FireSIGHT license is included with your Defense Center and allows you to perform host, application, and user discovery. Discovery data allows the system to create a complete, up-to-the-minute profile of your network, and correlate threat, endpoint, and network intelligence with user identity information. You can use discovery data to perform traffic profiling, assess network compliance, and implement correlation policies.

Your FireSIGHT license also determines how many individual hosts and users you can monitor with the Defense Center and its managed devices. Note that the user limit applies *independently* to the following:

- the Users database, which contains a record for each user detected by the Sourcefire 3D System
- the number of users you can use in access control rules to perform user control, also called *access-controlled users*

For information on the consequences of reaching the licensed limit, see Understanding FireSIGHT Host and User License Limits on page 2127.

Without a FireSIGHT license, you can still perform basic system configuration, monitoring, network-based access control (zone, network, VLAN, and port rule conditions), connection logging, and reporting. Additionally, you can receive endpoint-based malware events from the Sourcefire cloud without a FireSIGHT license, although your organization does need a FireAMP subscription.

TIP! The License statements in this guide assume your Defense Center has a FireSIGHT license. However, if the Defense Center was previously running Version 4.10.x, you may be able to use legacy RNA Host and RUA User licenses instead of a FireSIGHT license. For more information, see the next section, RNA Host and RUA User.

RNA Host and RUA User

LICENSE: Custom

In Version 4.10.x of the Sourcefire 3D System, RNA Host and RUA User feature licenses determined your monitored host and user limits, respectively. If your Defense Center was previously running Version 4.10.x, you may be able to use your legacy host and user licenses instead of a FireSIGHT license.

Version 5.3 Defense Centers using legacy licenses use the RNA Host limit as the FireSIGHT host limit and the RUA User limit as both the FireSIGHT user and access-controlled user limit. The FireSIGHT Host License Limit health module alerts appropriately for your licensed limit; see Understanding FireSIGHT Host and

User License Limits on page 2127.

Note that RNA Host and RUA User limits are cumulative. That is, you can add multiple licenses of each type to the Defense Center to monitor the total number of hosts or users allowed by the licenses.

If you later add a FireSIGHT license, the Defense Center uses the higher of the limits. For example, the FireSIGHT license on the DC1500 supports up to 50,000 hosts and users. If the RNA Host limit on your Version 4.10.x DC1500 was higher than 50,000, using that legacy host license on the same Defense Center running Version 5.3 gives you the higher limit. For your convenience, the web interface displays only the licenses that represent the higher limits.

IMPORTANT! Because FireSIGHT licensed limits are matched to the hardware capabilities of Defense Centers, Sourcefire does **not** recommend exceeding them. For guidance, contact Sourcefire Support.

Because there is no update path from Version 4.10.x to Version 5.3, you must use an ISO file to "restore" a physical Defense Center. Similarly, you must install new versions of any virtual Defense Centers you want to use with legacy licenses. Note that Version 5.3 Defense Centers cannot manage Version 4.10.x devices. You can, however, restore and update Version 4.10.x devices to the latest version.

During the restore process on a physical Defense Center, you are prompted to delete license and network settings. Keep these settings, but if you accidentally delete them you can re-add them later. Because you reinstall rather than restore virtual Defense Centers, you cannot keep these settings.

Note that you restore or reinstall appliances to major versions of the Sourcefire 3D System. After you complete this process, Sourcefire recommends you also install any available patches or feature updates. For detailed information on the restore and reinstall processes, see the *Sourcefire 3D System Installation Guide* and the *Sourcefire 3D System Virtual Installation Guide*.

WARNING! Restoring or reinstalling an appliance results in the loss of all configuration and event data on the appliance. Consider backing up your appliance before you begin the process. Also, you must make sure the appliance supports the new version. The release notes list supported hardware and hosting environments.

Protection

LICENSE: Protection
SUPPORTED DEVICES: Series 3, virtual, X-Series

A Protection license allows you to perform intrusion detection and prevention, file control, and Security Intelligence filtering:

- *Intrusion detection and prevention* allows you to analyze network traffic for intrusions and exploits and, optionally, drop offending packets.
- *File control* allows you to detect and, optionally, block users from uploading (sending) or downloading (receiving) files of specific types over specific application protocols. With a Malware license (see Malware on page 2125), you can also inspect and block a restricted set of those file types based on their malware dispositions.
- *Security Intelligence filtering* allows you to blacklist—deny traffic to and from—specific IP addresses, before the traffic is subjected to analysis by access control rules. Dynamic feeds allow you to immediately blacklist connections based on the latest intelligence. Optionally, you can use a "monitor-only" setting for Security Intelligence filtering.

Although you can configure an access control policy to perform Protection-related inspection without a license, you cannot apply the policy until you first add a Protection license to the Defense Center, then enable it on the devices targeted by the policy.

If you delete your Protection license from the Defense Center or disable Protection on managed devices, the Defense Center stops acknowledging intrusion and file events from the affected devices. As a consequence, correlation rules that use those events as a trigger criteria stop firing. Additionally, the Defense Center will not contact the internet for either Sourcefire-provided or third-party Security Intelligence information. You cannot reapply existing policies until you re-enable Protection.

Because a Protection license is required for URL Filtering, Malware, and Control licenses, deleting or disabling a Protection license has the same effect as deleting or disabling your URL Filtering, Malware, or Control license.

IMPORTANT! Series 2 devices automatically have most Protection capabilities; you do not have to purchase or enable Protection licenses for these devices. However, Series 2 devices cannot perform Security Intelligence filtering.

Control

LICENSE: Control
SUPPORTED DEVICES: Series 3, virtual, X-Series
SUPPORTED DEFENSE CENTERS: feature dependent

A Control license allows you to implement user and application control by adding user and application conditions to access control rules. It also allows you to

configure your Series 3 managed devices to perform switching and routing (including DHCP relay and NAT), as well as cluster managed devices. To enable Control on a managed device, you must also enable Protection.

IMPORTANT! Although you can enable a Control license on a virtual device or Sourcefire Software for X-Series, these devices do **not** support switching, routing, stacking, or clustering.

Although you can add user and application conditions to access control rules without a Control license, you cannot apply the policy until you first add a Control license to the Defense Center, then enable it on the devices targeted by the policy.

Note that the DC500 Defense Center does not support adding user conditions in access control rules.

Without a Control license, you cannot create switched, routed, or hybrid interfaces on your managed devices; create NAT entries; or configure DHCP relay for virtual routers. Although you can create virtual switches and routers, they are not useful without switched and routed interfaces to populate them. Further, you cannot apply a device configuration that includes switching or routing to a managed device where you have not enabled Control. Additionally, establishing clustering between managed devices requires that the devices are enabled for Control.

If you delete your Control license from the Defense Center or disable Control on individual devices, the affected devices do **not** stop performing switching or routing, nor do device clusters break. Although you can edit and delete existing configurations, you cannot apply your changes to the affected devices. You cannot add new switched, routed, or hybrid interfaces, nor can you add new NAT entries, configure DHCP relay, or establish device clustering. Finally, you cannot reapply existing access control policies if they include rules with user or application conditions.

URL Filtering

LICENSE: URL Filtering
SUPPORTED DEVICES: Series 3, virtual, X-Series
SUPPORTED DEFENSE CENTERS: Any except DC500

URL filtering allows you to write access control rules that determine the traffic that can traverse your network based on URLs requested by monitored hosts, correlated with information about those URLs, which is obtained from the Sourcefire cloud by the Defense Center. To enable URL Filtering, you must also

enable a Protection license.

TIP! Without a URL Filtering license, you can specify individual URLs or groups of URLs to allow or block. This gives you granular, custom control over web traffic, but does not allow you to use URL category and reputation data to filter network traffic.

URL filtering requires a subscription-based URL Filtering license. Although you can add category and reputation-based URL conditions to access control rules without a URL Filtering license, the Defense Center will not contact the cloud for URL information. You cannot apply the access control policy until you first add a URL Filtering license to the Defense Center, then enable it on the devices targeted by the policy.

You may lose access to URL filtering if you delete the license from the Defense Center or disable URL Filtering on managed devices. Also, URL Filtering licenses may expire. If your license expires or if you delete or disable it, access control rules with URL conditions immediately stop filtering URLs, and your Defense Center can no longer contact the cloud. You cannot reapply existing access control policies if they include rules with category and reputation-based URL conditions.

Malware

LICENSE: Malware
SUPPORTED DEVICES: Series 3, virtual, X-Series
SUPPORTED DEFENSE CENTERS: Any except DC500

A Malware license allows you to perform advanced malware protection, that is, use managed devices to detect and block malware in files transmitted over your network. To enable Malware on a managed device, you must also enable Protection.

You configure malware detection as part of a file policy, which you then associate with one or more access control rules. File policies can detect your users uploading or downloading files of specific types over specific application protocols. The Malware license allows you to inspect a restricted set of those file types for malware, as well as download and submit specific file types to the Sourcefire cloud for dynamic and Spero analysis to determine whether they contain malware. The Malware license also allows you add specific files to a file list and enable the file list within a file policy, allowing those files to be automatically allowed or blocked on detection.

Although you can add a malware-detecting file policy to an access control rule without a Malware license, the file policy is marked with a warning icon ( ) in the access control rule editor. Within the file policy, Malware Cloud Lookup rules are also marked with the warning icon. Before you can apply an access control policy that includes a malware-detecting file policy, you **must** add a Malware license, then enable it on the devices targeted by the policy. If you later disable

the license on the devices, you cannot reapply an existing access control policy to those devices if it includes file policies that perform malware detection.

If you delete all your Malware licenses or they all expire, the Defense Center stops performing malware cloud lookups, and also stops acknowledging retrospective events sent from the Sourcefire cloud. You cannot reapply existing access control policies if they include file policies that perform malware detection. Note that for a very brief time after a Malware license expires or is deleted, the system can use cached dispositions for files detected by Malware Cloud Lookup file rules. After the time window expires, the system assigns a disposition of `Unavailable` to those files, rather than performing a lookup.

Note that a Malware license is only required if you want the system to detect malware in network traffic. Without a Malware license, the Defense Center can receive endpoint-based malware events from the Sourcefire cloud if your organization has a FireAMP subscription. For more information, see Understanding Malware Protection and File Control on page 1228.

VPN

LICENSE: VPN
SUPPORTED DEVICES: Series 3

VPN allows you to establish secure tunnels between endpoints via a public source, such as the Internet or other network. You can configure the Sourcefire 3D System to build secure VPN tunnels between the virtual routers of Sourcefire managed devices. To enable VPN, you must also enable Protection and Control licenses.

Without a VPN license, you cannot configure a VPN deployment with your managed devices. Although you can create deployments, they are not useful without at least one VPN-enabled routed interface to populate them.

If you delete your VPN license from the Defense Center or disable VPN on individual devices, the affected devices do **not** break the current VPN deployments. Although you can edit and delete existing deployments, you cannot apply your changes to the affected devices.

Licensing High Availability Pairs

LICENSE: Any
SUPPORTED DEFENSE CENTERS: DC1000, DC1500, DC3000, DC3500

Defense Centers in a high availability pair do **not** share licenses. You must apply equivalent licenses to each member of the pair. Because Sourcefire generates licenses based on each Defense Center's unique license key, you cannot use the same licenses on different Defense Centers.

Licensing Stacked and Clustered Devices

LICENSE: Any
SUPPORTED DEVICES: feature dependent

Individual devices must have equivalent licenses before they can be stacked or clustered. After you stack devices, you can change the licenses for the entire stack. However, you cannot change the enabled licenses on a device cluster.

You can stack 3D8140, 3D8200 family, 3D8300 family, and 3D9900 devices of the same model that meet the requirements described in Managing Stacked Devices on page 280. You can cluster two devices of the same Series 3 model that meet the requirements described in Clustering Devices on page 262.

Licensing Series 2 Appliances

LICENSE: Protection
SUPPORTED DEVICES: Series 2

With the exception of the DC500, Series 2 and Series 3 Defense Center licensing is identical. Because the DC500 does not support URL filtering or network-based malware detection, it cannot take advantage of URL Filtering or Malware licenses.

Series 2 devices automatically have the capabilities, except for Security Intelligence, enabled by a Protection license. You cannot disable the Protection license on Series 2 devices, and you cannot enable other licenses.

See the following sections for more information:

- License Types and Restrictions on page 2119 describes the types of licenses available in a Sourcefire 3D System deployment.
- Supported Capabilities by Managed Device Model on page 46 summarizes supported and unsupported features on Series 2 appliances.

Understanding FireSIGHT Host and User License Limits

LICENSE: FireSIGHT

The FireSIGHT license on your Defense Center determines how many individual hosts and users you can monitor with the Defense Center and its managed devices, as well as how many users you can use to perform user control. FireSIGHT host and user license limits are model specific, as listed in the following table.

FireSIGHT Limits by Defense Center Model

DEFENSE CENTER MODEL	FIRESIGHT HOST AND USER LIMIT
DC500	1000
DC750	2000

FireSIGHT Limits by Defense Center Model (Continued)

Defense Center Model	FireSIGHT Host and User Limit
DC1000	20,000
DC1500	50,000
DC3000	100,000
DC3500	300,000
virtual	50,000

For example, you can monitor 1000 hosts and 1000 users with the DC500.

If your Defense Center was previously running Version 4.10.x of the Sourcefire 3D System and you used an ISO file to "restore" the appliance to Version 5.x factory defaults, you may be able to use your legacy RNA Host and RUA User licenses instead of a FireSIGHT license.

For more information, see the following sections:

- Understanding the FireSIGHT Host Limit on page 2128
- Understanding the FireSIGHT User Limit on page 2129
- Understanding the Access-Controlled User Limit on page 2130
- RNA Host and RUA User on page 2121

Understanding the FireSIGHT Host Limit

License: FireSIGHT

The FireSIGHT license on your Defense Center determines how many individual hosts you can monitor with the Defense Center and its managed devices, and therefore how many hosts you can store in your network map.

Note that the system counts MAC-only hosts separately from hosts identified by both IP addresses and MAC addresses. All IP addresses associated with a host are counted together as one host.

When the system detects activity associated with a host with an IP address in your monitored network (as defined by your network discovery policy), that host is added to the network map.

If you reach the host limit and the system detects a new host, whether the new host is added to the network map depends on the **When Host Limit Reached** setting in your network discovery policy. You can configure the system either to stop

adding new hosts to the database, or to replace the hosts that have remained inactive for the longest time.

IMPORTANT! Even if you cannot add a new host to the network map, the system still performs access control on that host's network traffic. Although reaching the FireSIGHT host limit does not prevent you from performing access control on hosts discovered after you reached your licensed limit, you cannot view or perform analysis on those hosts using host profile data. For example, you cannot use compliance white lists to monitor network compliance for those hosts, or use those hosts in host profile qualifications, and so on.

You can also manually delete a host, an entire subnet, or all of your hosts from the network map. Keep in mind, however, that if the system detects activity associated with a deleted host, it re-adds the host to the network map.

Note also that if the system has not detected network traffic from a host in the last **Host Timeout** period specified in your network discovery policy, the host is removed from the network map. The default setting is 10080 minutes (7 days).

To help you track your host license use, the FireSIGHT Host License Limit health module warns you if you have fewer than a configurable number of host licenses left.

Understanding the FireSIGHT User Limit

LICENSE: FireSIGHT

The FireSIGHT license on your Defense Center determines how many individual users you can monitor. When the system detects activity from a new user, that user is added to the Users database. You can detect users in the following ways:

- You can use the network discovery policy to configure managed devices to passively detect logins for LDAP, AIM, POP3, IMAP, Oracle, SIP (VoIP), and SMTP users.
- You can install Sourcefire User Agents on your Microsoft Active Directory LDAP servers to detect authentications against Active Directory credentials.

After you reach the licensed limit, in most cases the system stops adding new users to the database. To add new users, you must either manually delete users from the database, or purge all users from the database.

However, the system favors authoritative user logins. If you have reached the licensed limit and the system detects an authoritative user login for a previously

undetected user, the system deletes the non-authoritative user who has remained inactive for the longest time, and replaces it with the new user.

TIP! Note that if you are using managed devices to detect user activity, you can restrict user logging by protocol to help minimize username clutter and preserve FireSIGHT user licenses. For example, monitoring users discovered via AIM, POP3, and IMAP may add users not relevant to your organization due to network access from contractors, visitors, and other guests. For more information, see Restricting User Logging on page 1343.

Understanding the Access-Controlled User Limit

LICENSE: Control
SUPPORTED DEVICES: Series 3, virtual, X-Series

The FireSIGHT license on your Defense Center determines not only how many individual users you can monitor, but also how many users you can use in access control rules to perform user control. These users are called *access-controlled users*.

IMPORTANT! To perform user control, your organization **must** use Microsoft Active Directory. The system uses Sourcefire User Agents running on Active Directory servers to associate access-controlled users with IP addresses, which is what allows access control rules to trigger.

You specify the groups that access-controlled users must belong to by configuring a connection (called a *user awareness authentication object*) between the Defense Center and an Active Directory server. Then, on a regular basis, the Defense Center queries the server and retrieves a list of the users in the groups you specified in the authentication object. You can then use these users to perform access control.

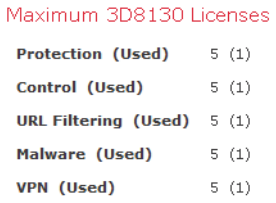
You **must** make sure the total number of users in the groups you specify in the authentication object is less than your FireSIGHT user license. If your parameters are too broad, the Defense Center obtains information on as many users as it can and reports the number of users it failed to retrieve in the task queue. For performance and licensing reasons, Sourcefire recommends that you specify only the groups that represent the users you want to use in access control.

Viewing Your Licenses

LICENSE: Any

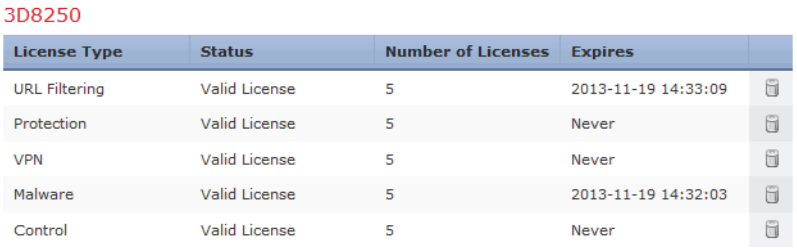
Use the Licenses page to view the licenses for a Defense Center and its managed devices. For each type of appliance in your deployment, the page lists

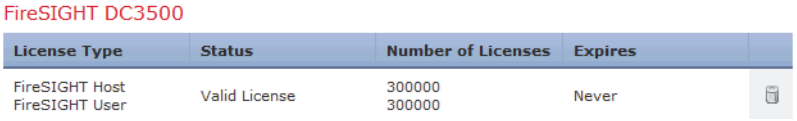
the total number of licenses you have as well as the portion of those licenses that are in use.



Keep in mind that on this page, the number of FireSIGHT User licenses in use represents the number of users detected by the Sourcefire 3D System, that is, the number of users in the Users database. It does not represent the number of access-controlled users you are using for access control. For more information, see Understanding FireSIGHT Host and User License Limits on page 2127.

The Licenses page also provides details on each of your licenses. For each model, you can see how many licenses of each type you have, and how many managed devices you can license with each type of license. For licenses that expire, the page provides you with the expiration date.





Other than the Licenses page, there are a few other ways you can view licenses and license limits:

- The Product Licensing dashboard widget provides an at-a-glance overview of your licenses.
- The Device Management page (**Devices > Device Management**) lists the licenses applied to each of your managed devices.
- Two health modules, License Monitor and FireSIGHT Host License Limit, communicate license status when used in a health policy.

To view your licenses:

ACCESS: Admin

▶ Select **System > Licenses**.

The Licenses page appears.

Adding a License to the Defense Center

LICENSE: Any

Before you add a license to the Defense Center, make sure you have the activation key provided by Sourcefire when you purchased the license. If you do not have the key, log on to the Sourcefire Support Site (https://support.sourcefire.com/) and check the **Entitlements** tab.

With the exception of FireSIGHT, you **must** enable licenses on your managed devices before you can use licensed features. You can enable a license either when you add a device to the Defense Center, or by editing the device's general properties after you add the device, Note that because Series 2 devices automatically have Protection capabilities, with the exception of Security Intelligence filtering, you cannot disable these capabilities, nor can you apply other licenses to a Series 2 device. See Changing a Device's Licensed Capabilities on page 2134.

IMPORTANT! If you add licenses after a backup has completed, these licenses will not be removed or overwritten if this backup is restored. To prevent a conflict on restore, remove those licenses before restoring the backup, noting where the licenses were used, and add and reconfigure them after restoring the backup. If a conflict occurs, contact Sourcefire Support.

To add a license:

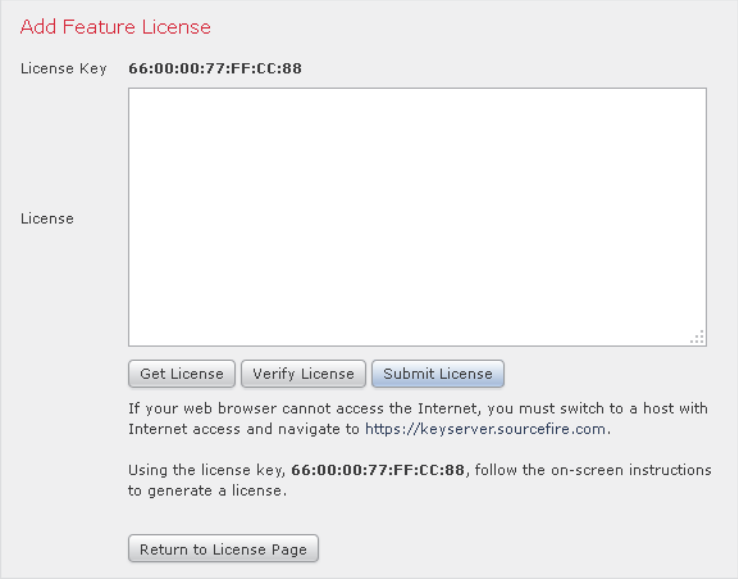
ACCESS: Admin

1. Select **System > Licenses**.

   The Licenses page appears.

2. Click **Add New License**.

   The Add License page appears.



3. Did you receive an email with your license?

   - If yes, copy the license from the email, paste it into the **License** field, and click **Submit License**.

     If the license is correct, the license is added. Skip the rest of the procedure.

   - If no, click **Get License**.

     The Licensing Center web site appears. If you cannot access the Internet, switch to a computer that can. Note the license key at the bottom of the page and browse to https://keyserver.sourcefire.com/.

4. Follow the on-screen instructions to obtain your license, which will be sent to you in an email.

TIP! You can also request a license on the **Licenses** tab after you log into the Support Site.

5. Copy the license from the email, paste it into the **License** field in the Defense Center's web interface, and click **Submit License**.

   If the license is valid, it is added. You can now enable the license's capabilities on your managed devices, as described in Changing a Device's Licensed Capabilities on page 2134.

Deleting a License

LICENSE: Any

Use the following procedure if you need to delete a license for any reason. Keep in mind that because Sourcefire generates licenses based on each Defense Center's unique license key, you cannot delete a license from one Defense Center and then reuse it on a different Defense Center.

In most cases, deleting a license removes your ability to use features enabled by that license. For more information, see License Types and Restrictions on page 2119.

To delete a license:

ACCESS: Admin

1. Select **System > Licenses**.

   The Licenses page appears.

2. Next to the license you want to delete, click the delete icon ( ).

   Deleting a license removes the licensed capability from all devices using that license. For example, if your Protection license is valid for and enabled on 100 managed devices, deleting the license removes Protection capabilities from all 100 devices.

3. Confirm that you want to delete the license.

   The license is deleted.

Changing a Device's Licensed Capabilities

LICENSE: Any
SUPPORTED DEVICES: Series 3, virtual, X-Series

To change the licensed capabilities of a Series 3 device, virtual device, or Sourcefire Software for X-Series, edit the device's general properties on the Device Management page. Although there are some exceptions, you cannot use the features associated with a license if you disable it on a managed device.

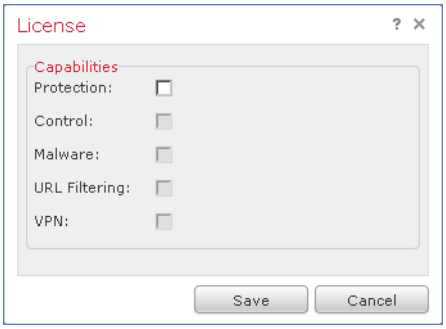
Series 2 devices automatically have Protection capabilities, with the exception of Security Intelligence filtering. You cannot disable these capabilities, nor can you apply other licenses to a Series 2 device. Note that, although you cannot use a Malware or URL Filtering license with a DC500 Defense Center, you can use a DC500 to enable or change these and other licensed capabilities of a Series 3 device, virtual device, or Sourcefire Software for X-Series.

For detailed information on the licenses you can enable, including version, model, and other requirements, see License Types and Restrictions on page 2119.

To enable or disable a device's licensed capabilities:

Access: Admin/Network Admin

1. Select **Devices > Device Management**.
   The Device Management page appears.
2. Next to the device where you want to enable or disable a license, click the edit icon ( ).
   The Interfaces tab for that device appears.
3. Click **Device**.
   The Device tab appears.
4. Next to the License section, click the edit icon ( ).
   The License pop-up window appears.



5. Enable or disable the licensed capabilities of the device by clearing or selecting the appropriate check boxes.
6. Click **Save**.
   The changes are saved but do not take effect until you apply the device configuration; see Applying Changes to Devices on page 253.

CHAPTER 51
UPDATING SYSTEM SOFTWARE

Sourcefire electronically distributes several different types of updates, including major and minor updates to the system software itself, as well as rule updates, geolocation database (GeoDB) updates, and Sourcefire Vulnerability Database (VDB) updates.

WARNING! This chapter contains general information on updating the Sourcefire 3D System. Before you update any part of the Sourcefire 3D System, including the VDB, GeoDB, or intrusion rules, you **must** read the release notes or advisory text that accompanies the update. The release notes provide important information, including supported platforms, compatibility, prerequisites, warnings, and specific installation and uninstallation instructions.

Unless otherwise documented in the release notes or advisory text, updating an appliance does not modify its configuration; the settings on the appliance remain intact.

See the following sections for more information:

Understanding Update Types

LICENSE: Any

Sourcefire electronically distributes several different types of updates, including major and minor updates to the system software itself, as well as intrusion rule updates and VDB updates.

The following table describes the types of updates provided by Sourcefire. For most update types, you can schedule their download and installation; see Scheduling Tasks on page 2006 and Using Recurring Rule Updates on page 2159.

Sourcefire 3D System Update Types

UPDATE TYPE	DESCRIPTION	SCHEDULE?	UNINSTALL?
patches to the Sourcefire 3D System	Patches include a limited range of fixes (and usually change the fourth digit in the version number; for example, 5.0.0.1).	yes	yes
feature updates to the Sourcefire 3D System	Feature updates are more comprehensive than patches and generally include new features (and usually change the third digit in the version number; for example, 5.0.1).	yes	yes
major updates (major and minor version releases) to the Sourcefire 3D System	Major updates, sometimes referred to as upgrades, include new features and functionality and may entail large-scale changes to the product (and usually change the first or second digit in the version number; for example, 5.2 or 5.3).	no	no
VDB	VDB updates affect the vulnerabilities reported by the Sourcefire 3D System as well as the detected operating systems, applications, and clients.	yes	no
intrusion rules	Intrusion rule updates provide new and updated intrusion rules and preprocessor rules, modified states for existing rules, and modified default intrusion policy settings. Rule updates may also delete rules, provide new rule categories and default variables, and modify default variable values.	yes	no
geolocation database (GeoDB)	GeoDB updates provide updated information on physical locations, connection types, and so on that your system can associate with detected routable IP addresses. You can use geolocation data as a condition in access control rules. You must install the GeoDB to view geolocation details. The DC500 Defense Center does not support this feature.	yes	no

Note that while you can uninstall patches and other minor updates to the Sourcefire 3D System, you cannot uninstall major updates or return to previous versions of the VDB, GeoDB, or intrusion rules. If you updated your appliance to a new major version of the Sourcefire 3D System, and you need to revert to an older version, contact Support.

Performing Software Updates

LICENSE: Any

There are a few basic steps to updating your Sourcefire 3D System deployment. First, you must prepare for the update, including reading the release notes and completing any required pre-update tasks. Then, you can begin the update — first update your Defense Centers, then the devices they manage. You must monitor the update's progress until it completes, then verify the update's success. Finally, complete any required post-update steps.

For more information, see the following sections:

- Planning for the Update on page 2138
- Understanding the Update Process on page 2140
- Updating a Defense Center on page 2144
- Updating Managed Devices on page 2146
- Monitoring the Status of Major Updates on page 2148

Planning for the Update

LICENSE: Any

Before you begin the update, you must thoroughly read and understand the release notes, which you can download from the Sourcefire Support Site. The release notes describe supported platforms, new features and functionality, known and resolved issues, and product compatibility. The release notes also contain important information on prerequisites, warnings, and specific installation and uninstallation instructions.

The following sections provide an overview of some of the factors you must consider when planning for the update.

Sourcefire 3D System Version Requirements

You must make sure your appliances (including software-based devices) are running the correct version of the Sourcefire 3D System. The release notes indicate the required version. If you are running an earlier version, you can obtain updates from the Sourcefire Support Site.

Operating System Requirements

Make sure the computers where you installed software-based devices are running the correct versions of their operating systems. The release notes indicate the required versions. For information on supported operating systems for virtual devices, see the *Sourcefire 3D System Virtual Installation Guide*. For information on supported operating systems for Sourcefire Software for X-Series, see the *Sourcefire Software for X-Series Installation Guide*.

Time and Disk Space Requirements

Make sure you have enough free disk space and allow enough time for the update. When you update a managed device, the update requires additional disk space on the Defense Center. The release notes indicate space and time requirements.

Configuration and Event Backup Guidelines

Before you begin a major update, Sourcefire recommends that you delete any backups that reside on the appliance after copying them to an external location. Regardless of the update type, you should also back up current event and configuration data to an external location. Event data is **not** backed up as part of the update process.

You can use the Defense Center to back up event and configuration data for itself and the devices it manages; see Using Backup and Restore on page 2286.

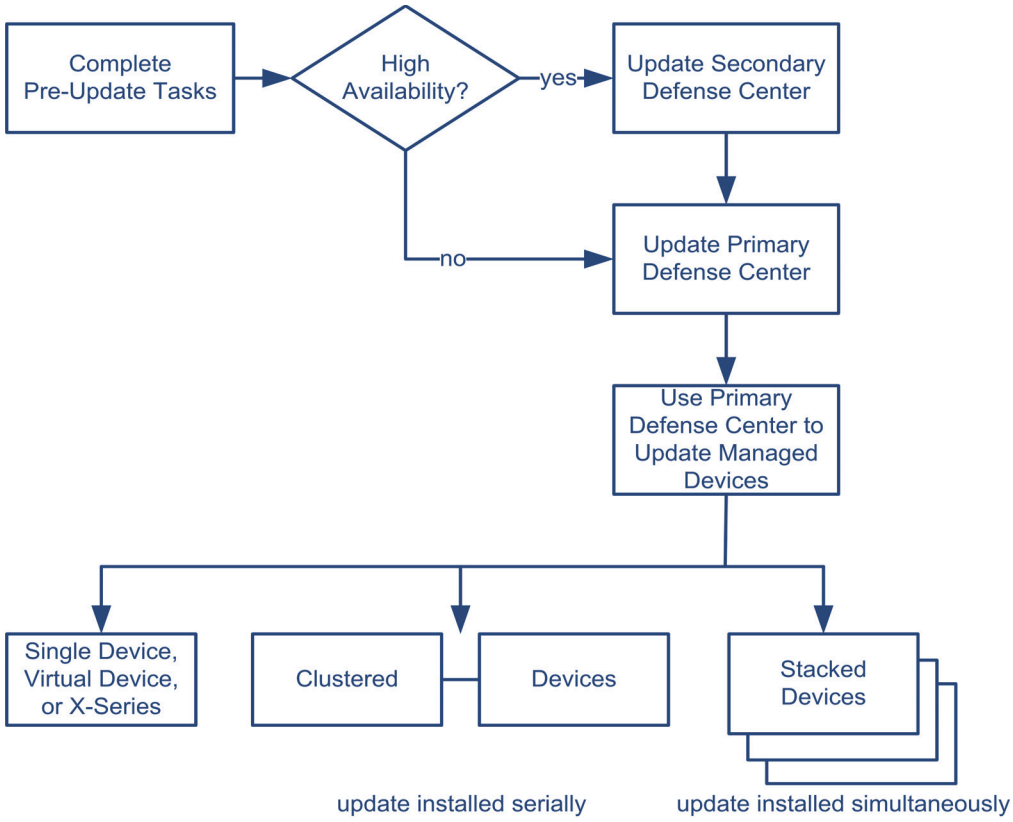
When to Perform the Update

Because the update process may affect traffic inspection, traffic flow, and link state, and because the Data Correlator is disabled while an update is in progress, Sourcefire recommends you perform the update in a maintenance window or at a time when the interruption will have the least impact on your deployment.

Understanding the Update Process

LICENSE: Any

The following diagram summarizes the update process.



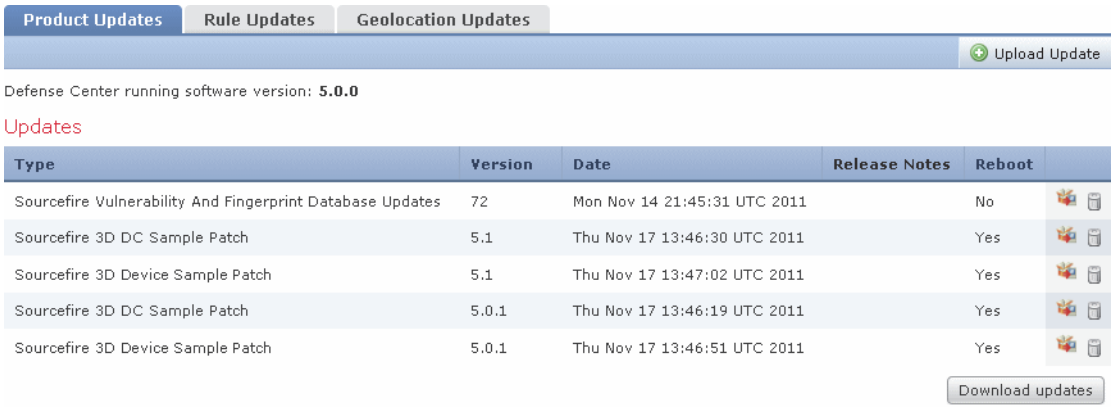
Order of Update

You **must** update your Defense Centers before you can update the devices they manage.

Use the Defense Center to Perform the Update

Sourcefire recommends that you use the Defense Center's web interface to update not only itself, but also the devices it manages. You **must** use the Defense Center to update managed devices that do not have a web interface, such as virtual devices and Sourcefire Software for X-Series. For major updates to Sourcefire Software for X-Series, you may need to uninstall the previous version and install the new version. See the *Sourcefire Software for X-Series Installation Guide* for more information.

The Product Updates page (**System > Updates**) shows the version of each update, as well as the date and time it was generated. It also indicates whether a reboot is required as part of the update.



When you upload updates obtained from Sourcefire Support to your appliance, they appear on the page. Uninstallers for patch and feature updates also appear; see Uninstalling Software Updates on page 2150. On the Defense Center, the page can list VDB updates.

TIP! For patches and feature updates, you can take advantage of the automated update feature; see Automating Software Updates on page 2022.

Updating Paired Defense Centers

When you begin to update one Defense Center in a high availability pair, the other Defense Center in the pair becomes the primary, if it is not already. In addition, the paired Defense Centers stop sharing configuration information; paired Defense Centers do not receive software updates as part of the regular synchronization process.

To ensure continuity of operations, do **not** update paired Defense Centers at the same time. First, complete the update procedure for the secondary Defense Centers, then update the primary.

Updating Clustered Devices

When you install an update on clustered devices or clustered stacks, the system performs the update on the devices or stacks one at a time. When the update starts, the system first applies it to the backup device or stack, which goes into maintenance mode until any necessary processes restart and the device or stack is processing traffic again. The system then applies the update to the active device or stack, which follows the same process.

To update devices in a clustered stack, you must perform the update from the managing Defense Center on all members of a cluster at once; you cannot perform the upgrade directly from the devices.

Updating Stacked Devices

When you install an update on stacked devices, the system performs the updates simultaneously. Each device resumes normal operation when the update completes. Note that:

- If the primary device completes the update *before* all of the secondary devices, the stack operates in a limited, mixed-version state until all devices have completed the update.
- If the primary device completes the upgrade *after* all of the secondary devices, the stack resumes normal operation when the update completes on the primary device.

Traffic Flow and Inspection

When you install or uninstall updates from a managed device, the following capabilities may be affected:

- traffic inspection, including application and user awareness and control, URL filtering, Security Intelligence filtering, intrusion detection and prevention, and connection logging
- traffic flow, including switching, routing, and related functionality
- link state

The Data Correlator does not run during system updates. It resumes when the update is complete.

The manner and duration of network traffic interruption depends on the components of the Sourcefire 3D System that the update affects, how your devices are configured and deployed, and whether the update reboots the device. For specific information on how and when network traffic is affected for a particular update, see the release notes.

TIP! When you update clustered devices, the system performs the updates one at a time to avoid traffic interruption.

Using the Web Interface During the Update

Regardless of the type of update, do **not** use the web interface of the appliance you are updating to perform tasks other than monitoring the update.

To prevent you from using an appliance during a major update, and to allow you to easily monitor a major update's progress, the system streamlines the appliance's web interface. You can monitor a minor update's progress in the task queue

(**System > Monitoring > Task Status**). Although you are not prohibited from using the web interface during a minor update, Sourcefire recommends against it.

TIP! To monitor updates to its managed devices, use the task queue on the Defense Center.

Even for minor updates, the web interface on the updating appliance may become unavailable during the update process, or the appliance may log you out. This is expected behavior. If this occurs, log in again to view the task queue. If the update is still running, you **must** continue to refrain from using the web interface until the update has completed. Note that while updating, managed devices may reboot a second time; this is also expected behavior.

WARNING! If you encounter issues with the update (for example, if the web interface indicates that the update has failed or if a manual refresh of the task queue or Update Status page shows no progress), do **not** restart the update. Instead, contact Support.

After the Update

You **must** complete all of the post-update tasks listed in the release notes to ensure that your deployment is performing properly.

The most important post-update task is to reapply access control policies, both after you update the Defense Center and then again after you update its managed devices. Note that applying an access control policy may cause a short pause in traffic flow and processing, and may also cause a few packets to pass uninspected; see Applying an Access Control Policy on page 506.

Additionally, you should:

- verify that the update succeeded
- make sure that all appliances in your deployment are communicating successfully
- update your intrusion rules, VDB, and GeoDB, if necessary
- make any required configuration changes, based on the information in the release notes
- perform any additional post-update tasks listed in the release notes

Updating a Defense Center

LICENSE: Any

Update the Defense Center in one of two ways, depending on the type of update and whether your Defense Center has access to the Internet:

- You can use the Defense Center to obtain the update directly from the Sourcefire Support Site, if your Defense Center has access to the Internet. This option is **not** supported for major updates.
- You can manually download the update from the Sourcefire Support Site and then upload it to the Defense Center. Choose this option if your Defense Center does not have access to the Internet or if you are performing a major update.

WARNING! To ensure continuity of operations, do **not** update paired Defense Centers at the same time; see Updating Paired Defense Centers on page 2141.

For major updates, updating the Defense Center removes uninstallers for previous updates.

To update the Defense Center:

ACCESS: Admin

1. Read the release notes and complete any required pre-update tasks.

   Pre-update tasks may include making sure that: the Defense Center is running the correct version of the Sourcefire software, you have enough free disk space to perform the update, you set aside adequate time to perform the update, you backed up event and configuration data, and so on.

2. Upload the update to the Defense Center. You have two options, depending on the type of update and whether your Defense Center has access to the Internet:

   - For all except major updates, and if your Defense Center has access to the Internet, select **System > Updates**, then click **Download Updates** to check for the latest updates on the Sourcefire Support Site.
   - For major updates, or if your Defense Center does not have access to the Internet, you must first manually download the update from the Sourcefire Support Site. Select **System > Updates**, then click **Upload Update**. Browse to the update and click **Upload**.

   IMPORTANT! Download the update directly from the Sourcefire Support Site, either manually or by clicking **Download Updates** on the Product Updates tab. If you transfer an update file by email, it may become corrupted.

   The update is uploaded to the Defense Center.

3. Make sure that the appliances in your deployment are successfully communicating and that there are no issues being reported by the health monitor.
4. Select **System > Monitoring > Task Status** to view the task queue and make sure that there are no jobs in process.

   Tasks that are running when the update begins are stopped and cannot be resumed; you must manually delete them from the task queue after the update completes. The task queue automatically refreshes every 10 seconds. You must wait until any long-running tasks are complete before you begin the update.
5. Select **System > Updates**.

   The Product Updates page appears.
6. Click the install icon next to the update you uploaded.

   The Install Update page appears.
7. Select the Defense Center and click **Install**. If prompted, confirm that you want to install the update and reboot the Defense Center.

   The update process begins. How you monitor the update depends on whether the update is a major or minor update. See the Sourcefire 3D System Update Types table on page 2137 and the release notes to determine your update type:

   - For minor updates, you can monitor the update's progress in the task queue (**System > Monitoring > Task Status**).
   - For major updates, you can begin monitoring the update's progress in the task queue. However, after the Defense Center completes its necessary pre-update checks, you are logged out. When you log back in, the Upgrade Status page appears. See Monitoring the Status of Major Updates on page 2148 for information.

   WARNING! Regardless of the update type, do **not** use the web interface to perform tasks other than monitoring the update until the update has completed and, if necessary, the Defense Center reboots. For more information, see Using the Web Interface During the Update on page 2142.
8. After the update finishes, if necessary, log into the Defense Center.

   If you are the first user to log in after a major update, the End User License Agreement (EULA) may appear. You must review and accept the EULA to continue.
9. Clear your browser cache and force a reload of the browser. Otherwise, the user interface may exhibit unexpected behavior.

10. Select **Help > About** and confirm that the software version is listed correctly. Also note the versions of the rule update and VDB on the Defense Center; you will need this information later.
11. Verify that all managed devices are successfully communicating with the Defense Center.
12. If the rule update available on the Sourcefire Support Site is newer than the rules on your Defense Center, import the newer rules.

    For more information, see Importing Rule Updates and Local Rule Files on page 2154.
13. Reapply access control policies.

    Applying an access control policy may cause a short pause in traffic flow and processing, and may also cause a few packets to pass uninspected. For more information, see Applying an Access Control Policy on page 506.
14. If the VDB available on the Sourcefire Support Site is newer than the VDB on your Defense Center, install the latest VDB.

    Installing a VDB update causes a short pause in traffic flow and processing, and may also cause a few packets to pass uninspected. For more information, see Updating the Vulnerability Database on page 2152.
15. Continue with the next section, Updating Managed Devices, to update Sourcefire software on the devices that the Defense Center manages.

Updating Managed Devices

LICENSE: Any

After you update your Defense Centers, Sourcefire recommends that you use them to update the devices they manage. You **must** use the Defense Center to update managed devices that do not have a web interface, such as virtual devices and Sourcefire Software for X-Series. For major updates to Sourcefire Software for X-Series, you may need to uninstall the previous version and install the new version.

Updating managed devices is a two-step process. First, download the update from the Sourcefire Support Site and upload it to the managing Defense Center. Next, install the software.

IMPORTANT! Traffic inspection, traffic flow, and link state may be affected during the update, depending on how your devices are configured and deployed, the components that the update affects, and whether the update reboots the devices. For specific information on how and when network traffic is affected for a particular update, see the release notes for that update.

To update managed devices:

Access: Admin

1. Read the release notes and complete any required pre-update tasks.

   Pre-update tasks may include updating your managing Defense Center, backing up event and configuration data, and making sure that the devices are running the correct version of the Sourcefire software, that computers where you installed software-based devices are running the correct version of their operating systems, that you have enough free disk space to perform the update, that you have set aside adequate time to perform the update, and so on.

2. Update the Sourcefire software on the devices' managing Defense Center; see Updating a Defense Center on page 2144.

3. Download the update from the Sourcefire Support Site.

   Different device models may use different updates. For information on the updates you can download, see the release notes.

   IMPORTANT! Download the update directly from the Sourcefire Support Site. If you transfer an update file by email, it may become corrupted.

4. Make sure that the appliances in your deployment are successfully communicating and that there are no issues being reported by the health monitor.

5. On the managing Defense Center, select **System > Updates**.

   The Product Updates page appears.

6. Click **Upload Update** to browse to the update you downloaded, then click **Upload**.

   The update is uploaded to the Defense Center. The Product Updates tab shows the type of update you just uploaded, its version number, and the date and time when it was generated. The page also indicates whether a reboot is required as part of the update.

7. Click the install icon next to the update you are installing.

   The Install Update page appears.

8. Select the devices where you want to install the update, then click **Install**; you can update multiple devices at once if they use the same update. If prompted, confirm that you want to install the update and reboot the devices.

   The update process begins. Depending on the size of the file, it may take some time to install the update on all devices. You can monitor the update's progress in the Defense Center's task queue (**System > Monitoring > Task Status**). Note that managed devices may reboot twice during the update; this is normal.

   WARNING! If you encounter issues with the update (for example, if the task queue indicates that the update has failed or if a manual refresh of the task queue shows no progress), do **not** restart the update. Instead, contact Support.

9. Optionally, after a major update, log in to the device's local web interface.

   If you are the first user to log in after a major update, the End User License Agreement (EULA) may appear. You must review and accept the EULA to continue. Note that the EULA also appears, and must be accepted, if your first login is via the command line interface rather than the web interface.

10. On the Defense Center, select **Devices > Device Management** and confirm that the devices you updated have the correct version listed.

11. Verify that the devices you updated are successfully communicating with the Defense Center.

12. Reapply access control policies.

    Applying an access control policy may cause a short pause in traffic flow and processing, and may also cause a few packets to pass uninspected. For more information, see Applying an Access Control Policy on page 506.

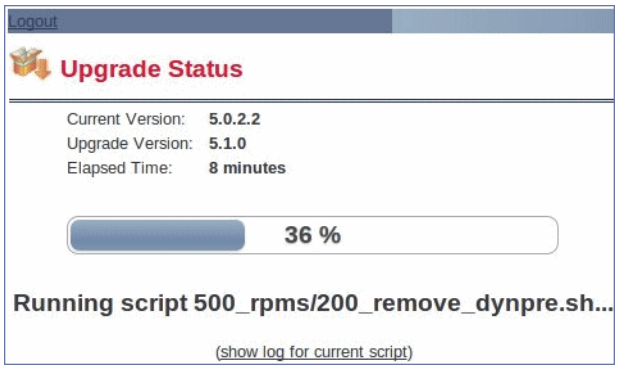
Monitoring the Status of Major Updates

LICENSE: Any

For major updates, the Sourcefire 3D System provides you with a streamlined web interface so that you can easily monitor the update process. The streamlined interface also prevents you from using the web interface to perform tasks other than monitoring the update.

You can begin monitoring the update's progress in the task queue (**System > Monitoring > Task Queue**). However, after the appliance completes its necessary pre-update checks, you and all other users are logged out of the web interface. Unless you are an administrator or a maintenance user, you cannot log back in until the update is complete.

For administrators, when you log back in, the streamlined update page appears. The following graphic shows the Defense Center version of the page.



When using a Defense Center to update a managed device, Sourcefire recommends that you monitor the update's progress from the Defense Center's task queue. Note, however, that if you attempt to log into the device's local web interface after the appliance finishes its pre-update checks, the streamlined update page appears and you can use it to monitor the update's progress.

The page displays the version of the Sourcefire 3D System you are updating from, the version you are updating to, and the time that has elapsed since the update began. It also displays a progress bar and gives details about the script currently running.

TIP! Click **show log for current script** to see the update log. Click **hide log for current script** to hide the log again.

If the update fails for any reason, the page displays an error message indicating the time and date of the failure, which script was running when the update failed, and instructions on how to contact Support. Do **not** restart the update.

WARNING! If you encounter any other issue with the update (for example, if a manual refresh of the page shows no progress for an extended period of time), do **not** restart the update. Instead, contact Support.

When the update completes, the appliance displays a success message and reboots. After the appliance finishes rebooting, refresh the page to log in and complete any required post-update steps.

Uninstalling Software Updates

LICENSE: Any

When you apply a patch or feature update to a Sourcefire appliance, the update process creates an uninstaller that allows you to remove the update from that appliance, using its web interface.

When you uninstall an update, the resulting Sourcefire software version depends on the update path for your appliance. For example, consider a scenario where you updated an appliance directly from Version 5.0 to Version 5.0.0.2. Uninstalling the Version 5.0.0.2 patch might result in an appliance running Version 5.0.0.1, even though you never installed the Version 5.0.0.1 update. For information on the resulting Sourcefire software version when you uninstall an update, see the release notes.

IMPORTANT! Uninstalling from the web interface is not supported for major updates. If you updated your appliance to a new major version of the Sourcefire 3D System and you need to revert to an older version, contact Support.

Order of Uninstallation

Uninstall the update in the reverse order that you installed it. That is, first uninstall the update from managed devices, then from Defense Centers.

Use the Local Web Interface to Uninstall the Update

You must use the local web interface to uninstall updates; you cannot use the Defense Center to uninstall updates from managed devices. For information on uninstalling a patch from a device that does not have a local web interface (for example, virtual devices or Sourcefire Software for X-Series), see the release notes.

Note that, although you can use this process to uninstall minor updates for Sourcefire Software for X-Series, you cannot use this process to uninstall the Sourcefire Software for X-Series application from the X-Series platform. For more information, see the *Sourcefire Software for X-Series Installation Guide*.

Uninstalling the Update from Clustered or Paired Appliances

Clustered devices and Defense Centers in high availability pairs must run the same version of the Sourcefire 3D System. Although the uninstallation process triggers an automatic failover, appliances in mismatched pairs or clusters do not share configuration information, nor do they install or uninstall updates as part of their synchronization. If you need to uninstall an update from redundant appliances, plan to perform the uninstallations in immediate succession.

You cannot uninstall an update from devices in a clustered stack if uninstalling would revert these devices to a version in which clustered stacking is not supported.

To ensure continuity of operations, uninstall the update from clustered devices and paired Defense Centers one at a time. First, uninstall the update from the secondary appliance. Wait until the uninstallation process completes, then immediately uninstall the update from the primary appliance.

WARNING! If the uninstallation process on a clustered device or paired Defense Center fails, do **not** restart the uninstall or change configurations on its peer. Instead, contact Support.

Uninstalling the Update from Stacked Devices

All devices in a stack must run the same version of the Sourcefire 3D System. Uninstalling the update from any of the stacked devices causes the devices in that stack to enter a limited, mixed-version state.

To minimize impact on your deployment, Sourcefire recommends that you uninstall an update from stacked devices simultaneously. The stack resumes normal operation when the update completes on all devices in the stack.

You cannot uninstall an update from devices in a clustered stack if uninstalling would revert these devices to a version in which clustered stacking is not supported.

Traffic Flow and Inspection

Uninstalling an update from managed devices may affect traffic inspection, traffic flow, and link state. For specific information on how and when network traffic is affected for a particular update, see the release notes.

After the Uninstallation

After you uninstall the update, there are several steps you should take to ensure that your deployment is performing properly. These include verifying that the uninstall succeeded and that all appliances in your deployment are communicating successfully. For specific information for each update, see the release notes.

To uninstall a patch or feature update using the local web interface:

Access: Admin

1. Select **System > Updates**.

   The Product Updates page appears.

2. Click the install icon next to the uninstaller for the update you want to remove.
   - On the Defense Center, the Install Update page appears. Select the Defense Center and click **Install**.
   - On a managed device, there is no intervening page.

   In either case, if prompted, confirm that you want to uninstall the update and reboot the appliance.

   The uninstall process begins. You can monitor its progress in the task queue (**System > Monitoring > Task Status**).

   WARNING! Do **not** use the web interface to perform tasks other than monitoring the update until the uninstall has completed and, if necessary, the appliance reboots. For more information, see Using the Web Interface During the Update on page 2142.

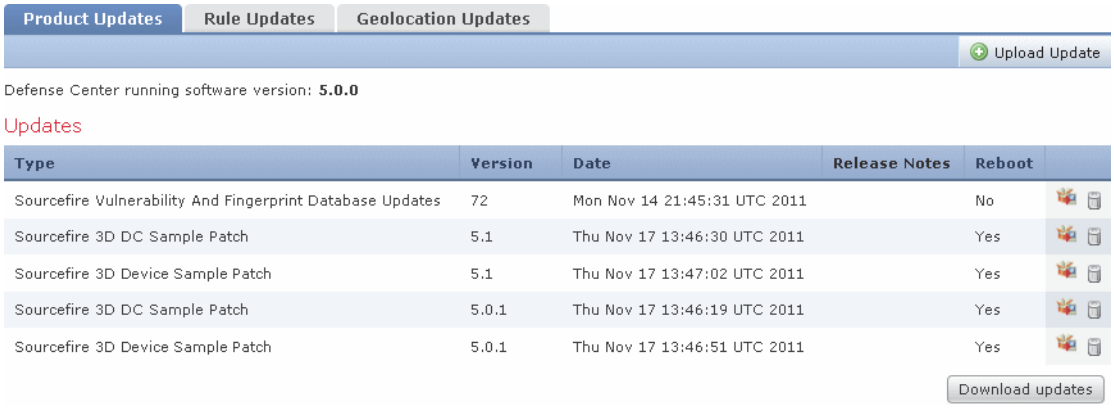
3. After the uninstall finishes, if necessary, log into the appliance.
4. Clear your browser cache and force a reload of the browser. Otherwise, the user interface may exhibit unexpected behavior.
5. Select **Help > About** and confirm that the software version is listed correctly.
6. Verify that the appliance where you uninstalled the patch is successfully communicating with its managed devices (for the Defense Center) or its managing Defense Center (for managed devices).

Updating the Vulnerability Database

LICENSE: Any

The Sourcefire Vulnerability Database (VDB) is a database of known vulnerabilities to which hosts may be susceptible, as well as fingerprints for operating systems, clients, and applications. The Sourcefire 3D System correlates the fingerprints with the vulnerabilities to help you determine whether a particular host increases your risk of network compromise. The Sourcefire Vulnerability Research Team (VRT) issues periodic updates to the VDB.

To update the VDB, use the Product Updates page on the Defense Center.



When you upload VDB updates obtained from Sourcefire Support to your appliance, they appear on the page along with updates and uninstaller updates for the Sourcefire 3D System.

The time it takes to update vulnerability mappings depends on the number of hosts in your network map. You may want to schedule the update during low system usage times to minimize the impact of any system downtime. As a rule of thumb, divide the number of hosts on your network by 1000 to determine the approximate number of minutes to perform the update.

IMPORTANT! When you install a VDB update with changes to application detectors or operating system fingerprints, Sourcefire recommends that you check whether any of your managed devices are out-of-date and need to be reapplied. Installing a VDB update with detection updates may cause a short pause in traffic flow and processing on your managed devices, and may also cause a few packets to pass uninspected.

This section explains how to plan for and perform manual VDB updates. You can take advantage of the automated update feature to schedule VDB updates; see Automating Vulnerability Database Updates on page 2028.

To update the vulnerability database:

Access: Admin

1. Read the VDB Update Advisory Text for the update.

   The advisory text includes information about the changes to the VDB made in the update, as well as product compatibility information.

2. Select **System > Updates**.

   The Product Updates page appears.

3. Upload the update to the Defense Center:
   - If your Defense Center has access to the Internet, click **Download Updates** to check for the latest updates on the Sourcefire Support Site.
   - If your Defense Center does not have access to the Internet, manually download the update from the Sourcefire Support Site, then click **Upload Update**. Browse to the update and click **Upload**.

   IMPORTANT! Download the update directly from the Sourcefire Support Site either manually or by clicking **Download Updates**. If you transfer an update file by email, it may become corrupted.

   The update is uploaded to the Defense Center.
4. Click the install icon next to the VDB update.

   The Install Update page appears.
5. Select the Defense Center, then click **Install**.

   The update process begins. Depending on the number of hosts in your network map, installing the update may take some time. You can monitor the update's progress in the task queue (**System > Monitoring > Task Status**).

   WARNING! Do **not** use the web interface to perform tasks related to mapped vulnerabilities until the update has completed. If you encounter issues with the update (for example, if the task queue indicates that the update has failed or if a manual refresh of the task queue shows no progress) **do not** restart the update. Instead, contact Support.
6. After the update finishes, select **Help > About** to confirm that the VDB build number matches the update you installed.

Importing Rule Updates and Local Rule Files

LICENSE: Any

As new vulnerabilities become known, the Sourcefire Vulnerability Research Team (VRT) releases rule updates. Rule updates provide new and updated intrusion rules and preprocessor rules, modified states for existing rules, and modified default intrusion policy settings. Rule updates may also delete rules and provide new rule categories and default variables.

IMPORTANT! Rule updates may contain new binaries. Make sure your process for downloading and installing rule updates complies with your security policies. In addition, rule updates may be quite large, so make sure to import rules during periods of low network use.

The following are additional important points you should keep in mind when you import rules:

- For new rules in rule updates, the rule state may be different in each default policy. For example, a new rule may be enabled in the Security over Connectivity default policy and disabled in the Connectivity over Security default policy. See Using Default Intrusion Policies on page 738 for more information.

  Rule updates may also change the default state of existing rules. For information on choosing whether to allow rule updates to change the default states of existing rules in intrusion policies you create, see Allowing Rule Updates to Modify the Base Policy on page 740.
- Rule updates are cumulative, so the newest rule update contains the intrusion rules of all previous updates. You cannot import a rule update that either matches or predates the version of the currently installed rules.
- When you use a default policy provided by Sourcefire as your base policy, you can choose whether to allow rule updates to modify your base policy with any changes to intrusion rules, preprocessor rules, and advanced settings. See Understanding the Base Policy on page 737 and Allowing Rule Updates to Modify the Base Policy on page 740 for more information.
- Rule updates may include new default variables and modified values for existing default variables. New variables are always added to your system. Your existing variable values are updated only if you have not modified them. See Working with Variable Sets on page 196for more information.
- Rule updates may include new rule categories. New rule categories in rule updates are always added to your system. See Understanding Rule Categories on page 766 for more information.
- The Rule Updates page lists intrusion policies with cached changes and the users who made those changes. Importing a rule update discards all cached changes. See Committing Intrusion Policy Changes on page 725 for more information.
- When a rule update includes shared object rules, applying an access control policy for this first time after the rule import causes a short pause in traffic flow and processing, and may also cause a few packets to pass uninspected.
- If your Sourcefire 3D System deployment includes two Defense Centers configured as a high availability pair, you only need to update rules on one of the Defense Centers. The second Defense Center receives the rule update as part of the regular synchronization process.
- Optionally, when the import completes, you can automatically reapply intrusion policies owned by the appliance where you import the rule update.

See the following sections for more information:

- Using One-Time Rule Updates on page 2156 explains how to import a single rule update from the Sourcefire Support Site.
- Using Recurring Rule Updates on page 2159 explains how to use an automated feature on the web interface to download and install rule updates from the Sourcefire Support Site.
- Importing Local Rule Files on page 2162 explains how to import a copy of a standard text rules file that you have created on a local machine.
- Viewing the Rule Update Log on page 2164 explains the rule update log.

Using One-Time Rule Updates

LICENSE: Any

There are two methods that you can use for one-time rule updates:

- Using Manual One-Time Rule Updates on page 2156 explains how to manually download a rule update from the Sourcefire Support Site to your local machine and then manually install the rule update.
- Using Automatic One-Time Rule Updates on page 2158 explains how to use an automated feature on the web interface to search the Sourcefire Support Site for new rule updates and upload them.

Using Manual One-Time Rule Updates

LICENSE: Any

The following procedure explains how to import a new rule update manually. This procedure is especially useful if your Defense Center does not have Internet access.

To manually import a rule update:

ACCESS: Admin

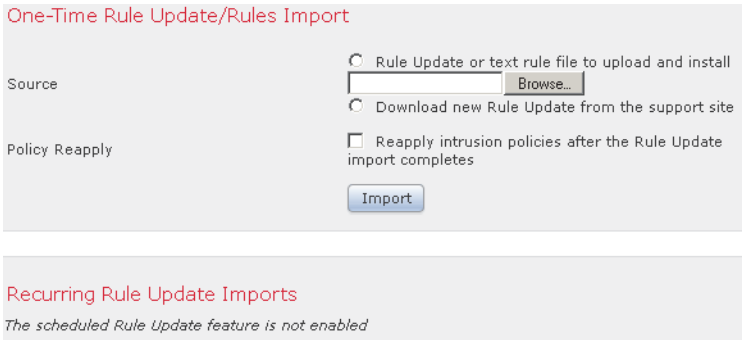
1. From a computer that can access the Internet, access and log into the Sourcefire Support Site.
2. Click **Download**, then click **Rules**.
3. Navigate to the latest rule update.

   TIP! Rule updates are cumulative, so the newest rule update contains the intrusion rules and new features of all previous rule updates. You cannot import a rule update with a version number lower than the version of the currently installed update.

4. Click the rule update file that you want to download and save it to your computer.

5. Log into your appliance's web interface.
6. Select **System > Updates**, then select the **Rule Updates** tab.

   The Rule Updates page appears.



TIP! You can also click **Import Rules** on the Rule Editor page, which you access by selecting **Policies > Intrusion > Rule Editor**.

7. Optionally, click **Delete All Local Rules**, then click **OK** to move all user-defined rules that you have created or imported to the deleted folder. See Deleting Custom Rules on page 1217 for more information.
8. Select **Rule Update or text rule file to upload and install** and click **Browse** to navigate to and select the rule update file.
9. Optionally, select **Reapply intrusion policies after the Rule Update import completes** to automatically reapply intrusion policies currently applied from this appliance when the rule update import completes.

   Note that you cannot apply access control policies to stacked devices that are running different versions of the Sourcefire 3D System (for example, if an upgrade on one of the devices fails). See Managing Stacked Devices on page 280 for more information.

10. Click **Import**.

    The rule update is installed and the system displays the Rule Update Log detailed view. See Understanding the Rule Update Import Log Detailed View on page 2170 for more information.

    If you selected **Reapply intrusion policies after the Rule Update import completes** in step 9, the system applies only the intrusion policies in the currently applied access control policy but does not apply the access control policy. See Applying an Access Control Policy on page 506 for more information.

    If you did not select **Reapply intrusion policies after the Rule Update import completes**, changes in the rule update are not implemented until the next time you apply the affected intrusion policies. See Reapplying an Intrusion Policy on page 726 for more information.

IMPORTANT! Contact Support if you receive an error message while installing the rule update.

Using Automatic One-Time Rule Updates

LICENSE: Any

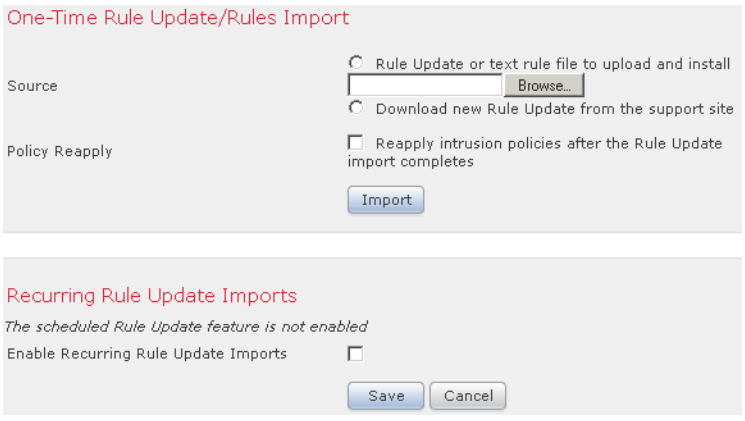
The following procedure explains how to import a new rule update by automatically connecting to the Sourcefire Support Site. You can use this procedure only if the appliance has Internet access.

To automatically import a rule update:

ACCESS: Admin

1. Select **System > Updates**, then select the **Rule Updates** tab.

   The Rule Updates page appears.



TIP! You can also click **Import Rules** on the Rule Editor page, which you access by selecting **Policies > Intrusion > Rule Editor**.

2. Optionally, click **Delete All Local Rules**, then click **OK** to move all user-defined rules that you have created or imported to the deleted folder. See Deleting Custom Rules on page 1217 for more information.
3. Select **Download new Rule Update from the support site**.
4. Optionally, select **Reapply intrusion policies after the Rule Update import completes** to automatically reapply intrusion policies currently applied from this appliance when the rule update completes.

   Note that you cannot apply intrusion policies to stacked devices that are running different versions of the Sourcefire 3D System (for example, if an upgrade on one of the devices fails). See Managing Stacked Devices on page 280 and Reapplying an Intrusion Policy on page 726 for more information.
5. Click **Import**.

   The rule update is installed and the system displays the Rule Update Log detailed view workflow. See Rule Update Import Log Detailed View Fields on page 2170 for more information.

   If you selected **Reapply intrusion policies after the Rule Update import completes** in step 4, the system applies only the intrusion policies in the currently applied access control policy but does not apply the access control policy. See Applying an Access Control Policy on page 506 for more information.

   If you did not select **Reapply intrusion policies after the Rule Update import completes**, changes in the rule update are not implemented until the next time you apply the affected intrusion policies. See Reapplying an Intrusion Policy on page 726 for more information.

IMPORTANT! Contact Support if you receive an error message while installing the rule update.

Using Recurring Rule Updates

LICENSE: Any

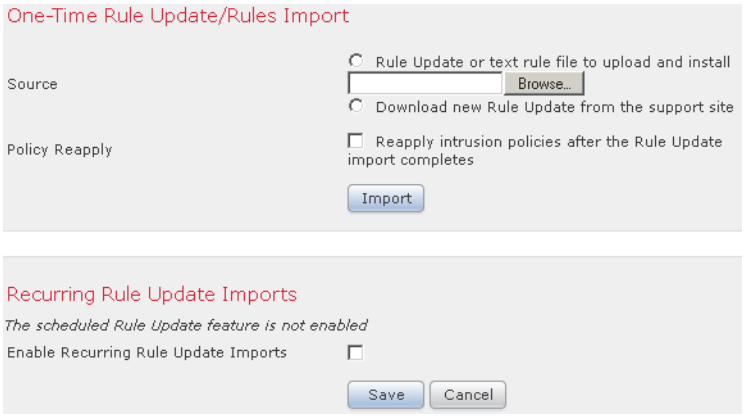
You can import rule updates on a daily, weekly, or monthly basis, using the Rule Updates page. If your Sourcefire 3D Systemdeployment includes two Defense Centers configured as a high availability pair, you only need to update rules on one of the Defense Centers. The second Defense Center receives the rule update as part of the regular synchronization process.

To schedule recurring rule updates:

Access: Admin

1. Select **System > Updates**, then select the **Rule Updates** tab.

   The Rule Updates page appears.



TIP! You can also click **Import Rules** on the Rule Editor page, which you access by selecting **Policies > Intrusion > Rule Editor**.

2. Optionally, click **Delete All Local Rules**, then click **OK** to move all user-defined rules that you have created or imported to the deleted folder. See Deleting Custom Rules on page 1217 for more information.

3. Select **Enable Recurring Rule Update Imports**.

   The page expands to display options for configuring recurring imports.

   Import status messages appear beneath the **Recurring Rule Update Imports** section heading. Recurring imports are enabled when you save your settings.

TIP! To disable recurring imports, clear the **Enable Recurring Rule Update Imports** check box and click **Save**.

4. In the **Import Frequency** field, select **Daily**, **Weekly**, or **Monthly** from the drop-down list.

   TIP! You can select from a recurring task drop-down list either by clicking on your selection or by typing the first letter or number in the selection one or more times and pressing Enter.

5. If you selected **Weekly** in the **Import Frequency** field, use the drop-down list that appears to select the day of the week when you want to import rule updates.
6. If you selected **Monthly** in the **Import Frequency** field, use the drop-down list that appears to select the day of the month when you want to import rule updates.
7. In the **Import Frequency** field, specify the time when you want to start your recurring rule update import.
8. Optionally, select **Reapply intrusion policies after the Rule Update import completes** to automatically reapply intrusion policies currently applied from this appliance when the rule update import completes.

   Note that you cannot apply intrusion policies to stacked devices that are running different versions of the Sourcefire 3D System (for example, if an upgrade on one of the devices fails). See Managing Stacked Devices on page 280 for more information.
9. Click **Save** to enable recurring rule update imports using your settings.

   The status message under the Recurring Rule Update Imports section heading changes to indicate that the rule update has not yet run.

   The rule update is installed at the scheduled time and the rules are updated. You can log off or use the web interface to perform other tasks before or during the import. When accessed during an import, the Rule Update Log displays a red status icon (). See Viewing the Rule Update Log on page 2164 for more information. During an import, you can also view

messages as they occur in the Rule Update Log detailed view. See Rule Update Import Log Detailed View Fields on page 2170 for more information.

IMPORTANT! Depending on rule update size and content, several minutes may pass before status messages appear in the Rule Update Log or Rule Update Log detailed view.

If you selected **Reapply intrusion policies after the Rule Update import completes** in step 8, the system applies only the intrusion policies in the currently applied access control policy but does not apply the access control policy. See Applying an Access Control Policy on page 506 for more information.

If you did not select **Reapply intrusion policies after the Rule Update import completes**, changes in the rule update are not implemented until the next time you apply the affected intrusion policies. See Reapplying an Intrusion Policy on page 726 for more information.

Applicable subtasks in the rule update import occur in the following order: download, install, base policy update, and policy reapply. When one subtask completes, the next subtask begins. Note that you can only apply policies previously applied by the appliance where the recurring import is configured.

IMPORTANT! Contact Support if you receive an error message while installing the rule update.

Importing Local Rule Files

LICENSE: Any

A local rule is a custom standard text rule that you import in an ASCII text file from a local machine. You can create local rules using the instructions in the Snort users manual, which is available at http://www.snort.org.

Note the following regarding importing local rules:

- The text file name can include alphanumeric characters, spaces, and no special characters other than underscore (_), period (.), and dash (-).
- You do not have to specify a Generator ID (GID); if you do, you can specify only GID 1 for a standard text rule or 138 for a sensitive data rule.
- Do **not** specify a Snort ID (SID) or revision number when importing a rule for the first time; this avoids collisions with SIDs of other rules, including deleted rules.

  The system will automatically assign the rule the next available custom rule SID of 1000000 or greater, and a revision number of 1.

- You **must** include the SID assigned by the system and a revision number greater than the current revision number when importing an updated version of a local rule that you have previously imported.

  To view the revision number for a current local rule, display the Rule Editor page (**Policies > Intrusion > Rule Editor**), click on the local rule category to expand the folder, then click **Edit** next to the rule.
- You can reinstate a local rule that you have deleted by importing the rule using the SID assigned by the system and a revision number greater than the current revision number. Note that the system automatically increments the revision number when you delete a local rule; this is a device that allows you to reinstate local rules.

  To view the revision number for a deleted local rule, display the Rule Editor page (**Policies > Intrusion > Rule Editor**), click on the deleted rule category to expand the folder, then click **Edit** next to the rule.
- You cannot import a rule file that includes a rule with a SID greater than 2147483647; the import will fail.
- If you import a rule that includes a list of source or destination ports that is longer than 64 characters, the import will fail.
- The system always sets local rules that you import to the disabled rule state; you must manually set the state of local rules before you can use them in your intrusion policy. See Setting Rule States on page 770 for more information.
- You must make sure that the rules in the file do not contain any escape characters.
- The rules importer requires that all custom rules are imported in ASCII or UTF-8 encoding.
- All imported local rules are automatically saved in the local rule category.
- All deleted local rules are moved from the local rule category to the deleted rule category.
- The system imports local rules preceded with a single pound character (#).
- The system ignores local rules preceded with two pound characters (##) and does not import them.
- Sourcefire strongly recommends that you import local rules on the primary Defense Center in a High Availability Pair to avoid SID numbering issues.
- Policy validation fails if you enable an imported local rule that uses the deprecated `threshold` keyword in combination with the intrusion event thresholding feature in an intrusion policy. See Configuring Event Thresholding on page 774 for more information.

To import local rule files:

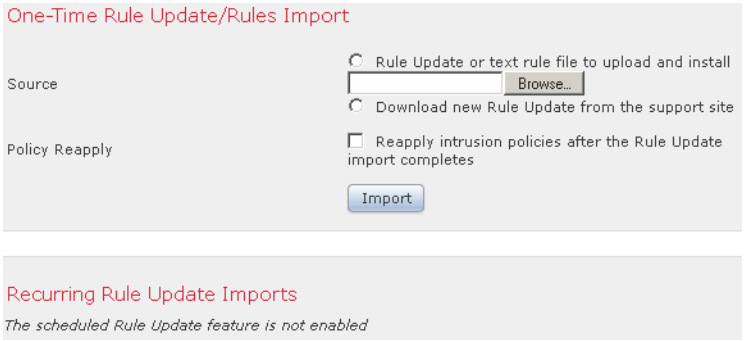
ACCESS: Admin

1. Select **Policies > Intrusion > Rule Editor**.

   The Rule Editor page appears.

2. Click **Import Rules**.

   The Import Rules page appears.



TIP! You can also select **System > Updates**, then select the **Rule Updates** tab.

3. Select **Rule Update or text rule file to upload and install** and click **Browse** to navigate to the rule file. Note that all rules uploaded in this manner are saved in the local rule category.

4. Click **Import**.

   The rule file is imported. Make sure you enable the appropriate rules in your intrusion policies. The rules are not activated until the next time you apply the affected policies.

IMPORTANT! Managed devices do **not** use the new rule set for inspection until after you apply their intrusion policies. See Applying an Access Control Policy on page 506 for procedures.

Viewing the Rule Update Log

LICENSE: Any

The Defense Center generates a record for each rule update and local rule file that you import.

Each record includes a time stamp, the name of the user who imported the file, and a status icon indicating whether the import succeeded or failed. You can maintain a list of all rule updates and local rule files that you import, delete any record from the list, and access detailed records for all imported rules and rule update components. The fields in the Rule Update Log are described in the Rule

Update Log Actions table.

Rule Update Log Actions

To...	You can...
learn more about the contents of the columns in the table	find more information in Understanding the Rule Update Log Table on page 2166.
delete an import file record from the import log, including detailed records for all objects included with the file	click the delete icon ( ) next to the file name for the import file. **Important!** Deleting the file from the log does not delete any object imported in the import file, but only deletes the import log records.
view details for each object imported in a rule update or local rule file	click the view icon ( ) next to the file name for the import file.

See the following sections for more information:

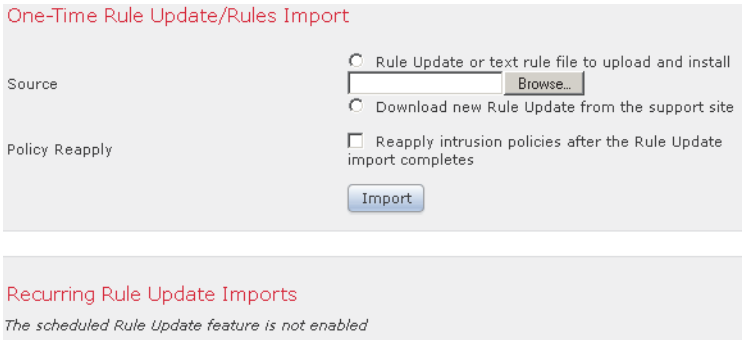
- Understanding the Rule Update Log Table on page 2166 describes the fields in the list of rule updates and local rule files that you import.
- Viewing Rule Update Import Log Details on page 2167 describes the detailed record for each object imported in a rule update or local rule file.
- Understanding the Rule Update Import Log Detailed View on page 2170 describes each field in the Rule Update Log detailed view.
- Searching the Rule Update Import Log on page 2171 explains how you can search the import log for specific records or for all records matching the search criteria.

To view the Rule Update Log:

ACCESS: Admin

1. Select **System > Updates**, then select the **Rule Updates** tab.

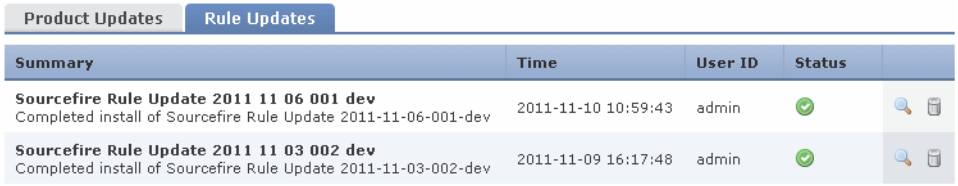
   The Rule Updates page appears.



TIP! You can also click **Import Rules** on the Rule Editor page, which you access by selecting **Policies > Intrusion > Rule Editor**.

2. Click **Rule Update Log**.

   The Rule Update Log page appears. This page lists each imported rule update and local rule file.



Understanding the Rule Update Log Table

LICENSE: Any

The fields in the list of rule updates and local rule files that you import are described in the Rule Update Log Fields table.

Rule Update Log Fields

FIELD	DESCRIPTION
Summary	The name of the import file. If the import fails, a brief statement of the reason for the failure appears under the file name.
Time	The time and date that the import started.

Rule Update Log Fields (Continued)

Field	Description
User ID	The user name of the user that triggered the import.
Status	Whether the import: • succeeded ( ) • failed or is currently in progress ( ) **TIP!** The red status icon indicating an unsuccessful or incomplete import appears on the Rule Update Log page during the import and is replaced by the green icon only when the import has successfully completed.

Click the view icon ( ) next to the rule update or file name to view the Rule Update Log detailed page for the rule update or local rule file, or click the delete icon ( ) to delete the file record and all detailed object records imported with the file.

TIP! You can view import details as they appear while a rule update import is in progress.

Viewing Rule Update Import Log Details

License: Any

The Rule Update Import Log detailed view lists a detailed record for each object imported in a rule update or local rule file. You can also create a custom workflow or report from the records listed that includes only the information that matches your specific needs.

The Rule Update Import Log Detailed View Actions table below describes specific actions you can perform on a Rule Update Import Log detailed view workflow page.

Rule Update Import Log Detailed View Actions

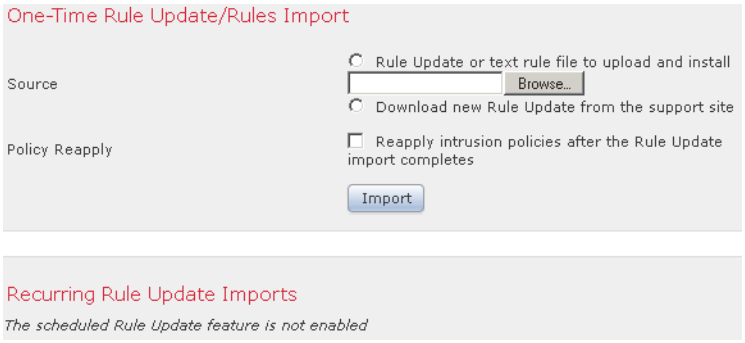
To...	You can...
learn more about the contents of the columns in the table	find more information in Understanding the Rule Update Import Log Detailed View on page 2170.
sort and constrain records on the current workflow page	find more information in Sorting Drill-Down Workflow Pages on page 1910.
temporarily use a different workflow	click **(switch workflows)**. For information on selecting workflows, see Selecting Workflows on page 1885. For information on creating custom workflows, see Creating Custom Workflows on page 1916.
bookmark the current page so that you can quickly return to it	click **Bookmark This Page**. For more information, see Using Bookmarks on page 1913.
navigate to the bookmark management page	click **View Bookmarks**. For more information, see Using Bookmarks on page 1913.
generate a report based on the data in the current view	click **Report Designer**. For more information, see Creating a Report Template from an Event View on page 1797.
search the entire Rule Update Import Log database for rule update import records	click **Search**. From more information, see Searching the Rule Update Import Log on page 2171.
open a search page prepopulated with the current single constraint	select **Edit Search** or **Save Search** next to Search Constraints. From more information, see the Table View and Drill-Down Page Features table on page 1890.

To view the Rule Update Import Log Detailed View:

Access: Admin

1. Select **System > Updates**, then select the **Rule Updates** tab.

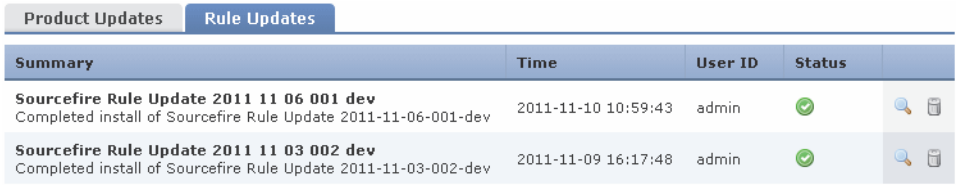
   The Rule Updates page appears.



> **TIP!** You can also click **Import Rules** on the Rule Editor page, which you access by selecting **Policies > Intrusion > Rule Editor**.

2. Click **Rule Update Log**.

   The Rule Update Log page appears.



3. Click the view icon ( ) next to the file whose detailed records you want to view.

   The table view of detailed records appears.

Understanding the Rule Update Import Log Detailed View

LICENSE: Any

You can view a detailed record for each object imported in a rule update or local rule file. The fields in the Rule Update Log detailed view are described in the Rule Update Import Log Detailed View Fields table.

Rule Update Import Log Detailed View Fields

FIELD	DESCRIPTION
Time	The time and date the import began.
Name	The name of the imported object, which for rules corresponds to the rule Message field, and for rule update components is the component name.
Type	The type of imported object, which can be one of the following: • `rule update component` (an imported component such as a rule pack or policy pack) • `rule` (for rules, a new or updated rule; note that in Version 5.0.1 this value replaced the `update` value, which is deprecated) • `policy apply` (the **Reapply intrusion policies after the Rule Update import completes** option was enabled for the import)
Action	An indication that one of the following has occurred for the object type: • `new` (for a rule, this is the first time the rule has been stored on this appliance) • `changed` (for a rule update component or rule, the rule update component has been modified, or the rule has a higher revision number and the same GID and SID) • `collision` (for a rule update component or rule, import was skipped because its revision conflicts with an existing component or rule on the appliance) • `deleted` (for rules, the rule has been deleted from the rule update) • `enabled` (for a rule update edit, a preprocessor, rule, or other feature has been enabled in a default policy provided by Sourcefire) • `disabled` (for rules, the rule has been disabled in a default policy provided by Sourcefire) • `drop` (for rules, the rule has been set to Drop and Generate Events in a default policy provided by Sourcefire) • `error` (for a rule update or local rule file, the import failed) • `apply` (the **Reapply intrusion policies after the Rule Update import completes** option was enabled for the import)
Default Action	The default action defined by the rule update. When the imported object type is `rule`, the default action is `Pass`, `Alert`, or `Drop`. For all other imported object types, there is no default action.
GID	The generator ID for a rule. For example, `1` (standard text rule) or `3` (shared object rule). See the Generator IDs table on page 811 for more information.
SID	The SID for a rule.

Rule Update Import Log Detailed View Fields (Continued)

Field	Description
Rev	The revision number for a rule.
Policy	For imported rules, this field displays `All`, which indicates that the imported rule was included in all default intrusion policies. For other types of imported objects, this field is blank.
Details	A string unique to the component or rule. For rules, the GID, SID, and previous revision number for a changed rule, displayed as `previously (GID:SID:Rev)`. This field is blank for a rule that has not changed.
Count	The count (`1`) for each record. The Count field appears in a table view when the table is constrained, and the Rule Update Log detailed view is constrained by default to rule update records.

Searching the Rule Update Import Log

License: Any

You can search the import log for specific records or for all records matching the search criteria. You may want to create customized searches and save them to reuse later.

TIP! You search the entire Rule Update Import Log database even when you initiate a search by clicking **Search** on the toolbar from the Rule Update Import Log detailed view with only the records for a single import file displayed. Make sure you set your time constraints to include all objects you want to include in the search. See Specifying Time Constraints in Searches on page 1847 for more information.

The search criteria you can use are described in the Rule Update Import Log Search Criteria table. Note that record searches are case-insensitive. For example, searching for `RULE` or `rule` yields the same results.

Rule Update Import Log Search Criteria

Search Field	Description	Example
Time	Specify the date and time the record was generated. See Specifying Time Constraints in Searches on page 1847 for the syntax for entering time.	`> 2006-01-15 13:30:00` returns all rule records imported after January 15, 2006 at 1:30 PM.
Name	Specify all or part of the content of the rule Message field. You can use an asterisk (*) as a wildcard character in this field.	`*dhcp*` returns all rule records with DHCP in the Message field.
Type	Specify the type of record, which can be `rule update component`, `rule`, or `policy apply`. Note that you can use the `update` search value to search for rules imported prior to Version 5.0.1.	`update` returns imported rule update components such as a rule pack or policy pack; `rule` returns rule updates, including new rules; `policy apply` returns a table row of information for rule updates where intrusion policies were automatically reapplied following the update.
Action	Specify an action for the object you want to view. See the Rule Update Import Log Detailed View Fields table on page 2170 for a list of actions you can specify.	When the type is `rule`, `new` returns all rules imported for the first time on the appliance.
GID	Specify the generator ID for the rule.	`3` returns all shared object rules.
SID	Specify a signature ID or a range of SIDs for a rule.	`923` returns the record for the rule with the SID 923.
Rev	Specify the revision number for the rule.	`3` returns rules with the revision number 3.
Policy	Specify the default policy the rule is imported into.	`All` returns rules imported into all default policies.
Rule Update	Specify the Rule Update filename.	*`filename`* returns all records for the specified import file.
Details	Specify details on the imported object.	`previously*` returns the record for all rules that have changed.

For more information on searching, including how to load and delete saved searches, see Searching for Events on page 1842.

To search the Rule Update Import Log:

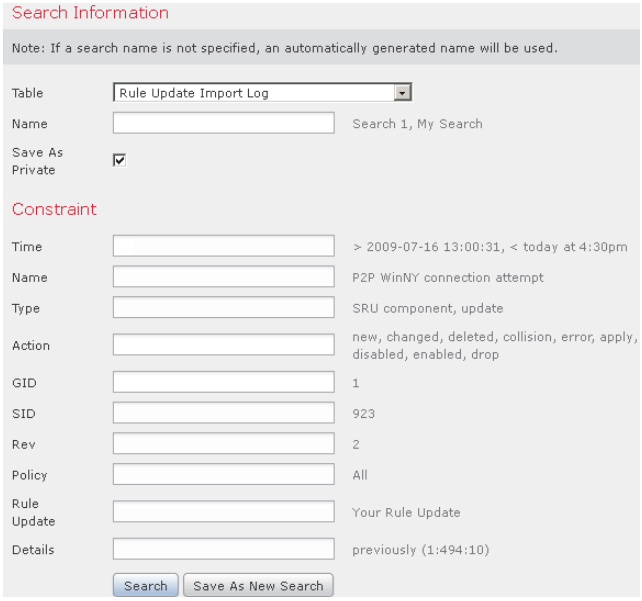
ACCESS: Admin/Intrusion Admin

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Rule Update Import Log**.

   The page reloads with the appropriate constraints.



TIP! You can also click **Search** on the Rule Update Log detailed view; see Viewing Rule Update Import Log Details on page 2167.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, the web interface automatically creates one when you save it.

4. Enter your search criteria in the appropriate fields, as described in the Rule Update Import Log Search Criteria table on page 2172. If you enter multiple criteria, the search returns the records that match all the criteria.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

   If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in the default Rule Update Import Log detailed view workflow. To use a different workflow, including a custom workflow, click **(switch workflows)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**) so that you can run it at a later time.

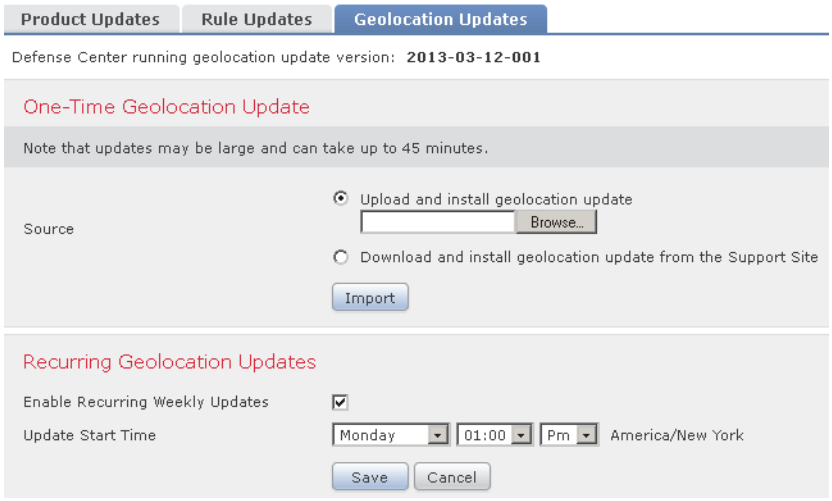
Updating the Geolocation Database

LICENSE: FireSIGHT
SUPPORTED DEFENSE CENTERS: Any except DC500

The Sourcefire Geolocation Database (GeoDB) is a database of geographical data (such as country, city, coordinates, and so on) and connection-related data (such as internet service provider, domain name, connection type, and so on) associated with routable IP addresses. When your system detects GeoDB information that matches a detected IP address, you can view the geolocation information associated with that IP address. You must install the GeoDB on your system to view any geolocation details other than country or continent. Sourcefire issues periodic updates to the GeoDB.

To update the GeoDB, use the Geolocation Updates page (**System > Updates > Geolocation Updates**) on the Defense Center. When you upload GeoDB updates

you obtained from Sourcefire Support or from your appliance, they appear on this page.



Time needed to update the GeoDB depends on your appliance; the installation usually takes 30 to 40 minutes. Although a GeoDB update does not interrupt any other system functions (including the ongoing collection of geolocation information), the update does consume system resources while it completes. Consider this when planning your updates.

This section explains how to plan for and perform manual GeoDB updates. You can also take advantage of the automated update feature to schedule GeoDB updates; for more information, see Automating Geolocation Database Updates on page 2019.

To update the geolocation database:

Access: Admin

1. Select **System > Updates**.

   The Product Updates page appears.

2. Click the **Geolocation Updates** tab.

   The Geolocation Updates page appears.

3. Upload the update to the Defense Center.
   - If your Defense Center has access to the Internet, click **Download and install geolocation update from the Support Site** to check for the latest updates on the Sourcefire Support Site.
   - If your Defense Center does not have access to the Internet, manually download the update from the Sourcefire Support Site, then click **Upload and install geolocation update**. Browse to the update and click **Import**.

   IMPORTANT! Download the update directly from the Sourcefire Support Site, either manually or by clicking **Download and install geolocation update from the Support Site** on the Geolocation Updates page. If you transfer an update file by email, it may become corrupted.

   The update process begins. The average duration of update installation is 30 to 40 minutes; this may vary depending on your appliance hardware. You can monitor the update's progress in the task queue (**System > Monitoring > Task Status**).

4. After the update finishes, return to the Geolocation Updates page or select **Help > About** to confirm that the GeoDB build number matches the update you installed.

   The GeoDB update overrides any previous versions of the GeoDB and is effective immediately. When you update the GeoDB, the Defense Center automatically updates its managed devices. Although it may take a few minutes for a GeoDB update to take effect throughout your deployment, you do not have to reapply access control policies after you update.

CHAPTER 52
MONITORING THE SYSTEM

The Sourcefire 3D System provides many useful monitoring features to assist you in the daily administration of your system, all on a single page. For example, on the Host Statistics page you can monitor basic host statistics and intrusion event information, as well as statistics for the Data Correlator and network discovery processes for the current day. You can also monitor both summary and detailed information on all processes that are currently running on the Defense Center or managed device. The following sections provide more information about the monitoring features that the system provides:

- Viewing Host Statistics on page 2178 describes how to view host information such as:
  - system uptime
  - disk and memory usage
  - Data Correlator statistics
  - system processes
  - intrusion event information
- On the Defense Center, you can also use the health monitor to monitor disk usage and alert on low disk space conditions. For more information, see Understanding Health Monitoring on page 2192.
- Monitoring System Status and Disk Space Usage on page 2181 describes how to view basic event and disk partition information.
- Viewing System Process Status on page 2182 describes how to view basic process status.
- Understanding Running Processes on page 2185 describes the basic system processes that run on the appliance.

You can use the options in **Overview > Summary** to view and graph statistics for intrusion and discovery events. For more information, see:

- Viewing Intrusion Event Statistics on page 642
- Viewing Intrusion Event Graphs on page 648
- Viewing Discovery Event Statistics on page 1442
- Viewing Discovery Performance Graphs on page 1448

Viewing Host Statistics

LICENSE: Any

The Statistics page lists the current status of the following:

- general host statistics; see the Host Statistics table on page 2178 for details
- Data Correlator statistics (Defense Center only — requires FireSIGHT); see the Data Correlator Process Statistics table on page 2179 for details
- intrusion event information (requires Protection); see the Intrusion Event Information table on page 2180 for details

The Host Statistics table describes the host statistics listed on the Statistics page.

Host Statistics

CATEGORY	DESCRIPTION
Time	The current time on the system.
Uptime	The number of days (if applicable), hours, and minutes since the system was last started.
Memory Usage	The percentage of system memory that is being used.
Load Average	The average number of processes in the CPU queue for the past 1 minute, 5 minutes, and 15 minutes.
Disk Usage	The percentage of the disk that is being used. Click the arrow to view more detailed host statistics. See Monitoring System Status and Disk Space Usage on page 2181 for more information.
Processes	A summary of the processes running on the system. See Viewing System Process Status on page 2182 for more information.

If your Sourcefire 3D System deployment includes a Defense Center with a FireSIGHT license, you can also view statistics about the Data Correlator and

network discovery processes for the current day. As the managed devices perform data acquisition, decoding, and analysis, the network discovery process correlates the data with the fingerprint and vulnerability databases, then produces binary files that are processed by the Data Correlator running on the Defense Center. The Data Correlator analyzes the information from the binary files, generates events, and creates the discovery network map.

The statistics that appear for network discovery and the Data Correlator are averages for the current day, using statistics gathered between 12:00 AM and 11:59 PM for each device.

The Data Correlator Process Statistics table describes the statistics displayed for the Data Correlator process.

Data Correlator Process Statistics

Category	Description
Events/Sec	Number of discovery events that the Data Correlator receives and processes per second
Connections/Sec	Number of connections that the Data Correlator receives and processes per second
CPU Usage — User (%)	Average percentage of CPU time spent on user processes for the current day
CPU Usage — System (%)	Average percentage of CPU time spent on system processes for the current day
VmSize (KB)	Average size of memory allocated to the Data Correlator for the current day, in kilobytes
VmRSS (KB)	Average amount of memory used by the Data Correlator for the current day, in kilobytes

On managed devices and on Defense Centers that manage devices, you can also view the date and time of the last intrusion event, the total number of events that have occurred in the past hour and the past day, and the total number of events in the database.

IMPORTANT! The information in the Intrusion Event Information section of the Statistics page is based on intrusion events stored on the managed device rather than those sent to the Defense Center. If you manage your device so that intrusion events are not stored locally, no intrusion event information is listed on this page. This is also the case for managed devices that cannot store events locally.

The Intrusion Event Information table describes the statistics displayed in the Intrusion Event Information section of the Statistics page.

Intrusion Event Information

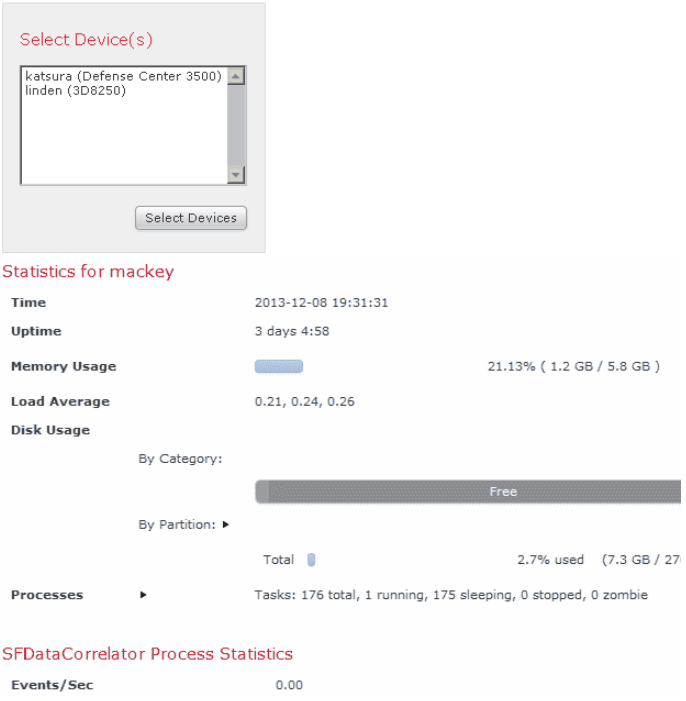
STATISTIC	DESCRIPTION
Last Alert Was	The date and time that the last event occurred
Total Events Last Hour	The total number of events that occurred in the past hour
Total Events Last Day	The total number of events that occurred in the past twenty-four hours
Total Events in Database	The total number of events in the events database

To view the Statistics page:

ACCESS: Admin/Maint

1. Select **System > Monitoring > Statistics**.

   The Statistics page appears. The Defense Center version of the page is shown below.



2. On the Defense Center, you can also list statistics for managed devices. From the **Select Device(s)** box, click **Select Devices**. You can use the Shift and Ctrl keys to select multiple devices at once.

   The Statistics page is updated with statistics for the devices you selected.

Monitoring System Status and Disk Space Usage

LICENSE: Any

The Disk Usage section of the Statistics page provides a quick synopsis of disk usage, both by category and by partition status. If you have a malware storage pack installed on a device, you can also check its partition status. You can monitor this page from time to time to ensure that enough disk space is available for system processes and the database.

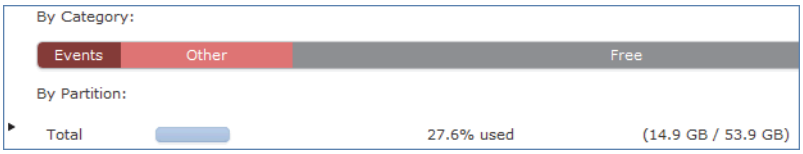
TIP! On the Defense Center, you can also use the health monitor to monitor disk usage and alert on low disk space conditions. For more information, see Understanding Health Monitoring on page 2192.

To access disk usage information:

ACCESS: Admin/Maint

1. Select **System > Monitoring > Statistics**.

   The Statistics page appears.

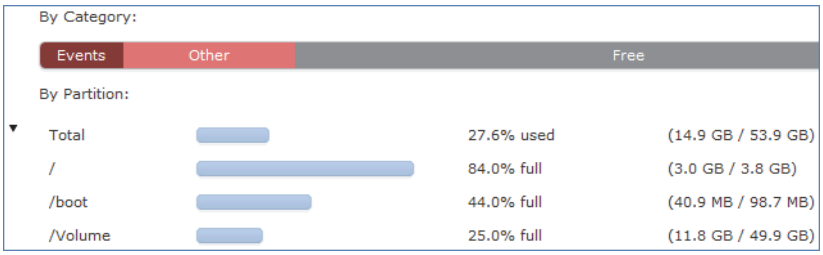


2. Hover your pointer over a disk usage category in the By Category stacked bar to view (in order):
   - the percentage of available disk space used by that category
   - the actual storage space on the disk
   - the total disk space available for that category

   For more information on the disk usage categories, see Understanding the Disk Usage Widget on page 106.

3. Click the down arrow next to **Total** to expand it.

   The Disk Usage section expands, displaying partition usage. If you have a malware storage pack installed, the `/var/storage` partition usage is also displayed.



If your deployment includes multiple managed devices, you may want to constrain disk usage data by specific devices.

On the Defense Center, to view disk usage information for a specific device:

ACCESS: Admin/Maint

1. Select the device name from the **Select Device(s)** box, and click **Select Devices**.

   The page reloads, listing host statistics for each device you selected.

2. Click the down arrow next to **Disk Usage** to expand it.

   The Disk Usage section expands.

Viewing System Process Status

LICENSE: Any

The Processes section of the Host Statistics page allows you to see the processes that are currently running on an appliance. It provides general process information and specific information for each running process. If you are managing devices with a Defense Center, you can use the Defense Center's web interface to view the process status for any managed device.

The Process Status table describes each column that appears in the process list.

Process Status

COLUMN	DESCRIPTION
Pid	The process ID number
Username	The name of the user or group running the process
Pri	The process priority

Process Status (Continued)

Column	Description
Nice	The *nice* value, which is a value that indicates the scheduling priority of a process. Values range between -20 (highest priority) and 19 (lowest priority)
Size	The memory size used by the process (in kilobytes unless the value is followed by `m`, which indicates megabytes)
Res	The amount of resident paging files in memory (in kilobytes unless the value is followed by `m`, which indicates megabytes)
State	The process state: • D — process is in uninterruptible sleep (usually Input/Output) • N — process has a positive nice value • R — process is runnable (on queue to run) • S — process is in sleep mode • T — process is being traced or stopped • W — process is paging • X — process is dead • Z — process is defunct • < — process has a negative nice value
Time	The amount of time (in hours:minutes:seconds) that the process has been running
Cpu	The percentage of CPU that the process is using
Command	The executable name of the process

To expand the process list:

Access: Admin/Maint

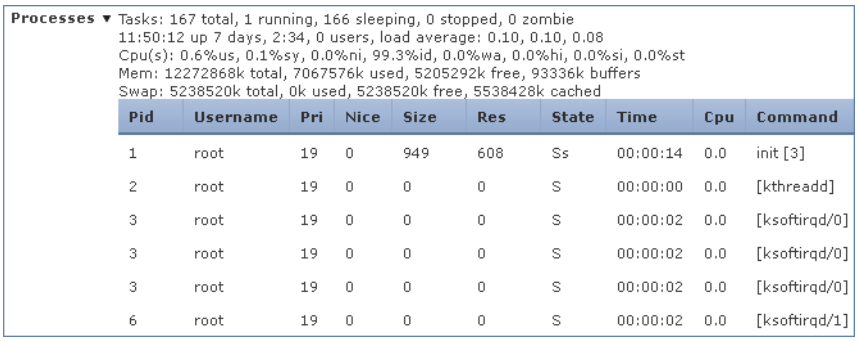
1. Select **System > Monitoring > Statistics**.

   The Statistics page appears.

2. On the Defense Center, select the device or devices you want to view process statistics for from the **Select Device(s)** box and click **Select Devices**.

3. Click the down arrow next to **Processes**.

   The process list expands, listing general process status information that includes the number and types of running tasks, the current time, the current system uptime, the system load average, CPU, memory, and swap information, and specific information about each running process.



Cpu(s) lists the following CPU usage information:

- user process usage percentage
- system process usage percentage
- nice usage percentage (CPU usage of processes that have a negative nice value, indicating a higher priority)

  Nice values indicate the scheduled priority for system processes and can range between -20 (highest priority) and 19 (lowest priority).
- idle usage percentage

Mem lists the following memory usage information:

- total number of kilobytes in memory
- total number of used kilobytes in memory
- total number of free kilobytes in memory
- total number of buffered kilobytes in memory

Swap lists the following swap usage information:

- total number of kilobytes in swap
- total number of used kilobytes in swap
- total number of free kilobytes in swap
- total number of cached kilobytes in swap

IMPORTANT! For more information about the types of processes that run on the appliance, see Understanding Running Processes on page 2185.

To collapse the process list:

ACCESS: Admin/Maint

▶ Click the up arrow next to **Processes**.

The process list collapses.

Understanding Running Processes

LICENSE: Any

There are two different types of processes that run on an appliance: daemons and executable files. Daemons always run, and executable files are run when required.

See the following sections for more information:

- Understanding System Daemons on page 2185
- Understanding Executables and System Utilities on page 2187

Understanding System Daemons

LICENSE: Any

Daemons continually run on an appliance. They ensure that services are available and spawn processes when required. The System Daemons table lists daemons that you may see on the Process Status page and provides a brief description of their functionality.

IMPORTANT! The table below is not an exhaustive list of all processes that may run on an appliance.

System Daemons

DAEMON	DESCRIPTION
crond	Manages the execution of scheduled commands (cron jobs)
dhclient	Manages dynamic host IP addressing
fpcollect	Manages the collection of client and server fingerprints
httpd	Manages the HTTP (Apache web server) process
httpsd	Manages the HTTPS (Apache web server with SSL) service, and checks for working SSL and valid certificate authentication; runs in the background to provide secure web access to the appliance

System Daemons (Continued)

Daemon	Description
keventd	Manages Linux kernel event notification messages
klogd	Manages the interception and logging of Linux kernel messages
kswapd	Manages Linux kernel swap memory
kupdated	Manages the Linux kernel update process, which performs disk synchronization
mysqld	Manages Sourcefire 3D System database processes
ntpd	Manages the Network Time Protocol (NTP) process
pm	Manages all Sourcefire processes, starts required processes, restarts any process that fails unexpectedly
reportd	Manages reports
safe_mysqld	Manages safe mode operation of the database; restarts the database daemon if an error occurs and logs runtime information to a file
SFDataCorrelator	Manages data transmission
sfestreamer (Defense Center only)	Manages connections to third-party client applications that use the Event Streamer
sfmgr	Provides the RPC service for remotely managing and configuring an appliance using an sftunnel connection to the appliance
SFRemediateD (Defense Center only — requires FireSIGHT)	Manages remediation responses
sftimeserviced (Defense Center only)	Forwards time synchronization messages to managed devices
sfmbservice (requires Protection)	Provides access to the sfmb message broker process running on a remote appliance, using an sftunnel connection to the appliance. Currently used only by health monitoring to send health events and alerts from a managed device to a Defense Center or, in a high availability environment, between Defense Centers

System Daemons (Continued)

DAEMON	DESCRIPTION
sftroughd	Listens for connections on incoming sockets and then invokes the correct executable (typically the Sourcefire message broker, sfmb) to handle the request
sftunnel	Provides the secure communication channel for all processes requiring communication with a remote appliance
sshd	Manages the Secure Shell (SSH) process; runs in the background to provide SSH access to the appliance
syslogd	Manages the system logging (syslog) process

Understanding Executables and System Utilities

LICENSE: Any

There are a number of executables on the system that run when executed by other processes or through user action. The System Executables and Utilities table describes the executables that you may see on the Process Status page.

System Executables and Utilities

EXECUTABLE	DESCRIPTION
awk	Utility that executes programs written in the **awk** programming language
bash	GNU Bourne-Again SHell
cat	Utility that reads files and writes content to standard output
chown	Utility that changes user and group file permissions
chsh	Utility that changes the default login shell
SFDataCorrelator (Defense Center only — requires FireSIGHT)	Analyzes binary files created by FireSIGHT to generate events, connection data, and the network map
cp	Utility that copies files
df	Utility that lists the amount of free space on the appliance

System Executables and Utilities (Continued)

Executable	Description
echo	Utility that writes content to standard output
egrep	Utility that searches files and folders for specified input; supports extended set of regular expressions not supported in standard grep
find	Utility that recursively searches directories for specified input
grep	Utility that searches files and directories for specified input
halt	Utility that stops the server
httpsdctl	Handles secure Apache Web processes
hwclock	Utility that allows access to the hardware clock
ifconfig	Indicates the network configuration executable. Ensures that the MAC address stays constant
iptables	Handles access restriction based on changes made to the Access Configuration page. See Configuring the Access List for Your Appliance on page 2048 for more information about access configuration.
iptables-restore	Handles iptables file restoration
iptables-save	Handles saved changes to the iptables
kill	Utility that can be used to end a session and process
killall	Utility that can be used to end all sessions and processes
ksh	Public domain version of the Korn shell
logger	Utility that provides a way to access the syslog daemon from the command line
md5sum	Utility that prints checksums and block counts for specified files
mv	Utility that moves (renames) files
myisamchk	Indicates database table checking and repairing

System Executables and Utilities (Continued)

Executable	Description
mysql	Indicates a database process; multiple instances may appear
openssl	Indicates authentication certificate creation
perl	Indicates a perl process
ps	Utility that writes process information to standard output
sed	Utility used to edit one or more text files
sfheartbeat	Identifies a heartbeat broadcast, indicating that the appliance is active; heartbeat used to maintain contact between a device and Defense Center
sfmb	Indicates a message broker process; handles communication between Defense Centers and device.
sh	Public domain version of the Korn shell
shutdown	Utility that shuts down the appliance
sleep	Utility that suspends a process for a specified number of seconds
smtpclient	Mail client that handles email transmission when email event notification functionality is enabled
snmptrap	Forwards SNMP trap data to the SNMP trap server specified when SNMP notification functionality is enabled
snort (requires Protection)	Indicates that Snort is running
ssh	Indicates a Secure Shell (SSH) connection to the appliance
sudo	Indicates a sudo process, which allows users other than admin to run executables
top	Utility that displays information about the top CPU processes

System Executables and Utilities (Continued)

EXECUTABLE	DESCRIPTION
touch	Utility that can be used to change the access and modification times of specified files
vim	Utility used to edit text files
wc	Utility that performs line, word, and byte counts on specified files

CHAPTER 53
USING HEALTH MONITORING

The health monitor provides numerous tests for determining the health of an appliance from the Defense Center. You can use the health monitor to create a collection of tests, referred to as a *health policy*, and apply the health policy to one or more appliances. You can create one health policy for every appliance in your system, customize a health policy for the specific appliance where you plan to apply it, or use the default health policy. You can also import a health policy exported from another Defense Center.

The tests, referred to as *health modules*, are scripts that test for criteria you specify. You can modify a health policy by enabling or disabling tests or by changing test settings, and you can delete health policies that you no longer need. You can also suppress messages from selected appliances by blacklisting them.

The tests in a health policy run automatically at the interval you configure. You can also run all tests, or a specific test, on demand. The health monitor collects health events based on the test conditions configured. Optionally, you can also configure email, SNMP, or syslog alerting in response to health events.

On the Defense Center, you can view health status information for the entire system or for a particular appliance. Fully customizable event views allow you to quickly and easily analyze the health status events gathered by the health monitor. These event views allow you to search and view event data and to access other information that may be related to the events you are investigating.

You can also generate troubleshooting files for an appliance if you are asked to do so by Support.

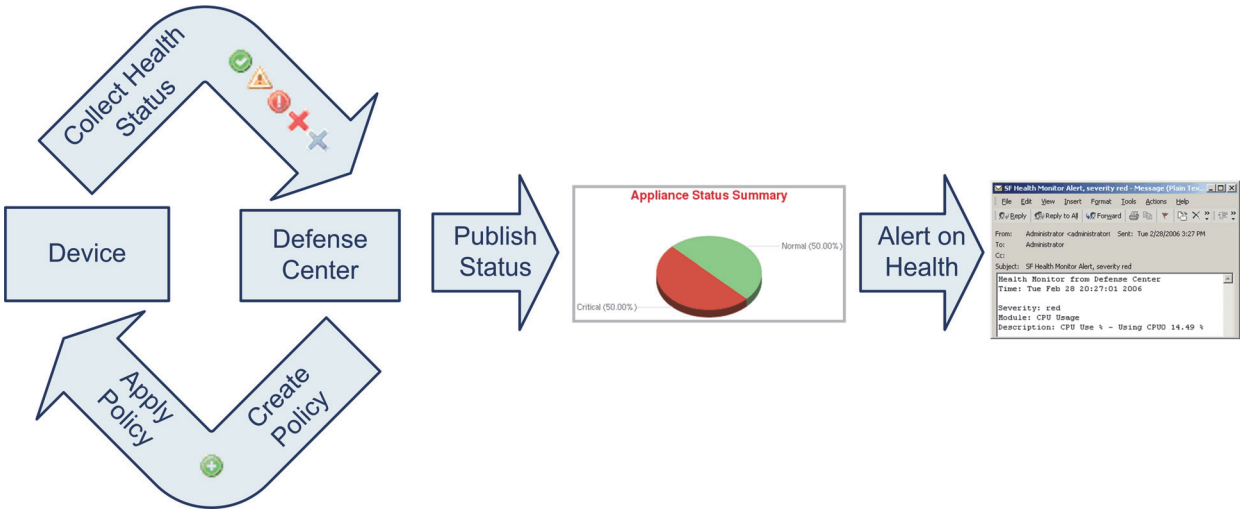
See the following sections for more information:

- Understanding Health Monitoring on page 2192
- Configuring Health Policies on page 2198

Understanding Health Monitoring

LICENSE: Any

You can use the health monitor to check the status of critical functionality across your Sourcefire 3D System deployment. Monitor the health of your entire Sourcefire 3D System through the Defense Center by applying health policies to each of the managed devices and collecting the resulting health data at the Defense Center. Pie charts and status tables on the Health Monitor page visually represent the health status for monitored appliances, so you can check status at a glance, then drill down into status details if needed.



You can use the health monitor to access health status information for the entire system or for a particular appliance. The Health Monitor page provides a visual summary of the status of all appliances on your system. Individual appliance health monitors let you drill down into health details for a specific appliance.

You can also view health events in the standard Sourcefire 3D System table view. From an individual appliance's health monitor, you can open a table view of occurrences of a specific event, or you can retrieve all the health events for that appliance. You can also search for specific health events. For example, if you want to see all the occurrences of CPU usage with a certain percentage, you can search for the CPU usage module and enter the percentage value.

You can also configure email, SNMP, or syslog alerting in response to health events. A *health alert* is an association between a standard alert and a health status level. For example, if you need to make sure an appliance never fails due to hardware overload, you can set up an email alert. You can then create a health alert that triggers that email alert whenever CPU, disk, or memory usage reaches the Warning level you configure in the health policy applied to that appliance. You can set alerting thresholds to minimize the number of repeating alerts you receive.

Because health monitoring is an administrative activity, only users with administrator user role privileges can access system health data. For more information on assigning user privileges, see Modifying User Privileges and Options on page 1988.

IMPORTANT! Except for the Defense Center, Sourcefire 3D System devices do not have health monitoring policies applied to them by default. Managed devices report hardware status automatically via the Hardware Alarms health module; if you want to use other modules to monitor a managed device, you must apply a health policy to that device. For more information on the Sourcefire-provided default health policy for your appliances, see Understanding the Default Health Policy on page 2199. For more information on creating customized health policies, see Creating Health Policies on page 2200. For details on applying policies, see Applying Health Policies on page 2228.

For more information on health policies and the health modules you can run to test system health, see the following topics:

- Understanding Health Policies on page 2193
- Understanding Health Modules on page 2194
- Understanding Health Monitoring Configuration on page 2197

Understanding Health Policies

LICENSE: Any

A *health policy* is a collection of health module settings you apply to an appliance to define the criteria that the Defense Center uses when checking the health of the appliance. The health monitor tracks a variety of health indicators to ensure that your Sourcefire 3D System hardware and software are working correctly.

When you create health policies, you choose which tests to run to determine appliance health. You can also apply the default health policy to any appliance.

Understanding Health Modules

LICENSE: Any

Health modules, also sometimes referred to as *health tests,* are scripts that test for the criteria you specify in a health policy. The available health modules are described in the Health Modules table.

Health Modules

MODULE	DESCRIPTION
Advanced Malware Protection	This module alerts if the Defense Center cannot contact the Sourcefire cloud, either to retrieve file disposition information for files detected in network traffic or to submit files for dynamic analysis, or if an excessive number of files are detected in network traffic, based on the file policy configuration. This module runs on all Defense Centers except the DC500, which does not support advanced malware protection.
Appliance Heartbeat	This module determines if an appliance heartbeat is being heard from the appliance and alerts based on the appliance heartbeat status.
Automatic Application Bypass Status	This module determines if an appliance has been bypassed because it did not respond within the number of seconds set in the bypass threshold, and alerts when a bypass occurs.
CPU Usage	This module checks that the CPU on the appliance is not overloaded and alerts when CPU usage exceeds the percentages configured for the module. This module is not available for health policies applied to 3D9900 devices.
Card Reset	This module checks for network cards which have restarted due to hardware failure and alerts when a reset occurs.
Discovery Event Status	This module indicates whether a specified period of time has passed since any discovery events have been detected by a device.
Disk Status	This module examines performance of the hard disk, and malware storage pack (if installed) on the appliance. It alerts when the hard disks and RAID controller (if installed) are in danger of failing, or if the malware storage pack is not detected after installation or inauthentic.
Disk Usage	This module compares disk usage on the appliance's hard drive and malware storage pack to the limits configured for the module and alerts when usage exceeds the percentages configured for the module. This module also alerts when the system excessively deletes files in monitored disk usage categories, or when disk usage excluding those categories reaches excessive levels, based on module thresholds.

Health Modules (Continued)

Module	Description
FireAMP Status Monitor	The module alerts if the Defense Center cannot connect to the Sourcefire cloud after an initial successful connection, or if you deregister a cloud connection using the FireAMP portal. This module only runs on Defense Centers.
FireSIGHT Host License Limit	This module determines if sufficient FireSIGHT host licenses remain and alerts based on the warning level configured for the module. This module only runs on Defense Centers.
Hardware Alarms	This module determines if hardware needs to be replaced on a Series 3 or 3D9900 device and alerts based on the hardware status. The module also reports on the status of hardware-related daemons and on the status of clustered appliances. For more information on the details reported for these devices, see Interpreting Hardware Alert Details for 3D9900 Devices on page 2261 and Interpreting Hardware Alert Details for Series 3 Devices on page 2263.
Health Monitor Process	This module monitors the status of the health monitor itself and alerts if the number of minutes since the last health event received by the Defense Center exceeds the Warning or Critical limits. This module only runs on Defense Centers.
Inline Link Mismatch Alarms	This module monitors the ports associated with inline sets and alerts if the two interfaces of an inline pair negotiate different speeds.
Intrusion Event Rate	This module compares the number of intrusion events per second to the limits configured for this module and alerts if the limits are exceeded. If the Intrusion Event Rate is zero, the intrusion process may be down or the managed device may not be sending events. Select **Analysis > Intrusions > Events** to check if events are being received from the device.
License Monitor	This module determines if sufficient licenses for Control, Protection, URL Filtering, Malware, and VPN remain. It also alerts when devices in a stack have mismatched license sets. It alerts based on a warning level automatically configured for the module. You cannot change the configuration of this module. This module only runs on Defense Centers.
Link State Propagation	This module determines when a link in a paired inline set fails and triggers the link state propagation mode.
Memory Usage	This module compares memory usage on the appliance to the limits configured for the module and alerts when usage exceeds the levels configured for the module.

Health Modules (Continued)

Module	Description
Power Supply	This module determines if power supplies on the device require replacement and alerts based on the power supply status. This module runs on these Defense Centers: DC1500, DC3500. This module runs on these devices: 3D3500, 3D4500, 3D6500, 3D9900, and Series 3.
Process Status	This module determines if processes on the appliance exit or terminate outside of the process manager. If a process is deliberately exited outside of the process manager, the module status changes to Warning and the health event message indicates which process exited, until the module runs again and the process has restarted. If a process terminates abnormally or crashes outside of the process manager, the module status changes to Critical and the health event message indicates the terminated process, until the module runs again and the process has restarted.
RRD Server Process	This module determines if the round robin data server that stores time series data is running properly and alerts based on the number of recent RRD server restarts. This module only runs on Defense Centers.
Security Intelligence	This module alerts in a variety of situations involving Security Intelligence filtering, including feed update, feed corruption, and memory issues. This module runs on all Defense Centers except the DC500, which does not support Security Intelligence filtering.
Time Series Data Monitor	This module tracks the presence of corrupt files in the directory where time series data (such as compliance event counts) are stored and alerts when files are flagged as corrupt and removed. This module only runs on Defense Centers.
Time Synchronization Status	This module tracks the synchronization of a device clock that obtains time using NTP with the clock on the NTP server and alerts if the difference in the clocks is more than ten seconds.
Traffic Status	This module determines if the device currently collects traffic and alerts based on the traffic status.

Health Modules (Continued)

Module	Description
URL Filtering Monitor	This module tracks communication between the Defense Center and the Sourcefire cloud, where the system obtains its URL filtering (category and reputation) data for commonly visited URLs. The module alerts if the Defense Center fails to successfully communicate with or retrieve an update from the cloud. This module also tracks communications between the Defense Center and any managed devices where you have enabled URL filtering. The module alerts if the Defense Center cannot push URL filtering data to those devices. This module only runs on all Defense Centers except the DC500, which does not support URL filtering.
User Agent Status Monitor	This module alerts when heartbeats are not detected for any Sourcefire User Agents connected to the Defense Center. This module only runs on Defense Centers.
VPN Status	This module alerts when the system detects that the VPN feature is not functioning. This module only runs on Defense Centers.

Understanding Health Monitoring Configuration

License: Any

There are several steps to setting up health monitoring on your Sourcefire 3D System, as indicated in the following procedure:

1. Create health policies for your appliances.

   You can set up specific policies for each kind of appliance you have in your Sourcefire 3D System, enabling only the appropriate tests for that appliance.

   TIP! If you want to quickly enable health monitoring without customizing the monitoring behavior, you can apply the default policy provided for that purpose.

   For more information on setting up health policies, see Configuring Health Policies on page 2198.

2. Apply a health policy to each appliance where you want to track health status. For information on the default health policy available for immediate application, see Understanding the Default Health Policy on page 2199.

3. Optionally, configure health monitor alerts.

   You can set up email, syslog, or SNMP alerts that trigger when the health status level reaches a particular severity level for specific health modules.

   For more information on setting up health monitor alerts, see Configuring Health Monitor Alerts on page 2241.

After you set up health monitoring on your system, you can view the health status at any time on the Health Monitor page or the Health Events table view. For more information about viewing system health data, see the following topics:

- Using the Health Monitor on page 2245
- Using Appliance Health Monitors on page 2248
- Working with Health Events on page 2256

Configuring Health Policies

LICENSE: Any

A health policy contains configured health test criteria for several modules. You can control which health modules run against each of your appliances and configure the specific limits used in the tests run by each module. For more information on the health modules you can configure in a health policy, see Understanding Health Monitoring on page 2192.

You can create one health policy that can be applied to every appliance in your system, customize each health policy to the specific appliance where you plan to apply it, or use the default health policy provided for you. You can also import a health policy exported from another Defense Center.

When you configure a health policy, you decide whether to enable each health module for that policy. You also select the criteria that control which health status each enabled module reports each time it assesses the health of a process.

For more information on the default health policy, which is applied to the Defense Center automatically, see Understanding the Default Health Policy on page 2199.

For more information, see the following topics:

- Understanding the Default Health Policy on page 2199
- Creating Health Policies on page 2200
- Applying Health Policies on page 2228
- Editing Health Policies on page 2229
- Comparing Health Policies on page 2232
- Deleting Health Policies on page 2236

Understanding the Default Health Policy

LICENSE: Any

The Defense Center health monitor includes a default health policy to make it easier for you to quickly implement health monitoring for your appliances. The default health policy is automatically applied to the Defense Center. You cannot edit the default health policy, but you can copy it to create custom policies based on its configuration. For more information, see Creating Health Policies on page 2200.

To also monitor device health, you can push health policies to your managed devices.

IMPORTANT! You cannot apply a health policy to Sourcefire Software for X-Series.

In the default health policy, most of the health modules available on the running platform are automatically enabled. The Default Active Health Modules table details the modules activated in the default policy for Defense Centers and managed devices.

Default Active Health Modules

Module	Defense Center	Managed Device
Advanced Malware Protection	yes	no
Appliance Heartbeat	yes	no
Automatic Application Bypass	no	yes
CPU Usage	no	no
Card Reset	no	no
Discovery Event Status	no	no
Disk Status	yes	yes
Disk Usage	yes	yes
FireAMP Status Monitor	yes	no
FireSIGHT Host License Limit	yes	no
Hardware Alarm	no	yes

Default Active Health Modules (Continued)

Module	Defense Center	Managed Device
Health Monitor Process	no	no
Inline Link Mismatch Alarms	no	yes
Intrusion Event Rate	no	yes
License Monitor	yes	no
Link State Propagation	no	yes
Memory Usage	yes	yes
Power Supply	no	yes
Process Status	yes	yes
RRD Server Process	yes	no
Security Intelligence	yes	no
Time Series Data Monitor	yes	no
Time Synchronization Status	yes	yes
Traffic Status	no	yes
URL Filtering Monitor	yes	no
User Agent Status Monitor	yes	no
VPN Status	yes	no

Creating Health Policies

License: Any

If you want to customize a health policy to use with your appliances, you can create a new policy. The settings in the policy initially populate with the settings from the health policy you select as a basis for the new policy. You can enable or

disable modules within the policy and change the alerting criteria for each module as needed.

TIP! Instead of creating a new policy, you can export a health policy from another Defense Center and then import it onto your Defense Center. You can then edit the imported policy to suit your needs before you apply it. For more information, see Importing and Exporting Configurations on page 2308.

To create a health policy:

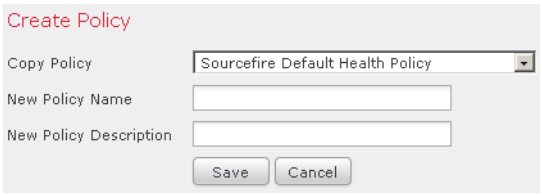
Access: Admin/Maint

1. Select **Health > Health Policy**.

   The Health Policy page appears.

2. Click **Create Policy**.

   The Create Health Policy page appears.



3. Select the existing policy that you want to use as the basis for the new policy from the **Copy Policy** drop-down list.
4. Enter a name for the policy.
5. Enter a description for the policy.
6. Select **Save** to save the policy information.

   The Health Policy Configuration page appears, including a list of the modules.
7. Configure settings on each module you want to use to test the health status of your appliances, as described in the following sections:
   - Configuring Policy Run Time Intervals on page 2203
   - Configuring Advanced Malware Protection Monitoring on page 2203
   - Configuring Appliance Heartbeat Monitoring on page 2204
   - Configuring Automatic Application Bypass Monitoring on page 2205
   - Configuring CPU Usage Monitoring on page 2206
   - Configuring Card Reset Monitoring on page 2207

- Configuring Discovery Event Status Monitoring on page 2208
- Configuring Disk Status Monitoring on page 2209
- Configuring Disk Usage Monitoring on page 2209
- Configuring FireAMP Status Monitoring on page 2211
- Configuring FireSIGHT Host Usage Monitoring on page 2212
- Configuring Hardware Alarm Monitoring on page 2213
- Configuring Health Status Monitoring on page 2214
- Configuring Inline Link Mismatch Alarm Monitoring on page 2215
- Configuring Intrusion Event Rate Monitoring on page 2216
- Understanding License Monitoring on page 2217
- Configuring Link State Propagation Monitoring on page 2217
- Configuring Memory Usage Monitoring on page 2218
- Configuring Power Supply Monitoring on page 2219
- Configuring Process Status Monitoring on page 2220
- Configuring RRD Server Process Monitoring on page 2221
- Configuring Security Intelligence Monitoring on page 2222
- Configuring Time Series Data Monitoring on page 2223
- Configuring Time Synchronization Monitoring on page 2224
- Configuring Traffic Status Monitoring on page 2225
- Configuring URL Filtering Monitoring on page 2225
- Configuring User Agent Status Monitoring on page 2226
- Configuring VPN Status Monitoring on page 2227

IMPORTANT! Make sure you enable each module that you want to run to test the health status on each Health Policy Configuration page as you configure the settings. Disabled modules do not produce health status feedback, even if the policy that contains the module has been applied to an appliance.

8. Click **Save Policy and Exit** to save the policy.

   You must apply the policy to each appliance for it to take effect. For more information on applying health policies, see Applying Health Policies on page 2228.

Configuring Policy Run Time Intervals

LICENSE: Any

You can control how often health tests run by modifying the Policy Run Time Interval for the health policy. The maximum run time interval you can set is 99999 minutes.

WARNING! Do not set a run interval of less than five minutes.

To configure a policy run time interval:

ACCESS: Admin/Maint

1. On the Health Policy Configuration page, select **Policy Run Time Interval**.

   The Health Policy Configuration — Policy Run Time Interval page appears.

2. In the **Run Interval (mins)** field, enter the time in minutes that you want to elapse between automatic repetitions of the test.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate appliances if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Advanced Malware Protection Monitoring

LICENSE: Malware

This module tracks the state and stability of the Defense Center's ability to query the Sourcefire cloud and detect files in network traffic. If the system detects that your connection with the cloud is interrupted, the encryption keys used for the connection are invalid, or the number of files detected in a time frame is excessive, the status classification for this module changes to Warning and the module generates a health alert.

To configure Advanced Malware Protection health module settings:

Access: Admin/Maint

1. In the Health Policy Configuration page, select Advanced Malware Protection.

   The Health Policy Configuration — Advanced Malware Protection page appears.

2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate appliances if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Appliance Heartbeat Monitoring

License: Any

The Defense Center receives heartbeats from its managed devices once every two minutes or every 200 events, whichever comes first, as an indicator that the device is running and communicating properly with the Defense Center. Use the Appliance Heartbeat health status module to track whether the Defense Center receives heartbeats from managed appliances. If the Defense Center does not detect a heartbeat from a device, the status classification for this module changes to Critical. That status data feeds into the health monitor.

To configure Appliance Heartbeat health module settings:

Access: Admin/Maint

1. In the Health Policy Configuration page, select **Appliance Heartbeat**.

   The Health Policy Configuration — Appliance Heartbeat page appears.

2. Select **On** for the **Enabled** option to enable use of the module for health status testing.

3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate appliances if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Automatic Application Bypass Monitoring

LICENSE: Any

Use this module to detect when a managed device is bypassed because it did not respond within the number of seconds configured as the bypass threshold. If a bypass occurs, this module generates an alert. That status data feeds into the health monitor.

For more information on automatic application bypass, see Automatic Application Bypass on page 295.

To configure automatic application bypass monitoring status:

ACCESS: Admin/Maint

1. In the Health Policy Configuration page, select **Automatic Application Bypass Status**.

   The Health Policy Configuration — Automatic Application Bypass Status page appears.

2. Select **On** for the **Enabled** option to enable use of the module for health status testing.

3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate managed device if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring CPU Usage Monitoring

License: Any
Supported Devices: Any except 3D9900
Supported Defense Centers: Any

Excessive CPU usage may indicate that you need to upgrade your hardware or that there are processes that are not functioning correctly. Use the CPU Usage health status module to set CPU usage limits.

If the CPU usage on the monitored appliance exceeds the Warning limit, the status classification for that module changes to Warning. If the CPU usage on the monitored appliance exceeds the Critical limit, the status classification for that module changes to Critical. That status data feeds into the health monitor.

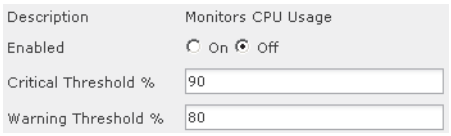
The maximum percentage you can set for either limit is 100 percent, and the Critical limit must be higher than the Warning limit.

To configure CPU usage limits:

Access: Admin/Maint

1. On the Health Policy Configuration page, select **CPU Usage**.

   The Health Policy Configuration — CPU Usage page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. In the **Critical Threshold %** field, enter the percentage of CPU usage that should trigger a critical health status.
4. In the **Warning Threshold %** field, enter the percentage of CPU usage that should trigger a warning health status.

5. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate appliances if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Card Reset Monitoring

LICENSE: Any

Use the card reset monitoring health status module to track when the network card restarts because of hardware failure. If a reset occurs, this module generates an alert. That status data feeds into the health monitor.

To configure card reset monitoring:

ACCESS: Admin/Maint

1. In the Health Policy Configuration page, select **Card Reset**.

   The Health Policy Configuration — Card Reset Monitoring page appears.

2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate Defense Center if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Discovery Event Status Monitoring

License: FireSIGHT

Use the Discovery Event Status module to monitor the health of the discovery process on a device from the Defense Center by generating alerts when too many seconds elapse between discovery events received by the Defense Center. You can configure the elapsed duration between events, in seconds, that causes an alert to be generated. If the wait exceeds the number of seconds configured in the Warning Seconds since last event limit, the status classification for that module changes to Warning. If the wait exceeds the Critical Seconds since last event limit, the status classification for that module changes to Critical. That status data feeds into the health monitor.

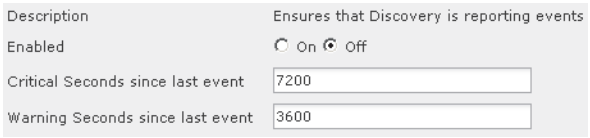
The maximum number of seconds you can set for either limit is 7200, and the Critical limit must be higher than the Warning limit. The minimum number of seconds is 3600.

To configure Discovery Event Status module settings:

Access: Admin/Maint

1. In the Health Policy Configuration page, select **Discovery Event Status**.

   The Health Policy Configuration — Discovery Event Status page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. In the **Critical Seconds since last event** field, enter the maximum number of seconds to wait between events, before triggering a critical health status.
4. In the **Warning Seconds since last event** field, enter the maximum number of seconds to wait between events, before triggering a warning health status.
5. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the Defense Center for your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Disk Status Monitoring

LICENSE: Any

Use the Disk Status health module to monitor the current status of your appliance's hard disk, and malware storage pack if installed. This module generates a Warning (yellow) health alert when the hard disk and RAID controller (if installed) are in danger of failing, or if an additional hard drive is installed that is not a malware storage pack. This module generates an Alert (red) health alert when an installed malware storage pack cannot be detected.

To configure Disk Status health module settings:

ACCESS: Admin/Maint

1. On the Health Policy Configuration page, click **Disk Status**.

   The Health Policy Configuration — Disk Status page appears.

2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Disk Usage Monitoring

LICENSE: Any

Without sufficient disk space, an appliance cannot run. The health monitor can identify low disk space conditions on your appliance's hard drive and malware storage pack before space runs out. The health monitor can also alert when hard drive file draining occurs too frequently. Use the Disk Usage health status module

to monitor disk usage for the / and `/volume` partitions on the appliance and track draining frequency.

IMPORTANT! Although the disk usage module lists the `/boot` partition as a monitored partition, the size of the partition is static so the module does not alert on the boot partition.

If the overall disk usage on the monitored appliance exceeds the Warning limit, the status classification for that module changes to Warning. If the overall disk usage on the monitored appliance exceeds the Critical limit, the status classification for that module changes to Critical. The maximum percentage you can set for either limit is 100 percent, and the Critical limit must be higher than the Warning limit.

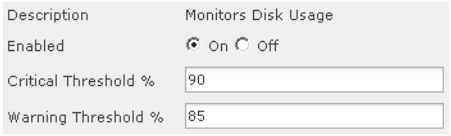
If the system deletes unprocessed events, the status classification for that module changes to Warning. If the system drains files in any disk usage category too frequently based on module thresholds, or if disk usage for files not in a monitored disk usage category grows too large based on module thresholds, the status classification for that module changes to Critical. For more information on disk usage categories, see Understanding the Disk Usage Widget on page 106.

To configure Disk Usage health module settings:

Access: Admin/Maint

1. On the Health Policy Configuration page, select **Disk Usage**.

   The Health Policy Configuration — Disk Usage page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. In the **Critical Threshold %** field, enter the percentage of disk usage that should trigger a critical health status.
4. In the **Warning Threshold %** field, enter the percentage of disk usage that should trigger a warning health status.

5. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate appliances if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring FireAMP Status Monitoring

License: Any

Use the FireAMP Status Monitor module to alert you in the following situations:

- the Defense Center cannot connect to the Sourcefire cloud after an initial successful connection
- you deregister a cloud connection using the FireAMP portal

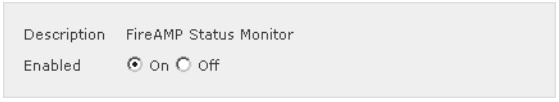
In these cases, the module status changes to Critical and provides the cloud name associated with the failed connection. For information on configuring a cloud connection, see Working with Sourcefire Cloud Connections for FireAMP on page 1254.

To configure FireAMP Status Monitor module settings:

Access: Admin/Maint

1. In the Health Policy Configuration page, select **FireAMP Status Monitor**.

   The Health Policy Configuration — FireAMP Status Monitor page appears.



2. Select **On** for the **Enabled** option to enable use of the module for FireAMP status monitoring.

3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the Defense Center if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring FireSIGHT Host Usage Monitoring

License: FireSIGHT

Use the FireSIGHT Host License Limit health status module to set FireSIGHT Host amount warning limits. If the number of remaining FireSIGHT Hosts on the monitored device falls below the Warning Hosts limit, the status classification for that module changes to Warning. If the number of remaining FireSIGHT Hosts on the monitored device falls below the Critical Hosts limit, the status classification for that module changes to Critical. That status data feeds into the health monitor.

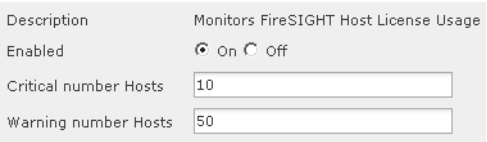
The maximum number of hosts you can set for either limit is 1000, and the Critical host limit number must be lower than the Warning limit.

To configure FireSIGHT Host License Limit health module settings:

Access: Admin/Maint

1. In the Health Policy Configuration page, select **FireSIGHT Host License Limit**.

   The Health Policy Configuration — FireSIGHT Host License Limit page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. In the **Critical number Hosts** field, enter the remaining number of available hosts that should trigger a critical health status.
4. In the **Warning number Hosts** field, enter the remaining number of available hosts that should trigger a warning health status.

5. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Hardware Alarm Monitoring

LICENSE: Any
SUPPORTED DEVICES: Series 3, 3D9900

Use the Hardware Alarms health status module to detect hardware failure on a Series 3 or 3D9900 device. If the Hardware Alarms module finds a hardware component that has failed or clustered devices that are not communicating with each other, the status classification for that module changes to Critical. That status data feeds into the health monitor.

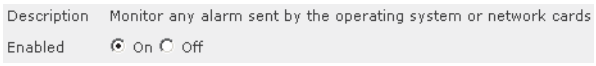
For more information on the hardware status conditions that can cause hardware alerts on 3D9900 devices, see Interpreting Hardware Alert Details for 3D9900 Devices on page 2261.

To configure Hardware Alarm health module settings:

ACCESS: Admin/Maint

1. In the Health Policy Configuration page, select **Hardware Alarms**.

   The Health Policy Configuration — Hardware Alarm Monitor page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.

3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Health Status Monitoring

License: Any

Use the Health Monitor Process module to monitor the health of the health monitor on a Defense Center by generating alerts when too many minutes elapse between health events received from monitored appliances.

For example, if a Defense Center (`myrtle.example.com`) monitors a device (`dogwood.example.com`), you apply a health policy with the Health Monitor Process module enabled to `myrtle.example.com`. The Health Monitor Process module then reports events that indicate how many minutes have elapsed since the last event was received from `dogwood.example.com`.

You can configure the elapsed duration between events, in minutes, that causes an alert to be generated. If the wait exceeds the number of minutes configured in the Warning Minutes since last event limit, the status classification for that module changes to Warning. If the wait exceeds the Critical Minutes since last event limit, the status classification for that module changes to Critical. That status data feeds into the health monitor.

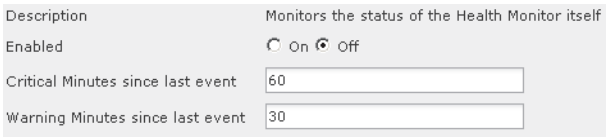
The maximum number of minutes you can set for either limit is 144, and the Critical limit must be higher than the Warning limit. The minimum number of minutes is 5.

To configure Health Monitor Process module settings:

Access: Admin/Maint

1. In the Health Policy Configuration page, select **Health Monitor Process**.

   The Health Policy Configuration — Health Monitor Process page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. In the **Critical Minutes since last event** field, enter the maximum number of minutes to wait between events, before triggering a critical health status.
4. In the **Warning Minutes since last event** field, enter the maximum number of minutes to wait between events, before triggering a warning health status.
5. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the Defense Center for your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Inline Link Mismatch Alarm Monitoring

LICENSE: Any

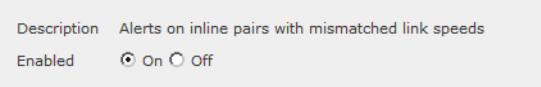
Use the Inline Link Mismatch Alarm health status module to track when the interfaces on either side of an inline set negotiate different connection speeds. If different negotiated speeds are detected, this module generates an alert.

To configure inline link mismatch monitoring:

ACCESS: Admin/Maint

1. In the Health Policy Configuration page, select **Inline Link Mismatch Alarms**.

   The Health Policy Configuration — Inline Link Mismatch Alarms page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.

3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate Defense Center if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Intrusion Event Rate Monitoring

License: Protection

Use the Intrusion Event Rate health status module to set limits for the number of packets per second that trigger a change in the health status. If the event rate on the monitored device exceeds the number of events per second configured in the Events per second (Warning) limit, the status classification for that module changes to Warning. If the event rate exceeds the number of events per second configured in the Events per second (Critical) limit, the status classification for that module changes to Critical. That status data feeds into the health monitor.

Typically, the event rate for a network segment averages 20 events per second. For a network segment with this average rate, Events per second (Critical) should be set to 50 and Events per second (Warning) should be set to 30. To determine limits for your system, find the Events/Sec value on the Statistics page for your device (**System > Monitoring > Statistics**), then calculate the limits using these formulas:

- Events per second (Critical) = Events/Sec * 2.5
- Events per second (Warning) = Events/Sec * 1.5

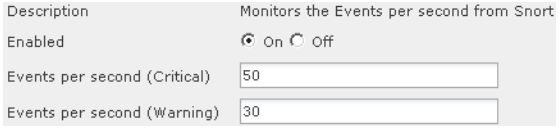
The maximum number of events you can set for either limit is 999, and the Critical limit must be higher than the Warning limit.

To configure Intrusion Event Rate Monitor health module settings:

Access: Admin/Maint

1. On the Health Policy Configuration page, select **Intrusion Event Rate**.

   The Health Policy Configuration — Intrusion Event Rate page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. In the **Events per second (Critical)** field, enter the number of events per second that should trigger a critical health status.
4. In the **Events per second (Warning)** field, enter the number of events per second that should trigger a warning health status.
5. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Understanding License Monitoring

LICENSE: Any

Use the License Monitoring health status module to determine if sufficient licenses remain for Control, Protection, URL Filtering, Malware, and VPN. This module alerts if the number of remaining licenses is low or insufficient.

This module also alerts if the system detects that devices in a stacked configuration have mismatched license sets (stacked devices must have identical sets of licenses).

The License Monitoring module is automatically configured. Because you cannot change or disable this module, it does not appear on the Health Policy Configuration page.

Configuring Link State Propagation Monitoring

LICENSE: Any

Use the Link State Propagation health status module to detect the link state propagation status on an inline pair. If a link state propagates to the pair, the status classification for that module changes to Critical and the state reads:

`Module Link State Propagation: eth`*x*`_eth`*y*` is Triggered`

where *x* and *y* are the paired interface numbers.

To configure Link State Propagation health module settings:

ACCESS: Admin/Maint

1. On the Health Policy Configuration page, select **Link State Propagation**.

   The Health Policy Configuration — Link State Propagation monitor page appears.

2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Memory Usage Monitoring

LICENSE: Any

Use the Memory Usage health status module to set memory usage limits. The module calculates free memory by considering free memory, cached memory, and swap memory. If the memory usage on the monitored appliance exceeds the Warning limit, the status classification for that module changes to Warning. If the memory usage on the monitored appliance exceeds the Critical limit, the status classification for that module changes to Critical. That status data feeds into the health monitor.

For appliances with more than 4GB of memory, the preset alert thresholds are based on a formula that accounts for proportions of available memory likely to cause system problems.

IMPORTANT! On >4GB appliances, because the interval between Warning and Critical thresholds may be very narrow, Sourcefire recommends that you manually set the **Warning Threshold %** value to 50. This will further ensure that you receive memory alerts for your appliance in time to address the issue.

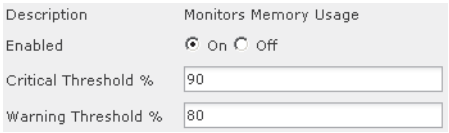
The maximum percentage you can set for either limit is 100 percent, and the Critical limit must be higher than the Warning limit.

To configure Memory Usage health module settings:

ACCESS: Admin/Maint

1. On the Health Policy Configuration page, select **Memory Usage**.

   The Health Policy Configuration — Memory Usage page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. In the **Critical Threshold %** field, enter the percentage of memory usage that should trigger a critical health status.
4. In the **Warning Threshold %** field, enter the percentage of memory usage that should trigger a warning health status.
5. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate appliances if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Power Supply Monitoring

LICENSE: Any
SUPPORTED DEVICES: 3D3500, 3D4500, 3D6500, 3D9900, Series 3
SUPPORTED DEFENSE CENTERS: DC1500, DC3500

Use the Power Supply health status module to detect a power supply failure on any of the supported platforms. If the module finds a power supply that has no power, the status classification for that module changes to No Power. If the module cannot detect the presence of the power supply, the status changes to Critical Error. That status data feeds into the health monitor. You can expand the Power Supply item on the Alert Detail list in the health monitor to see specific status items for each power supply.

To configure Power Supply health module settings:

ACCESS: Admin/Maint

1. In the Health Policy Configuration page, select **Power Supply**.

   The Health Policy Configuration — Power Supply page appears.

2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Process Status Monitoring

LICENSE: Any

Use the Process Status health module to monitor for processes running on the appliance that exit or terminate outside of the process manager. The response of the Process Status module to a process ending depends on how the process ends:

- If the process terminates inside the process manager, the module does not report any health events.
- If a process is deliberately exited outside of the process manager, the module status changes to Warning and the health event message indicates which process exited until the module runs again and the process has restarted.
- If a process terminates abnormally or crashes outside of the process manager, the module status changes to Critical and the health event message indicates the terminated process until the module runs again and the process has restarted.

To configure Process Status health module settings:

ACCESS: Admin/Maint

1. In the Health Policy Configuration page, select **Process Status**.

   The Health Policy Configuration — Process Status page appears.

2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate appliances if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring RRD Server Process Monitoring

LICENSE: Any

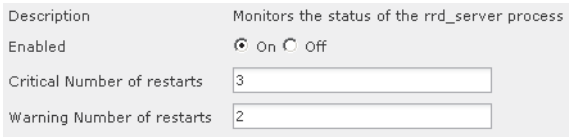
Use the RRD Server Process module to see if the RRD server that stores time series data is working properly. The module will alert If the RRD server has restarted since the last time it updated; it will enter Critical or Warning status if the number of consecutive updates with an RRD server restart reaches the numbers specified in the module configuration.

To configure RRD server process monitoring settings:

ACCESS: Admin/Maint

1. In the Health Policy Configuration page, select **RRD Server Process**.

   The Health Policy Configuration — RRD Server Process page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.

3. In the **Critical Number of restarts** field, enter the number of consecutive detected RRD server resets that should trigger a critical health status.
4. In the **Warning Number of restarts** field, enter the number of consecutive detected RRD server resets that should trigger a warning health status.
5. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Security Intelligence Monitoring

LICENSE: Protection
SUPPORTED DEFENSE CENTERS: Any except DC500

Use the Security Intelligence module to warn you in a variety of situations involving Security Intelligence filtering. The module alerts if Security Intelligence is in use and:

- the Defense Center cannot update a feed, or if feed data is corrupt or contains no recognizable IP addresses
- a managed device had a problem receiving updated Security Intelligence data from the Defense Center
- a managed device cannot load all of the Security Intelligence data provided to it by the Defense Center, due to memory issues

TIP! If a Security Intelligence memory warning appears in the health monitor, you can reapply the affected device's access control policy to increase the memory allocated to Security Intelligence. See Applying an Access Control Policy on page 506 for more information.

For more information on Security Intelligence filtering, see Filtering Traffic Based on Security Intelligence Data on page 475 and Working with Security Intelligence Lists and Feeds on page 178.

To configure Security Intelligence module settings:

Access: Admin/Maint

1. In the Health Policy Configuration page, select **Security Intelligence**.

   The Health Policy Configuration — Security Intelligence page appears.

2. Select **On** for the **Enabled** option to enable use of the module for Security Intelligence monitoring.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Time Series Data Monitoring

License: Any

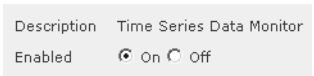
Use the Time Series Data Monitor module to monitor the status of time series data (such as lists of compliance events) that your system has stored. This module scans your time series data storage directory for corrupt files. If the module finds corrupted data, it enters a Warning status and reports the names of all affected files.

To configure time series data monitoring settings:

Access: Admin/Maint

1. In the Health Policy Configuration page, select **Time Series Data Monitor**.

   The Health Policy Configuration — Time Series Data Monitor page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.

3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Time Synchronization Monitoring

LICENSE: Any

Use the Time Synchronization Status module to detect when the time on a managed device that uses NTP to obtain time from an NTP server differs by 10 seconds or more from the time on the server.

To configure time synchronization monitoring settings:

ACCESS: Admin/Maint

1. In the Health Policy Configuration page, select **Time Synchronization Status**.

   The Health Policy Configuration — Time Synchronization Status page appears.

   
2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring Traffic Status Monitoring

LICENSE: FireSIGHT

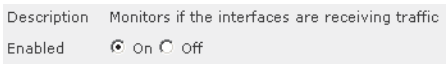
Use the Traffic Status health status module to detect whether a device receives traffic. If the Traffic Status module determines that a device does not receive traffic, the status classification for that module changes to Critical. That status data feeds into the health monitor.

To configure Traffic Status health module settings:

ACCESS: Admin/Maint

1. In the Health Policy Configuration page, select **Traffic Status**.

   The Health Policy Configuration — Traffic Status page appears.

2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring URL Filtering Monitoring

LICENSE: URL Filtering
SUPPORTED DEFENSE CENTERS: Any except DC500

Use the URL Filtering Monitor module to track communications between the Defense Center and the Sourcefire cloud, where the system obtains its URL filtering (category and reputation) data for commonly visited URLs. If the Defense Center fails to successfully communicate with or retrieve an update from the cloud, the status classification for that module changes to Critical.

In a high availability configuration, only the primary Defense Center communicates with the URL filtering cloud; all data from this module refers only to that primary appliance.

The URL Filtering Monitor module also tracks communications between the Defense Center and any managed devices where you have enabled URL filtering.

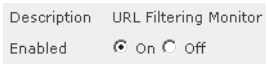
If the Defense Center is successfully communicating with the cloud, the module status changes to Warning if the Defense Center cannot push new URL filtering data to its managed devices.

To configure URL Filtering Monitor health module settings:

Access: Admin/Maint

1. In the Health Policy Configuration page, select **URL Filtering Monitor**.

   The Health Policy Configuration — URL Filtering Monitor page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the Defense Center if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring User Agent Status Monitoring

License: FireSIGHT

You can use the Sourcefire User Agent Status Monitor health module to monitor the heartbeat of agents connected to a Defense Center. If you enable the module in an applied health policy, the module generates a health alert if the Defense Center does not detect a heartbeat for any agent configured on the Defense Center.

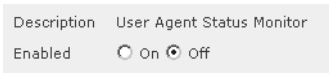
If you have legacy user agents reporting to your Defense Center, the health module alerts that the agents are not issuing heartbeats.

To configure User Agent Status Monitor health module settings:

Access: Admin/Maint

1. In the Health Policy Configuration page, select **User Agent Status Monitor**.

   The Health Policy Configuration — User Agent Status Monitor page appears.



2. Select **On** for the **Enabled** option to enable use of the module for health status testing.
3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the Defense Center if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Configuring VPN Status Monitoring

LICENSE: VPN
SUPPORTED DEFENSE CENTERS: Any except Series 2

Use the VPN Status health module to monitor the current status of your configured Gateway VPN tunnels; information for each individual tunnel is displayed. This module generates a Critical (red) health alert when any of your VPN tunnels is not working.

To configure VPN Status health module settings:

ACCESS: Admin/Maint

1. On the Health Policy Configuration page, click **VPN Status**.

   The Health Policy Configuration — VPN Status page appears.

2. Select **On** for the **Enabled** option to enable use of the module for health status testing.

3. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.

   You must apply the health policy to the appropriate devices if you want your settings to take effect. See Applying Health Policies on page 2228 for more information.

Applying Health Policies

LICENSE: Any

When you apply a health policy to an appliance, the health tests for all the modules you enabled in the policy automatically monitor the health of the processes and hardware on the appliance. Health tests then continue to run at the intervals you configured in the policy, collecting health data for the appliance and forwarding that data to the Defense Center.

If you enable a module in a health policy and then apply the policy to an appliance that does not require that health test, the health monitor reports the status for that health module as disabled.

If you apply a policy with all modules disabled to an appliance, it removes all applied health policies from the appliance so no health policy is applied.

When you apply a different policy to an appliance that already has a policy applied, expect some latency in the display of new data based on the newly applied tests.

IMPORTANT! Custom health policies created on Defense Centers in a high availability pair will be replicated between both appliances. However, changes to default health policies are not replicated; each appliance uses the local default health policy configured for that appliance.

To apply a health policy:

ACCESS: Admin/Maint

1. Select **Health > Health Policy**.

   The Health Policy page appears.

2. Click the apply icon ( ) next to the policy you want to apply.

   The Health Policy Apply page appears.

TIP! The status icon ( ) next to the Health Policy column indicates the current health status for the appliance. The status icon ( ) next to the System Policy column indicates the communication status between the Defense Center and the device. Note that you can remove the currently applied policy by clicking the remove icon (✖).

3. Select the appliances where you want to apply the health policy.
4. Click **Apply** to apply the policy to the selected appliances.

   The Health Policy page appears, with a message indicating if the application of the policy was successful. Monitoring of the appliance starts as soon as the policy is successfully applied.

Editing Health Policies

LICENSE: Any

You can modify a health policy by enabling or disabling modules or by changing module settings. If you modify a policy that is already applied to an appliance, the changes do not take effect until you reapply the policy.

Applicable health models for various appliances are listed in the Health Modules Applicable to Appliances table.

Health Modules Applicable to Appliances

Module	Applicable Appliance
Advanced Malware Protection	Defense Centers, except DC500
Appliance Heartbeat	Defense Center
Automatic Application Bypass Status	Any managed device
CPU Usage	Any except 3D9900
Card Reset	Any managed device
Discovery Event Status	Defense Center
Disk Status	Any
Disk Usage	Any
FireAMP Status Monitor	Defense Center
FireSIGHT Host License Limit	Defense Center
Hardware Alarms	Series 3, 3D9900
Health Monitor Process	Defense Center
Inline Link Mismatch Alarms	Any managed device
Intrusion Event Rate	Managed devices with Protection
License Monitor	Defense Center
Link State Propagation	Managed devices with Protection
Memory Usage	Any
Power Supply	Defense Centers: DC1500, DC3500 Devices: 3D3500, 3D4500, 3D6500, 3D9900, Series 3
Process Status	Any

Health Modules Applicable to Appliances (Continued)

Module	Applicable Appliance
RRD Server Process	Defense Center
Security Intelligence	Defense Center, except DC500
Time Series Data Monitor	Defense Center
Time Synchronization Status	Any
Traffic Status	Any managed device
URL Filtering Monitor	Defense Centers, except DC500
User Agent Status Monitor	Defense Center
VPN Status	Defense Center

To edit a health policy:

Access: Admin/Maint

1. Select **Health > Health Policy**.

   The Health Policy page appears.

2. Click the edit icon ( ) next to the policy you want to modify.

   The Health Policy Configuration page appears, with the Policy Run Time Interval settings selected.

3. Modify settings as needed, as described in the following sections:
   - Configuring Policy Run Time Intervals on page 2203
   - Configuring Advanced Malware Protection Monitoring on page 2203
   - Configuring Appliance Heartbeat Monitoring on page 2204
   - Configuring Automatic Application Bypass Monitoring on page 2205
   - Configuring CPU Usage Monitoring on page 2206
   - Configuring Card Reset Monitoring on page 2207
   - Configuring Discovery Event Status Monitoring on page 2208
   - Configuring Disk Status Monitoring on page 2209
   - Configuring Disk Usage Monitoring on page 2209

- Configuring FireAMP Status Monitoring on page 2211
- Configuring FireSIGHT Host Usage Monitoring on page 2212
- Configuring Hardware Alarm Monitoring on page 2213
- Configuring Health Status Monitoring on page 2214
- Configuring Inline Link Mismatch Alarm Monitoring on page 2215
- Configuring Intrusion Event Rate Monitoring on page 2216
- Understanding License Monitoring on page 2217
- Configuring Link State Propagation Monitoring on page 2217
- Configuring Memory Usage Monitoring on page 2218
- Configuring Power Supply Monitoring on page 2219
- Configuring Process Status Monitoring on page 2220
- Configuring RRD Server Process Monitoring on page 2221
- Configuring Security Intelligence Monitoring on page 2222
- Configuring Time Series Data Monitoring on page 2223
- Configuring Time Synchronization Monitoring on page 2224
- Configuring Traffic Status Monitoring on page 2225
- Configuring URL Filtering Monitoring on page 2225
- Configuring User Agent Status Monitoring on page 2226
- Configuring VPN Status Monitoring on page 2227

4. You have three options:
   - To save your changes to this module and return to the Health Policy page, click **Save Policy and Exit**.
   - To return to the Health Policy page without saving any of your settings for this module, click **Cancel**.
   - To temporarily save your changes to this module and switch to another module's settings to modify, select the other module from the list at the left of the page. If you click **Save Policy and Exit** when you are done, all changes you made will be saved; if you click **Cancel**, you discard all changes.
5. Reapply the policy to the appropriate appliances as described in Applying Health Policies on page 2228.

Comparing Health Policies

LICENSE: Any

To review policy changes for compliance with your organization's standards or to optimize health monitoring performance, you can examine the differences between two health policies. You can compare any two health policies or two revisions of the same health policy, for the health policies you can access. To

quickly compare your active health policy to another, you can select the **Running Configuration** option. Optionally, after you compare, you can then generate a PDF report to record the differences between the two policies or policy revisions.

There are two tools you can use to compare health policies or health policy revisions:

- The comparison view displays only the differences between two health policies or health policy revisions in a side-by-side format; the name of each policy or policy revision appears in the title bar on the left and right sides of the comparison view.

  You can use this to view and navigate both policy revisions on the web interface, with their differences highlighted.

- The comparison report creates a record of only the differences between two health policies or health policy revisions in a format similar to the health policy report, but in PDF format.

  You can use this to save, copy, print and share your policy comparisons for further examination.

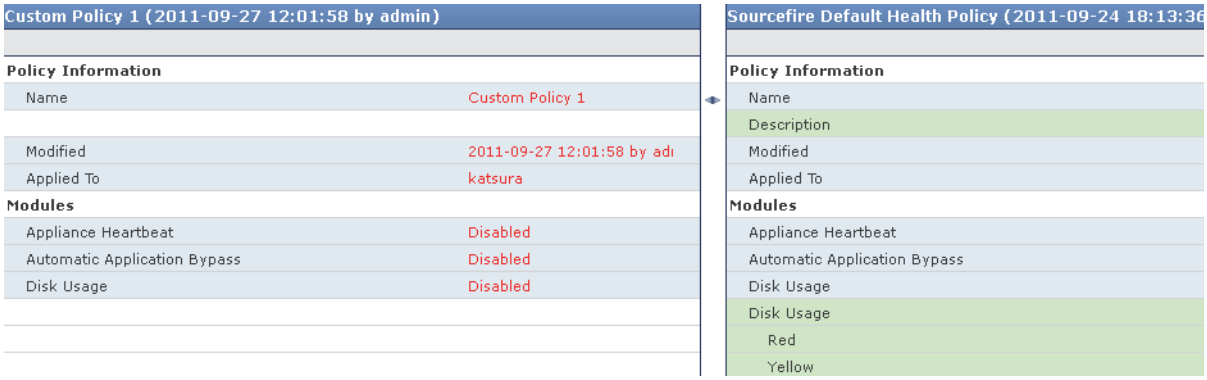
For more information on understanding and using the health policy comparison tools, see:

- Using the Health Policy Comparison View on page 2233
- Using the Health Policy Comparison Report on page 2234

Using the Health Policy Comparison View

LICENSE: Any

The comparison view displays both health policies or policy revisions in a side-by-side format, with each policy or policy revision identified by name in the title bar on the left and right sides of the comparison view. The time of last modification and the last user to modify are displayed to the right of the policy name. Note that the Health Policy page displays the time a policy was last modified in local time, but the health policy report lists the time modified in UTC.



Differences between the two health policies or policy revisions are highlighted:

- Blue indicates that the highlighted setting is different in the two policies or policy revisions, and the difference is noted in red text.
- Green indicates that the highlighted setting appears in one policy or policy revision but not the other.

You can perform any of the actions in the Health Policy Comparison View Actions table.

Health Policy Comparison View Actions

TO...	YOU CAN...
navigate individually through changes	click **Previous** or **Next** above the title bar. The double-arrow icon (◂▸) centered between the left and right sides moves, and the **Difference** number adjusts to identify which difference you are viewing.
generate a new health policy comparison view	click **New Comparison.** The **Select Comparison** window appears. See Using the Health Policy Comparison Report for more information.
generate a health policy comparison report	click **Comparison Report**. The health policy comparison report creates a PDF containing information identical to the comparison view.

Using the Health Policy Comparison Report

LICENSE: Any

A health policy comparison report is a record of all differences between two health policies or two revisions of the same health policy identified by the health policy comparison view, presented as a PDF. You can use this report to further examine the differences between two health policy configurations and to save and disseminate your findings.

You can generate a health policy comparison report from the comparison view for any health policies to which you have access. Remember to commit any potential changes before you generate a health policy report; only committed changes appear in the report.

Depending on your configuration, a health policy comparison report can contain one or more sections. The following sample graphic displays the Policy Information and Modules sections of a health policy comparison report, and lists the configuration for each rule for both health policy configurations. Each section uses the same format and provides the same level of detail. Note that the Value A

and Value B columns represent the policies or policy revisions you configured in the comparison view.

Policy Information

Field	Value A	Value B
Name	Example Health Policy	Test Health Policy
Description	Example Health Policy	Test Health Policy
Modified	2012-05-24 17:01:50 by admin	2012-05-24 17:29:05 by admin

Policy Run Time Interval

Field	Value A	Value B
Run Interval (mins)	5	20

Modules

Field	Value A	Value B
Automatic Application Bypass	Enabled	Disabled
Hardware Alarms	Enabled	Disabled
Process Monitor	Enabled	Disabled
Snort Event Rate > Red	50	40
Snort Event Rate > Yellow	30	20
Time Synchronization	Enabled	Disabled

You use a similar procedure to compare other types of policies on the Sourcefire 3D System. For more information, see:

- Comparing Two Access Control Policies on page 503
- Comparing Two Intrusion Policies on page 731
- Comparing System Policies on page 2043

To compare two health policies or two revisions of the same policy:

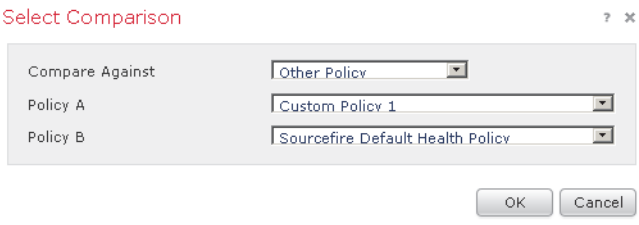
Access: Admin/Maint

1. Select **Health > Health Policy**.

   The Health Policy page appears.

2. Click **Compare Policies**.

   The Select Comparison window appears.



3. From the **Compare Against** drop-down list, select the type of comparison you want to make:
   - To compare two different policies, select **Other Policy**.
   - To compare two revisions of the same policy, select **Other Revision**.
   - To compare another policy to the currently active policy, select **Running Configuration.**

   Remember to commit any changes before you generate a health policy report; only committed changes appear in the report.
4. Depending on the comparison type you selected, you have the following choices:
   - If you are comparing two different policies, select the policies you want to compare from the **Policy A** and **Policy B** drop-down lists.
   - If you are comparing two revisions of the same policy, select the policy from the **Policy** drop-down list, then select the revisions you want to compare from the **Revision A** and **Revision B** drop-down lists.
   - If you are comparing the running configuration to another policy, select the second policy from the **Policy B** drop-down list.
5. Click **OK** to display the health policy comparison view.

   The comparison view appears.
6. Click **Comparison Report** to generate the health policy comparison report.

   The health policy report appears. Depending on your browser settings, the report may appear in a pop-up window, or you may be prompted to save the report to your computer.

Deleting Health Policies

LICENSE: Any

You can delete health policies that you no longer need. If you delete a policy that is still applied to an appliance, the policy settings remain in effect until you apply a different policy. In addition, if you delete a health policy that is applied to a device, any health monitoring alerts in effect for the device remain active until you disable the underlying associated alert response; see Enabling and Disabling Alert Responses on page 579.

TIP! To stop health monitoring for an appliance, create a health policy with all modules disabled and apply it to the appliance. For more information on creating health policies, see Creating Health Policies on page 2200. For more information on applying health policies, see Applying Health Policies on page 2228.

To delete a health policy:

ACCESS: Admin/Maint

1. Select **Health > Health Policy**.
   The Health Policy page appears.
2. Click the delete icon ( ) next to the policy you want to delete.
   A message appears, indicating if the deletion was successful.

Using the Health Monitor Blacklist

LICENSE: Any

In the course of normal network maintenance, you disable appliances or make them temporarily unavailable. Because those outages are deliberate, you do not want the health status from those appliances to affect the summary health status on your Defense Center.

You can use the health monitor blacklist feature to disable health monitoring status reporting on an appliance or module. For example, if you know that a segment of your network will be unavailable, you can temporarily disable health monitoring for a managed device on that segment to prevent the health status on the Defense Center from displaying a warning or critical state because of the lapsed connection to the device.

When you disable health monitoring status, health events are still generated, but they have a disabled status and do not affect the health status for the health monitor. If you remove the appliance or module from the blacklist, the events that were generated during the blacklisting continue to show a status of disabled.

To temporarily disable health events from an appliance, go to the blacklist configuration page and add an appliance to the blacklist. After the setting takes effect, the system no longer includes the blacklisted appliance when calculating the overall health status. The Health Monitor Appliance Status Summary lists the appliance as disabled.

At times it may be more practical to just blacklist an individual health monitoring module on an appliance. For example, when you run out of FireSIGHT host licenses on an appliance, you can blacklist the FireSIGHT Host License Limit status messages.

Note that on the main Health Monitor page you can distinguish between appliances that are blacklisted if you expand to view the list of appliances with a particular status by clicking the arrow in that status row. For more information on expanding that view, see Using the Health Monitor on page 2245.

A blacklist icon ( ) and a notation are visible after you expand the view for a blacklisted or partially blacklisted appliance.

IMPORTANT! On a Defense Center, Health Monitor blacklist settings are local configuration settings. Therefore, if you blacklist a device, then delete it and later re-register it with the Defense Center, the blacklist settings remain persistent. The newly re-registered device remains blacklisted.

For more information, see:

- Blacklisting Health Policies or Appliances on page 2238
- Blacklisting an Appliance on page 2239
- Blacklisting a Health Policy Module on page 2240

Blacklisting Health Policies or Appliances

License: Any

If you want to set health events to disabled for all appliances with a particular health policy, you can blacklist the policy. If you need to disable the results of a group of appliances' health monitoring, you can blacklist the group of appliances. After the blacklist settings take effect, the appliance shows as disabled in the Health Monitor Appliance Module Summary and Device Management page. Health events for the appliance have a status of disabled.

Note that if your Defense Center is in a high availability configuration, you can blacklist a managed device on one high availability peer and not the other. You can also blacklist the high availability peer to cause it to mark events generated by it and the devices from which it receives health events as disabled. Defense Centers in a high availability pair have the option to completely or partially blacklist their peer.

To blacklist an entire health policy or group of appliances:

Access: Admin/Maint

1. Select **Health > Blacklist**.

   The Blacklist page appears.

2. Use the drop-down list on the right to sort the list by group, policy, or model. (Groups on a Defense Center are managed devices.)

   Note that appliances with some, but not all, health modules blacklisted will appear as **(Partially Blacklisted)**. If you edit their blacklist status on the main blacklist page, you can either blacklist all modules on those appliances or remove all blacklisting. For information on blacklisting individual health modules on an appliance, see Blacklisting a Health Policy Module on page 2240.

   TIP! The status icon next to the Health Policy column ( ) indicates the current health status for the appliance. The status icon next to the System Policy column ( ) indicates the communication status between the Defense Center and the device.

3. You have two options:
   - To blacklist all appliances in a group, model, or policy category, select the category, then click **Blacklist Selected Devices**.
   - To clear blacklisting from all appliances in a group, model, or policy category, select the category, then click **Clear Blacklist on Selected Devices**.

   The page refreshes, now indicating the new blacklist state of the appliances.

Blacklisting an Appliance

LICENSE: Any

If you need to set the events and health status for an individual appliance to disabled, you can blacklist the appliance. After the blacklist settings take effect, the appliance shows as disabled in the Health Monitor Appliance Module Summary and health events for the appliance have a status of disabled.

To blacklist an individual appliance:

ACCESS: Admin/Maint

1. Select **Health > Blacklist**.

   The Blacklist page appears.

2. Use the drop-down list on the right to sort the list by appliance group, model, or by policy.
3. You have two options:
   - To blacklist all appliances in a group, model, or policy category, select the category, then click **Blacklist Selected Devices**.
   - To clear blacklisting from all appliances in a group, model, or policy category, select the category, then click **Clear Blacklist on Selected Devices**.

   The page refreshes and indicates the new blacklist state of the appliances. Click **Edit** and see Blacklisting a Health Policy Module on page 2240 to blacklist individual health policy modules.

Blacklisting a Health Policy Module

LICENSE: Any

You can blacklist individual health policy modules on appliances. You may want to do this to prevent events from the module from changing the status for the appliance to warning or critical.

When any part of a module is blacklisted, the line for that module appears in boldface type in the Defense Center web interface.

TIP! After the blacklist settings take effect, the appliance shows as **Partially Blacklisted** or **All Modules Blacklisted** on the Blacklist page and in the Appliance Health Monitor Module Status Summary, but only in expanded views on the main Appliance Status Summary page. Make sure that you keep track of individually blacklisted modules so you can reactivate them when you need them. You may miss necessary warning or critical messages if you accidentally leave a module disabled.

To blacklist an individual health policy module:

ACCESS: Admin/Maint

1. Select **Health > Blacklist**.

   The Blacklist page appears.

2. Sort by Group, Policy, or Model, then click **Edit** to display the list of health policy modules for an appliance.

   The health policy modules appear.

3. Select each module that you want to blacklist.
4. Click **Save**.

Configuring Health Monitor Alerts

LICENSE: Any

You can set up alerts to notify you through email, through SNMP, or through the system log when the status changes for the modules in a health policy. You can associate an existing alert response with health event levels to trigger and alert when health events of a particular level occur.

For example, if you are concerned that your appliances may run out of hard disk space, you can automatically send an email to a system administrator when the remaining disk space reaches the warning level. If the hard drive continues to fill, you can send a second email when the hard drive reaches the critical level.

For more information, see the following topics:

- Creating Health Monitor Alerts on page 2241
- Interpreting Health Monitor Alerts on page 2243
- Editing Health Monitor Alerts on page 2244
- Deleting Health Monitor Alerts on page 2245

Creating Health Monitor Alerts

LICENSE: Any

When you create a health monitor alert, you create an association between a severity level, a health module, and an alert response. You can use an existing

alert or configure a new one specifically to report on system health. When the severity level occurs for the selected module, the alert triggers.

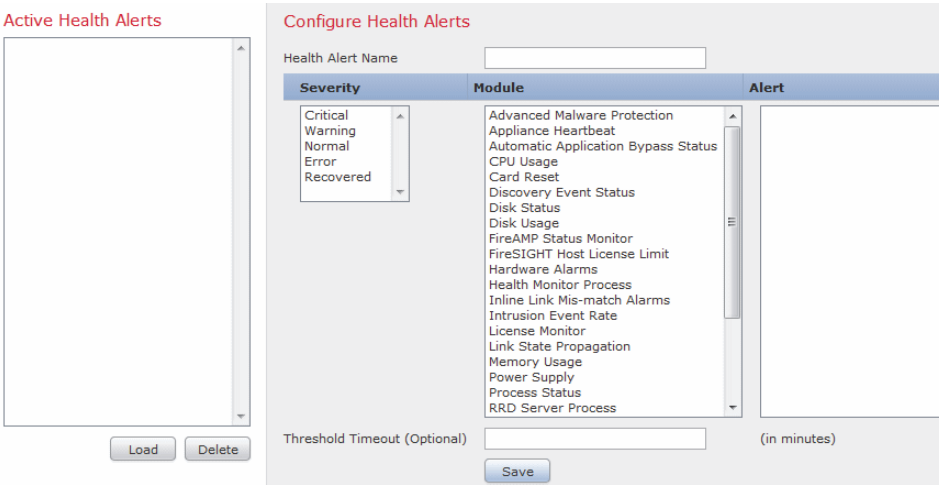
Note that if you create or update a threshold in a way that duplicates an existing threshold, you are notified of the conflict. When duplicate thresholds exist, the health monitor uses the threshold that generates the fewest alerts and ignores the others. The timeout value for the threshold must be between 5 and 4,294,967,295 minutes.

To create health monitor alerts:

Access: Admin

1. Select **Health > Health Monitor Alerts**.

   The Health Monitor Alerts page appears.



2. Type a name for the health alert in the **Health Alert Name** field.
3. From the **Severity** list, select the severity level you want to use to trigger the alert.
4. From the **Module** list, select the modules for which you want the alert to apply.

   TIP! To select multiple modules, press Shift + Ctrl and click the module names.

5. From the **Alert** list, select the alert response that you want to trigger when the selected severity level is reached.

   TIP! Click **Alerts** to open the Alerts page. For more information on creating alerts, see Working with Alert Responses on page 571.

6. Optionally, in the **Threshold Timeout** field, type the number of minutes that should elapse before each threshold period ends and the threshold count resets. The default value is 5 minutes.

   Note that even if the policy run time interval value is less than the threshold timeout value, the interval between two reported health events from a given module is always greater, such that if the threshold timeout is 8 minutes and the policy run time interval is 5 minutes, there will be a 10-minute interval (5 x 2) between reported events.

7. Click **Save** to save the health alert.

   A message appears, indicating if the alert configuration was successfully saved. The Active Health Alerts list now includes the alert you created.

Interpreting Health Monitor Alerts

License: Any

The alerts generated by the health monitor contain the following information:

- Severity, which indicates the severity level of the alert.
- Module, which specifies the health module whose test results triggered the alert.
- Description, which includes the health test results that triggered the alert.

For more information on health alert severity levels, see the Alert Severities table.

Alert Severities

Severity	Description
Critical	The health test results met the criteria to trigger a Critical alert status.
Warning	The health test results met the criteria to trigger a Warning alert status.
Normal	The health test results met the criteria to trigger a Normal alert status.
Error	The health test did not run.
Recovered	The health test results met the criteria to return to a normal alert status, following a Critical or Warning alert status.

For more information on health modules, see Understanding Health Modules on page 2194.

Editing Health Monitor Alerts

LICENSE: Any

You can edit existing health monitor alerts to change the severity level, health module, or alert response associated with the health monitor alert.

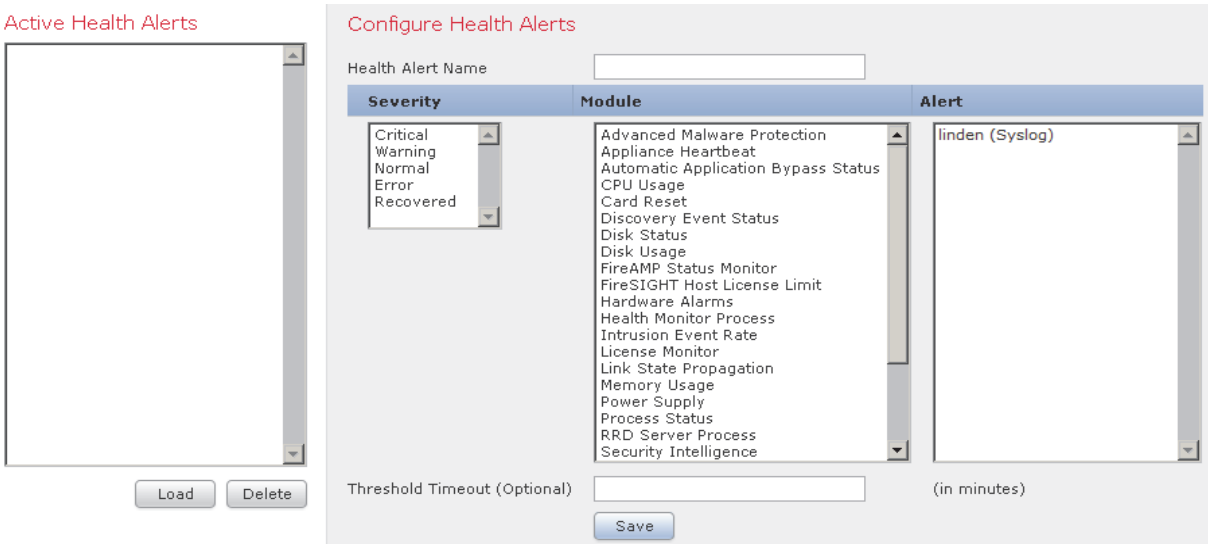
To edit health monitor alerts:

ACCESS: Admin

1. Select **Health > Health Monitor Alerts**.

   The Health Monitor Alerts page appears.

2. Select the alert you want to modify in the **Active Health Alerts** list.



3. Click **Load** to load the configured settings for the selected alert.
4. Modify settings as needed. For more information, see Creating Health Monitor Alerts on page 2241.
5. Click **Save** to save the modified health alert.

   A message appears, indicating if the alert configuration was successfully saved.

Deleting Health Monitor Alerts

LICENSE: Any

You can delete existing health monitor alerts.

IMPORTANT! Deleting a health monitor alert does not delete the associated alert response. You must disable or delete the underlying alert response to ensure that alerting does not continue. For more information, see Enabling and Disabling Alert Responses on page 579 and Deleting an Alert Response on page 579.

To delete health monitor alerts:

ACCESS: Admin

1. Select **Health > Health Monitor Alerts**.

   The Health Monitor Alerts page appears.

2. Select the alert you want to delete in the **Active Health Alerts** list.

3. Click **Delete**.

   A message appears, indicating if the alert configuration was successfully deleted.

Using the Health Monitor

LICENSE: Any

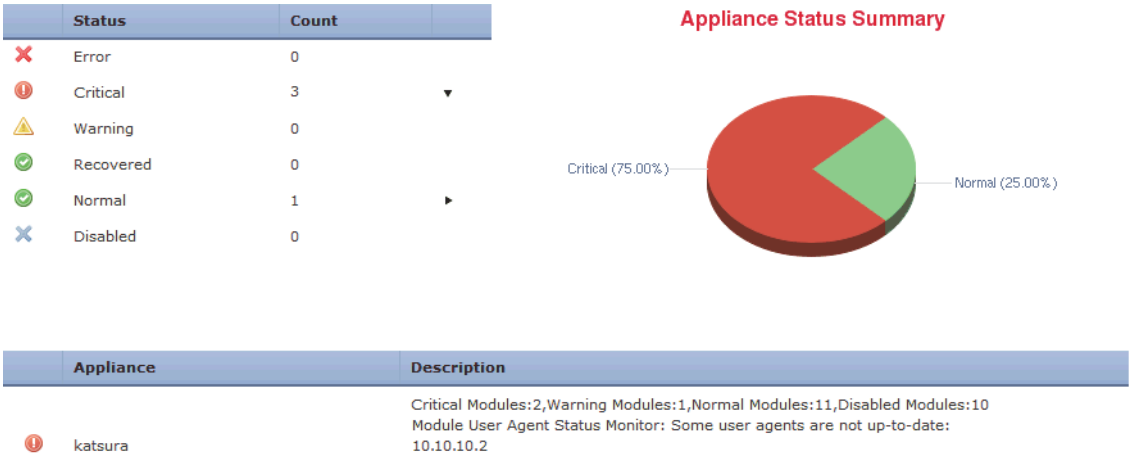
The Health Monitor page provides the compiled health status for all devices managed by the Defense Center, plus the Defense Center. The Status table provides a count of the managed appliances for this Defense Center by overall health status. The pie chart supplies another view of the health status breakdown, indicating the percentage of appliances currently in each health status category.

To use the health monitor:

Access: Admin/Maint/Any Security Analyst

1. Click **Health > Health Monitor**.

   The Health Monitor page appears.



2. Select the appropriate status in the Status column of the table or the appropriate portion of the pie chart to the list appliances with that status.

TIP! If the arrow in the row for a status level points down, the appliance list for that status shows in the lower table. If the arrow points right, the appliance list is hidden.

The following topics provide details on the tasks you can perform from the Health Monitor page:

- Interpreting Health Monitor Status on page 2247
- Using Appliance Health Monitors on page 2248
- Configuring Health Policies on page 2198
- Configuring Health Monitor Alerts on page 2241

Interpreting Health Monitor Status

LICENSE: Any

Available status categories, by severity, include Error, Critical, Warning, Normal, Recovered, and Disabled, as described in the Health Status Indicator table.

Health Status Indicator

STATUS LEVEL	STATUS ICON	STATUS COLOR	DESCRIPTION
Error		White	Indicates that at least one health monitoring module has failed on the appliance and has not been successfully re-run since the failure occurred. Contact your technical support representative to obtain an update to the health monitoring module.
Critical		Red	Indicates that the critical limits have been exceeded for at least one health module on the appliance and the problem has not been corrected.
Warning		Yellow	Indicates that warning limits have been exceeded for at least one health module on the appliance and the problem has not been corrected.
Normal		Green	Indicates that all health modules on the appliance are running within the limits configured in the health policy applied to the appliance.
Recovered		Green	Indicates that all health modules on the appliance are running within the limits configured in the health policy applied to the appliance, including modules that were in a Critical or Warning state.
Disabled		Blue	Indicates that an appliance is disabled or blacklisted, that the appliance does not have a health policy applied to it, or that the appliance is currently unreachable.

Using Appliance Health Monitors

LICENSE: Any

The Appliance health monitor provides a detailed view of the health status of an appliance.

IMPORTANT! Your session normally logs you out after 1 hour of inactivity (or another configured interval). If you plan to passively monitor the health monitor for long periods of time, consider exempting some users from session timeout, or changing the system timeout settings. For more information, see Managing User Login Settings on page 1979 and Configuring User Interface Settings on page 2073.

To view the status summary for a specific appliance:

ACCESS: Admin/Maint/Any Security Analyst

1. Select **Health > Health Monitor**.

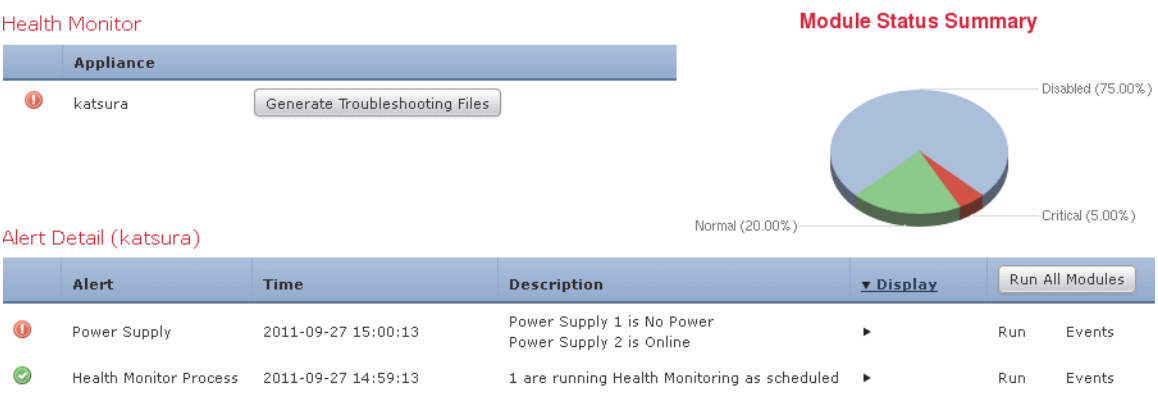
   The Health Monitor page appears.

2. To show the list of appliances with a particular status, click the arrow in that status row.

   TIP! If the arrow in the row for a status level points down, the appliance list for that status shows in the lower table. If the arrow points right, the appliance list is hidden.

3. In the **Appliance** column of the appliance list, click the name of the appliance for which you want to view details in the health monitor toolbar.

   The Health Monitor Appliance page appears.



4. Optionally, in the **Module Status Summary** graph, click the color for the event status category you want to view. The Alert Detail list toggles the display to show or hide events.

   For more information, see the following sections:

   - Understanding Health Modules on page 2194
   - Interpreting Health Monitor Status on page 2247
   - Viewing Alerts by Status on page 2249
   - Running All Modules for an Appliance on page 2249
   - Running a Specific Health Module on page 2251
   - Generating Health Module Alert Graphs on page 2252
   - Using the Health Monitor to Troubleshoot on page 2253

Viewing Alerts by Status

License: Any

You can show or hide categories of alerts by status.

To show alerts by status:

Access: Admin/Maint/Any Security Analyst

▶ Click the status icon or the color segment in the pie chart that corresponds to the health status of the alerts you want to view. The alerts for that category appear in the Alert Detail list.

To hide alerts by status:

Access: Admin/Maint/Any Security Analyst

▶ Click the status icon or the color segment in the pie chart that corresponds to the health status of the alerts you want to view. The alerts in the Alert Detail list for that category disappear.

Running All Modules for an Appliance

License: Any

Health module tests run automatically at the policy run time interval you configure when you create a health policy. However, you can also run all health module tests on demand to collect up-to-date health information for the appliance.

To run all health modules for the appliance:

Access: Admin/Maint/Any Security Analyst

1. Select **Health > Health Monitor**.

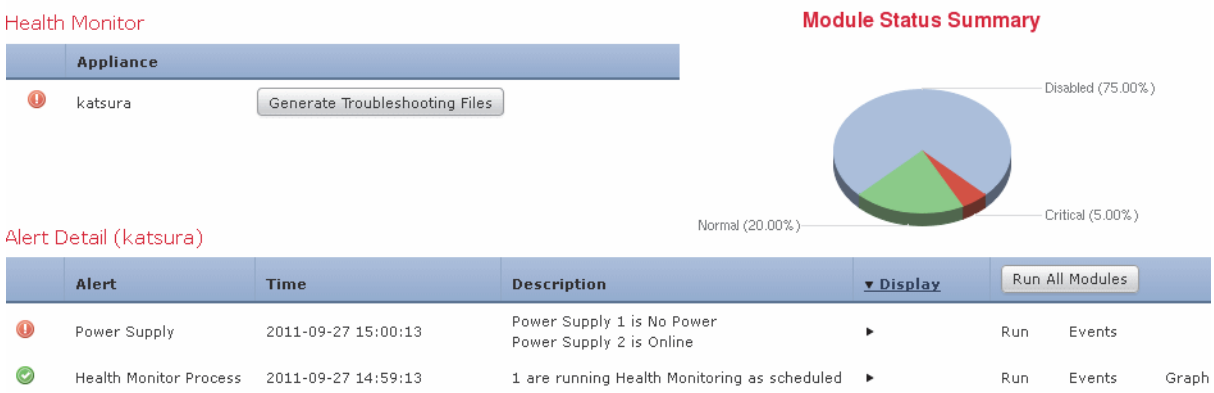
   The Health Monitor page appears.

2. To expand the appliance list to show appliances with a particular status, click the arrow in that status row.

TIP! If the arrow in the row for a status level points down, the appliance list for that status shows in the lower table. If the arrow points right, the appliance list is hidden.

3. In the **Appliance** column of the appliance list, click the name of the appliance for which you want to view details.

   The Health Monitor Appliance page appears.



4. Click **Run All Modules**.

   The status bar indicates the progress of the tests, then the Health Monitor Appliance page refreshes.

IMPORTANT! When you manually run health modules, the first refresh that automatically occurs may not reflect the data from the manually run tests. If the value has not changed for a module that you just ran manually, wait a few seconds, then refresh the page by clicking the device name. You can also wait for the page to refresh again automatically.

Running a Specific Health Module

LICENSE: Any

Health module tests run automatically at the policy run time interval you configure when you create a health policy. However, you can also run a health module test on demand to collect up-to-date health information for that module.

To run a specific health module:

ACCESS: Admin/Maint/Any Security Analyst

1. Select **Health > Health Monitor**.

   The Health Monitor page appears.

2. To expand the appliance list to show appliances with a particular status, click the arrow in that status row.

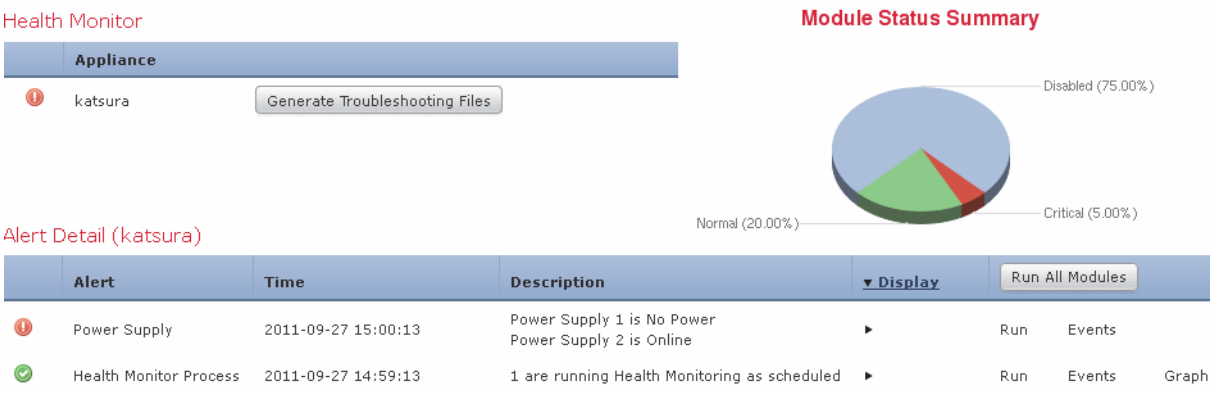
   TIP! If the arrow in the row for a status level points down, the appliance list for that status shows in the lower table. If the arrow points right, the appliance list is hidden.

3. In the **Appliance** column of the appliance list, click the name of the appliance for which you want to view details.

   The Health Monitor Appliance page appears.

4. In the **Module Status Summary** graph of the Health Monitor Appliance page, click the color for the health alert status category you want to view.

   The Alert Detail list expands to list the health alerts for the selected appliance for that status category.



5. In the **Alert Detail** row for the alert for which you want to view a list of events, click **Run**.

   The status bar indicates the progress of the test, then the Health Monitor Appliance page refreshes.

IMPORTANT! When you manually run health modules, the first refresh that automatically occurs may not reflect the data from the manually run tests. If the value has not changed for a module that you just manually ran, wait a few seconds, then refresh the page by clicking the device name. You can also wait for the page to refresh automatically again.

Generating Health Module Alert Graphs

LICENSE: Any

You can graph the results over a period of time of a particular health test for a specific appliance.

To generate a health module alert graph:

ACCESS: Admin/Maint/Any Security Analyst

1. Select **Health > Health Monitor**.

   The Health Monitor page appears.

2. To expand the appliance list to show appliances with a particular status, click the arrow in that status row.

TIP! If the arrow in the row for a status level points down, the appliance list for that status shows in the lower table. If the arrow points right, the appliance list is hidden.

3. In the **Appliance** column of the appliance list, click the name of the appliance for which you want to view details.

   The Health Monitor Appliance page appears.

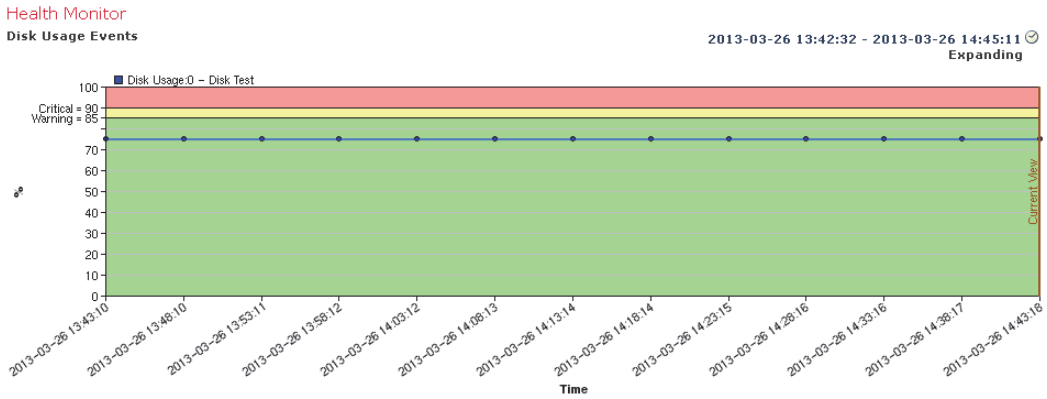
4. In the **Module Status Summary** graph of the Health Monitor Appliance page, click the color for the health alert status category you want to view.

   The Alert Detail list expands to list the health alerts for the selected appliance for that status category.

5. In the **Alert Detail** row for the alert for which you want to view a list of events, click **Graph**.

   A graph appears, showing the status of the event over time. The Alert Detail section below the graph lists all health alerts for the selected appliance.

TIP! If no events appear, you may need to adjust the time range. See Setting Event Time Constraints on page 1896 for more information.



Using the Health Monitor to Troubleshoot

LICENSE: Any

In some cases, if you have a problem with your appliance, Sourcefire Support may ask you to generate troubleshooting files to help them diagnose the problem. You can select any of the options listed in the following table to customize the troubleshooting data that the health monitor reports.

Selectable Troubleshoot Options

THIS OPTION...	REPORTS...
Snort Performance and Configuration	data and configuration settings related to Snort on the appliance
Hardware Performance and Logs	data and logs related to the performance of the appliance hardware
System Configuration, Policy, and Logs	configuration settings, data, and logs related to the current system configuration of the appliance
Detection Configuration, Policy, and Logs	configuration settings, data, and logs related to detection on the appliance

Selectable Troubleshoot Options (Continued)

THIS OPTION...	REPORTS...
Interface and Network Related Data	configuration settings, data, and logs related to inline sets and network configuration of the appliance
Discovery, Awareness, VDB Data, and Logs	configuration settings, data, and logs related to the current discovery and awareness configuration on the appliance
Upgrade Data and Logs	data and logs related to prior upgrades of the appliance
All Database Data	all database-related data that is included in a troubleshoot report
All Log Data	all logs collected by the appliance database
Network Map Information	current network topology data

Note that some options overlap in terms of the data they report, but the troubleshooting files will not contain redundant copies, regardless of what options you select.

For more information, see the following sections:

- Generating Appliance Troubleshooting Files on page 2254
- Downloading Troubleshooting Files on page 2255

Generating Appliance Troubleshooting Files

LICENSE: Any

Use the following procedure to generate customized troubleshooting files that you can send to Sourcefire Support.

To generate troubleshooting files:

ACCESS: Admin/Maint/Any Security Analyst

1. Select **Health > Health Monitor**.

   The Health Monitor page appears.

2. To expand the appliance list to show appliances with a particular status, click the arrow in that status row.

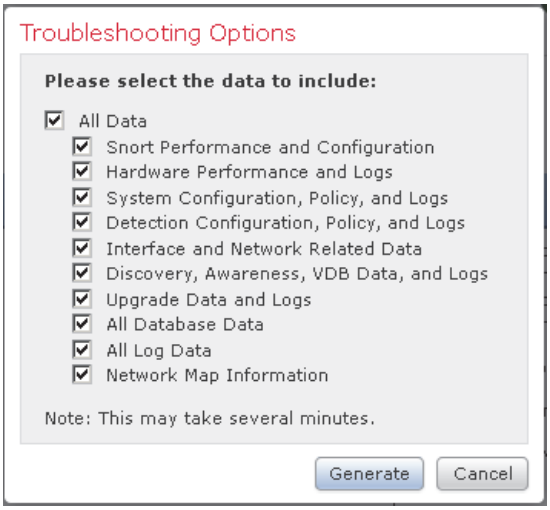
TIP! If the arrow in the row for a status level points down, the appliance list for that status shows in the lower table. If the arrow points right, the appliance list is hidden.

3. In the Appliance column of the appliance list, click the name of the appliance for which you want to view details.

   The Health Monitor Appliance page appears.

4. Click **Generate Troubleshooting Files**.

   The Troubleshooting Options pop-up window appears.



5. Select **All Data** to generate all possible troubleshooting data, or select individual check boxes to customize your report. For more information, see the Selectable Troubleshoot Options table on page 2253.

6. Click **OK**.

   The Defense Center generates the troubleshooting files. You can monitor the file generation process in the task queue (**System > Monitoring > Task Status**).

7. Continue with the procedure in the next section, Downloading Troubleshooting Files.

Downloading Troubleshooting Files

License: Any

Use the following procedure to download copies of your generated troubleshooting files.

To download troubleshooting files:

Access: Admin/Maint/Any Security Analyst

1. Select **System > Monitoring > Task Status**.

   The Task Status page appears.

2. Find the task that corresponds to the troubleshooting files you generated.

3. After the appliance generates the troubleshooting files and the task status changes to `Completed`, click **Click to retrieve generated files**.
4. Follow your browser's prompts to download the files.

   The files are downloaded in a single `.tar.gz` file.
5. Follow the directions from Support to send the troubleshooting files to Sourcefire.

Working with Health Events

LICENSE: Any

The Defense Center provides fully customizable event views that allow you to quickly and easily analyze the health status events gathered by the health monitor. These event views allow you to search and view event data and to easily access other information that may be related to the events you are investigating.

Many functions that you can perform on the health event view pages are constant across all event view pages. See Understanding Health Event Views on page 2256 for more information about these common procedures.

From the **Health > Health Events** menu option, you can view health events and can search for specific events.

See the following sections for more information about viewing events:

- Understanding Health Event Views on page 2256 describes the types of events that FireSIGHT generates.
- Viewing Health Events on page 2257 describes how to access and use the Event View page.
- Searching for Health Events on page 2266 describes how to search for specific events using the Event Search page.

Understanding Health Event Views

LICENSE: Any

The Defense Center health monitor logs health events, which you can see on the Health Event View page. If you understand what conditions each health module tests for, you can more effectively configure alerting for health events. For more information on the different types of health modules that generate health events, see Understanding Health Modules on page 2194.

For more information about viewing and searching for health events, see the following sections:

- Viewing Health Events on page 2257
- Understanding the Health Events Table on page 2265
- Searching for Health Events on page 2266

Viewing Health Events

LICENSE: Any

You can view the appliance health data collected by your health monitor in several ways.

For more information, see the following topics:

- Viewing All Health Events on page 2257
- Viewing Health Events by Module and Appliance on page 2258
- Working with the Health Events Table View on page 2260
- Interpreting Hardware Alert Details for 3D9900 Devices on page 2261
- Interpreting Hardware Alert Details for Series 3 Devices on page 2263

Viewing All Health Events

LICENSE: Any

The Table View of Health Events page provides a list of all health events on the selected appliance. For a description of the health modules that generated the events that you may see on this page, see Understanding Health Modules on page 2194.

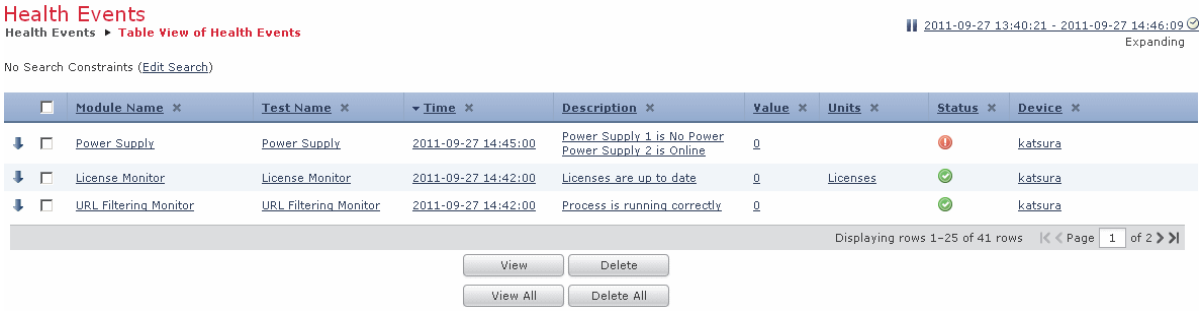
When you access health events from the Health Monitor page on your Defense Center, you retrieve all health events for all managed appliances.

To view all health events on all managed appliances:

ACCESS: Admin/Maint/Any Security Analyst

▶ Select **Health > Health Events**.

The Events page appears, containing all health events.



IMPORTANT! If no events appear, you may need to adjust the time range. See Setting Event Time Constraints on page 1896 for more information.

TIP! You can bookmark this view to allow you to return to the page in the health events workflow containing the Health Events table of events. The bookmarked view retrieves events within the time range you are currently viewing, but you can then modify the time range to update the table with more recent information if needed. For more information, see Setting Event Time Constraints on page 1896.

Viewing Health Events by Module and Appliance

LICENSE: Any

You can query for events generated by a specific health module on a specific appliance.

To view the health events for a specific module:

ACCESS: Admin/Maint/Any Security Analyst

1. Select **Health > Health Monitor**.

   The Health Monitor page appears.

2. To expand the appliance list to show appliances with a particular status, click the arrow in that status row.

TIP! If the arrow in the row for a status level points down, the appliance list for that status shows in the lower table. If the arrow points right, the appliance list is hidden.

3. In the Appliance column of the appliance list, click the name of the appliance for which you want to view details.

   The Health Monitor Appliance page appears.

4. In the Module Status Summary graph of the Health Monitor Appliance page, click the color for the health alert status category you want to view.

   The Alert Detail list expands to list the health alerts for the selected appliance for that status category.

5. In the Alert Detail row for the alert for which you want to view a list of events, click **Events**.

   The Health Events page appears, containing query results for a query with the name of the appliance and the name of the selected health alert module as constraints.

   If no events appear, you may need to adjust the time range. See Setting Event Time Constraints on page 1896 for more information.

6. If you want to view all health events for the selected appliance, expand **Search Constraints** and click the **Module Name** constraint to remove it.

Working with the Health Events Table View

LICENSE: Any

The following table describes each action you can perform from the Event View page.

Health Event View Functions

TO...	YOU CAN...
learn more about the contents of the columns that appear in the Health event view	find more information in Understanding the Health Events Table on page 2265.
modify the time and date range for events listed in the Health table view	find more information in Setting Event Time Constraints on page 1896. Note that events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.
sort the events that appear, change what columns display in the table of events, or constrain the events that appear	find more information in Sorting Drill-Down Workflow Pages on page 1910.
delete health events	select the check box next to the events you want to delete and click **Delete**. To delete all the events in the current constrained view, click **Delete All**, then confirm you want to delete all the events.
navigate through event view pages	find more information in Navigating to Other Pages in the Workflow on page 1911.
navigate to other event tables to view associated events	find more information in Navigating Between Workflows on page 1911.
bookmark the current page so that you can quickly return to it	click **Bookmark This Page**, provide a name for the bookmark and click **Save**. See Using Bookmarks on page 1913 for more information.
navigate to the bookmark management page	click **View Bookmarks** from any event view. See Using Bookmarks on page 1913 for more information.
generate a report based on data in the table view	click **Report Designer**. See Creating a Report Template from an Event View on page 1797 for more information.
select another health events workflow	click **(switch workflow)**. See Selecting Workflows on page 1885 for more information.

Health Event View Functions (Continued)

To...	You can...
view the details associated with a single health event	click the down arrow link on the left side of the event.
view event details for multiple health events	select the check box next to the rows that correspond with the events you want to view details for and then click **View**.
view event details for all events in the view	click **View All**.
view all events of a particular status	click the status icon in the Status column for an event with that status.

Interpreting Hardware Alert Details for 3D9900 Devices

License: Any

For 3D9900 device models, hardware alarms generate in response to the events described in the Conditions Monitored for 3D9900 Devices table. The triggering condition can be found in the message detail for the alert.

Conditions Monitored for 3D9900 Devices

Condition Monitored	Causes of Yellow or Red Error Conditions
NFE card presence	If NFE hardware is detected that is not valid for the appliance, health status for the Hardware Alarms module changes to red and the message details include a reference to the NFE card presence.
NFE temperature	• If NFE temperature exceeds 95 degrees Celsius, health status for the Hardware Alarms module changes to yellow and the message details include a reference to the NFE temperature. • If NFE temperature exceeds 99 degrees Celsius, health status for the Hardware Alarms module changes to red and the message details include a reference to the NFE temperature.
NFE Platform daemon	If the NFE Platform daemon goes down, health status for the Hardware Alarms module changes to red and the message details include a reference to the daemon.
NFE Message daemon	If the NFE Message daemon goes down, health status for the Hardware Alarms module changes to red and the message details include a reference to the daemon.

Conditions Monitored for 3D9900 Devices (Continued)

Condition Monitored	Causes of Yellow or Red Error Conditions
NFE `TCAM` daemon	If the NFE `TCAM` daemon goes down, health status for the Hardware Alarms module changes to red and the message details include a reference to the daemon.
LBIM presence	If the Load Balancing Interface Module (LBIM) switch assembly is not present or not communicating, health status for the Hardware Alarms module changes to red and the message details include a reference to the LBIM presence.
`Scmd` daemon	If the `Scmd` daemon goes down, health status for the Hardware Alarms module changes to red and the message details include a reference to the daemon.
`Psls` daemon	If the `Psls` daemon goes down, health status for the Hardware Alarms module changes to red and the message details include a reference to the daemon.
`Ftwo` daemon	If the `Ftwo` daemon goes down, health status for the Hardware Alarms module changes to red and the message details include a reference to the daemon.
`Rulesd` (host rules) daemon	If the `Rulesd` daemon goes down, health status for the Hardware Alarms module changes to yellow and the message details include a reference to the daemon.
`nfm_ipfragd` (host frag) daemon	If the `nfm_ipfragd` daemon goes down, health status for the Hardware Alarms module changes to red and the message details include a reference to the daemon.

Interpreting Hardware Alert Details for Series 3 Devices

For Series 3 devices, hardware alarms generate in response to the events described in the Conditions Monitored for Series 3 Devices table. The triggering condition appears in the message detail for the alert.

Conditions Monitored for Series 3 Devices

Condition Monitored	Causes of Yellow or Red Error Conditions
Cluster status	If clustered devices are no longer communicating with each other (due, for example, to a cabling problem), the Hardware Alarms module changes to red.
`ftwo` daemon status	If the `ftwo` daemon goes down, health status for the Hardware Alarms module changes to red and message details include a reference to the daemon.
NFE cards detected	Indicates the number of NFE cards detected on the system. If this value does not match the appliance's expected NFE count, the Hardware Alarms module changes to red.
NFE hardware status	If one or more NFE cards are not communicating, the Hardware Alarms module changes to red and the applicable card appears in the message details.
NFE heartbeat	If the system detects no NFE heartbeat, the Hardware Alarms module changes to red and message details include a reference to the relevant card(s).
NFE internal link status	If the link between the NMSB and NFE card(s) goes down, the Hardware Alarms module changes to red and message details include a reference to the relevant ports.
NFE Message daemon	If the NFE Message daemon goes down, health status for the Hardware Alarms module changes to red and the message details include a reference to the daemon (and, if applicable, the NFE card number).

Conditions Monitored for Series 3 Devices (Continued)

Condition Monitored	Causes of Yellow or Red Error Conditions
NFE temperature	• If NFE temperature exceeds 97 degrees Celsius, health status for the Hardware Alarms module changes to yellow and message details include a reference to the NFE temperature (and, if applicable, the NFE card number). • If NFE temperature exceeds 102 degrees Celsius, health status for the Hardware Alarms module changes to red and message details include a reference to the NFE temperature. (and, if applicable, the NFE card number).
NFE temperature status	Indicates the current temperature status of the given NFE card. The Hardware Alarms module indicates green for OK, yellow for Warning, and red for Critical (and, if applicable, the NFE card number).
NFE `TCAM` daemon	If the NFE `TCAM` daemon goes down, health status for the Hardware Alarms module changes to red and message details include a reference to the daemon (and, if applicable, the NFE card number).
`nfm_ipfragd` (host frag) daemon	If the `nfm_ipfragd` daemon goes down, health status for the Hardware Alarms module changes to red and message details include a reference to the daemon (and, if applicable, the NFE card number).
NFE Platform daemon	If the NFE Platform daemon goes down, health status for the Hardware Alarms module changes to red and message details include a reference to the daemon (and, if applicable, the NFE card number).
NMSB communications	If the Media assembly is not present or not communicating, health status for the Hardware Alarms module changes to red and message details include a reference to the NFE temperature (and, if applicable, the NFE card number).
`psls` daemon status	If the `psls` daemon goes down, health status for the Hardware Alarms module changes to red and message details include a reference to the daemon.
`Rulesd` (host rules) daemon	If the `Rulesd` daemon goes down, health status for the Hardware Alarms module changes to yellow and message details include a reference to the daemon (and, if applicable, the NFE card number).
`scmd` daemon status	If the `scmd` daemon goes down, health status for the Hardware Alarms module changes to red and message details include a reference to the daemon.

Understanding the Health Events Table

LICENSE: Any

You can use the Defense Center's health monitor to determine the status of critical functionality within the Sourcefire 3D System. You create and apply health policies to your appliances, which monitor a variety of aspects, including hardware and software status. The Health Monitor modules you choose to enable in your health policy run various tests to determine appliance health status. When the health status meets criteria that you specify, a health event is generated. For more information on health monitoring, see Monitoring the System on page 2177.

The fields in the health events table are described in the Health Event Fields table.

Health Event Fields

FIELD	DESCRIPTION
Test Name	The name of the health module that generated the event. For a list of health modules, see the Health Modules table on page 2194.
Time	The timestamp for the health event.
Description	The description of the health module that generated the event. For example, health events generated when a process was unable to execute are labeled `Unable to Execute`.
Value	The value (number of units) of the result obtained by the health test that generated the event. For example, if the Defense Center generates a health event whenever a device it is monitoring is using 80 percent or more of its CPU resources, the value could be a number from 80 to 100.
Units	The units descriptor for the result. You can use the asterisk (*) to create wildcard searches. For example, if the Defense Center generates a health event when a device it is monitoring is using 80 percent or more of its CPU resources, the units descriptor is a percentage sign (%).
Status	The status (Critical, Yellow, Green, or Disabled) reported for the appliance.
Device	The appliance where the health event was reported.

To display the table view of health events:

ACCESS: Admin/Maint/Any Security Analyst

▶ Select **Health > Health Events**.

The table view appears. For information on working with health events, see Working with Health Events on page 2256.

TIP! If you are using a custom workflow that does not include the table view of health events, click **(switch workflow)**. On the Select Workflow page, click **Health Events**.

Searching for Health Events

LICENSE: Any

You can search for specific health events. You may want to create searches customized for your network environment, then save them to reuse later. The following table describes the search criteria you can use.

Health Event Search Criteria

SEARCH FIELD	DESCRIPTION
Module Name	Specify the name of the module which generated the health events you want to view. For example, to view events that measure CPU performance, type `CPU`. The search should retrieve applicable CPU Usage and CPU temperature events.
Value	Specify the value (number of units) of the result obtained by the health test for the events you want to view. For example, if you specify a value of 15 and type `CPU` in the Units field, you retrieve events where the appliance CPU was running at 15% utilization at the time the test ran.
Description	Specify the description of the events you want to view. For example, you could enter `Unable to Execute` to view any health events where a process was unable to execute. You can use an asterisk (*) in this field to create wildcard searches.

Health Event Search Criteria (Continued)

Search Field	Description
Units	Specify the units descriptor for the result obtained by the health test for the events you want to view. You can use an asterisk (*) in this field to create wildcard searches. For example, if you type % in the Units field, you retrieve all events for the Disk Usage modules, because the Disk Usage module has a "%" label in the Units field (and no additional text). However, if you type *% in the Units field, you retrieve all events for any modules that contain text followed by a "%" sign in the Units field.
Status	Specify the status for the health events that you want to view. Valid status levels are Critical, Warning, Normal, Error, and Disabled. For example, type `Critical` to retrieve all health events that indicate a critical status.
Device	Specify the name of the device.

For more information on searching, including information on special search syntax as well as saving and loading searches, see Performing and Saving Searches on page 1843.

To run and save health event searches:

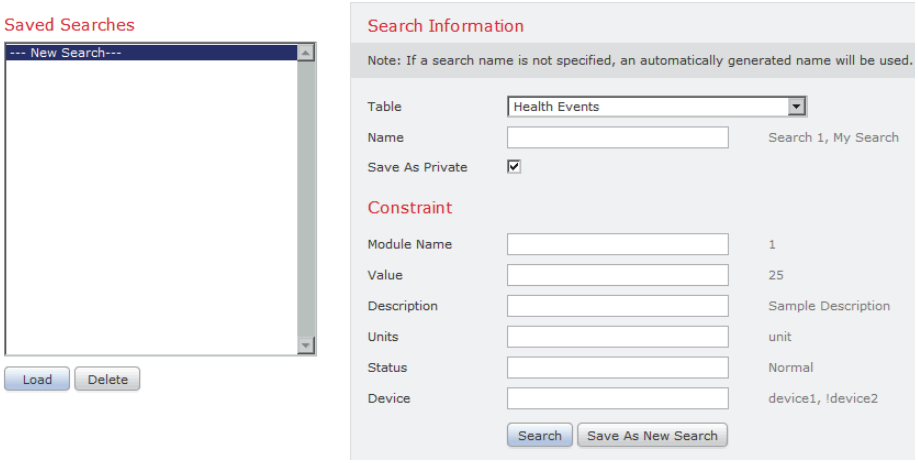
Access: Admin/Maint/Any Security Analyst

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Health Events**.

   The Health Event Search page appears.



3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields, as described in the Health Event Search Criteria table.

   If you enter multiple criteria, the search returns only the records that match all the criteria.

5. Optionally, if you want to save the search so that other users can access it, disable the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

   TIP! If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:

   - Click **Search** to start the search.

     Your search results appear in the default health events workflow, constrained by the current time range. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**), so that you can run it at a later time.

   For more information about searching, see the following sections:

   - Loading a Saved Search on page 1846
   - Deleting a Saved Search on page 1846

CHAPTER 54
AUDITING THE SYSTEM

You can audit activity on your system in two ways. The appliances that are part of the Sourcefire 3D System generate an audit record for each user interaction with the web interface, and also record system status messages in the system log.

The following sections provide more information about the monitoring features that the system provides:

- Managing Audit Records on page 2269 describes how to view and manage system audit information.
- Viewing the System Log on page 2282 describes how to view the system log, which contains system status messages.

TIP! Defense Centers and managed devices with Protection licenses also provide full reporting features that allow you to generate reports for almost any type of data accessible in an event view, including auditing data. For more information, see Working with Reports on page 1796.

Managing Audit Records

LICENSE: Any

Defense Centers and managed devices log read-only auditing information for user activity. Audit logs are presented in a standard event view that allows you to view, sort, and filter audit log messages based on any item in the audit view. You can easily delete and report on audit information and can view detailed reports of the changes that users make.

The audit log stores a maximum of 100,000 entries. When the number of audit log entries exceeds 100,000, the appliance prunes the oldest records from the database to reduce the number to 100,000.

IMPORTANT! If you reboot a Series 3 appliance, then log into the CLI as soon as you are able, any commands you execute are not recorded in the audit log until the web interface is available.

For more information, see the following sections:

- Viewing Audit Records on page 2270
- Suppressing Audit Records on page 2273
- Understanding the Audit Log Table on page 2278
- Using the Audit Log to Examine Changes on page 2278
- Searching Audit Records on page 2279

Viewing Audit Records

LICENSE: Any

You can use the appliance to view a table of audit records. Then, you can manipulate the view depending on the information you are looking for. The predefined audit workflow includes a single table view of events. You can also create a custom workflow that displays only the information that matches your specific needs. For information on creating a custom workflow, see Creating Custom Workflows on page 1916.

The Audit Log Actions table below describes some of the specific actions you can perform on an audit log workflow page.

Audit Log Actions

TO...	YOU CAN...
learn more about the contents of the columns in the table	find more information in Understanding the Audit Log Table on page 2278.
modify the time range used when viewing audit records	find more information at Setting Event Time Constraints on page 1896. Note that events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.
sort and constrain events on the current workflow page	find more information in Sorting Table View Pages and Changing Their Layout on page 1909.

Audit Log Actions (Continued)

TO...	YOU CAN...
navigate within the current workflow page	find more information in Navigating to Other Pages in the Workflow on page 1911.
navigate between pages in the current workflow, keeping the current constraints	click the appropriate page link at the top left of the workflow page. For more information, see Using Workflow Pages on page 1889.
drill down to the next page in the workflow	use one of the following methods: • To drill down to the next workflow page constraining on a specific value, click a value within a row. Note that this only works on drill-down pages. Clicking a value within a row in a table view constrains the table view and does **not** drill down to the next page. • To drill down to the next workflow page constraining on some events, select the check boxes next to the events you want to view on the next workflow page, then click **View**. • To drill down to the next workflow page keeping the current constraints, click **View All**. **TIP!** Table views always include "Table View" in the page name. For more information, see Constraining Events on page 1905.
constraining on a specific value	Click a value within a row. If you click a value on a drill-down page, you move to the next page and constrain on the value. Note that clicking a value within a row in a table view constrains the table view and does **not** drill down to the next page. **TIP!** Table views always include "Table View" in the page name. For more information, see Constraining Events on page 1905.
delete audit records	use one of the following methods: • To delete some items, select the check boxes next to events you want to delete, then click **Delete**. • To delete all items in the current constrained view, click **Delete All**, then confirm you want to delete all the events.
temporarily use a different workflow	click **(switch workflow)**. For more information, see Selecting Workflows on page 1885.
bookmark the current page so you can quickly return to it	click **Bookmark This Page**. For more information, see Using Bookmarks on page 1913.

Audit Log Actions (Continued)

To...	You can...
navigate to the bookmark management page	click **View Bookmarks**. For more information, see Using Bookmarks on page 1913.
generate a report based on the data in the current view	click **Report Designer**. For more information, see Creating a Report Template from an Event View on page 1797.
view a summary of a change recorded in the audit log	click the compare icon ( ) next to applicable events in the **Message** column. For more information, see Using the Audit Log to Examine Changes on page 2278.

To view audit records:

Access: Admin

▶ Select **System > Monitoring > Audit**.

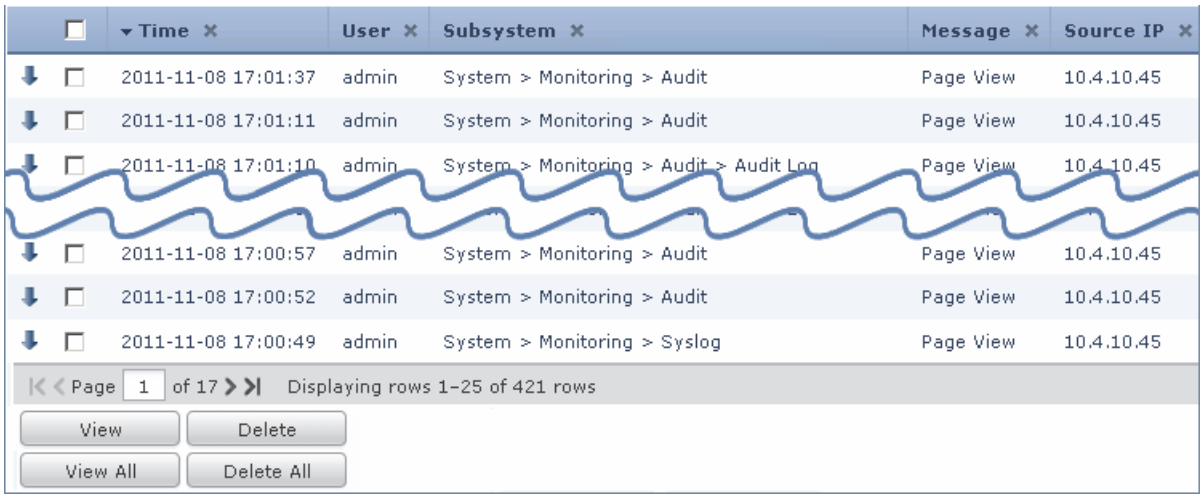
The first (and only) page of the default audit log workflow appears. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300. If no events appear, you may need to adjust the time range. For more information, see Setting Event Time Constraints on page 1896.

TIP! If you are using a custom workflow that does not include the table view of audit events, click **(switch workflow)**, then select **Audit Log**.

Working with Audit Events

LICENSE: Any

You can change the layout of the event view or constrain the events in the view by a field value.



When disabling columns, after you click the close icon (✖) in the column heading that you want to hide, in the pop-up window that appears, click **Apply**. When you disable a column, it is disabled for the duration of your session (unless you add it back later). Note that when you disable the first column, the Count column is added.

To hide or show other columns, or to add a disabled column back to the view, select or clear the appropriate check boxes before you click **Apply**.

Clicking a value within a row in a table view constrains the table view and does not drill down to the next page.

TIP! Table views always include "Table View" in the page name.

For more information, see the following topics:

- Constraining Events on page 1905.
- Using Compound Constraints on page 1908
- Sorting Drill-Down Workflow Pages on page 1910
- Understanding the Audit Log Table on page 2278

Suppressing Audit Records

LICENSE: Any

If your auditing policy does not require that you audit specific types of user interactions with the Sourcefire 3D System, you can prevent those interactions

from generating audit records. For example, by default, each time a user views the online help, the Sourcefire 3D System generates an audit record. If you do not need to keep a record of these interactions, you can automatically suppress them.

To configure audit event suppression, you must have access to an appliance's `admin` user account, and you must be able to either access the appliance's console or open a secure shell.

WARNING! Make sure that only authorized personnel have access to the appliance and to its `admin` account.

To suppress audit records, you must create one or more files in the `/etc/sf` directory in the following form:

`AuditBlock.`*type*

where *type* is `address`, `message`, `subsystem`, or `user`.

IMPORTANT! If you create an `AuditBlock.`*type* file for a specific type of audit message, but later decide that you no longer want to suppress them, you must delete the contents of the `AuditBlock.`*type* file but leave the file itself on the Sourcefire 3D System.

The contents for each audit block type must be in a specific format, as described in the Audit Block Types table. Make sure you use the correct capitalization for the file names. Note also that the contents of the files are case sensitive.

Audit Block Types

Type	Description
Address	Create a file named `AuditBlock.address` and include, one per line, each IP address that you want to suppress from the audit log. You can use partial IP addresses provided that they map from the beginning of the address. For example, the partial address `10.1.1` matches addresses from `10.1.1.0` through `10.1.1.255`.
Message	Create a file named `AuditBlock.message` and include, one per line, the message substrings that you want to suppress. Note that substrings are matched so that if you include `backup` in your file, all messages that include the word `backup` are suppressed.

Audit Block Types (Continued)

TYPE	DESCRIPTION
Subsystem	Create a file named `AuditBlock.subsystem` and include, one per line, each subsystem that you want to suppress. Note that substrings are **not** matched. You must use exact strings. See the Subsystem Names table for a list of subsystems that are audited.
User	Create a file named `AuditBlock.user` and include, one per line, each user account that you want to suppress. You can use partial string matching provided that they map from the beginning of the username. For example, the partial username `IPSAnalyst` matches the user names `IPSAnalyst1` and `IPSAnalyst2`.

Note that when you add an `AuditBlock` file, an audit record with a subsystem of `Audit` and a message of `Audit Filter` *`type`* `Changed` is added to the audit events. For security reasons, this audit record **cannot** be suppressed.

The following table lists audited subsystems.

Subsystem Names

NAME	INCLUDES USER INTERACTIONS WITH...
Admin	Administrative features such as system and access configuration, time synchronization, backup and restore, device management, user account management, and scheduling
Alerting	Alerting functions such as email, SNMP, and syslog alerting
Audit Log	Audit event views
Audit Log Search	Audit event searches
Command Line	Command line interface
Configuration	Email alerting
COOP	Continuity of operations feature
Date	Date and time range for event views
Default Subsystem	Options that do not have assigned subsystems
Detection & Prevention Policy	Menu options for intrusion policies

Subsystem Names (Continued)

NAME	INCLUDES USER INTERACTIONS WITH...
Error	System-level errors
eStreamer	eStreamer configuration
EULA	Reviewing the end user license agreement
Events	Intrusion and discovery event views
Events Clipboard	Intrusion event clipboard
Events Reviewed	Reviewed intrusion events
Events Search	Any event search
Failed to install rule update *rule_update_id*	Installing rule updates
Header	Initial presentation of the user interface after a user logs in
Health	Health monitoring
Health Events	Health monitoring event views
Help	Online help
High Availability	High availability feature
IDS Impact Flag	Impact flag configuration
IDS Policy	Intrusion policies
IDSPolicy > *policy_name* > Appliance > *det_engine_name*	Applying intrusion policies
IDSRule sid:*sig_id* rev:*rev_num*	Intrusion rules by SID
Incidents	Intrusion incidents
Insert Policy Apply Job	Applying policies
Install	Installing updates

Subsystem Names (Continued)

NAME	INCLUDES USER INTERACTIONS WITH...
Intrusion Events	Intrusion events
Login	Web interface login and logout functions
Menu	Any menu option
Object export > *obj_type* > *obj_name*	Importing objects of a specific type and name
Permission Escalation	User role escalation
Preferences	User preferences, such as the time zone for a user account and individual event preferences
Policy	Any policy, including intrusion policies
Register	Registering devices on a Defense Center
RemoteStorageDevice	Configuring remote storage devices
Reports	Report listing and report designer features
Rules	Intrusion rules, including the rule editor and the rule importation process
Rule Update Import Log	Viewing the rule update import log
Rule Update Install	Installing rule updates
Status	Syslog, as well as host and performance statistics
System	Various system-wide settings
System Policy > *policy_name* Appliance > *appliance_name*	Applying system policies
Task Queue	Viewing the task queue
Users	Creating and modifying user accounts and roles

Understanding the Audit Log Table

LICENSE: Any

Each appliance generates an audit event for each user interaction with the web interface. Each event includes a time stamp, the user name of the user whose action generated the event, a source IP, and text describing the event. The fields in the audit log table are described in the Audit Log Fields table.

Audit Log Fields

FIELD	DESCRIPTION
Time	Time and date that the appliance generated the audit record.
User	User name of the user that triggered the audit event.
Subsystem	Menu path the user followed to generate the audit record. For example, **System > Monitoring > Audit** is the menu path to view the audit log. In a few cases where a menu path is not relevant, the Subsystem field displays only the event type. For example, **Login** classifies user login attempts.
Message	Action the user performed. For example, `Page View` signifies that the user simply viewed the page indicated in the Subsystem, while `Save` means that the user clicked the **Save** button on the page. Changes made to the Sourcefire 3D System appear with a compare icon ( ) that you can click to see a summary of the changes. For more information, see Using the Audit Log to Examine Changes on page 2278.
Source IP	IP address associated with the host used by the user.
Count	The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows.

Using the Audit Log to Examine Changes

LICENSE: Any

You can use the audit log to view detailed reports of changes to your system. These reports compare the current configuration of your system to its most recent configuration before a particular change.

A compare icon ( ) appears next to audit log events that reflect changes to the system. You can click the compare icon to access the Compare Configurations page and view a detailed report of a change.

The Compare Configurations page displays the differences between the system configuration before changes and the running configuration in a side-by-side format. The audit event type, time of last modification, and name of the user who made the change are displayed in the title bar above each configuration.

Differences between the two configurations are highlighted:

- Blue indicates that the highlighted setting is different in the two configurations, and the difference is noted in red text.
- Green indicates that the highlighted setting appears in one configuration but not the other.

To examine a change in the audit log:

Access: Admin

1. Select **System > Monitoring > Audit**.

   The first page of the default audit log workflow appears.

   If you are using a custom workflow that does not include the table view of audit events, click **(switch workflow)**, then select **Audit Log**.

2. Click the compare icon ( ) next to an applicable audit log event in the **Message** column.

   The Compare Configurations page appears.

   Note that you can navigate through changes individually by clicking **Previous** or **Next** above the title bar. If the change summary is more than one page long, you can also use the scroll bar on the right to view additional changes.

Searching Audit Records

License: Any

You can search audit records to find information specific to a user, a specific subsystem, or an audit record message.

You may want to create searches customized for your network environment, then save them to reuse later. The search criteria you can use are described in the Audit Record Search Criteria table. Note that audit searches are not case

sensitive. For example, searching for `Analyst01` or `analyst01` yields the same results.

Audit Record Search Criteria

Search Field	Description	Example
User	Enter the user name of the user who triggered the audit events you want to see. You can use an asterisk (*) as a wildcard character in this field.	`jsmith` returns all audit records involving the user jsmith.
Subsystem	Enter the full menu path a user would follow to generate the audit records you want to see. You can use an asterisk (*) as a wildcard character in this field.	`System > Monitoring > Audit` and `*Audit` both return audit records that involve using the audit log. `*Audit*` returns all of the above records, plus records that involve searching for audit records.
Message	The action the user performed or the button the user clicked on the page. You can use an asterisk (*) as a wildcard character in this field.	`Apply` returns audit records where the user applied an intrusion policy. `Save Rule` returns audit records where the user saved a correlation rule. `Page View` returns audit records where the user viewed the page.
Time	Specify the date and time the audit record was generated. See Specifying Time Constraints in Searches on page 1847 for the syntax for entering time.	`> 2006-01-15 13:30:00` returns all audit records generated after January 15, 2006 at 1:30 PM.
Source IP	Enter the IP address of the host that you want to view audit records for. **IMPORTANT!** You **must** type a specific IP address. You cannot use IP ranges when searching audit logs.	`172.16.1.37` returns all audit records generated by a user from the 172.16.1.37 IP address.
Configuration Change	Specify whether or not you want to view audit records of configuration changes.	`yes` returns audit records of configuration changes.

For more information on searching, including how to load and delete saved searches, see Searching for Events on page 1842.

To search for audit records:

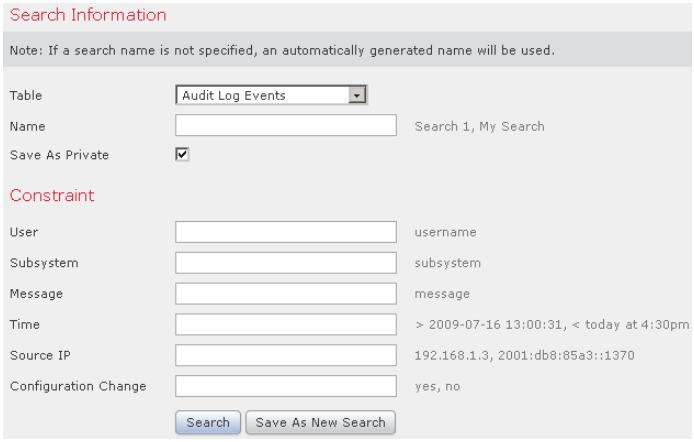
Access: Admin

1. Select **Analysis > Search**.

   The Search page appears.

2. From the **Table** drop-down list, select **Audit Log Events**.

   The Audit Log search page appears.



TIP! To search the database for a different kind of event, select it from the **Table** drop-down list.

3. Optionally, if you want to save the search, enter a name for the search in the **Name** field.

   If you do not enter a name, one is created automatically when you save the search.

4. Enter your search criteria in the appropriate fields, as described in the Audit Record Search Criteria table.

   If you enter multiple criteria, the search returns only the records that match all the criteria.

5. If you want to save the search so that other users can access it, clear the **Save As Private** check box. Otherwise, leave the check box selected to save the search as private.

TIP! If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search.

6. You have the following options:
   - Click **Search** to start the search.

     Your search results appear in the default audit log workflow, constrained by the current time range. To use a different workflow, including a custom workflow, click **(switch workflow)**. For information on specifying a different default workflow, see Configuring Event View Settings on page 2300.
   - Click **Save** if you are modifying an existing search and want to save your changes.
   - Click **Save as New Search** to save the search criteria. The search is saved (and associated with your user account if you selected **Save As Private**) so that you can run it at a later time.

Viewing the System Log

LICENSE: Any

The System Log (syslog) page provides you with system log information for the appliance. The system log displays each message generated by the system. The following items are listed in order:

- the date that the message was generated
- the time that the message was generated
- the host that generated the message
- the message itself

IMPORTANT! System log information is local. For example, you **cannot** use the Defense Center to view system status messages in the system logs on your managed devices.

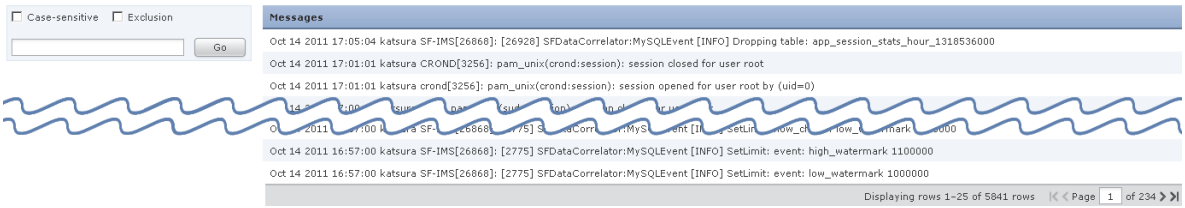
You can view system log messages for specific components by using the filter feature. For more information, see Filtering System Log Messages on page 2283.

To view the syslog:

ACCESS: Admin/Maint

▶ Select **System > Monitoring > Syslog**.

The System Log page appears. The Defense Center version of the page is shown below.



TIP! On the 3D9900, the Load Balancing Interface Module (LBIM) forwards messages to the device's syslog. You can find these messages by filtering on `lbim`.

Filtering System Log Messages

LICENSE: Any

You can view system log messages for specific components by using the filter feature. Filtering allows you to search for specific messages based on content.

The filter functionality uses the UNIX file search utility Grep, and as such, you can use most syntax accepted by Grep. This includes using Grep-compatible regular expressions for pattern matching. You can use a single word as a filter, or you can use Grep-supported regular expressions to search for content.

WARNING! The System Log page does not allow the use of pipe characters for OR expressions. For example, if you use `[word_1|word_2]`, you will receive an invalid filter error.

The System Log Filter Syntax table shows the regular expression syntax you can use in System Log filters:

System Log Filter Syntax

Syntax Component	Description	Example
`.`	Matches any character or white space	`Admi.` matches `Admin`, `AdmiN`, `Admi1`, and `Admi&`
`[[:alpha:]]`	Matches any alphabetic character	`[[:alpha:]]dmin` matches `Admin`, `bdmin`, and `Cdmin`
`[[:upper:]]`	Matches any uppercase alphabetic character	`[[:upper:]]dmin` matches `Admin`, `Bdmin`, and `Cdmin`
`[[:lower:]]`	Matches any lowercase alphabetic character	`[[:lower:]]dmin` matches `admin`, `bdmin`, and `cdmin`
`[[:digit:]]`	Matches any numeric character	`[[:digit:]]dmin` matches `0dmin`, `1dmin`, and `2dmin`
`[[:alnum:]]`	Matches any alphanumeric character	`[[:alnum:]]dmin` matches `1dmin`, `admin`, `2dmin`, and `bdmin`
`[[:space:]]`	Matches any white space, including tabs	`Feb[[:space:]]29` matches logs from February 29th.
`*`	Matches zero or more instances of the character or expression it follows	`ab*` matches `a`, `ab`, `abb`, `ca`, `cab`, and `cabb` `[ab]*` matches anything
`?`	Matches zero or one instances	`ab?` matches `a` or `ab`.
`\`	Allows you to search for a character typically interpreted as regular expression syntax	`alert\?` matches `alert?`.

The System Log Filter Examples table shows some example filters you can use on the System Log page.

System Log Filter Examples

To search for all log entries that...	Use...
Are generated on November 5	`Nov[[:space:]]*5`
Contain the user name "Admin"	`Admin`
Contain authorization debugging information on November 5	`Nov[[:space:]]*5.*AUTH.*DEBUG`

To search for specific message content in the system log:

Access: Admin/Maint

1. Select **System > Monitoring > Syslog**.

   The System Log page appears.

2. Enter a word or query in the **Filter** field.

   See the System Log Filter Syntax table on page 2284 and the System Log Filter Examples table on page 2285 for more information about the filter syntax you can use.

   IMPORTANT! Only Grep-compatible search syntax is supported. For example, you could search for all NTP-related system log messages by using `ntp` as a filter, or search for all messages generated in November by using `Nov` as a filter. You could view messages from November 27th by using `Nov[[:space:]]*27` or `Nov.*27`, but you could not, however, use `Nov 27` or `Nov*27` to view these messages.

3. Optionally, to make your search case-sensitive, check **Case-sensitive**. (By default, filters are not case-sensitive.)

4. Optionally, check **Exclusion** to search for all system log messages that do **not** meet the criteria you entered.

5. Click **Go**.

   The messages that match the filter appear.

CHAPTER 55
USING BACKUP AND RESTORE

Backup and restoration is an essential part of any system maintenance plan. While each organization's backup plan is highly individualized, the Sourcefire 3D System provides a mechanism for archiving data so that the Defense Center or managed device can be restored in case of disaster. Note that backups are valid only for the product version on which you created them, and you cannot create or restore backup files for virtual managed devices or Sourcefire Software for X-Series.

You can restore a backup onto a replacement appliance if the two appliances are the same model and are running the same version of the Sourcefire 3D System software.

WARNING! Do not use the backup and restore process to copy the configuration files between managed devices. The configuration files include information that uniquely identifies a device and cannot be shared.

By default, system configuration files are saved in the backup file. You can also choose to back up event data. You cannot back up captured files stored on the appliance.

WARNING! If you applied any Sourcefire rule updates, those updates are not backed up. You need to apply the latest rule update **after** you restore.

You can save backup files to the appliance or to your local computer. Additionally, if you are using a Defense Center, you can use remote storage as detailed in

Managing Remote Storage on page 2097.

WARNING! Never insert a USB drive into any USB port on a 3D9900. Additionally, remove any device with external storage (for example, a KVM switch with external storage) from a 3D9900 before upgrading or restoring the device.

See the following sections for more information:

- See Creating Backup Files on page 2287 for information about backing up files from the appliance.
- See Creating Backup Profiles on page 2290 for information about creating backup profiles that you can use later as templates for creating backups.
- See Backing up Your Managed Devices with a Defense Center on page 2291 for information about backing up managed devices with the Defense Center.
- See Uploading Backups from a Local Host on page 2292 for information about uploading backup files from a local host.
- See Restoring the Appliance from a Backup File on page 2293 for information about how to restore a backup file to the appliance.

Creating Backup Files

LICENSE: Any

To view and use existing system backups, go to the Backup Management page. You should periodically save a backup file that contains all of the configuration files required to restore the appliance, in addition to event and packet data. You may also want to back up the system when testing configuration changes so that you can revert to a saved configuration if needed. Note that you cannot include captured files in the backup file. You can choose to save the backup file on the appliance or on your local computer.

WARNING! You cannot create a backup file if your appliance does not have enough disk space; backups may fail if the backup process uses more than 85% of available disk space. If necessary, delete old backup files, transfer old backup files off the appliance, or use remote storage.

As an alternative, or if your backup file is larger than 4GB, copy it via SCP to a remote host. Uploading a backup from your local computer does not work on backup files larger than 4GB because web browsers do not support uploading files that large. On Defense Centers, the backup file can be saved to a remote

location; see Managing Remote Storage on page 2097 for more information.

IMPORTANT! While your backup task is collecting discovery events, data correlation is temporarily suspended.

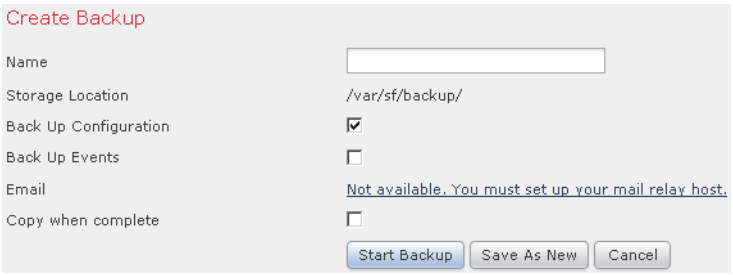
If you perform a backup, then delete reviewed intrusion events, your backup restores the deleted intrusion events but does not restore their reviewed status. You view those restored intrusion events under Intrusion Events, not under Reviewed Events. See Reviewing Intrusion Events on page 659.

If you restore a backup that contains intrusion event data on an appliance that already contains that data, duplicate events are created. To avoid this, restore intrusion event backups only on appliances without prior intrusion event data.

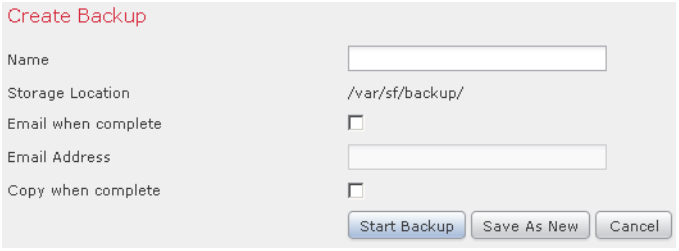
WARNING! If you configured any interface associations with security zones, these associations are not backed up. You must reconfigure them after you restore. For more information, see Working with Security Zones on page 227.

When you back up your managed device from the device itself, you back up the configuration only. Use the Defense Center that manages the physical device to perform a complete backup.

The Defense Center version of the page is shown below.



The physical managed device version of the page is shown below.



To create a backup file:

Access: Admin/Maint

1. Select **System > Tools > Backup/Restore**.

   The Backup Management page appears.

2. Click **Managed Device Backup** or **Defense Center Backup**.

   The Create Backup page appears.

3. In the **Name** field, type a name for the backup file. You can use alphanumeric characters, punctuation, and spaces.

4. On Defense Centers, you have two further options:
   - To archive the configuration, select **Back Up Configuration**.
   - To archive the entire event database, select **Back Up Events**.

5. Optionally, to be notified when the backup is complete, select the **Email when complete** check box and type your email address in the accompanying text box.

   IMPORTANT! To receive email notifications, you must configure a relay host as described in Configuring a Mail Relay Host and Notification Address on page 2060.

6. Optionally, on Defense Centers, to use secure copy (SCP) to copy the backup archive to a different machine, select the **Copy when complete** check box, then type the following information in the accompanying text boxes:
   - in the **Host** field, the hostname or IP address of the machine where you want to copy the backup
   - in the **Path** field, the path to the directory where you want to copy the backup
   - in the **User** field, the user name you want to use to log into the remote machine
   - in the **Password** field, the password for that user name
     If you prefer to access your remote machine with an SSH public key instead of a password, you must copy the contents of the **SSH Public Key** field to the specified user's `authorized_keys` file on that machine.

   With this option cleared, the system stores temporary files used during the backup on the remote server; temporary files are not stored on the remote server when this option is selected.

   TIP! Sourcefire recommends that you periodically save backups to a remote location so the appliance can be restored in case of system failure.

7. You have the following options:
   - To save the backup file to the appliance, click **Start Backup**.

     The backup file is saved in the `/var/sf/backup` directory. On Defense Centers, you can direct the backup file to a remote location; see Managing Remote Storage on page 2097.

     When the backup process is complete, you can view the file on the Restoration Database page. For information about restoring a backup file, see Restoring the Appliance from a Backup File on page 2293.
   - To save this configuration as a backup profile that you can use later, click **Save As New**.

     You can modify or delete the backup profile by selecting **System > Tools > Backup/Restore**, then clicking **Backup Profiles**. See Creating Backup Profiles on page 2290 for more information.

Creating Backup Profiles

LICENSE: Any

You can use the Backup Profiles page to create backup profiles that contain the settings that you want to use for different types of backups. You can later select one of these profiles when you back up the files on your appliance.

TIP! When you create a backup file as described in Creating Backup Files on page 2287, a backup profile is automatically created.

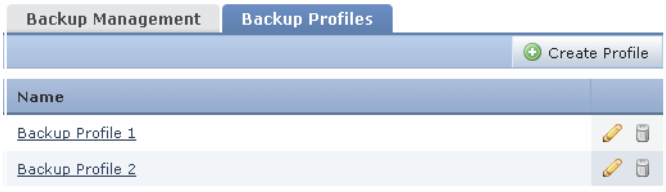
To create a backup profile:

ACCESS: Admin/Maint

1. Select **System > Tools > Backup/Restore**.

   The Backup Management page appears.
2. Click the **Backup Profiles** tab.

   The Backup Profiles page appears with a list of existing backup profiles.



TIP! You can click the edit icon ( ) to modify an existing profile or click the delete icon ( ) to delete a profile from the list.

3. Click **Create Profile**.

   The Create Backup page appears.

4. Type a name for the backup profile. You can use alphanumeric characters, punctuation, and spaces.

5. Configure the backup profile according to your needs.

   See Creating Backup Files on page 2287 for more information about the options on this page.

6. Click **Save As New** to save the backup profile.

   The Backup Profiles page appears and your new profile appears in the list.

Backing up Your Managed Devices with a Defense Center

LICENSE: Any

You can use the Defense Center to back up data on managed devices. The default name for the backup file uses the name of the managed device.

TIP! If you use a backup file name containing spaces or punctuation characters, they change to underscores.

You **cannot** use remote backup and restore to manage data on Sourcefire Software for X-Series.

To back up a managed device from a Defense Center:

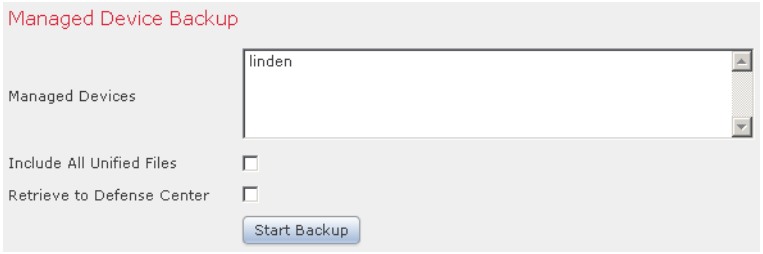
ACCESS: Admin/Maint

1. Select **System > Tools > Backup/Restore**.

   The Backup Management page appears.

2. Click **Managed Device Backup**.

   The Managed Device Backup page appears.



3. In the **Managed Devices** field, select the managed devices you want to back up.

4. To include event data in addition to configuration data, select the **Include All Unified Files** check box. Note that unified files are binary files that the Sourcefire 3D System uses to log event data.
5. To save the backup file on the Defense Center, select the **Retrieve to Defense Center** check box. To save each device's backup file on the device itself, leave this check box unselected.

IMPORTANT! If you select **Retrieve to Defense Center** and your Defense Center is configured for remote storage of backups, the device backup file will be saved to the configured remote location, not the Defense Center itself.

6. Click **Start Backup**.

   A success message appears and the backup task is created.

   It may take several minutes to complete the backup. You can monitor its progress on the Task Status page (**System > Monitoring > Task Status**). When the backup is complete, the backup file appears on the Backup Management page.

Uploading Backups from a Local Host

LICENSE: Any

If you download a backup file to your local host using the download function described in the Backup Management table on page 2294, you can upload it to a Defense Center.

TIP! You cannot upload a backup larger than 4GB from your local host because web browsers do not support uploading files that large. As an alternative, copy the backup via SCP to a remote host and retrieve it from there. On Defense Centers, the backup file can be saved to and retrieved from a remote location; see Managing Remote Storage on page 2097.

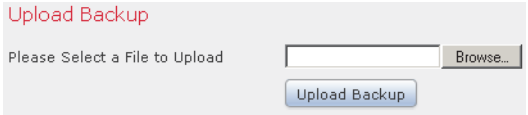
To upload a backup from your local host:

ACCESS: Admin/Maint

1. Select **System > Tools > Backup/Restore**.

   The Backup Management page appears.
2. Click **Upload Backup.**

   The Upload Backup page appears.



3. Click **Browse** and navigate to the backup file you want to upload.

   After you select the file to upload, click **Upload Backup**.

4. Click **Backup Management** to return to the Backup Management page.

   The backup file is uploaded and appears in the backup list. After the Defense Center appliance verifies the file integrity, refresh the Backup Management page to reveal detailed file system information.

Restoring the Appliance from a Backup File

LICENSE: Any

You can restore the appliance from backup files using the Backup Management page. To restore a backup, the VDB version in the backup file must match the current VDB version on your appliance. After you complete the restoration process, you **must** apply the latest Sourcefire Rule Update.

WARNING! Do not restore backups created on virtual Defense Centers to physical Defense Centers — this may stress system resources. If you must restore a virtual backup on a physical Defense Center, contact Sourcefire Support.

If you use local storage, backup files are saved to `/var/sf/backup`, which is listed with the amount of disk space used in the `/var` partition at the bottom of the Backup Management page. On Defense Centers, select **Remote Storage** at the top of the Backup Management page to configure remote storage options; then, to enable remote storage, select the **Enable Remote Storage for Backups** check box on the Backup Management page. If you use remote storage, the protocol, backup system, and backup directory are listed at the bottom of the page.

IMPORTANT! If you add licenses after a backup has completed, these licenses will not be removed or overwritten if this backup is restored. To prevent a conflict on restore, remove those licenses before restoring the backup, noting where the licenses were used, and add and reconfigure them after restoring the backup. If a conflict occurs, contact Sourcefire Support.

The Backup Management table describes each column and icon on the Backup Management page.

Backup Management

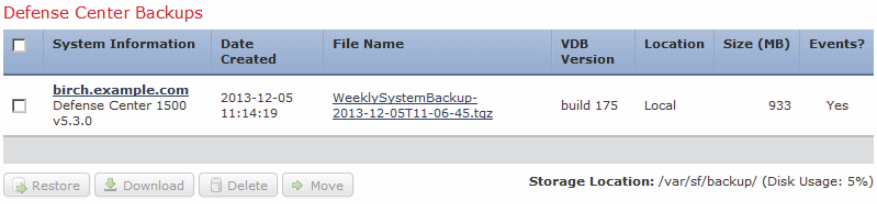
FUNCTIONALITY	DESCRIPTION
System Information	The originating appliance name, type, and version. Note that you can only restore a backup to an identical appliance type and version.
Date Created	The date and time that the backup file was created
File Name	The full name of the backup file
VDB Version	The build of the vulnerability database (VDB) running on the appliance at the time of backup.
Location	The location of the backup file
Size (MB)	The size of the backup file, in megabytes
Events?	"Yes" indicates the backup includes event data
View	Click the name of the backup file to view a list of the files included in the compressed backup file.
Restore	Click with the backup file selected to restore it on the appliance. If your VDB version does not match the VDB version in the backup file, this option is disabled.
Download	Click with the backup file selected to save it to your local computer.
Delete	Click with the backup file selected to delete it.
Move	On a Defense Center, when you have a previously created local backup selected, click to send the backup to the designated remote backup location.

To restore the appliance from a backup file:

Access: Admin

1. Select **System > Tools > Backup/Restore**.

   The Backup Management page appears. A Defense Center version of the page is shown.



2. To view the contents of a backup file, click the name of the file.

   The manifest appears, listing the name of each file, its owner and permissions, and its file size and date. The Defense Center version of the page is truncated to show a sample of the files that are backed up.

katsura2-2011-10-26T14-28-05.tgz

Perm	User	Size	Date	Time	Name
drwx------	www/www	0	2011-10-26	14:28	var/tmp/backupbj7d/

-rw-rw-rw-	www/www	653	2011-10-26	14:28	var/tmp/backupbj7d/files_to_tar
-rw-r--r--	root/root	170416654	2011-10-26	14:28	var/tmp/backupbj7d/db.dump
drwxr-xr-x	root/root	0	2011-10-22	17:09	etc/cron.d/
-rw-r--r--	root/root	570	2011-10-24	09:56	etc/group
-rw-r--r--	root/root	0	2011-10-10	20:40	etc/gshadow
-rw-r--r--	root/root	254	2011-10-24	10:11	etc/hosts
-rw-r-----	root/www	6024	2011-10-10	20:40	etc/httpd/httpsd.conf
-rw-r-----	root/www	103	2011-10-10	20:40	etc/httpd/ssl_certificates.conf
-rw-r--r--	root/root	1	2011-10-24	10:11	etc/issue
-rw-r--r--	root/root	8678	2011-10-10	22:08	etc/ldap.conf

3. Click **Backup Management** to return to the Backup Management page.

4. Select the backup file that you want to restore and click **Restore**.

   The Restore Backup page appears.

   Note that if the VDB version in the backup does not match the VDB version currently installed on your appliance, the **Restore** button is grayed out.

WARNING! This procedure overwrites all configuration files and, on the managed device, all event data.

5. To restore files, select either or both:
   - **Replace Configuration Data**
   - **Restore Event Data**

IMPORTANT! Note that, when you restore the configuration of a managed device from a backup file, any device configuration changes you made from the device's managing Defense Center will also be restored, even changes you made after you created that backup file.

6. Click **Restore** to begin the restoration.

   The appliance is restored using the backup file you specified.

7. Reboot the appliance.
8. Apply the latest Sourcefire Rule Update to reapply rule updates.
9. Reapply any access control, intrusion, network discovery, health, and system policies to the restored system.

CHAPTER 56
SPECIFYING USER PREFERENCES

You can configure the preferences that are tied to a single user account, such as the home page, account password, time zone, dashboard, and event viewing preferences.

Depending on your user role, you can specify certain preferences for your user account, including passwords, event viewing preferences, time zone settings, and home page preferences. See the following sections for more information:

- Changing Your Password on page 2298 explains how to change the password for your user account.
- Specifying Your Home Page on page 2299 explains how to use one of the existing pages as your default home page. After setting this value, this becomes the first page you see upon logging into the appliance.
- Configuring Event View Settings on page 2300 describes how the event preferences affect what you see as you view events.
- Setting Your Default Time Zone on page 2306 explains how to set the time zone for your user account and describes how that affects the time stamp on the events that you view.
- Specifying Your Default Dashboard on page 2307 explains how to choose which of the dashboards you want to use as your default dashboard.

Changing Your Password

LICENSE: Any
SUPPORTED DEVICES: Series 2, Series 3
SUPPORTED DEFENSE CENTERS: Any

All user accounts are protected with a password. You can change your password at any time, and depending on the settings for your user account, you may have to change your password periodically; see Changing an Expired Password on page 2298.

Note that if password strength checking is enabled, passwords must be at least eight alphanumeric characters of mixed case and must include at least one numeric character. Passwords cannot be a word that appears in a dictionary or include consecutive repeating characters.

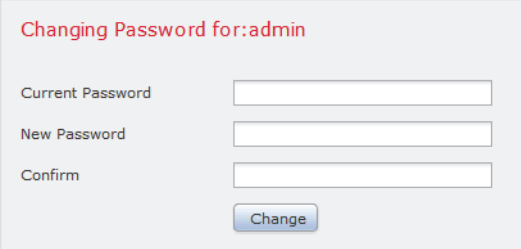
IMPORTANT! If you are an LDAP or a RADIUS user, you cannot change your password through the web interface.

To change your password:

ACCESS: Any

1. From the drop-down list under your user name, select **User Preferences**.

   The Change Password page appears.



2. In the **Current Password** field, type your current password and click **Change**.
3. In the **New Password** and **Confirm** fields, type your new password.
4. Click **Change**.

   A success message appears on the page when your new password is accepted by the system.

Changing an Expired Password

LICENSE: Any
SUPPORTED DEVICES: Series 2, Series 3
SUPPORTED DEFENSE CENTERS: Any

Depending on the settings for your user account, your password may expire. Note that the password expiration time period is set when your account is created and

cannot be changed. If your password has expired, the Password Expiration Warning page appears.

To respond to the password expiration warning:

Access: Any

▶ You have two choices:

- Click **Change Password** to change your password now.

  If you have zero warning days left, you **must** change your password. Also, if password strength checking is enabled, passwords must be at least eight alphanumeric characters of mixed case and must include at least one numeric character. Passwords cannot be a word that appears in a dictionary or include consecutive repeating characters.
- Click **Skip** to change your password later.

Specifying Your Home Page

License: Any

You can specify a page within the web interface as your home page for the appliance. The default home page is the Summary Dashboard (**Overview > Dashboards**), except for user accounts with no dashboard access, which use the Welcome page.

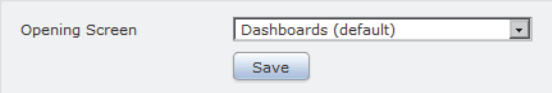
To specify your home page:

Access: Any except External Database User

1. From the drop-down list under your user name, select **User Preferences**.

   The Change Password page appears.
2. Click **Home Page**.

   The Home Page page appears.



3. Select the page you want to use as your home page from the drop-down list.

   The options in the drop-down list are based on the access privileges for your user account. For more information, see User Account Privileges on page 1990.
4. Click **Save**.

   Your home page preference is saved.

Configuring Event View Settings

LICENSE: Any

Use the Event View Settings page to configure characteristics of event views in the Sourcefire 3D System. Note that some event view configurations are available only for specific user roles. Users with the External Database User role can view parts of the event view settings user interface, but changing those settings has no meaningful result. For details, see the individual sections linked below.

To configure event preferences:

ACCESS: feature dependent

1. From the drop-down list under your user name, select **User Preferences**.

   The User Preferences page appears.
2. Click **Event View Settings**.

   The Event View Settings page appears.
3. Configure the basic characteristics of event views.

   For more information, see Event Preferences on page 2300.
4. Configure file download preferences.

   For more information, see File Preferences on page 2301.
5. Configure the default time window or windows.

   For more information, see Default Time Windows on page 2302.
6. Configure default workflows.

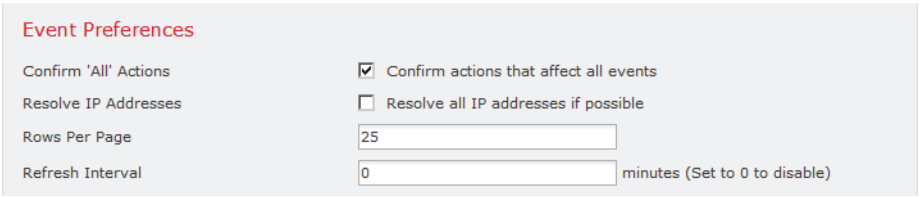
   For more information, see Default Workflows on page 2305.
7. Click **Save**.

   Your changes are implemented.

Event Preferences

LICENSE: Any

Use the Event Preferences section of the Event View Settings page to configure basic characteristics of event views in the Sourcefire 3D System. This section is available for all user roles, although it has little to no significance for users who cannot view events.



The following fields appear in the Event Preferences section:

- The **Confirm "All" Actions** field controls whether the appliance forces you to confirm actions that affect all events in an event view.

  For example, if this setting is enabled and you click **Delete All** on an event view, you must confirm that you want to delete all the events that meet the current constraints (including events not displayed on the current page) before the appliance will delete them from the database.
- The **Resolve IP Addresses** field allows the appliance, whenever possible, to display host names instead of IP addresses in event views.

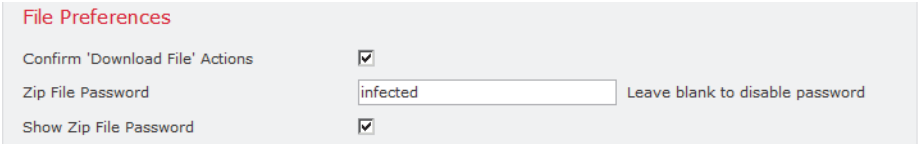
  Note that an event view may be slow to display if it contains a large number of IP addresses and you have enabled this option. Note also that for this setting to take effect, you must have a DNS server configured in the system settings; see Configuring Network Settings on page 2088.
- The **Rows Per Page** field controls how many rows of events per page you want to appear in drill-down pages and table views.
- The **Refresh Interval** field sets the refresh interval for event views in minutes. Entering "0" disables the refresh option. Note that this interval does not apply to dashboards.

File Preferences

LICENSE: Any
SUPPORTED DEVICES: feature dependent
SUPPORTED DEFENSE CENTERS: feature dependent

Use the File Preferences section of the Event View Settings page to configure basic characteristics of local file downloads. This section is only available to users with the Administrator, Security Analyst, or Security Analyst (Read Only) user roles.

Note that if your appliance does not support downloading captured files, these options are disabled. Because you cannot use a Malware license with a DC500, you cannot use those appliances to download files or modify these options.



The following fields appear in the File Preferences section:

- The **Confirm 'Download File' Actions** check box controls whether a File Download pop-up window appears each time you download a file, displaying a warning and prompting you to continue or cancel.

  WARNING! Sourcefire strongly recommends you do **not** download malware, as it can cause adverse consequences. Exercise caution when downloading any file, as it may contain malware. Ensure you have taken any necessary precautions to secure the download destination before downloading files.

  Note that you can disable this option any time you download a file. For more information on downloading files, see Downloading Stored Files to Another Location on page 1260.

- When you download a captured file, the system creates a password-protected .zip archive containing the file. The **Zip File Password** field defines the password you want to use to restrict access to the .zip file. If you leave this field blank, the system creates archive files without passwords.
- The **Show Zip File Password** check box toggles displaying plain text or obfuscated characters in the **Zip File Password** field. When this field is cleared, the **Zip File Password** displays obfuscated characters.

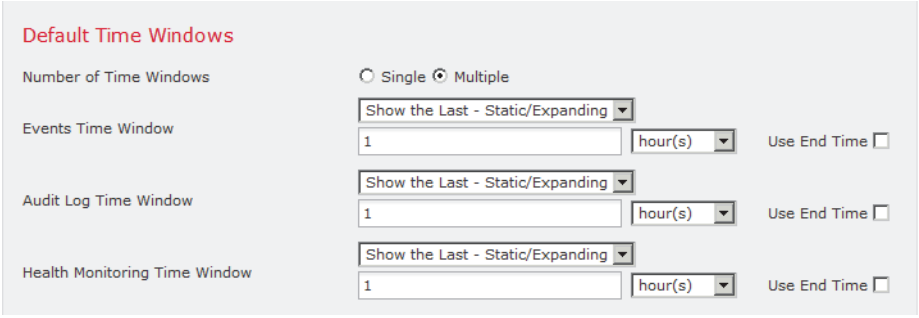
Default Time Windows

LICENSE: Any

The time window, sometimes called the time range, imposes a time constraint on the events in any event view. Use the Default Time Windows section of the Event View Settings page to control the default behavior of the time window.

User role access to this section is as follows:

- Administrators and Maintenance Users can access the full section.
- Security Analysts and Security Analysts (Read Only) can access all options except **Audit Log Time Window**.
- Access Admins, Discovery Admins, External Database Users, Intrusion Admins, Network Admins, and Security Approvers can access only the **Events Time Window** option.



Note that, regardless of the default time window setting, you can always manually change the time window for individual event views during your event analysis. Also, keep in mind that time window settings are valid for only the current session. When you log out and then log back in, time windows are reset to the defaults you configured on this page. For more information, see Setting Event Time Constraints on page 1896.

There are three types of events for which you can set the default time window:

- The **Events Time Window** sets a single default time window for most events that can be constrained by time.
- The **Audit Log Time Window** sets the default time window for the audit log.
- The **Health Monitoring Time Window** sets the default time window for health events.

You can only set time windows for event types your user account can access. All user types can set event time windows. Administrators, Maintenance Users, and Security Analysts can set health monitoring time windows. Administrators and Maintenance Users can set audit log time windows.

Note that because not all event views can be constrained by time, time window settings have no effect on event views that display hosts, host attributes, applications, clients, vulnerabilities, user identity, or white list violations.

You can either use **Multiple** time windows, one for each of these types of events, or you can use a **Single** time window that applies to all events. If you use a single

time window, the settings for the three types of time window disappear and a new **Global Time Window** setting appears.

There are three types of time window:

- *static*, which displays all the events generated from a specific start time to a specific end time
- *expanding*, which displays all the events generated from a specific start time to the present; as time moves forward, the time window expands and new events are added to the event view
- *sliding*, which displays all the events generated from a specific start time (for example, one day ago) to the present; as time moves forward, the time window "slides" so that you see only the events for the range you configured (in this example, for the last day)

The maximum time range for all time windows is from midnight on January 1, 1970 (UTC) to 3:14:07 AM on January 19, 2038 (UTC).

The following options appear in the **Time Window Settings** drop-down list:

- The **Show the Last - Sliding** option allows you configure a sliding default time window of the length you specify.

  The appliance displays all the events generated from a specific start time (for example, 1 hour ago) to the present. As you change event views, the time window "slides" so that you always see events from the last hour.
- The **Show the Last - Static/Expanding** option allows you to configure either a static or expanding default time window of the length you specify.

  For **static** time windows, enable the **Use End Time** check box. The appliance displays all the events generated from a specific start time (for example, 1 hour ago) to the time when you first viewed the events. As you change event views, the time window stays fixed so that you see only the events that occurred during the static time window.

  For **expanding** time windows, disable the **Use End Time** check box. The appliance displays all the events generated from a specific start time (for example, 1 hour ago) to the present. As you change event views, the time window expands to the present time.

- The **Current Day - Static/Expanding** option allows you to configure either a static or expanding default time window for the current day. The current day begins at midnight, based on the time zone setting for your current session.

  For **static** time windows, enable the **Use End Time** check box. The appliance displays all the events generated from midnight to the time when you first viewed the events. As you change event views, the time window stays fixed so that you see only the events that occurred during the static time window.

  For **expanding** time windows, disable the **Use End Time** check box. The appliance displays all the events generated from midnight to the present. As you change event views, the time window expands to the present time. Note that if your analysis continues for over 24 hours before you log out, this time window can be more than 24 hours.
- The **Current Week - Static/Expanding** option allows you to configure either a static or expanding default time window for the current week. The current week begins at midnight on the previous Sunday, based on the time zone setting for your current session.

  For **static** time windows, enable the **Use End Time** check box. The appliance displays all the events generated from midnight to the time when you first viewed the events. As you change event views, the time window stays fixed so that you see only the events that occurred during the static time window.

  For **expanding** time windows, disable the **Use End Time** check box. The appliance displays all the events generated from midnight Sunday to the present. As you change event views, the time window expands to the present time. Note that if your analysis continues for over 1 week before you log out, this time window can be more than 1 week.

Default Workflows

LICENSE: Any

A workflow is a series of pages displaying data that analysts use to evaluate events. For each event type, the appliance ships with at least one predefined workflow. For example, as a Security Analyst, depending on the type of analysis you are performing, you can choose among ten different intrusion event workflows, each of which presents intrusion event data in a different way.

The appliance is configured with a default workflow for each event type. For example, the Events by Priority and Classification workflow is the default for intrusion events. This means whenever you view intrusion events (including reviewed intrusion events), the appliance displays the Events by Priority and Classification workflow.

You can, however, change the default workflow for each event type using the Default Workflows sections of the Event View Settings page.

Keep in mind that the default workflows you are able to configure depend on your user role. For example, intrusion event analysts cannot set default discovery event workflows. For general information on workflows, see Understanding and Using Workflows on page 1865.

Setting Your Default Time Zone

LICENSE: Any

You can change the time zone used to display events from the standard UTC time that the appliance uses. When you configure a time zone, it applies only to your user account and is in effect until you make further changes to the time zone.

WARNING! The Time Zone function assumes that the default system clock is set to UTC time. If you have changed the system clock on the appliance to use a local time zone, you must change it back to UTC time in order to view accurate local time on the appliance. For more information about time synchronization between the Defense Center and the managed devices, see Synchronizing Time on page 2069.

To change your time zone:

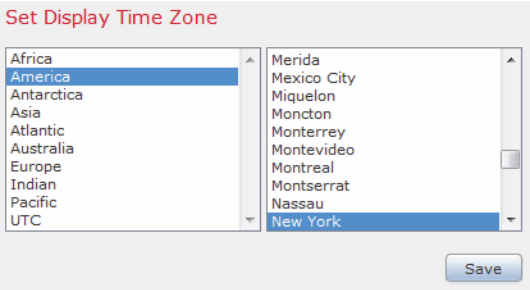
ACCESS: Any

1. From the drop-down list under your user name, select **User Preferences**.

   The Change Password page appears.

2. Click **Time Zone Settings**.

   The Time Zone Preference page appears.



3. From the left list box, select the continent or area that contains the time zone you want to use.

   For example, if you want to use a time zone standard to North America, South America, or Canada, select **America**.

4. From the right list box, select the zone (city name) that corresponds with the time zone you want to use.

   For example, if you want to use Eastern Standard Time, you would select **New York** after selecting **America** in the first time zone box.

5. Click **Save**.

   The time zone is set.

Specifying Your Default Dashboard

License: Any

You can specify one of the dashboards on the appliance as the default dashboard. The default dashboard appears when you select **Overview > Dashboards**. If you do not have a default dashboard defined, the Dashboard List page appears. For general information on dashboards, see Using Dashboards on page 73.

To specify your default dashboard:

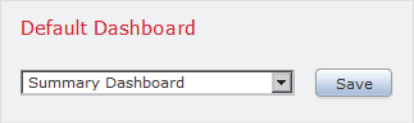
Access: Admin/Maint/Any Security Analyst

1. From the drop-down list under your user name, select **User Preferences**.

   The Change Password page appears.

2. Click **Dashboard Settings**.

   The Dashboard Settings page appears.



3. Select the dashboard you want to use as your default from the drop-down list.

   If you select **None**, when you select **Overview > Dashboards**, the Dashboard List page appears. You can then select a dashboard to view.

4. Click **Save**.

   Your default dashboard preference is saved.

APPENDIX A
IMPORTING AND EXPORTING CONFIGURATIONS

You can use the Import/Export feature to copy several types of configurations, including policies, from one appliance to another appliance of the same type. Configuration import and export is not intended as a backup tool, but can be used to simplify the process of adding new appliances to your Sourcefire 3D System.

You can import and export the following configurations:

- access control policies
- alert responses
- application detectors
- custom tables
- custom user roles
- custom workflows
- dashboards
- health policies
- intrusion policies
- report templates
- saved searches
- system policies
- third-party product mappings
- third-party vulnerability mappings

To import an exported configuration, both appliances must be running the same version of the Sourcefire 3D System. To import an exported intrusion policy (or an

access control policy that incorporates an intrusion policy), the rule update versions on both appliances must also match.

For more information, see the following sections:

- Exporting Configurations on page 2309
- Importing Configurations on page 2314

Exporting Configurations

LICENSE: Any

You can export a single configuration, or you can export a set of configurations (of the same type or of different types) at once. When you later import the package onto another appliance, you can choose which configurations in the package to import.

When you export a configuration, the appliance also exports revision information for that configuration. The Sourcefire 3D System uses that information to determine whether you can import that configuration onto another appliance; you cannot import a configuration revision that already exists on an appliance.

In addition, when you export a configuration, the appliance also exports system configurations that the configuration depends on, such as authentication objects. For example, if you set up authentication to an LDAP server on your Defense Center, then export a Defense Center system policy with authentication enabled, the authentication object is exported as well.

TIP! Many list pages in the Sourcefire 3D System include an export icon () next to list items. Where this icon is present, you can use it as a quick alternative to the export procedure that follows.

You can export the following configurations:

- *Alert responses* — An alert response is a set of configurations that allows the Sourcefire 3D System to interact with the external system where you plan to send the alert.
- *Custom tables* — A custom table is a table you can construct that combines fields from two or more of the predefined tables delivered with the Sourcefire 3D System.
- *Custom user roles* — A custom user role is a user role that you create with a specialized set of access privileges. Exporting a custom user role that requires saved searches also exports all of the necessary saved searches.

- *Custom workflows* — A custom workflow is a workflow that you create to meet the unique needs of your organization. On the Defense Center, you can export custom workflows that you create as well as the predefined custom workflows delivered with the appliance.

  Note that if a Defense Center does not allow you to view the table on which an exported custom workflow is based, you can import the workflow but will not be able to view it.

- *Dashboards* — A dashboard is a customizable tabbed view that provides you with an at-a-glance display of your current system status. Dashboards use various widgets to present data about the events collected and generated by the Sourcefire 3D System, as well as information about the status and overall health of the appliances in your deployment.

  Note that the dashboard widgets that you can view depend on the type of appliance you are using and on your user role. For more information, see Understanding Widget Availability on page 78.

- *Access control policies* — Access control policies include a variety of components that you can configure to determine how the system manages traffic on your network. These components include access control rules as well as any objects the rules use, and may also include referenced intrusion and file policies. Exporting an access control policy exports all settings and components for the policy except (where present) URL reputations and categories, which are equivalent across appliances and which users cannot change.

  If an access control policy that you export references an intrusion policy, the rule update version on the exporting and importing appliances must match.

  If an access policy that you export contains rules that reference geolocation data, the importing Defense Center's geolocation database (GeoDB) update version is used.

  If an access control policy that you export references an unsupported DC500 or Series 2 device policy feature or rule condition, you cannot use a DC500 to apply the policy and you cannot apply the policy to a Series 2 device. Neither the DC500 nor Series 2 devices support user or URL rule conditions, Security Intelligence, or file policies that include rules that use the Block Malware or Malware Cloud Lookup action. Additionally, Series 2 devices do not support application rule conditions.

- *Health policies* — A health policy comprises the criteria used when checking the health of appliances in your deployment, that is, whether your Sourcefire hardware and software are working correctly.

- *Intrusion policies* — Intrusion policies include a variety of components that you can configure to inspect your network traffic for intrusions and policy violations. These components include preprocessors; intrusion rules that inspect the protocol header values, payload content, and certain packet size characteristics; adaptive profile configurations; FireSIGHT recommended rules configurations; and tools that allow you to control how often events are logged and displayed.

  Exporting an intrusion policy exports all settings for the policy. For example, if you choose to set a rule to generate events, or if you set SNMP alerting for a rule, or if you turn on the SMTP preprocessor in a policy, those settings remain in place in the exported policy. Custom rules, custom rule classifications, and user-defined variables are also exported with the policy.

  Note that if you export an intrusion policy that uses a layer that is shared by a second intrusion policy, that shared layer is copied into the policy you are exporting and the sharing relationship is broken. When you import the intrusion policy on another appliance, you can edit the imported policy to suit your needs, including deleting, adding, and sharing layers.

  If you export an intrusion policy from one Defense Center to another, the imported policy may behave differently if the second Defense Center has differently configured default variables.

  IMPORTANT! You cannot use the Import/Export feature to update rules created by Sourcefire's Vulnerability Research Team (VRT). Instead, download and apply the latest rule update version; see Importing Rule Updates and Local Rule Files on page 2154.

- *Report templates* — Reports are document files formatted in PDF, HTML, or CSV that collate specific Sourcefire 3D System data. A report template specifies the data searches and formats for the report and its sections. When you export a report template, all saved searches, images, network objects, objects created in the object manager, and custom tables that are necessary for the report are exported also.
- *Saved searches* — A saved search provides access to predefined Sourcefire 3D System data for users with limited permissions. When you export a custom user role that requires saved searches, the necessary saved searches are exported also. You can also export individual user-defined saved searches.

- *System policies* — A system policy controls the aspects of an appliance that are likely to be similar to other Sourcefire 3D System appliances in your deployment, including database event limits, time settings, login banners, and so on.

  If external authentication is enabled in the system policy you are exporting, the associated authentication objects are exported as well.

  Note that system policies on Defense Centers contain database settings that do not apply to managed devices. If you export a system policy from a managed device and then import it onto a Defense Center, the database limits that you could not configure on the device are set to the default values on the Defense Center.
- *Third-party product mappings* — If you import data from a third-party application, you must map the product to the third-party name to assign vulnerabilities and perform impact correlation using that data. Mapping the product associates Sourcefire vulnerability information with the third-party product name, which allows the Sourcefire 3D System to perform impact correlation using that data. For information on creating a third-party product mapping, see Mapping Third-Party Products on page 1754.
- *Third-party vulnerability mappings* — To add vulnerability information from a third-party application to the vulnerability database, you must map the third-party identification string for each imported vulnerability to any existing Sourcefire, Bugtraq, or Snort ID. After you create a mapping for the vulnerability, the mapping works for all vulnerabilities imported to hosts in your network map and allows impact correlation for those vulnerabilities. For information on creating a third-party vulnerability mapping, see Mapping Third-Party Vulnerabilities on page 1759.
- *Application detectors* — When the system analyzes IP traffic, it uses detectors to collect information about and then identify the commonly used applications running on hosts on your network. You can export two kinds of detectors: user-defined detectors and individual add-on detectors provided by Sourcefire Professional Services. For more information on detectors, see Working with Application Detectors on page 1735.

IMPORTANT! Depending on the number of configurations being exported and the number of objects those configurations reference, the export process may take several minutes.

To export one or more configurations:

Access: Admin

1. Make sure that the appliance where you are exporting the configurations and the appliance where you plan to import the configurations are running the same version of the Sourcefire 3D System. If you are exporting an intrusion policy (or an access control policy that incorporates an intrusion policy), you must also make sure that the rule update versions match.

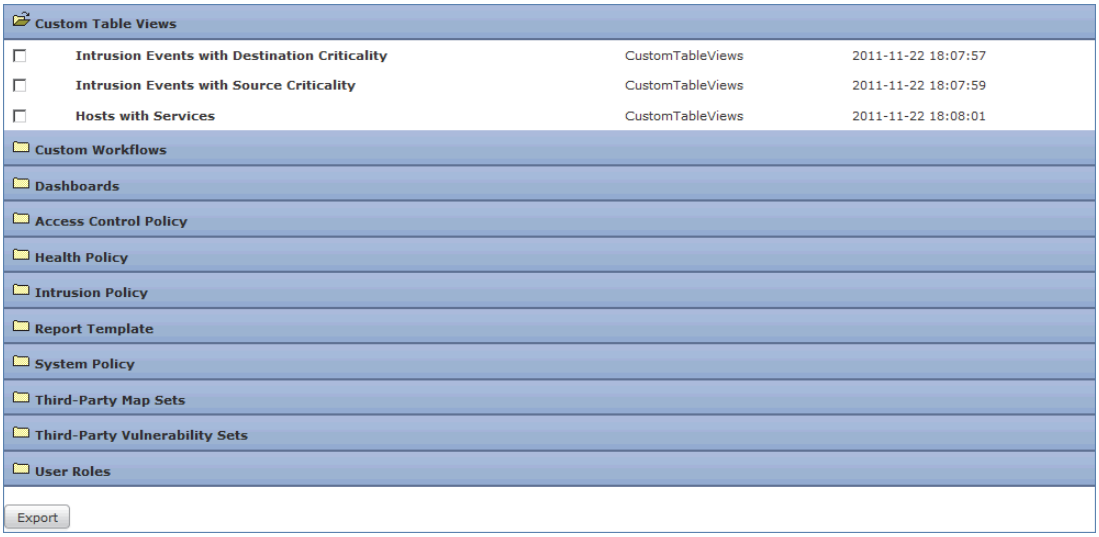
   If the versions of the Sourcefire 3D System (and, if applicable, the rule update versions) do not match, the import will fail.

2. Select **Systems > Tools > Import/Export**.

   The Import/Export page appears, including a list of the configurations on the appliance. Note that configuration categories with no configurations to export do not appear in this list.

   TIP! You can click the collapse icon () next to a configuration type to collapse the list of configurations. Click the expand folder icon () next to an configuration type to reveal configurations.

   The Defense Center version of the page is shown below with some configuration types collapsed.



3. Select the check boxes next to the configurations you want to export and click **Export**.

4. Follow your web browser's prompts to save the exported package to your computer.

Importing Configurations

LICENSE: Any

After you export a configuration from an appliance, you can import it onto a different appliance as long as that appliance supports it. Note, however, that some imported configurations may not be useful depending on the type of appliance you are using and on your user role.

Depending on the type of configuration you are importing, you should keep the following points in mind:

- You must make sure that the appliance where you import a configuration is running the same version of the Sourcefire 3D System as the appliance you used to export the configuration. If you are importing an intrusion policy (or an access control policy that incorporates an intrusion policy), the rule update versions on both appliances must also match. If the versions do not match, the import will fail.
- When you import a custom user role that requires saved searches, the necessary saved searches are imported also.
- The dashboard widgets that you can view depend on the type of appliance you are using and on your user role. For example, a dashboard created on the Defense Center and imported onto a managed device may display some invalid, disabled widgets.
- If you import an access control policy that evaluates traffic based on zones, you must map the zones in the imported policy to zones on devices managed by the importing Defense Center. When you map zones, their types must match. Therefore, you must create any zone types you need on the importing Defense Center before you begin the import. For more information about security zones, see Working with Security Zones on page 227.
- If you import an access control policy or saved search that includes an object or object group that has an identical name to an existing object or group, you must rename the object or group.
- If you import an access control policy or an intrusion policy, the import process replaces existing default variables in the default variable set with the imported default variables. If your existing default variable set contains a custom variable not present in the imported default variable set, the unique variable is preserved.

- If you import an intrusion policy that used a shared layer from a second intrusion policy, the export process breaks the sharing relationship and the previously shared layer is copied into the package. In other words, imported intrusion policies do not contain shared layers.

  IMPORTANT! You cannot use the Import/Export feature to update rules created by Sourcefire's Vulnerability Research Team (VRT). Instead, download and apply the latest rule update version; see Importing Rule Updates and Local Rule Files on page 2154.

- When you import a system policy that was exported from a Defense Center where external authentication is enabled, you also import the authentication objects on which the system policy depends.

Because you can export several configurations in a single package, when you import the package you must choose which configurations in the package to import. You can only import configurations that are supported on the destination appliance.

When you attempt to import a configuration, your appliance determines whether that configuration already exists on the appliance. If a conflict exists, you can:

- keep the existing configuration,
- replace the existing configuration with a new configuration,
- keep the newest configuration, or
- import the configuration as a new configuration.

If you import a configuration and then later make a modification to the configuration on the destination system, and then re-import the configuration, you must choose which version of the configuration to keep.

Depending on the number of configurations being imported and the number of objects those configurations reference, the import process may take several minutes.

For information on using imported configurations, see the following sections:

- Working with Alert Responses on page 571
- Using Custom Tables on page 1852
- Managing Custom User Roles on page 1984
- Using Custom Workflows on page 1915
- Working with Dashboards on page 116
- Applying an Access Control Policy on page 506
- Applying Health Policies on page 2228
- Managing Intrusion Policies on page 717
- Exporting and Importing Report Templates on page 1838
- Loading a Saved Search on page 1846

- Applying a System Policy on page 2042
- Mapping Third-Party Products on page 1754
- Mapping Third-Party Vulnerabilities on page 1759
- Activating and Deactivating Detectors on page 1750

To import one or more configurations:

Access: Admin

1. Make sure that the appliance where you are exporting the configurations and the appliance where you plan to import the configurations are running the same version of the Sourcefire 3D System. If you want to import an intrusion policy (or an access control policy that incorporates an intrusion policy), you must also make sure that the rule update versions match.

   If the versions of the Sourcefire 3D System (and, if applicable, the rule update versions) do not match, the import will fail.

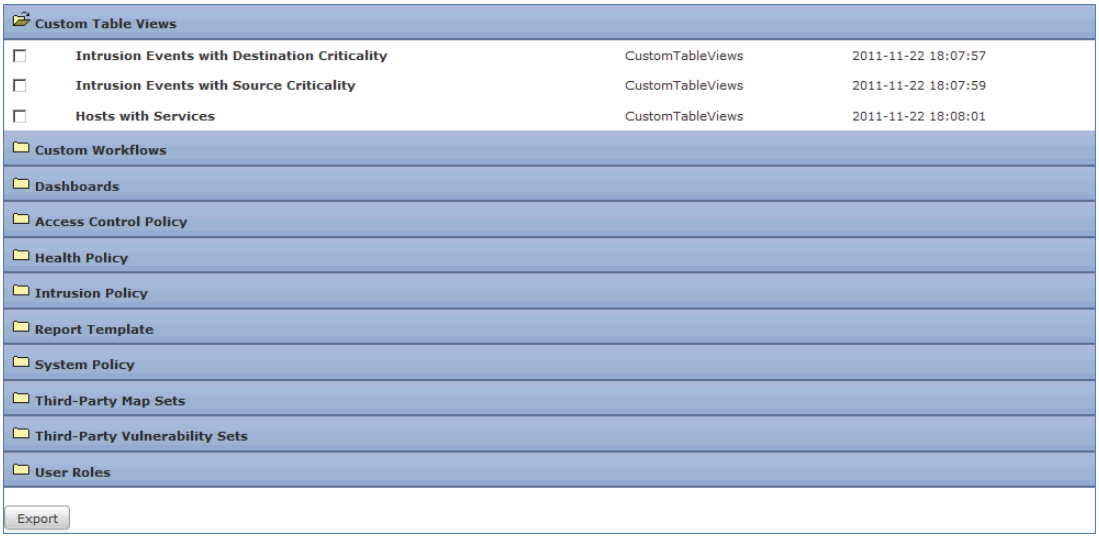
2. Export the configurations you want to import; see Exporting Configurations on page 2309.

3. On the appliance where you want to import the configurations, select **System > Tools > Import/Export**.

   The Import/Export page appears.

TIP! Click the collapse icon () next to a configuration type to collapse the list of configurations. Click the expand folder icon () next to a configuration type to reveal configurations.

The Defense Center version of the page is shown below with some configuration types collapsed.



4. Click **Upload Package**.

   The Upload Package page appears.

5. You have two options:
   - Type the path to the package you want to upload.
   - Click **Browse** to browse to locate the package.
6. Click **Upload**.

   The result of the upload depends on the contents of the package:
   - If the configurations in the package exactly match versions that already exist on your appliance, a message displays indicating that the versions already exist. The appliance has the most recent configurations, so you do not need to import them.
   - If there is a Sourcefire 3D System or (if applicable) rule update version mismatch between your appliance and the appliance where the package was exported, a message appears, indicating that you cannot import the package. Update the Sourcefire 3D System or the rule update version and attempt the process again.
   - If the package contains any configurations or rule versions that do not exist on your appliance, the Package Import page appears. Continue with the next step.
7. Select the configurations you want to import and click **Import**.

   The import process resolves, with the following results:
   - If the configurations you import do not have previous revisions on your appliance, the import completes automatically and a success message appears. Skip the rest of the procedure.
   - If you are importing an access control policy that includes security zones, the Access Control Import Resolution page appears. Continue with step 8.
   - If the configurations you import do have previous revisions on your appliance, the Import Resolution page appears. Continue with step 9.
8. Next to each incoming security zone, select an existing local security zone of a matching type to map to and click **Import**.

   Return to step 7.
9. Expand each configuration and select the appropriate option:
   - To keep the configuration on your appliance, select **Keep existing**.
   - To replace the configuration on your appliance with the imported configuration, select **Replace existing**.

- To keep the newest configuration, select **Keep newest**.
- To save the imported configuration as a new configuration, select **Import as new** and, optionally, edit the configuration name.

  If you are importing an access control policy that includes a file policy with either the clean list or custom detection list enabled, the **Import as new** option is not available.
- If you are importing an access control policy or saved search that includes a dependent object, either accept the suggested name or rename the object. The system always imports these dependent objects as new. You do not have the option to keep or to replace existing objects. Note that the system treats objects and object groups in the same manner.

10. Click **Import**.

    The configurations are imported.

APPENDIX B
PURGING DISCOVERY DATA FROM THE DATABASE

You can use the Discovery Data Purge page to purge files from the network discovery and user discovery event databases. Note that when you purge a database, the appropriate process is restarted.

WARNING! Purging a database removes the data you specify from the Defense Center. After the data is deleted, it **cannot** be recovered.

To purge the network and user discovery database:

ACCESS: Admin/Any Security Analyst

1. Select **System > Tools > Data Purge**.

   The Data Purge page appears.

2. Under **Network Discovery**, perform any or all of the following:
   - Select **Network Discovery Events** to remove all network discovery events from the database.
   - Select **Hosts** to remove all hosts and Indications of Compromise flags from the database.
   - Select **User Activity** to remove all user events from the database.
   - Select **User Identities** to remove all user login and user history data from the database.

3. Under **Connections**, perform any or all of the following:
   - Select **Connection Events** to remove all connection data from the database.
   - Select **Connection Summary Events** to remove all connection summary data from the database.
   - Select **Security Intelligence Events** to remove all Security Intelligence data from the database.

IMPORTANT! Selecting **Connection Events** does not remove Security Intelligence events; connections with Security Intelligence data will still appear in the Security Intelligence event viewer. Correspondingly, selecting **Security Intelligence Events** does not remove connection events with associated Security Intelligence data.

4. Click **Purge Selected Events**.

   The items are purged and the appropriate processes are restarted.

APPENDIX C
VIEWING THE STATUS OF LONG-RUNNING TASKS

Some tasks that you can perform on the Sourcefire 3D System, such as applying a policy or installing updates, do not complete instantly and require some time to run. You can check the progress of these long-running tasks in the task queue. The task queue also reports when they are successfully or unsuccessfully resolved.

For more information, see the following sections:

- Viewing the Task Queue on page 2321
- Managing the Task Queue on page 2323

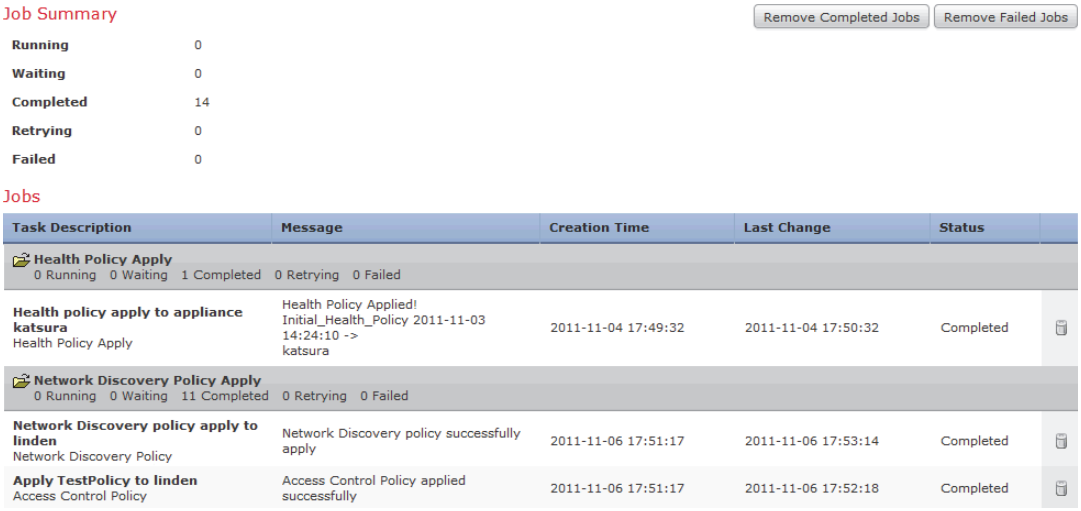
Viewing the Task Queue

LICENSE: Any

When you perform long-running tasks, such as applying a policy or installing updates, the status of these tasks is reported in the task queue. The task queue provides information about complex tasks and reports when they are complete.

You view the task queue on the Task Status page, which automatically refreshes every 10 seconds. You can always see the status of tasks that you initiated. If your user account has the Administrator user role, or a user role with the **View Other Users' Tasks** permission enabled, you can see the status of every task,

regardless of who initiated it. For more information on configuring user roles, see Configuring User Roles on page 1981.



The Job Summary section displays the state of the tasks listed on the page, as described in the following Task Queue Task Types table.

Task Queue Task Types

Task Type	Description
Running	The number of tasks currently in progress.
Waiting	The number of tasks waiting for an in-progress task to complete before running.
Completed	The number of tasks that completed successfully.
Retrying	The number of tasks that are automatically retrying. Note that not all tasks are permitted to try again.
Stopped	The number of tasks that were interrupted due to a system update. Stopped tasks cannot be resumed; you must manually delete them from the task queue.
Failed	The number of tasks that did not complete successfully.

The Jobs section provides information about each task, including a brief description, when the task was launched, the current status of the task, and when the status last changed. Tasks of the same type, such as Network Discovery Policy Apply, appear together in a task group.

To make sure that the Task Status page loads quickly, once per week, the Sourcefire 3D System removes from the queue all completed, failed, and stopped tasks that are over a month old, as well the oldest tasks from any task group that contains over 1000 tasks. You can also manually remove tasks from the queue;

see Managing the Task Queue for directions.

To view the task queue:

Access: Admin/Maint/Network Admin/Security Approver/Security Analyst

▶ You have two options:

- If you manually launched the task, click the **Task Status** link in the notification box that appeared when you launched the task.

  The Task Status page appears in a pop-up window.

- If you scheduled a task, or if a task was launched from a page you are not viewing, select **System > Monitoring > Task Status**.

  The Task Status page appears.

For information on the actions you can perform on the Task Status page, see Managing the Task Queue.

Managing the Task Queue

License: Any

If your user account is assigned the Administrator, Maintenance User, Network Admin, Security Approver, or Security Analyst user role, there are several actions you can perform while viewing the task queue (see Viewing the Task Queue on page 2321), as described in the following table.

Task Queue Actions

To...	You can...
remove all completed tasks from the task queue	click **Remove Completed Jobs**.
remove all failed tasks from the task queue	click **Remove Failed Jobs**.
remove a single task from the task queue	click the delete icon ( ) next to the task you want to delete. Note that you cannot delete a running task. If you need to delete a running task (for example, if a task repeatedly fails), contact Sourcefire Support.
collapse a task group and hide tasks	click the open folder icon ( ) next to the expanded task group.
expand a task group and view tasks	click the closed folder icon ( ) next to the collapsed task group.

APPENDIX D
COMMAND LINE REFERENCE

This reference explains the command line interface (CLI) for Sourcefire systems. You can use the CLI to view, configure, and troubleshoot your Sourcefire systems.

IMPORTANT! The command line interface is not supported on Defense Centers, Series 2 appliances, or Sourcefire Software for X-Series.

There are numerous CLI modes, such as `show` and `configuration`, that contain sets of commands beginning with the mode name. You may enter a mode and then enter valid commands within that mode, or you may enter an entire full command from any mode. For example, to display information about a user account called Analyst1, you can enter the following at the CLI prompt:

```
show user Analyst1
```

If you have previously entered `show` mode, enter the following at the CLI prompt:

```
user Analyst1
```

Within each mode, the commands available to a user depend on the user's CLI access. When you create a user account, you can assign it one of the following CLI access levels:

- Basic

  The user has read-only access and cannot run commands that impact system performance.

- Configuration

  The user has read-write access and can run commands that impact system performance.

- None

  The user is unable to log in to the shell.

On Series 3 devices, you can assign command line permissions on the User Management page in the web interface; see Managing Users on page 1923 for more information. On virtual devices, you assign command line permissions through the CLI itself.

IMPORTANT! If you reboot a Series 3 device and then log in to the CLI as soon as you are able, any commands you execute are not recorded in the audit log until the web interface is available.

Note that CLI commands are case-insensitive with the exception of parameters whose text is not part of the CLI framework, such as user names and search filters.

For information about logging into the command line, see Logging into the Appliance on page 64.

The following sections describe the CLI commands:

Basic CLI Commands

The basic CLI commands provide the ability to interact with the CLI. These commands do not affect the operation of the device. Basic commands are available to all CLI users.

The following sections describe the basic commands:

configure password

Allows the current user to change their password. After issuing the command, the CLI prompts the user for their current (or old) password, then prompts the user to enter the new password twice.

Access

Basic

Syntax

```
configure password
```

Example

```
> configure password
Enter current password:
Enter new password:
Confirm new password:
```

end

Returns the user to the default mode. (Moves the user up to the default mode from any lower-level CLI context.)

Access

Basic

Syntax

```
end
```

Example

```
configure network ipv4> end
>
```

exit

Moves the CLI context up to the next highest CLI context level. Issuing this command from the default mode logs the user out of the current CLI session, and is equivalent to issuing the `logout` CLI command.

Access

Basic

Syntax

```
exit
```

Example

```
configure network ipv4> exit
configure network>
```

help

Displays an overview of the CLI syntax.

Access

Basic

Syntax

```
help
```

Example

```
> help
```

history

Displays the command line history for the current session.

Access

Basic

Syntax

```
history limit
```

where *limit* sets the size of the history list. To set the size to unlimited, enter zero.

Example

```
history 25
```

logout

Logs the current user out of the current CLI console session.

Access

Basic

Syntax

```
logout
```

Example

```
> logout
```

? (question mark)

Displays context-sensitive help for CLI commands and parameters. Use the question mark (?) command as follows:

- To display help for the commands that are available within the current CLI context, enter a question mark (?) at the command prompt.
- To display a list of the available commands that start with a particular character set, enter the abbreviated command immediately followed by a question mark (?).
- To display help for a command's legal arguments, enter a question mark (?) in place of an argument at the command prompt.

Note that the question mark (?) is not echoed back to the console.

Access

Basic

Syntax

```
?
abbreviated_command ?
command [arguments] ?
```

Example

```
> ?
```

?? (double question marks)

Displays detailed context-sensitive help for CLI commands and parameters.

Access

Basic

Syntax

```
??
abbreviated_command end??
command [arguments] ??
```

Example

```
> configure manager add ??
```

Show Commands

Show commands provide information about the state of the device. These commands do not change the operational mode of the device and running them has minimal impact on system operation. Most show commands are available to

all CLI users; however, only users with configuration CLI access can issue the `show user` command.

The following sections describe the show commands:

access-control-config

Displays the currently applied access control configurations, including logging settings, Security Intelligence settings, file and malware detection limits (by file size), advanced settings, HTTP Response page content, all enabled access control rules, source ports for access control rules, variable set data, destination port data (including type and code for ICMP entries) and the number of connections that matched each access control rule (hit counts).

Access

Basic

Syntax

```
show access-control-config
```

Example

```
> show access-control-config
```

alarms

Displays currently active (failed/down) hardware alarms on the device. This command is not available on virtual devices.

Access

Basic

Syntax

```
show alarms
```

Example

```
> show alarms
```

arp-tables

Displays the Address Resolution Protocol tables applicable to your network. This command is not available on virtual devices.

Access

Basic

Syntax

```
show arp-tables
```

Example

```
> show arp-tables
```

audit-log

Displays the audit log in reverse chronological order; the most recent audit log events are listed first.

Access

Basic

Syntax

```
show audit-log
```

Example

```
> show audit-log
```

bypass

Lists the inline sets in use and shows the bypass mode status of those sets, either normal or bypass. This command is not available on virtual devices.

Access

Basic

Syntax

```
show bypass
```

Example

```
> show bypass
```

clustering

Displays information about device clustering configuration, status, and member stacks. This command is not available on virtual devices.

Access

Basic

config

Displays the clustering configuration on the device.

Syntax

```
show clustering config
```

Example

```
> show clustering config
```

clustering ha-statistics

Displays state sharing statistics for a device in a cluster.

Access

Basic

Syntax

```
show clustering ha-statistics
```

Example

```
> show clustering ha-statistics
```

cpu

Displays the current CPU usage statistics appropriate for the platform for all CPUs on the device. For managed devices, the following values are displayed:

- CPU

  Processor number.
- Load

  The CPU utilization, represented as a number from 0 to 100. 0 is not loaded and 100 is completely loaded.

For virtual devices, the following values are displayed:

- CPU

  Processor number.
- %user

  Percentage of CPU utilization that occurred while executing at the user level (application).
- %nice

  Percentage of CPU utilization that occurred while executing at the user level with nice priority.

- %sys

  Percentage of CPU utilization that occurred while executing at the system level (kernel). This does not include time spent servicing interrupts or softirqs. A softirq (software interrupt) is one of up to 32 enumerated software interrupts that can run on multiple CPUs at once.
- %iowait

  Percentage of time that the CPUs were idle when the system had an outstanding disk I/O request.
- %irq

  Percentage of time spent by the CPUs to service interrupts.
- %soft

  Percentage of time spent by the CPUs to service softirqs.
- %steal

  Percentage of time spent in involuntary wait by the virtual CPUs while the hypervisor was servicing another virtual processor.
- %guest

  Percentage of time spent by the CPUs to run a virtual processor.
- %idle

  Percentage of time that the CPUs were idle and the system did not have an outstanding disk I/O request.

Access

Basic

Syntax

```
show cpu [procnum]
```

where *procnum* is the number of the processor for which you want the utilization information displayed. Valid values are 0 to one less than the total number of processors on the system. If *procnum* is used for a managed device, it is ignored because for that platform, utilization information can only be displayed for all processors.

Example

```
> show cpu
```

database

The `show database` commands configure the device's management interface.

Access

Basic

processes

Displays a list of running database queries.

Access

Basic

Syntax

```
show database processes
```

Example

```
> show database processes
```

slow-query-log

Displays the slow query log of the database.

Access

Basic

Syntax

```
show database slow-query-log
```

Example

```
> show database slow-query-log
```

device-settings

Displays information about application bypass settings specific to the current device.

Access

Basic

Syntax

```
show device-settings
```

Example

```
> show device-settings
```

disk

Displays the current disk usage.

Access

Basic

Syntax

```
show disk
```

Example

```
> show disk
```

disk-manager

Displays detailed disk usage information for each part of the system, including silos, low watermarks, and high watermarks.

Access

Basic

Syntax

```
show disk-manager
```

Example

```
> show disk-manager
```

dns

Displays the current DNS server addresses and search domains.

Access

Basic

Syntax

```
show dns
```

Example

```
> show dns
```

expert

Invokes the shell.

Access

Basic

Syntax

```
expert
```

Example

```
> expert
```

fan-status

Displays the current status of hardware fans. This command is not available on virtual devices.

Access

Basic

Syntax

```
show fan-status
```

Example

```
> show fan-status
```

fastpath-rules

Displays the currently configured fastpath rules. This command is not available on virtual devices.

Access

Basic

Syntax

```
show fastpath-rules
```

Example

```
> show fastpath-rules
```

gui

Displays the current state of the web interface. This command is not available on virtual devices.

Access

Basic

Syntax

```
show gui
```

Example

```
> show gui
```

hostname

Displays the device's hostname and appliance UUID.

Access

Basic

Syntax

```
show hostname
```

Example

```
> show hostname
```

hyperthreading

Displays whether hyperthreading is enabled or disabled.

Access

Basic

Syntax

```
show hyperthreading
```

Example

```
> show hyperthreading
```

inline-sets

Displays configuration data for all inline security zones and associated interfaces.

Access

Basic

Syntax

```
show inline-sets
```

Example

```
> show inline-sets
```

interfaces

If no parameters are specified, displays a list of all configured interfaces. If a parameter is specified, displays detailed information about the specified interface.

Access

Basic

Syntax

```
show interfaces [interface]
```

where *interface* is the specific interface for which you want the detailed information.

Example

```
> show interfaces
```

lcd

Displays whether the LCD hardware display is enabled or disabled. This command is not available on virtual devices.

Access

Basic

Syntax

```
show lcd
```

Example

```
> show lcd
```

link-state

Displays type, link, speed, duplex state, and bypass mode of the ports on the device.

Access

Basic

Syntax

```
show link-state
```

Example

```
> show link-state
```

log-ips-connection

Displays whether the logging of connection events that are associated with logged intrusion events is enabled or disabled.

Access

Basic

Syntax

```
show log-ips-connection
```

Example

```
> show log-ips-connection
```

managers

Displays the configuration and communication status of the Defense Center. Registration key and NAT ID are only displayed if registration is pending. If a device is registered to a high availability pair, information about both managing Defense Centers is displayed. If a device is configured as a secondary device in a stacked configuration, information about both the managing Defense Center and the primary device is displayed.

Access

Basic

Syntax

```
show managers
```

Example

```
> show managers
```

memory

Displays the total memory, the memory in use, and the available memory for the device.

Access

Basic

Syntax

```
show memory
```

Example

```
> show memory
```

model

Displays model information for the device.

Access

Basic

Syntax

```
show model
```

Example

```
> show model
```

mpls-depth

Displays the number of MPLS layers configured on the management interface, from 0 to 6. This command is not available on virtual devices.

Access

Basic

Syntax

```
show mpls-depth
```

Example

```
> show mpls-depth
```

NAT

The `show nat` commands display NAT data and configuration information for the management interface. This command is not available on virtual devices.

Access

Basic

active-dynamic

Displays NAT flows translated according to dynamic rules. These entries are displayed when a flow matches a rule, and persist until the rule has timed out. Therefore, the list can be inaccurate.

Syntax

```
show nat active-dynamic
```

Example

```
> show nat active-dynamic
```

active-static

Displays NAT flows translated according to static rules. These entries are displayed as soon as you apply the rule to the device, and the list does not indicate active flows that match a static NAT rule.

Syntax

```
show nat active-static
```

Example

```
> show nat active-static
```

allocators

Displays information for all NAT allocators, the pool of translated addresses used by dynamic rules

Syntax

```
show nat allocators
```

Example

```
> show nat allocators
```

config

Displays the current NAT policy configuration for the management interface.

Syntax

```
show nat config
```

Example

```
> show nat config
```

dynamic-rules

Displays dynamic NAT rules that use the specified allocator ID.

Syntax

```
show nat dynamic-rules allocator_id
```

Example

```
> show nat dynamic-rules 9
```

where *allocator_id* is a valid allocator ID number.

flows

Displays the number of flows for rules that use the specified allocator ID.

Syntax

```
show nat flows allocator-id
```

Example

```
> show nat flows 81
```

where *allocator_id* is a valid allocator ID number.

static-rules

Displays all static NAT rules.

Syntax

```
show nat static-rules
```

Example

```
> show nat static-rules
```

network

Displays the IPv4 and IPv6 configuration of the management interface, its MAC address, and HTTP proxy address, port, and username if configured.

Access

Basic

Syntax

```
show network
```

Example

```
> show network
```

network-modules

Displays all installed modules and information about them, including serial numbers. This command is not available on virtual devices.

Access

Basic

Syntax

```
show network-modules
```

Example

```
> show network-modules
```

ntp

Displays the ntp configuration.

Access

Basic

Syntax

```
show ntp
```

Example

```
> show ntp
```

perfstats

Displays performance statistics for the device.

Access

Basic

Syntax

```
show perfstats
```

Example

```
> show perfstats
```

portstats

Displays port statistics for all installed ports on the device. This command is not available on virtual devices.

Access

Basic

Syntax

```
show portstats [copper | fiber | internal | external | all]
```

where `copper` specifies for all copper ports, fiber specifies for all fiber ports, internal specifies for all internal ports, external specifies for all external (copper and fiber) ports, and all specifies for all ports (external and internal).

Example

```
> show portstats fiber
```

power-supply-status

Displays the current state of hardware power supplies. This command is not available on virtual devices.

Access

Basic

Syntax

```
show power-supply-status
```

Example

```
> show power-supply-status
```

process-tree

Displays processes currently running on the device, sorted in tree format by type.

Access

Basic

Syntax

```
show process-tree
```

Example

```
> show process-tree
```

processes

Displays processes currently running on the device, sorted by descending CPU usage.

Access

Basic

Syntax

```
show processes [sort-flag] [filter]
```

where `sort-flag` can be `-m` to sort by memory (descending order), `-u` to sort by username rather than the process name, or `verbose` to display the full name and path of the command. The *`filter`* parameter specifies the search term in the command or username by which results are filtered. The header row is still displayed.

Example

```
> show processes -u user1
```

routing-table

If no parameters are specified, displays routing information for all virtual routers. If parameters are specified, displays routing information for the specified router and, as applicable, its specified routing protocol type. All parameters are optional. This command is not available on virtual devices.

Access

Basic

Syntax

```
show routing-table [name] [ ospf | rip | static ]
```

where *`name`* is the name of the specific router for which you want information, and `ospf`, `rip`, and `static` specify the routing protocol type.

Example

```
> show routing-table vrouter1 static
```

serial-number

Displays the chassis serial number. This command is not available on virtual devices.

Access

Basic

Syntax

```
show serial-number
```

Example

```
> show serial-number
```

stacking

Shows the stacking configuration and position on managed devices; on devices configured as primary, also lists data for all secondary devices. For clustered stacks, this command also indicates that the stack is a member of a cluster. The user must use the web interface to enable or (in most cases) disable stacking; if stacking is not enabled, the command will return `Stacking not currently configured`. This command is not available on virtual devices.

Access

Basic

Syntax

```
show stacking
```

Example

```
> show stacking
```

summary

Displays a summary of the most commonly used information (version, type, UUID, and so on) about the device. For more detailed information, see the following `show` commands: version on page 2347, interfaces on page 2337, device-settings on page 2334, and access-control-config on page 2330.

Access

Basic

Syntax

```
show summary
```

Example

```
> show summary
```

time

Displays the current date and time in UTC and in the local time zone configured for the current user.

Access

Basic

Syntax

```
show time
```

Example

```
> show time
```

traffic-statistics

If no parameters are specified, displays details about bytes transmitted and received from all ports. If a port is specified, displays that information only for the specified port.

Access

Basic

Syntax

```
show traffic-statistics [port]
```

where `port` is the specific port for which you want information.

Example

```
> show traffic-statistics s1p1
```

user

Applicable to virtual devices only. Displays detailed configuration information for the specified user(s). The following values are displayed:

- Login — the login name
- UID — the numeric user ID
- Auth (`Local` or `Remote`) — how the user is authenticated
- Access (`Basic` or `Config`) — the user's privilege level
- Enabled (`Enabled` or `Disabled`) — whether the user is active
- Reset (`Yes` or `No`) — whether the user must change password at next login
- Exp (`Never` or a number) — the number of days until the user's password must be changed
- Warn (`N/A` or a number) — the number of days a user is given to change their password before it expires
- Str (`Yes` or `No`) — whether the user's password must meet strength checking criteria
- Lock (`Yes` or `No`) — whether the user's account has been locked due to too many login failures
- Max (`N/A` or a number) — the maximum number of failed logins before the user's account is locked

Access

Configuration

Syntax

```
show user username username username ...
```

where *`username`* specifies the name of the user and the usernames are space-separated.

Example

```
> show user jdoe
```

users

Applicable to virtual devices only. Displays detailed configuration information for all local users. The following values are displayed:

- Login — the login name
- UID — the numeric user ID
- Auth (`Local` or `Remote`) — how the user is authenticated
- Access (`Basic` or `Config`) — the user's privilege level
- Enabled (`Enabled` or `Disabled`) — whether the user is active
- Reset (`Yes` or `No`) — whether the user must change password at next login
- Exp (`Never` or a number) — the number of days until the user's password must be changed
- Warn (`N/A` or a number) — the number of days a user is given to change their password before it expires
- Str (`Yes` or `No`) — whether the user's password must meet strength checking criteria
- Lock (`Yes` or `No`) — whether the user's account is locked due to too many login failures
- Max (`N/A` or a number) — the maximum number of failed logins before the user's account is locked

Access

Configuration

Syntax

```
show users
```

Example

```
> show users
```

version

Displays the product version and build. If the *detail* parameter is specified, displays the versions of additional components.

Access

Basic

Syntax

```
show version [detail]
```

Example

```
> show version
```

virtual-routers

If no parameters are specified, displays a list of all currently configured virtual routers with DHCP relay, OSPF, and RIP information. If parameters are specified, displays information for the specified router, limited by the specified route type. All parameters are optional. This command is not available on virtual devices.

Access

Basic

Syntax

```
show virtual-routers [ dhcprelay | ospf | rip ] [name]
```

where `dhcprelay`, `ospf`, and `rip` specify for route types, and *name* is the name of the specific router for which you want information. If you specify `ospf`, you can then further specify `neighbors`, `topology`, or `lsadb` between the route type and (if present) the router name.

Example

```
> show virtual-routers ospf VRouter2
```

virtual-switches

If no parameters are specified, displays a list of all currently configured virtual switches. If parameters are specified, displays information for the specified switch. This command is not available on virtual devices.

Access

Basic

Syntax

```
show virtual-switches [name]
```

Example

```
> show virtual-switches Vswitch1
```

VPN

The `show VPN` commands display VPN status and configuration information for VPN connections. This command is not available on virtual devices.

Access

Basic

config

Displays the configuration of all VPN connections.

Syntax

```
show vpn config
```

Example

```
> show vpn config
```

config by virtual router

Displays the configuration of all VPN connections for a virtual router.

Syntax

```
show vpn config [virtual router]
```

Example

```
> show vpn config VRouter1
```

status

Displays the status of all VPN connections.

Syntax

```
show vpn status
```

Example

```
> show vpn status
```

status by virtual router

Displays the status of all VPN connections for a virtual router.

Syntax

```
show vpn status [virtual router]
```

Example

```
> show vpn status VRouter1
```

counters

Displays the counters for all VPN connections.

Syntax

```
show vpn counters
```

Example

```
> show vpn counters
```

counters by virtual router

Displays the counters of all VPN connections for a virtual router.

Syntax

```
show vpn counters [virtual router]
```

Example

```
> show vpn counters VRouter1
```

Configuration Commands

The configuration commands enable the user to configure and manage the system. These commands affect system operation; therefore, with the exception of Basic-level **`configure password`**, only users with configuration CLI access can issue these commands.

The following sections describe the configuration commands:

clustering

Disables or configures bypass for clustering on the device. This command is not available on virtual devices or on devices configured as secondary stack members.

Access

Configuration

Syntax

```
configure clustering {disable | bypass}
```

Example

```
> configure clustering disable
```

bypass

Opens or closes the bypass mode of an inline pair. This command is not available on virtual devices.

Access

Configuration

Syntax

```
configure bypass {open | close} {interface}
```

where *interface* is the name of either hardware port in the inline pair.

Example

```
> configure bypass open s1p1
```

gui

Enables or disables the device web interface, including the streamlined upgrade web interface that appears during major updates to the system. This command is not available on virtual devices.

Access

Configuration

Syntax

```
configure gui {enable | disable}
```

Example

```
> configure gui disable
```

lcd

Enables or disables the LCD display on the front of the device. This command is not available on virtual devices.

Access

Configuration

Syntax

```
configure lcd {enable | disable}
```

Example

```
> configure lcd disable
```

log-ips-connections

Enables or disables logging of connection events that are associated with logged intrusion events.

Access

Configuration

Syntax

```
configure log-ips-connections {enable | disable}
```

Example

```
> configure log-ips-connections disable
```

manager

The `configure manager` commands configure the device's connection to its managing Defense Center.

Access

Configuration

add

Configures the device to accept a connection from a managing Defense Center. This command works only if the device is not actively managed.

A unique alphanumeric registration key is always required to register a device to a Defense Center. In most cases, you must provide the hostname or the IP address along with the registration key. However, if the device and the Defense Center are separated by a NAT device, you must enter a unique NAT ID, along with the registration key, and specify `DONTRESOLVE` instead of the hostname.

Syntax

```
configure manager add {hostname | IPv4_address |
IPv6_address | DONTRESOLVE} regkey [nat_id]
```

where {*hostname* | *IPv4_address* | *IPv6_address* | DONTRESOLVE} specifies the DNS host name or IP address (IPv4 or IPv6) of the Defense Center that manages this device. If the Defense Center is not directly addressable, use DONTRESOLVE. If you use DONTRESOLVE,*nat_id* is required. *regkey* is the unique alphanumeric registration key required to register a device to the Defense Center. *nat_id* is an optional alphanumeric string used during the registration process between the Defense Center and the device. It is required if the hostname is set to DONTRESOLVE.

Example

```
> configure manager add DONTRESOLVE abc123 efg456
```

delete

Removes the Defense Center's connection information from the device. This command only works if the device is not actively managed.

Syntax

```
configure manager delete
```

Example

```
> configure manager delete
```

mpls-depth

Configures the number of MPLS layers on the management interface. This command is not available on virtual devices.

Access

Configuration

Syntax

```
configure mpls-depth {depth}
```

where *depth* is a number between 0 and 6.

Example

```
> configure mpls-depth 3
```

network

The `configure network` commands configure the device's management interface.

Access

Configuration

dns searchdomains

Replaces the current list of DNS search domains with the list specified in the command.

Syntax

```
configure network dns searchdomains {searchlist}
```

where *searchlist* is a comma-separated list of domains.

Example

```
> configure network dns searchdomains foo.bar.com,bar.com
```

dns servers

Replaces the current list of DNS servers with the list specified in the command.

Syntax

```
configure nework dns servers {dnslist}
```

where *dnslist* is a comma-separated list of DNS servers.

Example

```
> configure network dns servers 10.123.1.10,10.124.1.10
```

hostname

Sets the hostname for the device.

Syntax

```
configure network hostname {name}
```

where *name* is the new hostname.

Example

```
> configure network hostname sfrocks
```

http-proxy

On Series 3 and virtual devices, configures an HTTP proxy. After issuing the command, the CLI prompts the user for the HTTP proxy address and port, whether proxy authentication is required, and if it is required, the proxy username, proxy password, and confirmation of the proxy password.

Use this command on a virtual device to configure an HTTP proxy server so the virtual device can submit files to the Sourcefire cloud for dynamic analysis.

Syntax

```
configure network http-proxy
```

Example

```
> configure network http-proxy
Manual proxy configuration
Enter HTTP Proxy address:
Enter HTTP Proxy Port:
Use Proxy Authentication? (y/n) [n]:
Enter Proxy Username:
Enter Proxy Password:
Confirm Proxy Password:
```

http-proxy-disable

On Series 3 and virtual devices, deletes any HTTP proxy configuration.

Syntax

```
configure network http-proxy-disable
```

Example

```
> configure network http-proxy-disable
Are you sure that you wish to delete the current http-proxy
configuration? (y/n):
```

ipv4 delete

Disables the IPv4 configuration of the device's management interface.

Syntax

```
configure network ipv4 delete
```

Example

```
> configure network ipv4 delete
```

ipv4 dhcp

Sets the IPv4 configuration of the device's management interface to DHCP. The management interface communicates with the DHCP server to obtain its configuration information.

Syntax

```
configure network ipv4 dhcp
```

Example

```
> configure network ipv4 dhcp
```

ipv4 manual

Manually configures the IPv4 configuration of the device's management interface.

Syntax

```
configure network ipv4 manual ipaddr netmask gw
```

where *ipaddr* is the IP address, *netmask* is the subnet mask, and *gw* is the IPv4 address of the default gateway.

Example

```
> configure network ipv4 manual 10.123.1.10 255.255.0.0
10.123.1.1
```

ipv6 delete

Disables the IPv6 configuration of the device's management interface.

Syntax

```
configure network ipv6 delete
```

Example

```
> configure network ipv6 delete
```

ipv6 dhcp

Sets the IPv6 configuration of the device's management interface to DHCP. The management interface communicates with the DHCP server to obtain its configuration information.

Syntax

```
configure network ipv6 dhcp
```

Example

```
> configure network ipv6 dhcp
```

ipv6 router

Sets the IPv6 configuration of the device's management interface to Router. The management interface communicates with the IPv6 router to obtain its configuration information.

Syntax

```
configure network ipv6 router
```

Example

```
> configure network ipv6 router
```

ipv6 manual

Manually configures the IPv6 configuration of the device's management interface.

Syntax

```
configure network ipv6 manual ip6addr/ip6prefix [ip6gw]
```

where *ip6addr/ip6prefix* is the IP address and prefix length and ip6*gw* is the IPv6 address of the default gateway.

Example

```
> configure network ipv6 manual
2001:DB8:3ffe:1900:4545:3:200:f8ff:fe21:67cf 64
```

management-port

Sets the value of the device's TCP management port.

Syntax

```
configure network management-port number
```

where *number* is the management port value you want to configure.

Example

```
> configure network management-port 8500
```

password

Allows the current user to change their password. After issuing the command, the CLI prompts the user for their current (or old) password, then prompts the user to enter the new password twice.

Access

Basic

Syntax

```
configure password
```

Example

```
> configure password
Enter current password:
Enter new password:
Confirm new password:
```

stacking disable

On managed devices, removes any stacking configuration present on that device: on devices configured as primary, the stack is removed entirely; on devices configured as secondary, that device is removed from the stack. This command is not available on virtual devices, and you cannot use it to break a clustered stack.

Use this command when you cannot establish communication with appliances higher in the stacking hierarchy. If the Defense Center is available for communication, a message appears instructing you to use the Defense Center web interface instead; likewise, if you enter `stacking disable` on a device configured as secondary when the primary device is available, a message appears instructing you to enter the command from the primary device.

Access

Configuration

Syntax

```
configure stacking disable
```

Example

```
> configure stacking disable
```

user

Applicable only to virtual devices, the `configure user` commands manage the device's local user database.

Access

Configuration

access

Modifies the access level of the specified user. This command takes effect the next time the specified user logs in.

Syntax

```
configure user access username [basic | config]
```

Example

```
> configure user access jdoe basic
```

where *username* specifies the name of the user for which you want to modify access, `basic` indicates basic access, and `config` indicates configuration access.

add

Creates a new user with the specified name and access level. This command prompts for the user's password.

Syntax

```
configure user add username [basic | config]
```

where *username* specifies the name of the new user, `basic` indicates basic access, and `config` indicates configuration access.

Example

```
> configure user add jdoe basic
Enter new password for user jdoe:
Confirm new password for user jdoe:
```

aging

Forces the expiration of the user's password.

Syntax

```
configure user aging username max_days warn_days
```

where *username* specifies the name of the user, *max_days* indicates the maximum number of days that the password is valid, and *warn_days* indicates the number of days that the user is given to change the password before it expires.

Example

```
> configure user aging jdoe 100 3
```

delete

Deletes the user and the user's home directory.

Syntax

```
configure user delete username
```

where *username* specifies the name of the user.

Example

```
> configure user delete jdoe
```

disable

Disables the user. Disabled users cannot login.

Syntax

```
configure user disable username
```

where *username* specifies the name of the user.

Example

```
> configure user disable jdoe
```

enable

Enables the user.

Syntax

```
configure user enable username
```

where *username* specifies the name of the user.

Example

```
> configure user enable jdoe
```

forcereset

Forces the user to change their password the next time they login. When the user logs in and changes the password, strength checking is automatically enabled.

Syntax

```
configure user forcereset username
```

where *username* specifies the name of the user.

Example

```
> configure user forcereset jdoe
```

maxfailedlogins

Sets the maximum number of failed logins for the specified user.

Syntax

```
configure user maxfailedlogins username number
```

where *username* specifies the name of the user and *number* specifies the maximum number of failed logins.

Example

```
> configure user maxfailedlogins jdoe 3
```

password

Sets the user's password. This command prompts for the user's password.

Syntax

```
configure user password username
```

where *username* specifies the name of the user.

Example

```
> configure user pasword jdoe
Enter new password for user jdoe:
Confirm new password for user jdoe:
```

strengthcheck

Enables or disables the strength requirement for a user's password. When a user's password expires or if the configure user forcereset command is used, this requirement is automatically enabled the next time the user logs in.

Syntax

```
configure user strengthcheck username {enable | disable}
```

where *username* specifies the name of the user, `enable` sets the requirement for the specified users password, and `disable` removes the requirement for the specified user's password.

Example

```
> configure user strengthcheck jdoe enable
```

unlock

Unlocks a user that has exceeded the maximum number of failed logins.

Syntax

```
configure user unlock username
```

where *username* specifies the name of the user.

Example

```
> configure user unlock jdoe
```

System Commands

The system commands enable the user to manage system-wide files and access control settings. Only users with configuration CLI access can issue commands in system mode.

The following sections describe the system commands:

access-control

The `system access-control` commands enable the user to manage the access control configuration on the device.

Access

Configuration

archive

Saves the currently applied access control policy as a text file on `/var/common`.

Syntax

```
system access-control archive
```

Example

```
> system access-control archive
```

clear-rule-counts

Resets the access control rule hit count to 0.

Syntax

```
system access-control clear-rule-counts
```

Example

```
> system access-control clear-rule-counts
```

rollback

Reverts the system to the previously applied access control configuration. You cannot use this command with clustered or stacked devices.

Syntax

```
system access-control rollback
```

Example

```
> system access-control rollback
```

disable-http-user-cert

Removes all HTTP user certification present on the system.

Access

Configuration

Syntax

```
system disable-http-user-cert
```

Example

```
> system disable-http-user-cert
```

file

The `system file` commands enable the user to manage the files in the common directory on the device.

Access

Configuration

copy

Uses FTP to transfer files to a remote location on the host using the login username. The local files must be located in the common directory.

Syntax

```
system file copy hostname username path filenames filenames
...
```

where *`hostname`* specifies the name or ip address of the target remote host, *`username`* specifies the name of the user on the remote host, *`path`* specifies the destination path on the remote host, and *`filenames`* specifies the local files to transfer; the file names are space-separated.

Example

```
> system file copy sfrocks jdoe /pub *
```

delete

Removes the specified files from the common directory.

Syntax

```
system file delete filenames filenames ...
```

where *filenames* specifies the files to delete; the file names are space-separated.

Example

```
> system file delete *
```

list

If no file names are specified, displays the modification time, size, and file name for all the files in the common directory. If file names are specified, displays the modification time, size, and file name for files that match the specified file names.

Syntax

```
system file list {filenames filenames ...}
```

where `filenames` specifies the files to display; the file names are space-separated.

Example

```
> system file list
```

secure-copy

Uses SCP to transfer files to a remote location on the host using the login username. The local files must be located in the `/var/common` directory.

Syntax

```
system file secure-copy hostname username path filenames
filenames ...
```

where *hostname* specifies the name or ip address of the target remote host, *username* specifies the name of the user on the remote host, *path* specifies the destination path on the remote host, and *filenames* specifies the local files to transfer; the file names are space-separated.

Example

```
> system file secure-copy 10.123.31.1 jdoe /tmp *
```

generate-troubleshoot

Generates troubleshooting data for analysis by Sourcefire.

Access

Configuration

Syntax

```
system generate-troubleshoot
```

This syntax displays a list of optional parameters to specify what troubleshooting data should be displayed.

Example

```
> system generate-troubleshoot
```

ldapsearch

Enables the user to perform a query of the specified LDAP server. Note that all parameters are required.

Access

Configuration

Syntax

```
system ldapsearch host port baseDN userDN basefilter
```

where *host* specifies the LDAP server domain, *port* specifies the LDAP server port, *baseDN* specifies the DN (distinguished name) that you want to search under, *userDN* specifies the DN of the user who binds to the LDAP directory, and *basefilter* specifies the record or records you want to search for.

Example

```
> system ldapsearch ldap.example.com 389 cn=users,
dc=example,dc=com cn=user1,cn=users,dc=example,dc=com,
cn=user2
```

lockdown-sensor

Removes the `expert` command and access to the bash shell on the device.

WARNING! This command is irreversible without a hotfix from Sourcefire Support. Use with care.

Access

Configuration

Syntax

```
system lockdown-sensor
```

Example

```
> system lockdown-sensor
```

nat rollback

Reverts the system to the previously applied NAT configuration. You cannot use this command with clustered or stacked devices.

Access

Configuration

Syntax

```
system nat rollback
```

Example

```
> system nat rollback
```

reboot

Reboots the device.

Access

Configuration

Syntax

```
system reboot
```

Example

```
> system reboot
```

restart

Restarts the device application.

Access

Configuration

Syntax

```
system restart
```

Example

```
> system restart
```

shutdown

Shuts down the device.

Access

Configuration

Syntax

```
system shutdown
```

Example

```
> system shutdown
```

APPENDIX E
THIRD-PARTY PRODUCTS

Sourcefire products contain certain third-party open source code products that are distributed for use in combination with the Sourcefire products. These products are free and distributed "as-is" under the terms set forth in their respective license agreements. The following table lists the major open source code products and applicable license agreements that are distributed by Sourcefire for use in combination with the Sourcefire products.

Open Source Software Licensing

OPEN SOURCE SOFTWARE	LICENSE AGREEMENT
Apache HTTPD Web Server 2.4.3	Apache License
Linux Kernel 2.6.32.24 (Series 2)	GNU General Public License Version 2 (GPLv2)
Linux Kernel 2.6.35.14 (Series 3)	GNU General Public License Version 2 (GPLv2)
Perl 5.10.1 and related modules	Perl Artistic License
Snort 2.9.6	GNU General Public License Version 2 (GPLv2)

A complete list of all third-party open source code products and the full text of all applicable license agreements that are distributed with the Sourcefire products can be obtained by logging into the product command line and viewing the following:

```
/usr/share/license-files
```

Appendix E

If you would like to receive the source code to any of the third-party open source code products used in combination with the Sourcefire products, you may do so by submitting a request to the Sourcefire Support Site.

APPENDIX F
END USER LICENSE AGREEMENT

SOURCEFIRE NETWORK SECURITY PRODUCTS

IMPORTANT: PLEASE READ THIS END USER LICENSE AGREEMENT CAREFULLY.

THIS END USER LICENSE AGREEMENT IS A LEGAL AGREEMENT BETWEEN YOU AND SOURCEFIRE LLC OR ONE OF ITS DESIGNATED SUBSIDIARIES OR AFFILIATES LICENSING THE LICENSED MATERIALS TO YOU HEREUNDER INSTEAD OF SOURCEFIRE LLC ("SOURCEFIRE"). SOURCEFIRE LLC IS A WHOLLY-OWNED SUBSIDIARY OF CISCO SYSTEMS, INC. THE TERMS AND CONDITIONS UNDER WHICH YOU MAY USE THE LICENSED MATERIALS ARE SET FORTH IN THIS END USER LICENSE AGREEMENT ("EULA"), IN ADDITION TO ANY OTHER TERMS AS MAY BE SET FORTH IN ANY SUPPLEMENTAL LICENSE AGREEMENT(S) WHICH MAY ACCOMPANY ANY SOURCEFIRE PRODUCTS (TOGETHER WITH THE EULA, THE "AGREEMENT"). BY DOWNLOADING, INSTALLING AND USING ANY OF THE SOURCEFIRE PRODUCTS, YOU ARE BINDING YOURSELF AND THE BUSINESS ENTITY THAT YOU REPRESENT (COLLECTIVELY, "YOU") TO THIS AGREEMENT AND AGREEING THAT THIS AGREEMENT WITH SOURCEFIRE IS ENFORCEABLE LIKE ANY WRITTEN CONTRACT SIGNED BY YOU.

IF YOU DO NOT AGREE TO ALL OF THE TERMS AND CONDITIONS CONTAINED IN THIS AGREEMENT, THEN SOURCEFIRE IS UNWILLING TO LICENSE THE LICENSED MATERIALS TO YOU, IN WHICH CASE YOU MAY NOT DOWNLOAD, INSTALL OR USE ANY OF THE LICENSED MATERIALS.

IF YOU DO NOT AGREE TO THE TERMS AND CONDITIONS OF THIS AGREEMENT DO NOT INITIATE USE OF THE PRODUCT. BY SELECTING "I ACCEPT," "OK," "CONTINUE," "YES," "NEXT" OR BY INSTALLING OR USING THE LICENSED MATERIALS IN ANY WAY, YOU ARE INDICATING YOUR

COMPLETE UNDERSTANDING AND ACCEPTANCE OF THE TERMS AND CONDITIONS OF THIS AGREEMENT. IF YOU DO NOT AGREE TO THE TERMS OF THIS AGREEMENT, DO NOT INSTALL OR USE THE PRODUCT.

This Agreement governs Your access and use of the Sourcefire Products, except to the extent there is a separate written agreement signed by both You and Sourcefire that expressly states that it governs Your use of the Sourcefire Products. In the event of a conflict between the provisions of such a written agreement and this Agreement, the order of precedence shall be (1) the separate signed agreement, and (2) this Agreement.

1. DEFINITIONS

The following capitalized terms shall have the following meanings in this EULA:

1.1. "Appliance" means any Sourcefire-branded network security appliance made available to You, consisting of Hardware and pre-installed Sourcefire Software and/or other Licensed Materials.

1.2. "Documentation" means written information contained in user manuals and technical specifications pertaining to the use of the Sourcefire Products made available by Sourcefire with the Sourcefire Products in any manner (including on CD-ROM, on-line or accessible within the Product).

1.3. "Hardware" means the hardware components of any Appliance on which Sourcefire Software is installed and runs.

1.4. "Laws" means, collectively, all international and national laws, treaties, statutes, ordinances, regulations and other types of government authority.

1.5. "Licensed Materials" means any Sourcefire Software, Documentation and Subscription Data licensed by Sourcefire to You hereunder.

1.6. "Party" or "Parties" means, individually each party hereto, and collectively all the parties to this Agreement.

1.7. "Products" means the Sourcefire Products and/or the Third Party Products.

1.8. "Reseller" means an authorized reseller or distributor of Sourcefire.

1.9 "Sourcefire Products" means the Appliance(s) and/or Licensed Materials.

1.10. "Sourcefire Software" means the machine-readable computer software programs licensed by Sourcefire to You hereunder including any software provided to You for use on a subscription, term or software-as-a-services (SaaS) basis, and all Updates to any of the foregoing.

1.11. "Subscription Data" means that data made available to You by Sourcefire for use with the Sourcefire Products including, but not limited to, URL data and IP address blacklists. Subscription Data may be made available separately from the software.

1.12 "Third Party Products" means any products or other materials made available to You for use with Sourcefire Products and which are not Sourcefire Products.

1.13. "Updates" means with respect to Licensed Materials any Sourcefire-approved periodic patches, bug-fixes, work-arounds, error corrections, enhancements, rules updates, vulnerability database updates, security enhancement updates and additions and other modifications thereto, or revised versions thereof, which may be made available from time to time.

Unless otherwise defined herein, the capitalized terms used in this EULA shall be defined in the context in which they are used.

2. YOUR PAYMENT OBLIGATIONS

In consideration for Your purchase of an Appliance and Your license to use the Licensed Materials, You agree to pay all amounts due or incurred by You, including all applicable taxes, as are specified in an invoice provided by Sourcefire or a Reseller, as applicable.

3. LICENSE GRANT

Subject to the terms and conditions of this Agreement, Sourcefire grants to You a limited, non-exclusive and non-transferable license to download, install and use for Your internal operations the Licensed Materials for which You have paid the required fees to Sourcefire or a Reseller, as applicable. Such Licensed Materials may be delivered to You pre-installed on an Appliance, made available to You separately via download by Sourcefire or otherwise made available on a subscription, term or software-as-a-service (SaaS) basis. In order to use the Products, You may be required to input a registration number, product authorization key or otherwise register such Products online at Sourcefire's designated website to obtain the necessary license key or license file. You shall own the Appliance that You purchase and the magnetic or other physical media upon which the Licensed Materials are originally or subsequently recorded or fixed, but Sourcefire and Sourcefire's licensors, as applicable, retain all title, copyright and other intellectual proprietary rights in, and ownership of, the Licensed Materials regardless of the media upon which the original or any copy may be recorded or fixed. You may make one (1) copy of the Licensed Materials solely for internal backup purposes. Sourcefire and its licensors expressly reserve any rights in Licensed Materials not granted herein.

4. SCOPE OF USE

If You purchased an Appliance, You may only use the Licensed Materials included on that Appliance for use on such Appliance. If Sourcefire Products are made available to You for use without an Appliance on a "virtual" basis, Your use of such Sourcefire Products may not exceed the applicable number of licenses purchased and other use limitations associated with the fees paid or payable by You for such use. If You purchased a license to use the Licensed Materials on a subscription or term basis, You may not deploy or use such Licensed Materials in a manner that exceeds the term of subscription, the permitted number of users, hosts or endpoints, or other subscription or term limitations associated with the applicable fees paid or payable by You.

5. LICENSE RESTRICTIONS

You agree not to directly or indirectly: (i) sell, lease, rent, distribute, sublicense, assign or transfer any of the Licensed Materials; (ii) reverse engineer, decompile, disassemble, decrypt or otherwise attempt to determine the source code of any of the Licensed Materials, except to the limited extent permitted by law; (iii) modify, make error corrections to or create derivative works based on the Licensed Materials; (iv) use any Licensed Materials for the benefit of any third parties (e.g., in an ASP, SaaS, outsourcing or service bureau relationship) or in any way other than in its intended manner, except as otherwise permitted by Sourcefire; (v) publish any results of benchmark tests run on the Sourcefire Software; (vi) remove, alter or obscure any proprietary or copyright notice, labels, or marks on the Hardware or within the Licensed Materials; (vii) disable or circumvent any access control or related security measure, process or procedure established with respect to the Appliance or any Licensed Materials or any other part thereof; (viii) create Internet "links" to the Subscription Data or "frame" or "mirror" the Subscription Data on any other server or wireless or Internet-based device; or (ix) utilize the Subscription Data in order to: (1) build a competitive product or service; (2) build a product using similar ideas, features, functions or graphics; (3) copy any ideas, features, functions or graphics; or (4) aggregate subscriptions to the Subscription Data, either by sublicensing or by rebranding of the Subscription.

You are responsible for all use of the Products obtained by You and for compliance with this Agreement; any breach of this Agreement by You or other user in connection with the use of those Products obtained by You shall be deemed to have been made by You.

6. INTELLECTUAL PROPERTY; TITLE

This Agreement does not transfer to You any title or any ownership right or interest in any Licensed Materials or in any other intellectual property rights of Sourcefire or Sourcefire's licensors. You acknowledge that the Appliance(s) and the Licensed Materials contain, embody and are based upon patented or patentable inventions, trade secrets, copyrights and other intellectual property rights owned by Sourcefire and its licensors. If You purchased an Appliance, title and risk of loss to each Appliance transfers to You when the Appliance is delivered to Sourcefire's designated carrier for shipment; Products are shipped FOB Sourcefire's designated shipping facility. If you purchased an Appliance from a Reseller, the terms of such purchase regarding price, title to the Appliance and delivery thereof are between You and such Reseller. If You purchased an Appliance directly from Sourcefire, the terms of such purchase are as set forth in the Sourcefire sales order submitted by You and accepted by Sourcefire. In all instances, Licensed Materials are licensed to You pursuant to this Agreement and not sold to You.

7. TECHNICAL SUPPORT

You may purchase technical support for Sourcefire Products by separately enrolling in Sourcefire's customer support plan (the "Support Plan") and paying Sourcefire or a Reseller the then-applicable customer support fee. Your rights and Sourcefire's obligations under the Support Plan are set forth in the Support Plan terms and conditions, a current copy of which is located at www.sourcefire.com/customer-support. All Updates received by You pursuant to the Support Plan shall be governed by, and licensed to You under, this Agreement.

8. CONFIDENTIALITY

As used herein, "Confidential Information" means any non-public technical or business information of either Party, including without limitation, the terms and conditions of this Agreement, any information relating to Sourcefire's techniques, algorithms, software, know-how and current or future product designs, financial information, procurement requirements, and manufacturing or business forecasts. Confidential Information does not include information that (i) is or becomes generally known to the public through no fault or breach of this Agreement by the receiving party; (ii) the receiving party can demonstrate by written evidence was rightfully in the receiving party's possession at the time of disclosure, without an obligation of confidentiality; (iii) is independently developed by the receiving party without use of or access to the disclosing party's Confidential Information or otherwise in breach of this Agreement; (iv) the receiving party rightfully obtains from a third party not under a duty of confidentiality and without restriction on use or disclosure; or (v) is required to be disclosed pursuant to, or by, any Laws, court order or other legal process to do so, provided that the receiving party shall, promptly upon learning that such disclosure is required, give written notice of such disclosure to the disclosing party. The party receiving Confidential Information will employ all reasonable measures to maintain the confidentiality of such Confidential Information, but in no event shall such measures be less than the measures the receiving party employs to protect its own confidential information. The party receiving the Confidential Information will limit the disclosure of the other party's Confidential Information to its employees and contractors with a bona fide need to access such Confidential Information in order to exercise its rights and obligations under this Agreement; provided that, all such employees and contractors are bound by a written non-disclosure agreement that contains restrictions at least as protective as those set forth herein. The Parties agree that the party disclosing Confidential Information will suffer irreparable harm in the event that the receiving party breaches any obligation under this Section 8 and that monetary damages will be inadequate to compensate the non-breaching party for such breach. In the event of a breach, or threatened breach, of any of the provisions of this Section 8, the non-breaching party, in addition to and not in limitation of any other rights, remedies or damages available to it at law or in equity, shall be entitled to seek a temporary restraining order, preliminary injunction and/or permanent injunction in order to prevent or to restrain any such breach.

9. INSTALLATION

You represent, warrant and covenant that You are solely responsible for the proper installation, configuration and management of the Appliance on which the Licensed Materials will be installed, as well as the installation of any separately provided Licensed Materials. You further understand and hereby acknowledge that the failure to properly configure and manage an Appliance, and the failure to properly install any separately provided Licensed Materials, may adversely affect the performance of the Appliance and the Licensed Materials. You represent, warrant and covenant that You will adhere to the recommended minimum requirements specified in the Documentation. Sourcefire shall have no obligation under this Agreement to the extent an Appliance or any separately provided Licensed Materials fails to substantially perform the functions described in the Documentation, in whole or in part, because (i) You fail to adhere to specified minimum operating requirements; (ii) Your separate hardware fails to perform properly; (iii) You improperly configured an Appliance; or (iv) the Licensed Materials had been improperly installed.

10. WARRANTY AND DISCLAIMER

Sourcefire warrants that, for a period of ninety (90) days from the date of initial shipment of the Appliance or, in the case of Sourcefire Software separately provided to You, the date the Sourcefire Software is made available to You for download or delivered on a fixed media (as the case may be, the "Software Warranty Period"), the unmodified Sourcefire Software will, under normal use, substantially perform the functions described in its Documentation. Sourcefire also warrants that for a period of one (1) year from the date of initial shipment of a new Appliance (the "Hardware Warranty Period") that the unmodified Hardware comprising such Appliance will, under normal use, be free of substantial defects in materials and workmanship. Neither of the aforementioned warranties apply if the Sourcefire Software or Appliance (i) has been altered, except by Sourcefire or its authorized representative; (ii) has not been installed, operated, repaired or maintained in accordance with the Documentation and/or instructions supplied by Sourcefire; (iii) has been subjected to abnormal physical or electrical stress, abnormal environmental conditions, misuse, negligence or accident by You; or (iv) is licensed for beta, evaluation, testing or demonstration purposes. If a court of competent jurisdiction determines that the statutory warranty periods of such jurisdiction apply rather than the Software Warranty Period and Hardware Warranty Periods referenced above, then such statutory warranty periods will control only in the event of a conflict with the terms of this Section 10.

EXCEPT AS EXPRESSLY WARRANTED IN THIS SECTION 10, THE SOURCEFIRE PRODUCTS (INCLUDING, ANY EVALUATION AND BETA PRODUCTS), AND ANY OTHER DOCUMENTATION, MATERIALS AND/OR DATA PROVIDED BY SOURCEFIRE ARE PROVIDED "AS IS" AND "WITH ALL FAULTS," AND SOURCEFIRE EXPRESSLY DISCLAIMS ALL OTHER WARRANTIES OF ANY KIND OR NATURE, WHETHER EXPRESS, IMPLIED OR STATUTORY, INCLUDING, BUT NOT LIMITED TO, ANY WARRANTIES OF OPERABILITY, CONDITION, TITLE, NON-INFRINGEMENT, NON-INTERFERENCE, QUIET ENJOYMENT, VALUE,

ACCURACY OF DATA, OR QUALITY, AS WELL AS ANY WARRANTIES OF MERCHANTABILITY, SYSTEM INTEGRATION, WORKMANSHIP, SUITABILITY, FITNESS FOR A PARTICULAR PURPOSE, OR THE ABSENCE OF ANY DEFECTS THEREIN, WHETHER LATENT OR PATENT.

THE SOURCEFIRE PRODUCTS ARE NOT FAULT-TOLERANT AND ARE NOT DESIGNED OR INTENDED FOR USE IN ANY HAZARDOUS ENVIRONMENT REQUIRING FAIL-SAFE PERFORMANCE OR OPERATION. SOURCEFIRE PRODUCTS ARE NOT FOR USE IN THE OPERATION OF AIRCRAFT NAVIGATION, NUCLEAR FACILITIES, WEAPONS SYSTEMS, DIRECT OR INDIRECT LIFE-SUPPORT SYSTEMS, AIR TRAFFIC CONTROL SYSTEMS, OR ANY APPLICATION OR INSTALLATION WHERE FAILURE COULD RESULT IN DEATH, PHYSICAL INJURY OR PROPERTY DAMAGE.

NO WARRANTY IS MADE BY SOURCEFIRE ON THE BASIS OF TRADE USAGE, COURSE OF DEALING OR COURSE OF TRADE. SOURCEFIRE DOES NOT WARRANT THAT THE APPLIANCE, THE LICENSED MATERIALS OR ANY OTHER INFORMATION, MATERIALS, DOCUMENTATION OR TECHNOLOGY PROVIDED UNDER THIS AGREEMENT WILL MEET YOUR REQUIREMENTS OR THAT THE OPERATION THEREOF WILL BE UNINTERRUPTED OR ERROR-FREE, OR THAT ALL ERRORS WILL BE CORRECTED. YOU ACKNOWLEDGE THAT SOURCEFIRE'S OBLIGATIONS UNDER THIS AGREEMENT ARE FOR YOUR BENEFIT ONLY. NOTWITHSTANDING ANYTHING TO THE CONTRARY IN THIS AGREEMENT, ANY THIRD PARTY PRODUCTS ARE PROVIDED "AS IS" WITHOUT ANY WARRANTY WHATSOEVER.

Sourcefire's sole obligation and liability, and Your sole and exclusive remedy under the warranties set forth in Section 10 shall be for Sourcefire to use commercially reasonable efforts to remedy the problem, or to replace the defective Hardware and/or the Sourcefire Software, if Sourcefire is notified in writing of all warranty problems during the applicable warranty period.

11. LIMITATION OF LIABILITY

IN NO EVENT WILL SOURCEFIRE'S OR ANY OF ITS SUBSIDIARIES' OR AFFILIATES' AGGREGATE LIABILITY (INCLUDING, BUT NOT LIMITED TO, LIABILITY FOR NEGLIGENCE, STRICT LIABILITY, BREACH OF CONTRACT, MISREPRESENTATION AND OTHER CONTRACT OR TORT CLAIMS) ARISING FROM OR RELATED TO THIS AGREEMENT, OR THE USE OF THE PRODUCTS, EXCEED THE AMOUNT OF FEES YOU PAID TO SOURCEFIRE OR ITS RESELLER, AS APPLICABLE, FOR THE PRODUCTS THAT GAVE RISE TO SUCH LIABILITY. UNDER NO CIRCUMSTANCES SHALL SOURCEFIRE OR ANY OF ITS SUBSIDIARIES, AFFILIATES, SUPPLIERS OR LICENSORS BE LIABLE FOR ANY OF THE FOLLOWING: (I) THIRD PARTY CLAIMS, EXCEPT AS SET FORTH IN SECTION 13; (II) LOSS OR DAMAGE TO ANY SYSTEMS, RECORDS OR DATA; (III) INDIRECT, INCIDENTAL, SPECIAL, CONSEQUENTIAL, PUNITIVE, RELIANCE, OR COVER DAMAGES (INCLUDING LOST PROFITS AND LOST SAVINGS); OR (IV) DAMAGES ARISING OUT OF ANY THIRD PARTY PRODUCTS, IN EACH CASE EVEN IF SOURCEFIRE HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. YOU ARE SOLELY RESPONSIBLE AND

LIABLE FOR VERIFYING THE SECURITY, ACCURACY AND ADEQUACY OF ANY OUTPUT FROM ANY PRODUCTS, AND FOR ANY RELIANCE THEREON. THE LIMITATIONS OF LIABILITY IN THIS SECTION 11 ARE INTENDED TO APPLY WITHOUT REGARD TO WHETHER OTHER PROVISIONS OF THIS AGREEMENT HAVE BEEN BREACHED OR HAVE PROVEN INEFFECTIVE.

12. ESSENTIAL BASIS

The disclaimers, exclusions and limitations of liability set forth in this Agreement form an essential basis of the bargain between the Parties, and, absent any of such disclaimers, exclusions or limitations of liability, the provisions of this Agreement, including, without limitation, the economic terms, would be substantially different.

13. INFRINGEMENT OBLIGATIONS

13.1. Sourcefire will defend You from any unaffiliated third party claim that Your use of the Sourcefire Software as provided by Sourcefire to You under this Agreement, when used within the scope of this Agreement, infringes any unaffiliated third party's U.S. copyright ("Claim"). Sourcefire's obligations to You under this Section 13 are limited solely to paying (i) counsel hired by Sourcefire to defend the Claim; (ii) the reasonable and verifiable out-of-pocket costs incurred directly by You in connection with defending the Claim and/or assisting Sourcefire in the defense thereof; and (iii) subject to Section 11 herein, any direct damages finally awarded to such third party by a court of competent jurisdiction (after any appeals) or any settlement of the Claim to which Sourcefire consents in writing. Sourcefire's obligations under this Section 13 are expressly contingent upon: (x) You giving prompt written notice to Sourcefire of any such Claim; (y) You allowing Sourcefire exclusive control of the defense and any related settlement of any such Claim; and (z) You furnishing Sourcefire with reasonable assistance in connection with the Claim without prejudicing Sourcefire in any manner. Subject to the foregoing conditions, nothing in this Agreement shall prohibit You from hiring separate counsel, at Your own expense.

13.2. If Your use of the Products hereunder is, or in Sourcefire's opinion is likely to be, enjoined due to the type of Claim specified in Section 13.1, then Sourcefire may, at its sole option and expense but without obligation to do so: (i) procure for You the right to continue to use the Products under the terms of this Agreement; (ii) replace the Products with a functional equivalent; (iii) modify the Products so that they become non-infringing (including disabling the challenged functionality), provided the modified Products remain substantially equivalent in function to the enjoined Products; or (iv) repurchase the affected Products less depreciation at the rate of twenty-five percent (25%) per year, or pro rata for the part of the year, from the date of payment to the date of removal of the Products, and terminate the Agreement with respect to those Products. Further, if as a result of a Claim a court of competent jurisdiction issues a final injunction (which has not been appealed) against Your use of any part of the Products, then Sourcefire will, at its sole option, perform one of the remedy options listed in this Section 13.2. In

either case, if Sourcefire selects option (ii), (iii) or (iv) listed in this Section 13.2, You shall immediately refrain from use of the allegedly infringing Products.

13.3. Sourcefire shall have no indemnification obligation or liability for any Claim to the extent that it arises out of or relates to: (i) Your use of the Products after Sourcefire notifies You to discontinue use due to a Claim; (ii) the combination of the Sourcefire Products with a non-Sourcefire application, product, data or business process; (iii) damages attributable to a non-Sourcefire application, product, data or business process; (iv) modifications to the Products made other than by Sourcefire; (v) changes made by Sourcefire on behalf of You; (vi) continued use of the Products for which Sourcefire has provided You with modifications or substitute Products if use of such modifications or substitute Products would have prevented the Claim; or (vii) use of the Products in a manner prohibited under this Agreement.

13.4. THE PROVISIONS OF THIS SECTION 13 SET FORTH SOURCEFIRE'S SOLE AND EXCLUSIVE OBLIGATIONS, AND YOUR SOLE AND EXCLUSIVE REMEDIES, WITH RESPECT TO INFRINGEMENT, VIOLATION OR MISAPPROPRIATION OF INTELLECTUAL PROPERTY RIGHTS OF ANY KIND. IN NO EVENT SHALL SOURCEFIRE'S LIABILITY TO YOU UNDER SECTION 13 EXCEED THE AMOUNT OF THE FEES PAID BY YOU FOR THE SOURCEFIRE PRODUCT THAT IS THE SUBJECT OF SUCH CLAIM.

14. VERIFICATION

You agree that Sourcefire or its designee shall have the right to periodically conduct on-site audits of Your use of the Products for the limited purpose of verifying that You are in compliance with Your obligations under this Agreement and have paid all applicable fees. These audits will be conducted during regular business hours, and Sourcefire will make reasonable efforts to minimize interference with Your regular business activities. Alternatively, Sourcefire may request that You complete a self-audit questionnaire in a form provided by Sourcefire. If an audit or such questionnaire reveals unlicensed use of the Products, You agree to promptly order and pay for sufficient licenses to permit all usage disclosed.

15. EXPORT; RE-EXPORT

The Products are subject to export controls under the Laws of the United States and other countries. You shall comply with all such Laws governing export, re-export, transfer and use of the Products and will obtain all required U.S. and local authorizations, permits and licenses. Sourcefire assumes no responsibility or liability for Your failure to obtain such necessary authorizations, permits and licenses. Information regarding U.S. export laws can be found at www.bis.doc.gov. You agree not to use or transfer the Products for any use relating to the operation of nuclear facilities, chemical or biological weapons, or missile technology, unless authorized by the U.S. Government by regulation or specific written license.

16. U.S. GOVERNMENT END USERS

The Licensed Materials, information and data provided under this Agreement are prepared entirely at private expense and are "Commercial Items" as that term is defined in 48 C.F.R. 2.101. If you are an agency, department, or other entity of the United States Government, or funded in whole or in part by the United States Government, then your use, duplication, reproduction, release, modification, disclosure or transfer of this commercial product and data, is restricted in accordance with 48 C.F.R. §12.211, 48 C.F.R. §12.212, 48 C.F.R. §227.7102-2, and 48 C.F.R. §227.7202, as applicable. Consistent with 48 C.F.R. §12.211, 48 C.F.R. §12.212, 48 C.F.R. §227.7102-1 through 48 C.F.R. §227.7102-3, and 48 C.F.R. §§227.7202-1 through 227.7202-4, as applicable, this commercial product and data are licensed to U.S. Government end users (i) only as Commercial Items, and (ii) with only those rights as are granted to all other users pursuant to the Sourcefire's standard end user license agreement. In case of conflict between any of the FAR and DFARS provisions listed herein and this Agreement, the construction that provides greater limitations on the U.S. Government's rights shall control. For purpose of any public disclosure provision under any federal, state or local law, it is agreed that this commercial product and data are a trade secret and proprietary commercial products and not subject to disclosure.

17. FREE SOFTWARE

You acknowledge and agree that while certain open source code Third Party Products are made available to You hereunder for free for use in combination with the Sourcefire Products, the terms and conditions under which such Third Party Products are being made available to You are as set forth in their respective third party agreements (the "Third Party Agreements"), and that this Agreement in no way supplements or detracts from any term or condition of such Third Party Agreements. Sourcefire is not giving any warranties for these Third Party Products and Your use of these Third Party Products will be subject solely to such Third Party Agreements. A listing of these Third Party Products, including the applicable Third Party Agreements and other applicable disclosures, is available in the Documentation. You may obtain the source code to such open source code software in accordance with the directions set forth in the Documentation.

18. EVALUATION PRODUCTS

If You have been provided Products on an evaluation-only basis or beta-release basis (each, "Evaluation Products") to evaluate their suitability for purchase and/or licensing on a for-fee basis (as the case may be, for "Evaluation"), You acknowledge and agree that the evaluation license key(s) for these Evaluation Products will be set with a set expiration date (the "Expiration Date"), pursuant to which upon activation of the Evaluation Products, You may use the Evaluation Products through the Expiration Date (the "Evaluation Period") solely for their Evaluation. All Evaluation Products are provided to You "AS IS" without warranty or any kind, whether express, implied, statutory, or otherwise, and the limited warranties referenced in Section 10 and the indemnification obligations referenced in Section 13 above will not be applicable to Your use of the Evaluation

Products. Sourcefire bears no liability for any damages resulting from use (or attempted use) of the Evaluation Products.

19. COLLECTION OF DATA

Sourcefire hereby informs You that the Products use data collection technology to collect and analyze certain information about Your network and endpoints including, but not limited to, the IP addresses of Your endpoints, other information which may contain personally identifiable information and the metadata of certain executable files in order to (i) identify malware on Your network and endpoints; (ii) provide support and related services to You regarding Your use of the Products; and (iii) improve Sourcefire's products. You do have the ability to configure the Products to limit some of the data that can be collected. You grant Sourcefire a perpetual right and license to use the information and data made available by You via the Products in order to attempt to prevent malware from running on Your network and endpoints, to conduct related analysis and provide support and for product improvement purposes. By accepting this Agreement, You (x) acknowledge and agree that the technology included in the Products can collect traffic and data from Your network and endpoints which may contain personally identifiable information in order to detect malware and conduct related analysis; (y) agree to upload from Your network and endpoints certain metadata and other required information for the purpose of being scanned by the remote cloud-based servers operated by Sourcefire; and (z) covenant that You have the right to provide Sourcefire all such information and data.

Sourcefire may engage other companies and individuals to perform functions on its behalf, such as payment processing, order fulfillment, marketing programs and customer service so Sourcefire may share such information with such subcontractors in order to perform these functions, but such subcontractors may not use Your personal information for other purposes, unless You agree.

20. GOVERNING LAW

If You acquired, as determined by the address on the order accepted by Sourcefire or Reseller, as applicable, the Sourcefire Product in the United States, Latin America, or the Caribbean, the Agreement and warranties ("Warranties") are controlled by and construed under the laws of the State of California, United States of America, notwithstanding any conflicts of law provisions; and the state and federal courts of California shall have exclusive jurisdiction over any claim arising under the Agreement or Warranties. If You acquired the Sourcefire Product in Canada, unless expressly prohibited by local law, the Agreement and Warranties are controlled by and construed under the laws of the Province of Ontario, Canada, notwithstanding any conflicts of law provisions; and the courts of the Province of Ontario shall have exclusive jurisdiction over any claim arising under the Agreement or Warranties. If You acquired the Sourcefire Product in Europe, the Middle East, Africa, Asia or Oceania (excluding Australia), unless expressly prohibited by local law, the Agreement and Warranties are controlled by and construed under the laws of England, notwithstanding any conflicts of law provisions; and the English courts shall have exclusive jurisdiction over any claim

arising under the Agreement or Warranties. In addition, if the Agreement is controlled by the laws of England, no person who is not a party to the Agreement shall be entitled to enforce or take the benefit of any of its terms under the Contracts (Rights of Third Parties) Act 1999. If You acquired the Sourcefire Product in Japan, unless expressly prohibited by local law, the Agreement and Warranties are controlled by and construed under the laws of Japan, notwithstanding any conflicts of law provisions; and the Tokyo District Court of Japan shall have exclusive jurisdiction over any claim arising under the Agreement or Warranties. If You acquired the Sourcefire Product in Australia, unless expressly prohibited by local law, the Agreement and Warranties are controlled by and construed under the laws of the State of New South Wales, Australia, notwithstanding any conflicts of law provisions; and the State and federal courts of New South Wales shall have exclusive jurisdiction over any claim arising under the Agreement or Warranties. If You acquired the Sourcefire Product in any other country, unless expressly prohibited by local law, the Agreement and Warranties are controlled by and construed under the laws of the State of California, United States of America, notwithstanding any conflicts of law provisions; and the state and federal courts of California shall have exclusive jurisdiction over any claim arising under the Agreement or Warranties.

For all countries referred to above, the Parties specifically disclaim the application of the UN Convention on Contracts for the International Sale of Goods. Notwithstanding the foregoing, either Party may seek interim injunctive relief in any court of appropriate jurisdiction with respect to any alleged breach of such Party's intellectual property or proprietary rights. If any portion hereof is found to be void or unenforceable, the remaining provisions of the Agreement and Warranties shall remain in full force and effect. Except as expressly provided herein, the Agreement constitutes the entire agreement between the Parties with respect to the license of the Licensed Materials and supersedes any conflicting prior oral or written communications or additional terms contained in any purchase order or elsewhere, all of which terms are excluded. The Agreement has been written in the English language, and the parties agree that the English version will govern.

21. ASSIGNMENT

You may not assign or otherwise transfer this Agreement or the license rights granted hereunder without Sourcefire's prior written consent. Notwithstanding the foregoing, You may assign this Agreement if a majority of Your outstanding voting capital stock is sold to a third party, or if You sell all or substantially all of Your assets or if You otherwise undergo a change of control, provided, that, in such instance such assignment will not become effective until You provide Sourcefire written notice of such event. Sourcefire may assign or transfer this Agreement, in whole or in part, at any time in its sole discretion without Your consent. This Agreement shall be binding upon and inure to the benefit of the Parties' successors and permitted assigns.

22. TERM; TERMINATION

This Agreement will continue in effect indefinitely, subject to the right of either Party to terminate as provided below. Either Party may terminate this Agreement if the other does not comply with any of its terms, if the one who is not complying is given written notice and reasonable time to comply. Sourcefire may terminate Your licenses and other rights herein, immediately by providing notice, if You breach or fail to comply with any of the terms and conditions of this Agreement. You agree that, upon such termination, You will cease using the Licensed Materials and either destroy or return all copies thereof.

23. GENERAL

Under no circumstances will the terms of any purchase order issued by You control or otherwise negate the terms set forth in this Agreement. Neither Party shall be liable for any delay or failure due to a force majeure event and other causes beyond its reasonable control, provided, however, this provision shall not apply to Your payment obligations. Any notices under this Agreement to Sourcefire will be personally delivered or sent by certified or registered mail, return receipt requested, or by nationally recognized overnight express courier, to 9770 Patuxent Woods Drive, Columbia, Maryland U.S.A. 21046, or such other address as Sourcefire may specify in writing. Such notices will be effective upon receipt, which may be shown by confirmation of delivery. All notices to Sourcefire shall be sent to the attention of General Counsel (unless otherwise specified by Sourcefire). Amendments or changes to this Agreement must be in mutually executed writings to be effective. Sections 1-2, 5-6, 8-12 and 14-23, including all warranty disclaimers and use restrictions, shall survive the termination or expiration of this Agreement. The Parties are independent contractors for all purposes under this Agreement.

-- End of Agreement --

Glossary

7000 Series	A group of Series 3 Sourcefire managed devices. The devices in this series include the 70xx Family (the 3D7010/7020/7030 models) and the 71xx Family (3D7110/7120/3D7115/3D7125 and AMP7150 models).
8000 Series	A group of Series 3 Sourcefire managed devices. The devices in this series include the 81xx Family (the 3D8120/8130/8140 and AMP8150 models), the 82xx Family (the 3D8250/8260/8270/8290 models), and the 83xx Family (the 3D8350/8360/8370/8390 models). 8000 Series devices are generally more powerful than 7000 Series devices.
access control	A feature of the Sourcefire 3D System that allows you to specify, inspect, and log the traffic that traverses your network. Access control includes the intrusion detection and prevention, file control, and advanced malware protection features, and also determines the traffic you can inspect with the discovery feature.
access control policy	A policy that you apply to managed devices to perform access control on the network traffic monitored by those devices. An access control policy may include multiple access control rules; it also specifies a default action, which determines the handling and logging of traffic that does not meet the criteria of any of those rules. An access control policy can also specify HTTP response page, Security Intelligence, and other advanced settings.
access control rule	A set of conditions the Sourcefire 3D System uses to examine your monitored network traffic and which allows you to achieve granular access control. Access control rules, which populate an access control policy, may perform simple IP address matching, or may characterize complex connections involving different users, applications, ports, and URLs. The access control rule action determines

	how the system handles traffic that meets the rule's conditions. Other rule settings determine how (and whether) the connection is logged, and whether an intrusion policy or file policy inspects matching traffic.
access control rule action	A setting that determines how the system handles network traffic that meets the conditions of an access control rule. You can *block* matching traffic (with or without resetting the connection); for HTTP traffic you can provide users with the option to bypass the block. You can also *trust* traffic to pass without further inspection, *allow* matching traffic, which optionally can be inspected with an intrusion policy and file policy, or continue to *monitor* the traffic with additional access control rules.
access-controlled user	A user whose network use you can control using access control. You specify the LDAP groups that access-controlled users must belong to when you configure a connection between a Microsoft Active Directory server and the Defense Center. When the Sourcefire User Agent reports logins by access-controlled users, those users are associated with IP addresses, which in turn allows access control rules with user conditions to trigger. Compare with non-access-controlled user.
access list	A list of IP addresses, configured in the system policy, that represents the hosts that can access an appliance. By default, anyone can access the web interface of an appliance using port 443 (HTTPS), as well as the command line using port 22 (SSH). You can also add SNMP access using port 161.
active detection	The discovery of host, application, and user information using active sources. Active sources include scanners such as Nmap, user input to the system's web interface, or host input to the network map using the command line or third-party application API calls. Compare with passive detection.
adaptive profile	An intrusion policy profile that uses discovery data to determine the operating system for the target host of a packet. Profiles within an intrusion policy then automatically adapt to cause preprocessors to defragment IP packets and reassemble streams in the same way as the operating system on the target host, and to cause Snort to analyze the data in the same format as that used by the destination host.
advanced malware protection	Abbreviated AMP, the Sourcefire 3D System's network-based malware detection and malware blocking feature. Compare this functionality with FireAMP, Sourcefire's endpoint-based AMP tool that requires a FireAMP subscription.
advanced setting	A preprocessor or other intrusion policy feature that requires specific expertise to configure. Advanced settings typically require little or no modification and are not common to every deployment.
alert	A notification that the system has generated a specific event. You can alert based on intrusion events (including their impacts), discovery events, network-based malware events, correlation policy violations, health status changes, and connections logged by specific access control rules. In most cases, you can alert

	via email, syslog, or SNMP trap.
alert response	A set of configurations that allows the system to send an alert via email, syslog, or SNMP trap. You can use a single alert response to alert you to multiple types of events.
appliance	A Defense Center or managed device. An appliance can be physical or software-based (virtual or Sourcefire Software for X-Series).
appliance statistics	Information you can obtain about an appliance, including uptime, system memory usage, load average, disk usage, a summary of system processes, and, on the Defense Center, information about data correlator processes.
application	A detected network asset, communications method, or HTTP content against which you can write access control rules. The system detects three types of application: application protocol, client application, and web application.
application business relevance	The likelihood that an application is used within the context of your organization's business operations, as opposed to recreationally. An application's business relevance can range from very low to very high.
application category	A general classification for an application that describes its most essential function. Each application belongs to at least one category.
application control	A feature that, as part of access control, allows you to specify which application traffic can traverse your network.
application detector	A tool that the system uses to identify applications on your network. Application detectors identify applications using ASCII or hexadecimal patterns in the packet headers, the port that the traffic uses, or both. Sourcefire may deliver additional detectors via system update, vulnerability database update, or the import/export feature. You can also create your own application protocol detectors.
application filter	One or more applications grouped according to criteria associated with the application risk, business relevance, type, categories, and tags. You can use these filters to constrain access control rules, searches, some dashboard widgets, and reports. You create application filters in the object manager or on the fly in the access control rule editor.
application protocol	A type of application that represents application protocol traffic detected during communications between server and client applications on hosts; for example, SSH or HTTP.
application risk	The likelihood that an application's use may violate your organization's security policy. An application's risk can range from very low to very high.
application tag	Information about an application that is not covered by its application category. For example, video streaming web applications often are tagged "high

bandwidth" and "displays ads." An application may have any number of tags, including none.

application type Whether an application is an application protocol, client application, or web application.

apply The action you take to have a policy, or changes to that policy, take effect. You apply most policies from the Defense Center to its managed devices; however, you activate and deactivate correlation policies because they do not involve changes to the configuration of managed devices.

audit event An event that describes a specific Sourcefire 3D System user interaction with the web interface. Each audit event contains a time stamp, the user name of the user whose action generated the event, a source IP address, and text describing the event. Audit events are recorded in the audit log.

audit log A record of user interactions with the web interface. The audit log comprises audit events.

authentication object A collection of settings that allows you to connect to an external authentication server for one of two reasons. One type of authentication object enables external authentication (RADIUS or LDAP) to the Sourcefire 3D System's web interface. Another type specifies the LDAP users and groups you can use in access control rules, and allows you to retrieve metadata for certain users whose activity was detected in network traffic or by the Sourcefire User Agent.

automatic application bypass (AAB) An advanced device setting that limits the time allowed to process packets through an interface and allows packets to bypass processing if the time is exceeded. Sourcefire recommends use of this feature for inline deployments in non-production environments.

banner See server banner.

base policy A selectable set of configurations that may be any default intrusion policy provided by Sourcefire, or a custom policy.

base policy layer A built-in layer in an intrusion policy comprised of default settings. The base policy selected for the intrusion policy determines the settings in the base policy layer.

blacklist See health monitor blacklist or Security Intelligence blacklist.

bookmark A saved link to a specific location and time in an event analysis. Bookmarks retain information about the workflow you are using, the part of the workflow you are viewing, the page number within the workflow you are viewing, the time window you selected, and any columns you disabled, as well as any constraints you imposed.

built-in layer — A read-only layer in an intrusion policy. An intrusion policy always includes a built-in base policy layer and, optionally, can include a built-in FireSIGHT Recommendations layer.

business relevance — The likelihood that an application is used within the context of your organization's business operations, as opposed to recreationally. An application's business relevance can range from very low to very high.

bypass mode — A characteristic of an inline set that allows traffic to continue flowing if the sensing interfaces in the set fail for any reason.

captured file — A file detected in network traffic that a device copies, either for submission to the Sourcefire cloud for dynamic analysis or Spero analysis, or for file storage to the device. You can review information about captured files from the event viewer.

category — See application category, file category, or URL category.

certificate authority — The certificate issuer used to create server or user certificates. Server and user certificates provide an additional confirmation of a server or a user identity.

certificate revocation list (CRL) — A list of certificates revoked by the certificate authority that issued the user certificates for your appliance. This allows you to restrict access to the Sourcefire 3D System web interface using client browser certificate checking. If the user selects a certificate that is listed in the CRL as a revoked certificate, the browser cannot load the web interface.

change reconciliation report — A detailed report of all system changes in the last 24 hours, based on snapshots taken whenever a new configuration is saved. You can configure the system to email these reports daily at a time that you specify.

clean list — A list of files as represented by their SHA-256 hash values. When the system detects a file in the list, it does not perform a malware cloud lookup, treating the file as clean, even if the disposition for the file in the Sourcefire cloud is Malware.

CLI — See command line interface.

client — Also called a client application, an application that runs on one host and relies on another host (a server) to perform some operation. For example, email clients allow you to send and receive email. When the system detects that a user on a host is using a specific client to access another host, it reports that information in the host profile and network map, including the name and version (if available) of the client.

client application — See client.

clipboard — A holding area where you can copy up to 25,000 intrusion events that you can later add to incidents.

cloud services	See Sourcefire cloud.
clustering	A feature that allows you to achieve redundancy of networking functionality and configuration data between two peer Series 3 devices or stacks. Clustering provides a single logical system for policy applies, system updates, and registration. Compare with high availability, which allows you to configure redundant Defense Centers.
command line interface	A restricted text-based interface on Series 3 and virtual devices. The commands that CLI users can run depend on the users' assigned level of access.
complex constraint	A constraint set in an event view or event search that constrains an event query using all the criteria from a specific event.
compliance white list	Along with correlation rules, one of the ways you can specify criteria that network traffic must meet in order to violate a correlation policy. You can use the Defense Center to configure compliance white lists to specify which operating systems, applications, and protocols are allowed to run on the hosts in a specific subnet. You can also configure the Defense Center to launch a response, such as an alert or remediation, when a white list is violated. Note that compliance white lists are not associated with the other types of whitelist.
compliance white list event	See white list event.
compliance white list violation	See white list violation.
configurable bypass	A characteristic of an inline set that allows you to configure bypass mode.
configuration, for import or export	A set of configurations, such as a policy or custom workflow, that is created on an appliance and can be exported from that appliance and imported by another appliance.
connection	A monitored session between two hosts. You can log connections detected by managed devices in the access control policy; you configure NetFlow connection logging in the network discovery policy.
connection event	An event generated when the system detects a connection between a monitored host and any other host. Connection events include information about the detected traffic. For connections detected by managed devices, depending on the access control rule action, default action, or Security Intelligence decision, you can log a connection event at the beginning or end of a connection, or both. You can log these connections to the Defense Center database; depending on the rule or default action, you can also log connection events to the syslog or to an SNMP trap server. NetFlow connections are end-of-connection and are always saved to the database.

connection graph — A way of displaying connection events in graphical form.

connection log — See connection event.

connection summary — Connection data aggregated over a five-minute interval. The system uses connection summaries to build connection graphs and traffic profiles. To be aggregated, multiple connections must represent the end of connections, have the same source and destination IP addresses, and use the same port on the responder (destination) host. They must use the same protocol (TCP or UDP) and application protocol. Finally, they must either be detected by the same Sourcefire managed device, or be exported by the same NetFlow-enabled device.

connection tracker — One or more conditions that constrain a correlation rule so that after the rule's initial criteria are met, the system begins tracking certain connections. The rule then triggers only if the tracked connections meet additional criteria.

Context Explorer — A page that displays detailed, interactive graphical information about your monitored network, using intrusion, connection, file, geolocation, malware, and discovery data. Distinct sections present information in the form of vivid line, bar, pie, and donut graphs, accompanied by detailed lists. You can easily create and apply custom filters to fine-tune your analysis, and you can examine data sections in more detail by clicking or hovering your cursor over graph areas. Compared with a dashboard, which is highly customizable, compartmentalized, and updates in real time, the Context Explorer is manually updated, designed to provide broader context for its data, and has a single, consistent layout designed for active user exploration.

context menu — A pop-up menu, available on many of the pages in the web interface, that you can use as a shortcut for accessing other features in the Sourcefire 3D System. The contents of the menu depend on several factors, including the page you are viewing, the specific data you are investigating, and your user role. Context menu options include links to intrusion rule, event, and host information; various intrusion rule settings, quick links to the Context Explorer; options to add a host to the Security Intelligence global blacklist or global whitelist by its IP address; and options to add a file to the global whitelist by its SHA-256 hash value.

Control license — A license that allows you to implement user control and application control by adding user and application conditions to access control rules. It also allows you to configure your managed devices to perform switching and routing (including DHCP relay and NAT), as well as clustering managed devices.

correlation — A feature you can use to build a correlation policy that responds in real time to threats on your network. The remediation component of correlation provides a flexible API that allows you to create and upload your own custom remediation modules to respond to policy violations.

correlation event An event generated by the Defense Center when a correlation rule triggers. Note that white list events, generated by white list violations, are a special kind of correlation event.

correlation policy A policy that describes the network activity that constitutes a security policy violation, using correlation rules and compliance white lists. You can specify responses to each rule or white list within a policy.

correlation rule With compliance white lists, one of the ways you can specify criteria that network traffic must meet in order to violate a correlation policy. You can use the Defense Center to configure correlation rules to trigger (and generate a correlation event) when a specific intrusion event, malware event, discovery event, host input event, or connection event occurs, or when your network traffic deviates from your normal network traffic pattern as characterized in a traffic profile. You can constrain correlation rules with host profile qualifications, connection trackers, snooze periods, and inactive periods. You can also configure the Defense Center to launch a response, such as an alert or remediation, when a correlation rule triggers.

CRL See certificate revocation list (CRL).

current identity The operating system or server identity that the system finds most likely to be correct for a particular network asset. The system uses this data in many ways; for example, to calculate statistics, assign vulnerability information, assess impact of an attack, and evaluate correlation rules.

current user The user that the system associates with a host. If the user is an access-controlled user, the system can perform user control on traffic to or from that host. If no access-controlled user is associated with the host, a non-access-controlled user can be the current user for the host. However, after an access-controlled user logs into the host, only a login by another access-controlled user changes the current user.

custom detection list A list of files as represented by their SHA-256 hash values. When the system detects a file in the list, it does not perform a malware cloud lookup, treating the file as malware, even if the disposition for the file in the Sourcefire cloud is Clean.

custom fingerprint See fingerprint.

custom table A table you can construct that combines fields from two or more of the predefined tables delivered with the Sourcefire 3D System. For example, you could combine the host criticality information from the host attributes table with information from the connection data table to examine connection data in a new context.

custom topology A feature that allows you to meaningfully organize and identify subnets in the host, mobile device, and network device network maps.

custom user role	A user role with specialized access privileges. Custom user roles may have any set of menu-based and system permissions, and may be completely original or based on a predefined user role.
custom workflow	A workflow that you create to meet the unique needs of your organization.
dashboard	A display that provides at-a-glance views of current system status, including data about the events collected and generated by the system. To augment the dashboards delivered with the system, you can create multiple custom dashboards, populated with the dashboard widgets you choose. Compare with the Context Explorer, which offers a broad, brief, and colorful picture of how your monitored network looks and acts.
dashboard widget	A small, self-contained dashboard component that provides insight into an aspect of the Sourcefire 3D System.
data correlator	A program that generates events and creates the network map on the Defense Center, using the data collected by the system.
database access	A feature that allows read-only access to the Defense Center database by a third-party client.
decoder	A component of intrusion detection and prevention that places sniffed packets into a format that can be understood by a preprocessor.
default action	As part of an access control policy, determines how to handle traffic that does not meet the conditions of any rule in the policy. When you apply an access control policy that does not contain any access control rules or Security Intelligence settings, the default policy action determines how non-fast-pathed traffic on your network is handled. You can set the default action to block or trust traffic without further inspection, or inspect it with a network discovery policy or intrusion policy.
Defense Center	A central management point that allows you to manage devices and automatically aggregate and correlate the events they generate.
defragmentation policy	A policy that describes how the IP defragmentation preprocessor (a component of intrusion detection and prevention) should reassemble fragmented IP packets, based on the target host's operating system. Note that adaptive profiles use adaptive defragmentation policies.
derived fingerprint	An operating system fingerprint created by the system from all passively collected fingerprints for a host by applying a formula which calculates the most likely identity, using the confidence value of each collected fingerprint and the amount of corroborating fingerprint data between identities.
device	A fault-tolerant, purpose-built appliance available in a range of throughputs. Depending on the licensed capabilities you enable on your devices, you can use them to passively monitor traffic to build a comprehensive map of your network

assets, application traffic, and user activity, perform intrusion detection and prevention, perform access control, and configure switching and routing. You must manage devices with a Defense Center.

device clustering See clustering.

device stacking See stacking.

discovery A component of the Sourcefire 3D System that uses managed devices to monitor your network and provide you with a complete, persistent view of your network. Network discovery determines the number and types of hosts (including network devices and mobile devices) on your network, as well as information about the operating systems, active applications, and open ports on those hosts. You can also configure Sourcefire managed devices to monitor user activity on your network, which allows you to identify the source of policy breaches, attacks, or network vulnerabilities.

discovery data Host, user, and application information that qualifies your network assets and traffic flow, as gathered by the discovery feature.

discovery event An event that details the discovery of new assets or changes to existing assets. A host input event is a special kind of discovery event. Sometimes, Sourcefire uses the term "discovery event" as a general reference to any discovery data or vulnerability information.

discovery policy See network discovery policy.

discovery rule Within a network discovery policy, specifies the networks and zones you want to monitor and the devices (including NetFlow-enabled devices) or you want to use to monitor them, as well as any ports you want to exclude from monitoring. Each rule also specifies whether you want to discover hosts, users, or applications on the monitored networks.

disposition See malware disposition.

drill-down page An intermediate workflow page used to constrain event views. Generally, a drill-down page presents constraints that you can select to advance to a more narrowly constrained page or a table view.

drop event An intrusion event generated when a drop rule triggers. In the event viewer, drop events are marked with black down arrows.

drop rule An intrusion rule whose rule state is set to Drop and Generate Events. When a malicious packet triggers the rule in an inline deployment, and the intrusion policy you apply is set to drop when inline, the system drops the packet and generates an intrusion event (specifically, a drop event).

dynamic analysis	A method of submitting captured files from a device to the Sourcefire cloud for malware analysis. The cloud runs the file in a test environment and returns a threat score and dynamic analysis summary report to the Defense Center. From the dynamic analysis summary report, you can also view the VRT's Analysis Report.
dynamic analysis summary report	A summary of why the Sourcefire cloud assigned a threat score to a file, including any threats discovered during dynamic analysis, as well as additional processes detected when running the file in the test environment. From here, you can also view the VRT's Analysis Report.
dynamic rule state	A intrusion rule state that is set for a specified period of time in response to a detected rate anomaly in traffic matching the rule.
endpoint	A computer or mobile device where your users install a FireAMP Connector as part of your organization's advanced malware protection strategy.
eStreamer	A component of the Sourcefire 3D System that allows you to stream event data from a Defense Center or managed device to external client applications.
event	A collection of details about a specific occurrence that you can view in the event viewer, using workflows. Events may represent attacks on your network, changes in your detected network assets, violations of your organization's security and network use policies, and so on. The system also generates events that contain information about the changing health status of appliances, your use of the web interface, rule updates, and launched remediations. Finally, the system presents certain other information as events, even though these "events" do not represent particular occurrences. For example, you can use the event viewer to view detailed information about detected hosts, applications, and their vulnerabilities.
Event Streamer	See eStreamer.
event suppression	A feature that allows you to use suppress intrusion events when a specific IP address or range of IP addresses triggers an intrusion rule. Event suppression is useful for eliminating false positives. For example, if you have an email server that transmits packets that look like a specific exploit, you can suppress events for the rules that are triggered by that server, so you only see the events for legitimate attacks.
event thresholding	A feature that allows you to limit the number of times the system logs and displays an intrusion event, based on how many times the event is generated within a specified time period. Use event thresholding if you are overwhelmed with a large number of identical events.
event viewer	A component of the system that allows you to view and manipulate events. The event viewer uses workflows to present a broad, then a more focused event view that contains only the events of interest to you. You can constrain the events in an event view by drilling down through the workflow, or by using a search.

export	A method that you can use to transfer various configurations (such as policies) from appliance to appliance. After you export a configuration from one appliance, you can import it onto another appliance of the same type.
external authentication	A method (such as LDAP authentication or RADIUS authentication) that uses externally stored user credentials to authenticate user names and passwords when users log into Sourcefire 3D System appliances. Compare with internal authentication.
failsafe	A characteristic of an inline set that allows packets to bypass processing and continue through the device if internal traffic buffers are full.
fast-path rule	A rule that you configure at a device's hardware level, using a limited set of criteria, to allow traffic that does not need to be analyzed to bypass processing.
feed	See Security Intelligence feed.
fingerprint	An established definition that the system compares against specific packet header values and other unique data from network traffic to identify a host's operating system. If the system misidentifies or cannot identify a host's operating system, you can create a custom fingerprint that identifies the host.
file capture	See captured file.
file category	A general classification for file types, such as graphics, executables, or archives.
file control	A feature that, as part of access control, allows you to specify and log the types of files that can traverse your network.
file disposition	See malware disposition.
file event	An event that represents a file detected in network traffic by a managed device.
file list	See clean list and custom detection list.
file policy	A policy that the system uses to perform file control and advanced malware protection. Populated by file rules, a file policy is invoked by an access control rule within an access control policy.
file rule	A set of criteria within a file policy that the Sourcefire 3D System uses to examine network traffic. If a transmitted file matches the rule criteria, the rule triggers and generates a file event. The rules's file rule action determine whether you block the file (based on file type or malware disposition) or simply allow the file to pass and log the transmission.
file rule action	A setting that determines how the system handles a file that meets the conditions of a file rule. You can detect and alert on specific file types, as well as block the transmission of those files. You can also perform malware cloud lookups

	on a subset of those file types and block the transmission of those files based on malware disposition.
file storage	See stored file.
file trajectory	See network file trajectory.
file type	A specific type of file format, such as PDF, EXE, or MP3.
FireAMP	Sourcefire's enterprise-class, endpoint-based, advanced malware analysis and protection solution that discovers, understands, and blocks malware outbreaks, persistent threats, and targeted attacks. If your organization has a FireAMP subscription, individual users install lightweight FireAMP Connectors on endpoints (computers, mobile devices), which then communicate with the Sourcefire cloud. This allows you to quickly identify and quarantine malware, as well as identify outbreaks when they occur, track their trajectory, understand their effects, and learn how to successfully recover. You can also use the FireAMP portal to create custom protections, block execution of certain applications, and create custom whitelists. Compare with network-based advanced malware protection.
FireAMP Connector	A lightweight agent that users in a subscription-based FireAMP deployment install on endpoints, such as computers and mobile devices. Connectors communicate with the Sourcefire cloud, exchanging information that allow you to quickly identify and quarantine malware throughout your organization. They can also identify indications of compromise on endpoint hosts.
FireAMP portal	The website, http://amp.sourcefire.com/, where you can configure your organization's subscription-based FireAMP deployment.
FireAMP subscription	A separately purchased subscription that allows your organization to use FireAMP as an advanced malware protection (AMP) solution. Compare with a Malware license, which you enable on managed devices to perform network-based AMP.
FireSIGHT license	The default license on the Defense Center, which allows you to perform host, application, and user discovery. The FireSIGHT license also determines how many individual hosts and users you can monitor with the Defense Center and its managed devices, as well as the number of access-controlled users you can use in access control rules to perform user control.
FireSIGHT Recommendations layer	A built-in layer in an intrusion policy that exists when you allow the system to modify rule states to those recommended by the FireSIGHT recommended rules feature.
FireSIGHT recommended rules	A feature that recommends which rules should be enabled or disabled in your intrusion policy, based on information from your network map. You can choose to allow the system to modify rule states based on recommendations, in which case the system adds a read-only FireSIGHT Recommendations layer.

GeoDB	See geolocation database.
geolocation	A feature that provides data on the geographical source of routable IP addresses detected in traffic on your monitored network, including connection type, internet service provider, and so on. You can see geolocation information, which is stored in the geolocation database, in connection events, intrusion events, file events, and malware events, as well as in host profiles.
geolocation database	Also called the GeoDB, a regularly updated database of known geolocation data associated with routable IP addresses.
GID	Generator ID, a number that indicates which component of the Sourcefire 3D System generated an intrusion event. GIDs help you analyze events more effectively by categorizing the type of event in the same way a rule's SID offers context for the packets that trigger rules.
global blacklist	A Security Intelligence object included by default in every access control policy's Security Intelligence blacklist. The global blacklist applies to all security zones. You can add individual IP addresses to the global blacklist using the IP address context menu in the dashboard, Context Explorer, and many event viewer pages.
global whitelist	A Security Intelligence object included by default in every access control policy's Security Intelligence whitelist. The global whitelist applies to all security zones. You can add individual IP addresses to the global whitelist using the IP address context menu in the dashboard, Context Explorer, and many event viewer pages.
HA link interface	Also called the high availability link interface, a physical interface that you configure on each member of a clustered pair of devices to act as a redundant communications channel for sharing health information between the devices.
health event	An event generated when one of the appliances in your deployment meets (or fails to meet) performance criteria specified in a health module. Health events can also generate alerts.
health module	A test of a particular performance aspect, such as CPU usage or available disk space, of the appliances in your deployment. Health modules, which you enable in a health policy, generate health events when the performance aspects they monitor reach a certain level.
health monitor	A feature that continuously monitors the performance of the appliances in your deployment. The health monitor uses health modules within an applied health policy to test the appliances.
health monitor blacklist	A configuration that temporarily disables aspects of health monitoring to prevent the generation of unnecessary health events. You can disable monitoring for a group of appliances, a single appliance, or a specific health module.

health policy — The criteria used when checking the health of an appliance in your deployment. Health policies use health modules to indicate whether your Sourcefire 3D System hardware and software are working correctly. You can use the default health policy or create your own.

high availability — A feature that allows you to configure redundant physical Defense Centers to manage groups of devices. Event data streams from managed devices to both Defense Centers and most configuration elements are maintained on both Defense Centers. If your primary Defense Center fails, you can monitor your network without interruption using the secondary Defense Center. Compare with clustering, which allows you to designate redundant devices.

host — A device that is connected to a network and has a unique IP address. To the Sourcefire 3D System, a host is any identified host that is not categorized as a mobile device, bridge, router, NAT device, or load balancer.

host attribute — A tool you can use to provide information about hosts detected by the system, classifying them in ways that are important to your network environment. The system has two predefined host attributes, host criticality and notes, as well as host attributes that indicate the compliance of each host with each active compliance white list. You can also create your own host attributes.

host criticality — A host attribute that indicates the business criticality (importance) of any given host detected by the system.

host history — A graphical representation of the last 24 hours of a user's activity. The host history, which you can view in a user's user details, displays the IP addresses of the hosts that the user logged into, with approximate login and logout times represented by bar graphs.

host input — A feature that allows you to import data from third-party sources using scripts or command-line files to augment the information in the network map. The web interface also provides some host input functionality; you can modify operating system or application protocol identities, validate or invalidate vulnerabilities, and delete various items from the network map, including clients and server ports.

host input event — A kind of discovery event that is generated when you use the host input feature. In general, the system treats host input and passive discovery events identically, though they are distinguished when building correlation rules.

host profile — Collected information about a specific detected host. This includes general host information, such as its name and operating system, as well as the protocols and applications running on the host. The host profile may also include user history, host attributes, VLAN information, applicable white list violations, detected vulnerabilities, and scan results for that host.

host profile qualification — A constraint placed on a traffic profile or correlation rule. A host profile qualification within a correlation rule specifies that the Defense Center should

generate a correlation event only if the host involved meets certain criteria. A host profile qualification within a traffic profile limits the hosts that are profiled.

host view — The final page in workflows that display discovery events or network assets. The host view displays the host profiles of the hosts involved in the events or assets you are viewing.

HTTP response page — A web page you can configure the system to display when a user's HTTP request is blocked by an access control policy. You can display a generic Sourcefire-provided response page, or you can provide custom HTML. If the request was blocked by an Interactive Block rule, you can allow users to click a button on the response page to continue to the originally requested site.

hybrid interface — A logical interface on a managed device that allows the system to bridge traffic between a virtual router and a virtual switch.

identity conflict — The conflict that occurs when the system reports a new passive operating system or server identity that conflicts with the current active identity and previously reported passive identities.

impact — For intrusion events, a numbered indicator of the correlation between intrusion data, discovery data, and vulnerability information. Impact level 1 (red impact icon) means that the targeted host is *vulnerable* to the attack represented by the intrusion event, impact level 2 (orange impact icon) means it is *potentially vulnerable*, and so on. Attacks directed at hosts on networks not monitored by the network discovery policy are impact level 0 (gray impact icon), which indicates that the Defense Center cannot determine the events' impact.

import — A method that you can use to transfer various configurations from appliance to appliance. You can import configurations that you previously exported from another appliance of the same type.

inactive period — An interval during which a correlation rule does not trigger. You can configure the time, frequency, and duration of inactive periods. See also snooze period.

incident — One or more intrusion events that you suspect are involved in a possible violation of your security policy. The system provides incident-handling features that you can use to collect and process information that is relevant to your investigation of the incident.

indications of compromise — Configured in the network discovery policy, a feature where the Sourcefire 3D System data correlator and FireAMP endpoint data analysis correlate events that may indicate a security compromise with hosts on your monitored network. Potentially compromised hosts are marked with tags to indicate their status, visible in the host profile and in relevant event views. Abbreviated as IOC.

inline deployment — A deployment of the Sourcefire 3D System where your managed devices are placed inline on a network. In this configuration, devices can affect network traffic flow using switching, routing, access control, and intrusion detection and prevention.

inline interface	A sensing interface configured to handle traffic in an inline deployment. You must add inline interfaces to inline sets in pairs.
inline set	One or more pairs of inline interfaces.
Interactive Block	An access control rule action that allows your users to click a button on an HTTP response page to continue to an initially blocked web site.
internal authentication	An authentication method that stores user credentials in a local database on the appliance. When a user logs into the appliance, the user name and password are checked against the information in the database. Compare with external authentication.
intrusion	A security breach, attack, or exploit that occurs on your network.
intrusion detection and prevention	The monitoring of your network traffic for security policy violations, and, in inline deployments, the ability to block or alter malicious traffic. In the Sourcefire 3D System, you perform intrusion detection and prevention when you associate an intrusion policy with an access control rule or default action.
intrusion event	An event that records an intrusion policy violation. Intrusion event data includes the date, time, and the type of exploit, as well as other contextual information about the attack and its target.
intrusion policy	A variety of components that you can configure to inspect your network traffic for intrusions and security policy violations. These components include intrusion rules that inspect the protocol header values, payload content, and certain packet size characteristics; variables commonly used in intrusion rules; a FireSIGHT recommended rules configuration; advanced settings such as preprocessors and other detection and performance features; and preprocessor rules that allow you to generate events for associated preprocessor options. When your network traffic meets the conditions in an access control rule, you can inspect that traffic with an intrusion policy; you can also associate an intrusion policy with the default action.
intrusion rule	A set of keywords and arguments that, when applied to monitored network traffic, identify potential intrusions, security policy violations, and security breaches. The system compares packets against rule conditions. If the packet data matches the conditions, the rule triggers and generates an intrusion event. Intrusion rules include drop rules and pass rules.
layer	A complete set of intrusion rule, preprocessor rule, and advanced setting configurations within an intrusion policy. You can add custom user layers to the built-in layer or layers in your policy. A setting in a higher layer in an intrusion policy overrides a setting in a lower layer.

LDAP authentication	A form of external authentication that verifies user credentials by comparing them to a Lightweight Directory Access Protocol (LDAP) directory stored on an LDAP directory server.
Lights-Out Management (LOM)	A Series 3 feature that allows you to use an out-of-band Serial over LAN (SOL) management connection to remotely monitor or manage appliances without logging into the web interface of the appliance. You can perform limited tasks, such as viewing the chassis serial number or monitoring such conditions as fan speed and temperature.
link state propagation	An option for inline sets in bypass mode that automatically brings down the second interface in a pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up also. In other words, if the link state of a paired interface changes, the link state of the other interface changes automatically to match it.
list	See Security Intelligence list.
load balancer	A network device that distributes traffic to optimize performance and resource use. Using discovery, the system can identify load balancers.
logical interface	A virtual subinterface that you define to handle traffic with specific VLAN tags as the tagged traffic passes through a physical interface.
malware blocking	A component of Sourcefire's network-based advanced malware protection (AMP) solution. After malware detection yields a malware disposition for a detected file, or the detected file is on the custom detection list, you can either block the file or allows its upload or download. Compare this functionality with FireAMP, Sourcefire's endpoint-based AMP tool that requires a FireAMP subscription.
malware cloud lookup	A process by which the Defense Center communicates with the Sourcefire cloud to determine the malware disposition of a file detected in network traffic, based on the file's SHA-256 hash value.
malware detection	A component of Sourcefire's network-based advanced malware protection (AMP) solution. File policies applied to managed devices as part of your overall access control configuration inspect network traffic. The Defense Center then performs malware cloud lookups for specific detected file types, and generates events that alert you to the files' malware dispositions. AMP malware blocking follows and either blocks the file or allows its upload or download. Compare this functionality with FireAMP, Sourcefire's endpoint-based AMP tool that requires a FireAMP subscription.
malware disposition	A determination by the Sourcefire cloud as to whether a file contains malware, based on the file's SHA-256 hash value, threat score, and whether the file is on the clean list or custom detection list.

malware disposition cache — A cache on the Defense Center that stores malware dispositions and threat scores for files. To improve performance, if the system already knows the disposition or threat score for a file based on its SHA-256 hash value, the Defense Center uses the cached information rather than performing a malware cloud lookup. Information in the cache times out after a certain period of time so that cache data does not become stale.

malware event — An event generated by one of Sourcefire's advanced malware protection solutions. Network-based malware events are generated when the Sourcefire cloud returns a malware disposition for a file detected in network traffic; retrospective malware events are generated when that disposition changes. Compare with endpoint-based malware events, which are generated when a deployed FireAMP Connector detects a threat, blocks malware execution, or quarantines or fails to quarantine malware.

Malware license — A license that allows you to perform advanced malware protection (AMP) in network traffic. Using a file policy, you can configure the system to perform malware cloud lookups on specific file types detected by managed devices. Compare with FireAMP subscription.

malware protection — See advanced malware protection.

malware storage pack — A secondary solid-state drive supplied by Sourcefire that you can install in certain devices to store captured files, freeing space on the device's primary hard drive for event and configuration storage.

managed device — See device.

management interface — The network interface that you use to administer a Sourcefire 3D System appliance. In most deployments, the management interface is connected to an internal protected network. Compare with sensing interface.

mobile device — In the Sourcefire 3D System, a host identified by the discovery feature as a mobile, handheld device (such as a mobile phone or tablet). The system can often detect whether a mobile device is jailbroken.

monitor — In an access control policy, a way to log traffic that matches a Security Intelligence blacklist or access control rule, but allows the system to continue to evaluate the traffic rather than immediately allowing or blocking it.

NAT — Network address translation, a feature most commonly used to share a single internet connection among multiple hosts on a private network. Using discovery, the system can identify network devices as load balancers. In addition, in a Layer 3 deployment of the Sourcefire 3D System, you can configure routing with NAT using a NAT policy.

NAT policy — A policy that uses NAT rules to perform routing with NAT.

NAT rule	A set of configurations and conditions that evaluate network traffic and specify how traffic matching those qualifications is translated. NAT rules are added to an existing NAT policy to perform routing using NAT.
NetFlow	An open but proprietary network protocol for collecting IP traffic information, developed by Cisco Systems to run on Cisco IOS-enabled equipment. You can use the information collected by NetFlow-enabled devices to supplement the discovery and connection data collected by the system and to monitor networks not covered by managed devices.
NetMod	A module that you install in the chassis of a managed device that contains the sensing interfaces for that device.
network device	In the Sourcefire 3D System, a host identified as a bridge, router, NAT device, or load balancer.
network discovery	See discovery.
network discovery policy	A policy that specifies the kinds of discovery data (including host, user, and application data) the system collects for specific network segments, including networks monitored by NetFlow-enabled devices. The network discovery policy also manages identity conflict resolution preferences, active detection source priorities, and indications of compromise.
network file trajectory	A visual representation of a file's path as hosts transfer it across your network. For any file with an associated SHA-256 hash value, the trajectory map displays the IP addresses of all hosts that have transferred the file, the time the file was detected, the file's malware disposition, associated file events and malware events, and so on.
network map	A detailed representation of your network. The network map allows you to view your network topology in terms of the hosts, mobile devices, and network devices running on your network, as well as their associated host attributes, application protocols, and vulnerabilities.
network object	A reusable object that represents one or more IP addresses, CIDR blocks, or prefix lengths.
Nmap	Network Mapper, an open source active scanner that you can use to detect operating systems and application protocols running on a host. Running an Nmap scan adds the information detected to your network map.
non-access-controlled user	Any user, whether detected by the User Agent or a managed device, that is not used for access control. A non-access-controlled user can only be the current user for a host if no access-controlled user has ever logged into the host.
non-bypass mode	A characteristic of an inline set that blocks traffic if the sensing interfaces in the set fail for any reason.

object	A reusable configuration that associates a name with a value (for example, an IP address or URL) so that when you want to use that value, you can use the named object instead. You can use objects in various places in the web interface, including discovery rules, access control rules, reports, dashboards, and event searches. See also network object, Security Intelligence object, port object, VLAN tag object, URL object, application filter, HA link interface, and security zone.
object manager	The page on the web interface where you manage objects and object groups, including application filters, the HA link interface, and security zones.
operating system identity	The operating system vendor and version details for an operating system on a host.
packet view	A type of workflow page that provides detailed information about the packet that triggered an intrusion rule or the preprocessor that generated an intrusion event. The packet view is the final page in workflows based on intrusion events.
pass rule	An intrusion rule that, when triggered, does **not** generate an intrusion event and does **not** log the details of the packet that triggered the rule. Pass rules allow you to prevent packets that meet specific criteria from generating an event in specific situations, as an alternative to disabling the intrusion rule. Compare with drop rule.
passive detection	The collection of discovery data through analysis of traffic passively collected by managed devices. Compare with active detection.
passive interface	A sensing interface configured to analyze traffic in a passive deployment.
pending (application protocol)	A designation given to an application protocol identity when the system can neither positively nor negatively identify the application protocol. Most often, the system needs to collect and analyze more data before it can identify a pending application protocol.
physical interface	An interface that represents a physical port on a NetMod.
policy	A mechanism for applying settings, most often to an appliance. See access control policy, correlation policy, file policy, health policy, intrusion policy, network discovery policy, and system policy.
policy target	An appliance or zone where you apply a policy. A policy may have multiple targets.
port object	A reusable object that represents an open port that uses transport layer protocols (for example, TCP, UDP, or ICMP).

preprocessor	A feature that normalizes traffic inspected by an intrusion policy and that helps identify network layer and transport layer protocol anomalies by identifying inappropriate header options, defragmenting IP datagrams, providing TCP stateful inspection and stream reassembly, and validating checksums. Preprocessors can also render specific types of packet data in a format that the system can analyze; these preprocessors are called data normalization preprocessors, or application layer protocol preprocessors. Normalizing application layer protocol encoding allows the system to effectively apply the same content-related intrusion rules to packets whose data is represented differently and obtain meaningful results. Preprocessors generate preprocessor events whenever packets trigger preprocessor options that you configure.
preprocessor event	A type of intrusion event that is generated when a packet triggers specified preprocessor options. Preprocessor events can help you detect anomalous protocol exploits.
preprocessor rule	An intrusion rule associated with a preprocessor or with the portscan flow detector. You must enable preprocessor rules if you want them to generate events. Preprocessor rules have a preprocessor-specific GID (generator ID).
private search	A named set of search criteria for a specific table, tied to your user account. Only you and users with Administrator access can use your private searches.
protected network	Your organization's internal network that is protected from users of other networks by a device such as a firewall. Many of the intrusion rules delivered with the Sourcefire 3D System use variables to define the protected network and the unprotected (or outside) network.
Protection license	A license for Series 3 devices, virtual devices, and Sourcefire Software for X-Series that allows you to perform intrusion detection and prevention, file control, and Security Intelligence filtering. Without a license, Series 2 devices automatically have Protection capabilities, with the exception of Security Intelligence.
RADIUS authentication	Remote Authentication Dial In User Service, a service used to authenticate, authorize, and account for user access to network resources. You can create an external authentication object to allow Sourcefire 3D System users to authenticate through a RADIUS server.
rate filtering	A form of anomaly detection that sets a new intrusion rule state for a rule based on the rate of matching traffic.
remediation	An action that mitigates potential attacks on your system. You can configure remediations and, within a correlation policy, associate them with correlation rules and compliance white lists so that when they trigger, the Defense Center launches the remediation. This can not only automatically mitigate attacks when you are not immediately available to address them, but can also ensure that your system remains compliant with your organization's security policy. The Defense Center ships with predefined remediation modules, and you also can use a flexible API to create custom remediations.

remediation instance	A set of configurations for a remediation module. You can configure multiple instances per module, for example, you could respond to different correlation policy violations using the same module, but different instances that have different settings. When a remediation instance triggers, the resulting action is called a remediation.
remediation module	A program that launches a remediation, using sets of configurations called remediation instances. The Sourcefire 3D System ships with several remediation modules that perform various actions; you can also use a flexible API to create your own modules.
remediation status event	An event generated when a remediation is launched.
report template	A template that specifies the data constraints and formats for a report and its sections.
reputation (IP address)	See Security Intelligence.
reputation (URL)	See URL reputation.
response	A reaction to a correlation policy violation — either an alert or a remediation.
retrospective malware event	A network-based malware event generated when the malware disposition for a previously detected file changes. When this occurs, the system also updates the dispositions for files and malware that share the retrospective event's SHA-256 hash value.
risk	See application risk.
routed interface	An interface that routes traffic in a Layer 3 deployment. You can set up physical routed interfaces for handling untagged VLAN traffic, and logical routed interfaces for handling traffic with designated VLAN tags. You can also add static Address Resolution Protocol (ARP) entries to routed interfaces.
router	A network device, located at a gateway, that forwards packets between networks. Using network discovery, the system can identify routers. In addition, you can configure managed devices as virtual routers that route traffic between two or more interfaces.
rule	A construct, usually within a policy, that provides criteria against which network traffic is examined.
rule action	A setting that determines how the system handles network traffic that meets the conditions of a rule. See access control rule action and file rule action.

rule state	Whether an intrusion rule is enabled (set to Generate Events or Drop and Generate Events), or disabled (set to Disable) within an intrusion policy. If you enable a rule, it is used to evaluate your network traffic; if you disable a rule, it is not used.
rule update	An as-needed intrusion rule update that contains new and updated standard text rules, shared object rules, and preprocessor rules. A rule update may also delete rules, modify default intrusion policy settings, and add or delete default variables and rule categories.
scheduled task	An administrative task that you can schedule to run once or at recurring intervals.
Security Intelligence	A feature that allows you to specify the traffic that can traverse your network, per access control policy, based on the source or destination IP address. This is especially useful if you want to blacklist—deny traffic to and from—specific IP addresses, before the traffic is subjected to analysis by access control rules. Optionally, you can use a monitor setting for Security Intelligence filtering, which allows the system to analyze connections that would have been blacklisted, but also logs the match to the blacklist.
Security Intelligence blacklist	In an access control policy, a list of IP addresses that allows you to deny traffic to and from those hosts, before the traffic is subjected to analysis by access control rules. A blacklist is comprised of Security Intelligence objects, including the global blacklist. An access control policy's Security Intelligence whitelist overrides its blacklist.
Security Intelligence feed	One of the types of Security Intelligence objects, a dynamic collection of IP addresses that the system downloads on a regular basis, at an interval you configure. Because feeds are regularly updated, using them ensures that the system uses up-to-date information to filter your network traffic using the Security Intelligence feature. See also Sourcefire Intelligence Feed.
Security Intelligence list	A simple static collection of IP addresses that you manually upload to the Defense Center as a Security Intelligence object. Use lists to augment and fine-tune Security Intelligence feeds as well as the global blacklist and global whitelist.
Security Intelligence object	A single configuration that represents one or more IP addresses, and that you add to an access control policy's Security Intelligence blacklist and Security Intelligence whitelist. Security Intelligence objects include Security Intelligence lists, Security Intelligence feeds, and network objects and groups. The global blacklist, global whitelist, and the categories in the Sourcefire Intelligence Feed are also considered Security Intelligence objects.
Security Intelligence whitelist	In an access control policy, a list of IP addresses that forces the policy to examine traffic to and from those hosts using access control rules, that is, to not deny the traffic using Security Intelligence. Because a policy's whitelist overrides its Security Intelligence blacklist, you can use it to fine-tune the blacklist. A whitelist is comprised of Security Intelligence objects, including the global whitelist.

security policy	An organization's guidelines for protecting its network. For example, your security policy might forbid the use of wireless access points. A security policy may also include an acceptable use policy (AUP), which provides employees with guidelines of how they may use their organization's systems.
security policy violation	A security breach, attack, exploit, or other misuse of your network.
security zone	A grouping of one or more inline, passive, switched, or routed interfaces that you can use to manage and classify traffic flow in various policies and configurations. The interfaces in a single zone may span multiple devices; you can also configure multiple security zones on a single device. You must assign each interface you configure to a security zone before it can handle traffic, and each interface can belong to only one security zone.
sensing interface	A network interface on a device that you use to monitor a network segment. Compare with management interface.
Series 2	The second series of Sourcefire appliance models. Because of resource, architecture, and licensing limitations, Series 2 appliances support a restricted set of Sourcefire 3D System features. Series 2 devices include the 3D500, 3D1000, 3D2000, 3D2100, 3D2500, 3D3500, 3D4500, 3D6500, and 3D9900. Series 2 Defense Centers include the DC500, DC1000, and DC3000.
Series 3	The third series of Sourcefire appliance models. Series 3 appliances include 7000 Series and 8000 Series devices, as well as the DC750, DC1500, and DC3500 Defense Centers.
server	The server application (compare with client application) installed on a host, identified by application protocol traffic.
server banner	The first 256 bytes of the first packet detected for a server, which can provide additional information that may help you identify the server. The system collects a server banner only once, the first time the server is detected.
server certificate	An encrypted certificate issued by a certificate authority that provides unalterable confirmation of the server identity. You can request a certificate from any certificate authority and upload that custom certificate to your appliance.
server identity	The application protocol type, vendor, and version details for a server on a host.
SFP module	A small form-factor pluggable transceiver that is inserted into a network module on a 71xx Family device. Sensing interfaces on SFP modules do not allow configurable bypass.
SHA-256 hash value	Sometimes abbreviated as SHA256, a 32-bit string that represents a file for which you are performing a malware cloud lookup. The hash value is calculated using a cryptographic hash function so that files with identical SHA-256 values are very likely to have identical contents.

shared layer	An intrusion policy layer that you allow to be used by other intrusion policies. Policies using a shared layer are updated with changes to intrusion rules and advanced settings in the shared layer when you commit those changes. A shared layer can be modified only in the policy that allows it to be shared; it is read-only in policies using it.
shared object rule	An intrusion rule delivered as a binary module compiled from C source code. You can use shared object rules to detect attacks in ways that standard text rules cannot. You cannot modify the rule keywords and arguments in a shared object rule; you are limited to either modifying variables used in the rule, or modifying aspects, such as the source and destination ports and IP addresses, and saving a new instance of the rule as a custom shared object rule. Shared object rules have a GID (generator ID) of 3.
SID	Signature ID (also Snort ID), a unique identifying number assigned to each intrusion rule. When you create a new rule or modify an existing standard text rule, it is given an SID of 1,000,000 or greater. The SIDs for shared object rules and standard text rules delivered with the Sourcefire 3D System are lower than 1,000,000. Also, preprocessors and decoders use SIDs to identify the different types of packets they detect.
snooze period	An interval specified in seconds, minutes, or hours after a correlation rule triggers during which the Defense Center stops firing that rule, even if the rule is violated again during the interval. When the snooze period has ended, the rule can trigger again (and start a new snooze period). See also inactive period.
Snort	An open source intrusion detection system that performs real-time traffic analysis and packet logging on IP networks. Snort can perform protocol analysis, content searching and matching, and can detect a variety of attacks and probes. Snort uses a flexible rules language to describe network traffic that it should collect or pass. The Sourcefire 3D System uses Snort to test packets against decoders, preprocessors, and intrusion rules.
Sourcefire cloud	Sometimes called *cloud services*, a Sourcefire-hosted external server where the Defense Center can obtain up-to-date, relevant information including malware, Security Intelligence, and URL filtering data. See also malware cloud lookup.
Sourcefire Intelligence Feed	A collection of regularly updated lists of IP addresses determined by the Sourcefire VRT to have a poor reputation. Each list in the feed represents a specific category: open relays, known attackers, bogus IP addresses (bogon), and so on. In an access control policy, you can blacklist any or all of the categories using Security Intelligence. Because the intelligence feed is regularly updated, using it ensures that the system uses up-to-date information to filter your network traffic.
Sourcefire Software for X-Series	A software-based Sourcefire application built on Blue Coat's scalable chassis-based system that provides the capabilities of a virtual device.

Sourcefire VRT	Sourcefire's Vulnerability Research Team.
Spero analysis	A method of submitting file structural characteristics to the Sourcefire cloud for malware analysis. The results supplement dynamic analysis.
stack	Two to four connected devices that share detection resources.
stacking	A feature that allows you to increase the amount of traffic inspected on a network segment by connecting two to four physical devices in a stacked configuration. When you establish a stacked configuration, you combine the resources of each stacked device into a single, shared configuration.
standard text rule	An intrusion rule created based on the identifiers, keywords, and arguments available in the rule editor. You can create your own custom standard text rules and modify Sourcefire-provided standard text rules. A standard text rule has a GID (generator ID) of 1.
state sharing	A feature that allows clustered devices or stacks to synchronize so that if either device or stack fails, the peer can take over with no interruption to traffic flow. State sharing ensures that strict TCP enforcement, unidirectional access control rules, blocking persistence, and dynamic NAT fail over properly.
stored file	A captured file that is saved to a device's hard drive or malware storage pack, if installed. Stored files can be downloaded and analyzed at a later time.
sub-server	A server called by another server on the same host.
suppression	See event suppression.
SVID	See vulnerability ID.
switch	A network device that acts as a multiport bridge. Using network discovery, the system identifies switches as bridges. In addition, you can configure managed devices as virtual switches, performing packet switching between two or more networks.
switched interface	An interface that you want to use to switch traffic in a Layer 2 deployment. You can set up physical switched interfaces for handling untagged VLAN traffic, and logical switched interfaces for handling traffic with designated VLAN tags.
system policy	Settings that are likely to be similar for multiple appliances in a deployment, such as mail relay host preferences and time synchronization settings. Use the Defense Center to apply a system policy to itself and its managed devices.
table view	A type of workflow page that displays event information, with one column for each of the fields in the database table. When performing event analysis, you can use drill-down pages to constrain the events you want to investigate before moving to the table view that shows you the details about the events you are interested in. The table view is often the next-to-last page in workflows delivered with the system.

tag (application)	See application tag.
tap mode	An advanced inline set option available on 3D9900 and Series 3 devices where a copy of each packet is analyzed and the network traffic flow is undisturbed instead of passing through the device. Because you are working with copies of packets rather than the packets themselves, the device cannot affect the packet stream even if you configure access control and intrusion policies to drop, modify, or block traffic.
target device	See policy target.
task queue	A queue of jobs that the appliance needs to perform. When you apply a policy, install software updates, and perform other long-running jobs, the jobs are queued and their status reported on the Task Status page. The Task Status page provides a detailed list of jobs and refreshes every ten seconds to update their status.
third-party vulnerability	Vulnerability data obtained from a third party. If your organization can write scripts or create command line import files to import network map data from third-party applications, you can use the host input feature to import third-party vulnerability data to augment the system's vulnerability data.
threat score	A rating of 1-100 assigned to a file as a result of submission to the Sourcefire cloud for dynamic analysis that measure the likelihood the file contains malware.
thresholding	See event thresholding.
time window	A time constraint on the events in any event view. Different event views may have different default time windows, depending on your user preferences. Note that not all event views can be constrained by time.
traffic profile	A profile of the traffic on your network, based on connection data logged over a time span that you specify. You can create profiles using all the traffic on a monitored network segment, or you can create more targeted profiles. Then, you can use the correlation feature to detect abnormal network traffic by evaluating new traffic against an existing profile.
transparent inline mode	An advanced inline set option that allows a device to act as a "bump in the wire" and to forward all the network traffic it sees, regardless of its source and destination.
unidentified host	A host whose operating system cannot be identified because the system has not yet gathered enough information about the host. Compare with unknown host.
Unified file	A binary file format that the Sourcefire 3D System uses to log event data.
unknown host	A host whose traffic has been analyzed by the system, but whose operating system does not match any known fingerprints. Compare with unidentified host.

URL category	A general classification for a URL, such as malware or social networking.
URL filtering	A feature that allows you to write access control rules that determine the traffic that can traverse your network based on URLs requested by monitored hosts, correlated with URL category and URL reputation information about those URLs, which is obtained from the Sourcefire cloud by the Defense Center. You can also achieve more granular, custom control over web traffic by specifying individual URLs or groups of URLs to allow or block.
URL Filtering license	A license that allows you to perform URL filtering based on URL category and URL reputation information. URL Filtering licenses may expire.
URL object	A reusable object that represents an individual URL.
URL reputation	A representation of how likely a URL is to be used for purposes that might be against your organization's security policy, as determined by the Sourcefire cloud.
user	A user whose network activity has been detected by a managed device or User Agent.
user activity	An event generated when the system detects a user login (optionally, including some failed login attempts) or the addition or deletion of a user record from the Defense Center database.
User Agent	An agent you install on a server to monitor users as they log into the network or when they authenticate against Active Directory credentials for any other reason. Activity by access-controlled users is only used for access control only when a User Agent reports it.
user awareness	A feature that allows your organization to correlate threat, endpoint, and network intelligence with user identity information, and that allows you to perform user control.
user certificate	An encrypted certificate that identifies a user's browser to the Sourcefire 3D System web server, allowing the server to do a secondary verification of user identity. The certificate must be issued by the same certificate authority that issued the server certificate for your appliance.
user control	A feature that, as part of access control, allows you to specify and log the user-associated traffic that can enter your network, exit it, or cross from within without leaving it.
user details	The final page in user identity and user activity workflows. Along with general information about the user, the user details also display a host history, which is a graphical representation of the last twenty-four hours of the user's activity.
user history	A graphical representation of the last twenty-four hours of user activity for a host. The user history, which you can view in a host's host profile, displays the user

	names of the users detected logging into the host, with approximate login and logout times represented by bar graphs.
user identity	See user.
user layer	A layer in an intrusion policy where you can modify settings in the policy.
user role	The level of access granted to a user of the Sourcefire 3D System. For example, you can grant different access privileges to the web interface for event analysts, the administrator managing the Sourcefire 3D System, users accessing the Defense Center database using third-party tools, and so on. You can also create custom roles with specialized access privileges.
user role escalation	A privilege you can give to custom user roles that allows users to enter a password to gain the permissions of another user role for the duration of a login session.
UTC time	Coordinated Universal Time. Also known as Greenwich Mean Time (GMT), UTC is the standard time common to every place in the world. The Sourcefire 3D System uses UTC, although you can set the local time using the Time Zone feature.
variable	A representation of a value that is commonly used in intrusion rules. The Sourcefire 3D System uses preconfigured variables to define networks and port numbers. Rather than hard-coding these values in multiple rules, to tailor a rule to accurately reflect your network environment, you can change the variable value.
variable set	A collection of variable configurations that you can link to an intrusion policy associated with an access control rule or the default action of an access control policy for the purpose of tailoring intrusion rules that you enable in your intrusion policy to closely match your network traffic.
VDB	See vulnerability database.
virtual Defense Center	A Defense Center that you can deploy on your own equipment in a virtual hosting environment.
virtual device	A managed device that you can deploy on your own equipment in a virtual hosting environment. Virtual devices do not support hardware-based features, such as high availability, clustering, stacking, NAT, VPN, and fast-path rules, and you cannot configure a virtual device as a virtual switch or virtual router.
virtual router	A group of routed interfaces that route Layer 3 traffic. In a Layer 3 deployment, you can configure virtual routers to route packets by making packet forwarding decisions according to the destination IP address. You can define static routes, configure Routing Information Protocol (RIP) and Open Shortest Path First (OSPF) dynamic routing protocols, as well as implement Network Address Translation (NAT).

virtual switch	A group of switched interfaces that process inbound and outbound traffic through your network. In a Layer 2 deployment, you can configure virtual switches on managed devices to operate as standalone broadcast domains, dividing your network into logical segments. A virtual switch uses the media access and control (MAC) address from a host to determine where to send packets.
VLAN	Virtual local area network. VLANs map hosts not by geographic location, but by some other criterion, such as by department or primary use. A monitored host's host profile shows any VLAN information associated with the host. VLAN information is also included in intrusion events, as the innermost VLAN tag in the packet that triggered the event. You can filter intrusion policies by VLAN and target compliance white lists by VLAN. In Layer 2 and Layer 3 deployments, you can configure virtual switches and virtual routers on managed devices to appropriately handle VLAN-tagged traffic.
VLAN tag object	A reusable object that represents an individual VLAN tag.
VPN	A feature that allows you to build secure VPN tunnels between the virtual routers of Sourcefire managed devices.
VPN license	A license that allows you to build secure VPN tunnels between the virtual routers of Sourcefire managed devices.
VRT	See Sourcefire VRT.
VRT's Analysis Report	A record of the Sourcefire VRT's analysis of a captured file submitted for dynamic analysis, detailing the information presented in the dynamic analysis summary report, as well as additional information discovered during dynamic analysis.
vulnerability	A description of a specific compromise to which a host is susceptible. The Defense Center provides information on the vulnerabilities to which each of your hosts is vulnerable in the hosts' host profiles. In addition, you can use the vulnerabilities network map to obtain an overall view of the vulnerabilities that the system has detected on your entire monitored network. If you deem a host or hosts no longer vulnerable to a specific compromise, you can deactivate, or mark as invalid, a specific vulnerability.
vulnerability database	Also called the VDB, a database of known vulnerabilities to which hosts may be susceptible. The system correlates the operating system, application protocols, and clients detected on each host with the VDB to help you determine whether a particular host increases your risk of network compromise. VDB updates may contain new and updated vulnerabilities, as well as new and updated application detectors.
vulnerability detail	The final page in vulnerability workflows. Vulnerability details provide information about a specific vulnerability, including technical details and known solutions.

vulnerability ID	An identification number associated with a particular vulnerability. The Sourcefire vulnerability database and third-party vulnerability databases, such as Bugtraq and CVE, have different vulnerability ID numbering schemes.
vulnerability mapping	The association of vulnerability information with discovery data, so that you can perform impact correlation.
web application	A type of application that represents the content of, or requested URL for, HTTP traffic.
whitelist	A compliance white list, a Security Intelligence whitelist, the HA link interface, or a list of IP addresses that you can configure within a remediation to exempt IP addresses from some kind of action.
white list event	An event generated when the system detects that a valid target host has become non-compliant with a compliance white list. White list events are a special kind of correlation event.
white list violation	Information that you can view in the event viewer that details how a host is non-compliant with a compliance white list.
widget	See dashboard widget.
workflow	A series of pages you can use to view and evaluate events by moving from a broad view of event data to a more focused view that contains only the events of interest to you. Workflows can include three types of pages, each of which performs a unique function: drill-down pages, table views, and a final page. Depending on the workflow type, the final page may be a table view, packet view, host view, vulnerability detail, or user details.
X-Series	The short name for Sourcefire Software for X-Series.
zone	See security zone.
